### PURPOSE

Prediction of arterial invasion by preoperative enhanced CT combined with radiomics-based classification model of pancreatic ductal adenocarcinoma (PDAC) on arteries and classify the invasion angle, to provide guidance for judging the resectability of PDAC.

### METHODS AND MATERIALS

Patients who were pathologically proven with PDAC were recruited retrospectively between January 2018 and December 2022. Firstly, the CNN-based Attention Unet segmentation models were developed four Individual Unet Models that segments pancreas, tumor, and arteries (celiac artery, hepatic artery, and superior mesenteric artery) separately. The segmentation efficacy was assessed using Accuracy and Dice similarity coefficient. Secondly, 1835 radiomics features were extracted from tumors and arteries and to build a classification model with support vector machine. Vascular invasion was divided into three grades. Grade 0 was no contact between tumor and blood vessels. The degree of vascular involvement was characterized as less than 180° in grade 1, and in grade 2, the degree was greater than 180°. The performance of this model was assessed in the training and validation cohorts using the area under the receiver operating curve (AUC).

### RESULTS

A total of 290 patients [mean (SD) age, 70.0 (9.4) years; 167 (57.6%) male and 123 (42.4%) female] were divided into the training cohort (n=195) and validation cohort (n=95). Firstly, the segmentation model achieve notable performance: pancreas (Accuracy: 0.819, Dice: 0.756), tumor (Accuracy: 0.695, Dice: 0.687), and artery (Accuracy: 0.920, Dice: 0.927). Secondly, a total of 1835 CT radiomic features were extracted. Nineteen, seventeen and five optimal features were selected to predict the invasion grade of lesions with celiac artery, hepatic artery and superior mesenteric artery, respectively. The radiomics-based model yielded an AUC of 0.938 (95%CI: 0.904-0.971), 0.903 (95% CI: 0.852-0.953) , and 0.870 (95% CI: 0.814-0.927) in the

training cohort, and an AUC of 0.765 (95%CI: 0.656-0.874), 0.811 (95% CI: 0.696-0.926), and 0.856 (95%CI: 0.780-0.932) in the validation cohort, respectively.

**CONCLUSION**

The model based on radiomics features that can reflect spatial information improves the accuracy of preoperative assessment of vascular invasion status, and help to predict the likelihood of achieving complete resection.

**CLINICAL RELEVANCE/APPLICATION**

The proposed segmentation model and radiomics classification model can be used for an array of preoperative assessments, involving accurate segmentation of preoperative lesions and blood vessels and grading of vascular invasion status in PDAC, thereby improving the decision-making process regarding the feasibility of surgery for PDAC patients.

Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To automatically generate clinically relevant reports that include both biomarkers easily obtained by radiologists, such as tumor presence, long/short diameters, and tumor types, and those not easily obtained, such as organ/tumor volumes, HU intensity distribution, and Radiomics features.

### METHODS AND MATERIALS

We developed AI algorithms to identify the margins of the liver, pancreas, and kidneys from CT scans and segment tumors, cysts, and blood vessels within these organs. We proposed an automatic tool, termed Segment2Report, to translate these body segments into comprehensive radiology reports. Segment2Report leverages multiomic data to enhance clinical decision-making by incorporating quantitative imaging biomarkers alongside traditional Radiological features. First, we utilized hepatic vessels to divide the liver into multiple sub-segments, precisely localizing tumors. Each tumor was measured using its long and short diameters on the largest CT slice, following WHO standards (illustrated in Figure), and its volume was calculated by multiplying the number of voxels by the spacing information provided in the DICOM header. We calculated the average Hounsfield Unit (HU) values for tumors and organs, integrating radiomic features that offer additional insights into tissue characterization. Segment2Report analyzed the interaction between tumors and adjacent blood vessels, providing critical information for tumor staging and risk stratification. Segment2Report, trained on large-scale, multicenter datasets, was externally evaluated on 165 CT volumes from UCSF, which included scans of normal patients and those with kidney, pancreas, and liver tumors.

### RESULTS

Without training on UCSF scans, our AI algorithms achieved a high DSC of 96.2%, 83.1%, and 92.3% for liver, pancreas, and kidney segmentation, and our AI-generated reports presented a Sensitivity of 85.6%, 92.6%, 99.2% and a Specificity of 64%, 86.7%, 93.8% for detecting tumors in the liver, pancreas, and kidney, respectively. A comprehensive list of tumors was generated for patients with multiple lesions.

### CONCLUSION

Leveraging precise per-voxel segmentations and a reproducible measuring system, our AI-generated reports can surpass human-written reports in the objective measurement of organs and tumors. Moreover, our framework performs in-depth analyses commonly omitted by humans.

### CLINICAL RELEVANCE/APPLICATION

Segment2Report can assist radiologists by automating lengthy tasks, enabling them to write more complete and detailed reports under tight time constraints. Providing comprehensive, precise and reproducible tumor evaluation, our AI-generated reports can improve cancer staging, progress monitoring, and treatment planning.

## S4-STCE1-2 NEXT-GEN RADIOLOGIC ASSISTANT INTEGRATING MULTI-MODAL DATA AND DOMAIN EXPERT PREDICTIONS WITH D-RAX

Hareem Nisar (*Abstract Co-Author*) Nothing to Disclose
Zhifan Jiang, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

With the increasing workload in radiology departments, generative artificial intelligence (AI) can reduce the work burden and potentially enhance healthcare delivery. Recent large vision language models (VLMs) can assist clinicians in interpreting complex medical images and provide feedback in natural language. Despite their advanced capabilities, these models are very general and prone to hallucinations, which limits their precision in answering radiology-specific questions. To address this, we propose D-Rax, an enhanced domain-specific, conversational radiologic assistance tool to provide interpretation of chest X-ray images (CXR).

**METHODS AND MATERIALS**

D-Rax was developed by fine-tuning a base VLM architecture (LLaVA) using a carefully curated and enhanced dataset. This dataset comprised of 129,232 CXR from the public MIMIC-CXR dataset, instructions derived from 429,000 CXR-related visual question-answer pairs (VQA) from the Medical-Diff-VQA dataset, and disease diagnosis (n=18 types) and demographic predictions (asian, black, white) obtained from multiple state-of-the-art (SOTA) pre-trained expert AI models for radiology available through TorchXRayVision. We conducted extensive experiments for end-to-end instruction tuning of the base LLaVA, LLaVA pretrained on RAD and SLAKE datasets, comparing their performance with and without expert model predictions. Performance was assessed using accuracy (%) for close-ended (C) questions and the ratio (%) of correctly generated words for open-ended (O) questions.

**RESULTS**

The expert model-enhanced instruction tuning of D-Rax showed improvements in model performance for both C and O questions. The averaged accuracy (%) with and without expert model predictions resulted in 78.6 vs. 77.3, 79.0 vs. 77.0, and 78.8 vs. 76.3, with p-value < 0.001 for the three LLaVA models respectively. The averaged ratio (%) resulted in 61.6 vs. 61.3 (p-value > 0.05), 61.6 vs. 60.4 (p-value < 0.001), and 61.7 vs. 60.4 (p-value < 0.001), respectively.

**CONCLUSION**

We established a novel training paradigm that incorporates predictions from expert models to improve the precision of VLMs in CXR analysis. Our results validated the hypothesis that domain-specific knowledge extracted from clinical radiology reports reduces hallucination. Secondly, the addition of expert information from SOTA AI models enhanced the accuracy of answering questions in a clinically-relevant conversation.

**CLINICAL RELEVANCE/APPLICATION**

Leveraging the power of SOTA AI diagnostic models combined with VLMs, D-Rax empowers clinicians to interact with medical images using natural language, which could potentially streamline their decision-making process, enhance diagnostic accuracy, and conserve their time.

## S4-STCE1-3 ENHANCING FEDERATED LEARNING IN MULTICENTER RADIOLOGY AI SYNTHETIC DATA GENERATION FOR IMPROVED MAMMOGRAPHY CLASSIFICATION

Daniel Sigrist (*Abstract Co-Author*) Nothing to Disclose
Marc Molina (*Abstract Co-Author*) Nothing to Disclose
Antje-Christin Knopf (*Abstract Co-Author*) Nothing to Disclose
Stephanie Nadine Benz (*Abstract Co-Author*) Nothing to Disclose
Cyril Fischer (*Abstract Co-Author*) Nothing to Disclose
Daniela Sarahi Ramirez Figueroa, MD (*Abstract Co-Author*) Nothing to Disclose
Felice A. Burn, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Federated learning (FL) has emerged as a very promising approach for Multicenter Radiology AI, enhancing collaborative model training while strongly preserving data privacy. However, class imbalance and limited data availability can critically impact model performance. This study investigates the potential of synthetic data generation to enhance FL-based mammography classification across multiple centers.

**METHODS AND MATERIALS**

We used an open-source mammography dataset containing 10,000 X-ray images labeled on a scale of 1-8, indicating cancer masking evaluated by 5 radiologists. The dataset was split into 9,500 training and 500 validation images. A baseline FL model was trained simulating 5 distinct centers. We developed a synthetic data generation pipeline using a class-conditioned Diffusion Transformer. This model doubled the size of each class while maintaining the original distribution of cancer masking. A privacy filter based on a self-supervised network trained with contrastive loss ensured that synthetic images were not direct training data copies. We trained a second FL model, providing each center access to its original data plus the complete synthetic data. Both FL models employed an EfficientNet-B4 architecture pre-trained on ImageNet. Training occurred over 30 rounds, with each client processing its entire dataset once per round using an AdamW optimizer and a learning rate of 0.0005. Client-side evaluation was used with the resulting metrics sent back to the server for aggregation and model updates. The model performance was assessed with adjusted mean absolute error (AMAE) and Kendall's tb.

**RESULTS**

Our analysis revealed that the synthetic-augmented FL model achieved a Kendall's tb of 0.74, indicating a stronger correlation between predicted and true classes compared to the baseline FL model, which scored 0.70. The AMAE showed a notable reduction from 1.08 in the baseline FL model to 0.88 in the synthetic augmented model.

**CONCLUSION**

Our study demonstrates another huge potential of multicenter AI radiology by combining the use of Federated Learning with synthetic data. By addressing class imbalances and augmenting limited datasets, this approach enhances model accuracy significantly while maintaining data privacy across multiple centers. These findings suggest a promising avenue for advancing collaborative AI development in clinical radiology.

**CLINICAL RELEVANCE/APPLICATION**

These findings suggest a promising avenue for advancing the collaborative development of radiology clinical studies and computer-aided diagnosis tools, particularly in scenarios where data is scarce within rare disease, and sharing is restricted. This method can remarkably enhance the scalability and effectiveness of AI in medical imaging, paving the way for improved diagnostic accuracy and patient outcomes across multiple centers.

## S4-STCE2-1 INLINE SNR-DRIVEN AUTOMATIC QUALITY CONTROL FOR PATIENT-SPECIFIC SCAN TIME MINIMIZATION AT 0.55T

Kelvin Chow, PhD (*Abstract Co-Author*) Employee, Siemens AG
Ahsan Javed (*Abstract Co-Author*) Nothing to Disclose
Adrienne Campbell (*Abstract Co-Author*) Nothing to Disclose
Rajiv Ramasawmy (*Abstract Co-Author*) Nothing to Disclose
Pierre Daude, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Conventional fixed duration acquisitions can result in patient-dependent image quality. We recently demonstrated a periodic inline automatic quality control based on signal-to-noise ratio (SNR) to achieve consistent diagnostic image quality for 2D phase-contrast flow cardiac MRI on a commercial 0.55T MR system. In this work, we aim to extend the SNR-driven quality control to a 3D ultra-short echo time (UTE) pulmonary MRI.

### METHODS AND MATERIALS

We implemented a closed-loop feedback framework between image reconstruction and data acquisition to automatically stop the acquisition when a target SNR is achieved. The quality control was optimized for minimal computational latency. A snapshot reconstruction was triggered 2min 30s after the start of imaging, and an SNR map was estimated using pseudo replica methods. The SNR of the lung parenchyma was automatically extracted. Based on this snapshot SNR, the total optimal subject specific time needed to achieve the target SNR was calculated. The predicted number of spiral shots corresponding to this duration is sent to the sequence controller and the acquisition is automatically stopped as soon as this number is reached.Ten healthy volunteers (HVs) were imaged on a 0.55T MRI scanner (MAGNETOM Free.Max, Siemens Healthineers AG, Erlangen, Germany) using a prototype free-breathing golden angle stack-of-spirals 3D ultrashort echo time sequence (TE/TR=0.8/7.5ms, FA=5°, (1.75mm)3 resolution, FOV=480x480x190 mm3, maximum scan time=12min). A target SNR of 4 was used to demonstrate the stopping criterion in real-time (1 HV) or retrospectively (10 HVs).

### RESULTS

By applying the quality control retrospectively, pulmonary acquisitions would have automatically stopped at 6min 49s ± 1min48s. The distribution of automated stopping times across the population (standard deviation > 1 minute) revealed the value of a subject-specific scan time. The computation time for the SNR-driven quality control was 40s which were compatible with the online deployment.

### CONCLUSION

Our proposed inline SNR-driven automatic quality control mimics the “ALARP” principle applied to MRI. This approach enables time-efficient subject-specific acquisitions while ensuring consistent diagnostic image quality. Additional metrics for stop criteria will be considered in future work. The ability to achieve a consistent image quality as efficiently as possible on a 0.55T MRI platform may help to avoid repeated scans, optimize scans workflow, and improve the accessibility of cardiac and pulmonary MRI.

### CLINICAL RELEVANCE/APPLICATION

We propose an inline automatic quality control to stop acquisitions when image quality is sufficient to answer the clinical question on a low field MRI system. This achieves the minimum possible scan time for each patient.

## S4-STCE2-2 DETERMINANTS OF IMAGE QUALITY IN RESPIRATORY TRIGGERED FREE BREATHING LUNG MRI AT 0.55T

Yoo Jin Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Peder E. Larson, PhD (*Abstract Co-Author*) Research Grant, General Electric Company;Research Grant, Bristol-Myers Squibb Company;Research Consultant, Human Longevity Inc;Advisory Board, Imaginostics, Inc;Shareholder, Imaginostics, Inc

Felicia Tang, BA, BS (*Abstract Co-Author*) Nothing to Disclose
Kiara Bowers (*Abstract Co-Author*) Nothing to Disclose
Richard Schonour, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Newly emerging respiratory-triggered low-field (0.55T) MR systems have shown promise in pulmonary imaging due to reduced susceptibility artifacts at the air-tissue interface, but variability in image quality remains a lingering challenge to overcome in clinical workflow. Our objective is to evaluate sets of anatomic imaging from 0.55T MR of the lungs and identify predictors of degraded image quality. We hypothesize that body mass index (BMI), respiratory pattern, and certain disease processes could have significant influence on image quality or its variability.

### METHODS AND MATERIALS

Participants with significant pulmonary disease who were scheduled to undergo CT or PET/CT were recruited to undergo same-day 0.55T MRI (MAGNETOM Free.Max, Siemens Healthcare, Erlangen, Germany) between January 2023 and August 2023. Examples of conditions that prompted participant enrollment included lung nodules, masses, cancer, infection, bronchiectasis, and pulmonary fibrosis. A total of 28 participants were enrolled. After acquisition of respiratory triggered T2-weighted (axial BLADE) and T1-weighted (ultra short-echo time) sequences, six radiologists assigned quantitative grades based on overall image quality. Analysis of clinical covariates in and between grade tertiles was performed. Tidal depth (TD), respiratory rate (RR), and respiration length were quantified to determine patient breathing patterns. Respiration length was the average duration of a single breath in the triggered sequence. Body surface area and BMI were calculated to determine if participant height and weight impacted image quality. One-way ANOVA was conducted to examine the effect of the potential predictor groups on image quality. Statistical significance was defined by P values of less than .05.

### RESULTS

28 participants (mean age, 59 years +/- 19; 17 women) were evaluated. The most common clinical condition associated with degraded image quality was fibrotic interstitial lung disease. Deeper tidal depth (P = .04), longer respiration length (P = .002), and higher BMI (P = .02) were found to be statistically significant predictors of degradation. Neither respiratory rate nor body surface area were found to have a significant association (P > .05) with poor image quality.

### CONCLUSION

High body mass index, fibrotic interstitial lung disease, deep tidal depth breathing, and longer respiratory length were associated with image degradation in pulmonary imaging with 0.55T MR.

### CLINICAL RELEVANCE/APPLICATION

Knowing what predicts image degradation in 0.55T Lung MR allows radiologists to prepare at-risk patients accordingly (e.g. free-breathing MR sequences or alternative imaging modality) to obtain the best possible images while guiding future research to improve image quality.

## S4-STCE2-3 MRI NEAR TITANIUM TOTAL HIP ARTHROPLASTY AT 0.55T COMPARED WITH 3T

Jay Acharya, MD (*Abstract Co-Author*) Nothing to Disclose
Jay R. Lieberman (*Abstract Co-Author*) Nothing to Disclose
Krishna S. Nayak, PhD (*Abstract Co-Author*) Nothing to Disclose
Brian A. Hargreaves, PhD (*Abstract Co-Author*) Research support, General Electric Company;Royalties, General Electric Company;Royalties, Koninklijke Philips NV;Royalties, Siemens AG
Jordan S. Gross, MD (*Abstract Co-Author*) Nothing to Disclose
Bochao Li (*Abstract Co-Author*) Nothing to Disclose
Kubra Keskin, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

MRI provides a non-invasive imaging tool that offers soft tissue contrast for evaluating tissues near metallic implants. Artifacts can occur due to magnetic susceptibility differences between tissues and implants, and these are proportional to the field strength. As a result, MRI performance, including metal artifact levels, can vary with field strength. This study aims to compare the imaging of patients with titanium total hip arthroplasty (THA) using 0.55T and 3T MRI.

### METHODS AND MATERIALS

Six patients with titanium THA were scanned with comparable protocols at 0.55T and 3T on the same day back-to-back. Protocols include Turbo Spin Echo (TSE), TSE with View-Angle Tilting (TSE-VAT), Slice Encoding for Metal Artifact Correction (SEMAC), and Short Tau Inversion Recovery with SEMAC (STIR-SEMAC). The 0.55T scans were performed using a whole-body prototype MAGNETOM Aera (Siemens Healthineers), while the 3T scans were performed on a whole-body MAGNETOM Prisma Fit (Siemens Healthineers). Images from both scanners were evaluated by two radiologists, who scored them on diagnostic confidence, perceived metal artifact, perceived sharpness, and perceived SNR with a 5-point Likert scale. Statistical differences between all the scores for 0.55T and 3T images for each sequence were determined via Wilcoxon signed-rank tests with a significance level of 0.05.

### RESULTS

We observed a significant reduction in the severity of metal artifacts at 0.55T compared to 3T. At 0.55T, TSE and TSE with VAT provided results comparable to SEMAC in terms of metal artifacts. However, imaging at 3T still required multi-spectral imaging (MSI) to reduce through-plane artifacts. There were remaining ripple artifacts near the stem and the femoral head at 3T, which were not observed at 0.55T. Reader study yielded statistically higher scores for 0.55T compared to 3T in terms of diagnostic confidence for all sequences.

### CONCLUSION

0.55T MRI offers substantially reduced metal artifacts and higher diagnostic confidence when imaging patients with titanium THA compared to 3T. Evaluation of these patients may not require advanced multi-spectral imaging at 0.55T. The use of 0.55T has the potential to improve radiological evaluation in these patients.

### CLINICAL RELEVANCE/APPLICATION

The ability to obtain diagnostic-quality MRI images at 0.55T in the presence of titanium implants, with significantly reduced artifact severity without advanced imaging techniques, offers a promising alternative to higher field strengths. This could facilitate broader access to MRI diagnostics for patients with metal implants and improve workflow efficiency.

## S5-SSBR02-1 ARTIFICIAL INTELLIGENCE SHOULD ONLY READ A MAMMOGRAM WHEN IT IS CONFIDENT: A HYBRID BREAST CANCER SCREENING READING STRATEGY

Mireille Broeders, PhD (*Abstract Co-Author*) Speaker, Siemens AG;Speaker, Hologic, Inc
Ioannis Sechopoulos, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation;Research Grant, Sectra AB;Research Grant, ScreenPoint Medical BV;Research Grant, Volpara Health Technologies Limited
Sarah D. Verboom, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

To incorporate and evaluate uncertainty quantification metrics in an artificial intelligence (AI) mammography interpretation model and test their ability to guide a novel hybrid reading strategy in breast cancer screening in which recall decisions are only made by AI when it exhibits high certainty.

### METHODS AND MATERIALS

A method to quantify uncertainty, based on structured Monte Carlo dropout, was added to an AI mammography interpretation model. The model consists of three steps: 1) a sensitive region detection algorithm that proposes regions of interest, 2) a region classification network, and 3) the generation of an exam level conclusion. Four metrics, based on the variance and entropy of one or all suspicious regions, were used to estimate the confidence of the AI malignancy-present decision. A hybrid reading approach was tested where recall decisions were only made by AI when predictions were deemed confident; otherwise, standard radiologist-double reading was applied. This new reading strategy was retrospectively tested with a previously-unseen set of mammographic screening examinations (n=41,469) acquired between 2003-2018 from a unit of the Dutch National Breast Cancer Screening Program with minimal 2-year follow-up.

### RESULTS

The AI mammography interpretation model achieved an area under the receiver operating characteristics curve (AUC) of 0.957 (95% CI 0.943-0.970). The best-performing uncertainty metric, entropy of the mean output of a single region, can result in a 50% reduced workload with a reading performance within the interquartile range of standard double reading with a recall rate of 27.1 per 1,000 (95% CI 25.6-28.7) and a cancer detection rate of 8.0 per 1,000 (95% CI 7.4-8.7). At this split the AI achieved an AUC of 0.983 (95% CI 0.969 - 0.994) for the cases with confident predictions, compared to 0.880 (95% CI 0.850 - 0.907) for the exams with the uncertain predictions.

### CONCLUSION

Uncertainty metrics can be used to classify exam predictions as certain or uncertain. Leveraging uncertainty to guide the reading strategy may halve the workload without changing cancer detection and recall rates, even with a model that has lower performance than that of a single radiologist.

### CLINICAL RELEVANCE/APPLICATION

Leveraging model uncertainty of an AI mammography interpretation model can reduce workload in screen reading without decreasing performance by only considering the model's interpretations when it is confident.

## S5-SSBR02-2 USE OF ARTIFICIAL INTELLIGENCE TO REDUCE THE INTERVAL CANCER RATE OF SCREENING DIGITAL BREAST TOMOSYNTHESIS

Saul Langarica (*Abstract Co-Author*) Nothing to Disclose
Synho Do, PhD, MS (*Abstract Co-Author*) Nothing to Disclose
Ariel Kniss, MD, PhD (*Abstract Co-Author*) Intern, General Electric Company
Manisha Bahl, MD, MPH (*Presenter*) Consultant, Lunit Inc;Expert Advisory Committee, 2nd.MD

### PURPOSE

The interval cancer rate, or symptomatic false-negative (FN) cancer rate, of screening digital breast tomosynthesis (DBT) is considered to be a surrogate marker for long-term patient outcomes. To our knowledge, there is no published literature that focuses on the use of artificial intelligence (AI) to detect FN cancers on screening DBT. The purpose of this study is to assess whether an AI algorithm can correctly localize FN cancers, both interval cancers (symptomatic FN cancers) and asymptomatic FN cancers, on screening DBT examinations and to compare features of interval cancers detected versus not detected by AI.

**METHODS AND MATERIALS**

In this Institutional Review Board-approved and Health Insurance Portability and Accountability Act-compliant study, FN screening DBT examinations from 2013 to 2022 at an academic institution were analyzed by an AI algorithm (INSIGHT DBT v1.0.0.2; Lunit, Inc.). Lesions were marked on the DBT slices and assigned a score from 0-100, with the examination-level score reflecting the highest lesion score. Examinations considered positive by AI (i.e., those with an examination score of 10 or higher) were reviewed by a breast imaging radiologist to determine if the mark corresponded to the correct site of the subsequently diagnosed breast cancer. Clinical, imaging, and pathological features were compared between cancers detected and not detected by AI using standard statistical tests.

**RESULTS**

There were 339 FN screening DBT examinations in 336 women (mean age, 59 years +/- 12 [standard deviation]). Two-thirds of the FN cases had dense breast tissue on mammography (66.1%, 224/339). The mean interval from the FN screening DBT examination to the tissue diagnosis of breast cancer was 213 days +/- 92 (standard deviation). AI correctly identified 27.4% (93/339) of all FN cancers and 35.7% (74/207) of interval cancers. AI detected a higher proportion of interval cancers than asymptomatic FN cancers (35.7% [74/207] versus 14.4% [19/132], $p<0.001$). Features associated with interval cancers detected by AI (versus not detected) included dense breast tissue (75.7% [56/74] versus 57.9% [77/133], $p=0.01$), the presence of a mammographic finding identified by the radiologist at the time of breast cancer diagnosis (94.2% [65/69] versus 73.6% [92/125], $p<0.001$), and large size on surgical pathology (37 mm versus 25 mm, $p=0.001$).

**CONCLUSION**

AI correctly identifies more than one-third of interval cancers on retrospective evaluation of screening DBT examinations.

**CLINICAL RELEVANCE/APPLICATION**

This study shows the potential of AI to reduce the interval cancer rate of screening DBT, which could ultimately lead to improved screening outcomes.

## S5-SSBR02-3 REAL-WORLD IMPACT OF AI CAD IN POPULATION-BASED BREAST CANCER SCREENING - COMPARING SCREENING METRICS BEFORE AND AFTER THE SCREENTRUSTCAD TRIAL

Fredrik Strand, MD, PhD (*Abstract Co-Author*) Speaker, Lunit Inc
Frida Pilblad (*Abstract Co-Author*) Nothing to Disclose
Karin Dembrower, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

ScreenTrustCAD (NCT04778670) was the first prospective interventional study of AI in population-based breast cancer screening conducted April 2021 to April 2022 with a total of 55,581 women included. In June 2023, the study hospital decided to fully replace one radiologist with AI. We have now analyzed how flagging, recall and cancer detection has changed compared to the time before the trial.

**METHODS AND MATERIALS**

At the same hospital where the ScreenTrustCAD trial was conducted, we analyzed all screening examinations from two six-month time periods - before and after the trial. The first period was January to June 2020, when regular radiologist double-reading and consensus discussions were performed, before the ScreenTrustCAD study. The second period was July to December 2023, when AI had replaced one of the two radiologists in double-reading, more than a year after the ScreenTrustCAD ended inclusions. The AI system Lunit INSIGHT MMG was used for our full-field mammograms from Philips mammography equipment. We calculated number of screened women, flaggings, recalls, cancers as well as cancer detection rates and positive predictive values for each period.

**RESULTS**

For the six-month period without any AI, 16,217 women were screened, 1,201 were flagged (7.4%), 608 (3.7%) were recalled and 93 cancers were screen-detected. The cancer detection rate was 5.7 per 1000 screened, and the positive predictive values were 7.7% of flagged and 15.3% of recalled. For the six-month period after clinical implementation of AI, 26,629 women were screened, 2,307 were flagged (8.7%), 683 (2.6%) were recalled and 154 cancers were screen-detected. The cancer detection rate was 5.8 per 1000 screened, and the positive predictive values were 6.7% of flagged and 22.5% of recalled. The second period, when AI was used, showed a reduction of 26,629 (50%) initial reads and an increase of 344 (17%) consensus discussions.

**CONCLUSION**

After implementing an AI system as one of two readers in double-reading of screening mammograms, the workload of initial reads decreased by 50% whilst consensus discussions increased by 17%. Cancer detection rates were similar with a smaller proportion of women recalled.

**CLINICAL RELEVANCE/APPLICATION**

The real-world results, comparing periods before and after AI implementation, reinforces the finding from the previous ScreenTrustCAD trial that AI may be favorably used as one of two readers in double-reading of screening mammograms.

## S5-SSBR02-4 IMPLEMENTATION OF A CONVOLUTIONAL NEURAL NETWORK-BASED DETECTION SOFTWARE AS AN INDEPENDENT THIRD READER IN THE GERMAN MAMMOGRAPHY SCREENING: A PROSPECTIVE STUDY

Thomas Lehnen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the impact of using a software for computer-aided detection in digital mammography as an independent third reader in the German breast cancer screening program on detection rates and on the screening process.

**METHODS AND MATERIALS**

In this prospective study, over a period of 6 months from August 23 to February 24, the screening mammograms of 15,377 participants aged 50 to 69 years were analyzed using a software for computer-aided detection (Transpara, Screenpoint Medical), additionally to independent double reading which was conducted without knowledge of the software results. The software assigns a score from 1 - 10, with 10 representing the highest probability for malignancy. Each lesion detected by the software is either categorized as density or calcification. All cases with a Score of 10 were brought into the consensus conference, consisting of the two readers and a program director radiologist, together with the cases selected by one or both of the readers. All screening cases deemed in need of further investigation during the consensus conference underwent further diagnostic evaluation.

**RESULTS**

Among the 15,377 cases, 114 breast cancers were diagnosed. 10 ( 8.8%) were solely identified by the software. This resulted in an increase in the detection rate of 8.7% ( from 0.68% to 0.74%). The PPV of the recalled cases was 13.6%, whereas without the use of the software, it would have been 15.0%. The additionally diagnosed cancers were all invasive and characterized by the software as densities, except for one case, which was a DCIS and identified as calcification. The invasive cancers were exclusively HR-positive, Her2-negative, with Ki-67 values up to 16%. 12 malignancies were software negative, 8 of them received a score of 9. 8 software negative cancers were invasive, of which 3 were triple negative, with Ki-67 values of 25% and above and rated with low scores of 7, 6 and 2 respectively.

**CONCLUSION**

Using the software as an independent third reader improved the cancer detection rate with reasonable additional burden on the screening attendees and workload in terms of decrease in PPV of the recalled cases. Including score 9 densities for presentation in the consensus conference may result in a further improvement of screening sensitivity without inadequately increasing the workload. Considerations about replacing readers with the software should take into account the weaknesses of the software in detecting triple negative breast cancers.

**CLINICAL RELEVANCE/APPLICATION**

Using an analyzing software as an independent third reader may be a suitable means to improve screening results. Including cases with a score of 9 classified as densities by the software may further improve the sensitivity of the screening and should be evaluated in future studies.

## S5-SSBR02-5 EARLY ALERTS - AN ANALYSIS OF TEMPORAL CHANGES IN THREE MAMMOGRAPHY-BASED ARTIFICIAL INTELLIGENCE ALGORITHM SCORES OVER THE COURSE OF A PATIENT'S SCREENING TIMELINE

Pantelis Gialias, MD (*Abstract Co-Author*) Nothing to Disclose
Fredrik Strand, MD, PhD (*Abstract Co-Author*) Speaker, Lunit Inc
Fernando Cossio Ramirez, BSc (*Abstract Co-Author*) Nothing to Disclose
Haiko Schurz, BSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Sophia Zackrisson, MD, PhD (*Abstract Co-Author*) Speaker, Siemens AG;Speaker, Bayer AG;Speaker,Pfizer Inc;Patent holder, PCT/EP2014/057372;

Sarah Hickman, MBBS (*Presenter*) Research collaboration, Vara;Research collaboration, ScreenPoint Medical BV;Research collaboration, Lunit Inc;Research collaboration, Kheiron Medical Technologies Ltd;Research collaboration, Alphabet Inc;Research collaboration, Volpara Health Technologies Limited

**PURPOSE**

Artificial intelligence computer-aided detection (AI CAD) scores have been validated for detection of breast cancer using a 1-to-2-year follow-up time in several studies. However, women attend screening over many years and analysing AI CAD scores over longer time periods could provide insight into the earlier detectable change.

**METHODS AND MATERIALS**

The retrospective VAI-B dataset from 4 different screening regions in Sweden was used for this study. All women with breast cancer were included and randomly selected healthy controls. Two-view full-field digital mammograms screening rounds in 2007 to 2021 were included. Exams with images from GE and Philips equipment were included. Cancer ground truth was based on histopathology and healthy status on at least three-year follow-up. The abnormality scores from three commercial AI CADs were determined at each screening episodes based on the images from that episode only. Population percentile cut-off points for AI CAD scores were calculated separately for each AI CAD and each age of the participating women in the full population.

**RESULTS**

In total 29,136 individuals and 83,723 exams were included, of which 10,350 individuals were diagnosed with breast cancer (35.5%). The median age of the cohort was 58.4 [IQR 49.2 - 65.9] with an average number of 3 screening episodes per cancer case included over a median of 4.1 years [IQR 2.1 - 6.2]. After up-sampling of healthy cases, the final study population included 1,024,794 individuals, to attain a proportion of diagnosed and healthy reflective of the source population (cancer proportion of 1%).The proportion of cancer cases with an age-adjusted AI CAD score above the 90th centile of the entire population, for AI-1, AI-2, and AI-3 respectively, at 5 years before diagnosis, were 19.5%, 18.5% and 19.6% . The proportions had increased at 3 years before diagnosis to 32.6%, 29.9% and 32.4%. And at 1 year before diagnosis were 80.5%, 71.2% and 77.5%.When set at the 75th centile, at 5 years before diagnosis, 39.4%, 36.5% and 42.7% of the cancer cases exceeded the threshold; which increased at 3 years before to 53.1%, 50.5%, 52.7%; and at 1 year before diagnosis to 88.8%, 82.4% and 87.9%.See Figure for AI CAD score dynamics up to 10 years out.

**CONCLUSION**

The AI CAD scores from sequential mammograms show that many years before diagnosis, the scores are disproportionately higher for women who will later be diagnosed with breast cancer compared to the overall population

**CLINICAL RELEVANCE/APPLICATION**

Based on AI CAD scores from three commercial AI systems, there is a potential to detect up to a third of current cancers around 3 years earlier by an intervention targeting 10% of the population, or, if preferred, to detect up to half of current cancers by targeting 25% of the population

## PURPOSE

The integration of artificial intelligence (AI) into breast screening holds significant promise for improving cancer detection accuracy and service efficiency, with the optimal workflow for implementing AI dependent on clinical site requirements. This evaluation aimed to compare and evaluate different workflows for integrating AI into breast screening, assessing their impact on screening outcomes and workload.

## METHODS AND MATERIALS

In a prospective evaluation, a commercially available AI system was implemented within a breast screening unit to examine AI integration workflow strategies, Fig 1. Women could choose to opt out of AI assessment. Each case received standard double reading (DR) with arbitration of discordant cases. If the DR process did not prompt recall but the AI flagged potential abnormalities (as a safety net), additional arbitration was employed. Women identified as needing further evaluation were recalled. Workflow variations using AI were assessed including a combination of AI as 1) a 'second reader' in a portion of cases (which was modelled), and 2) a safety net 'extra reader' (implemented live). Non-inferiority (alpha of 0.05) was tested for recall rate (RR), cancer detection rate (CDR), sensitivity (SEN), specificity (SPEC) and positive predictive value (PPV). Superiority was tested when non-inferiority passed alpha of 0.1.

## RESULTS

The evaluation included 10,889 women. The primary workflow resulted in additional arbitration for 1,345 (12.4%) women after being flagged by the AI, yielding an increased CDR of 1 per 1000 (11 extra cancers found), a modelled workload savings of 31% and relative RR reduction of 0.8%. Other workflow variations showed different trade-offs in terms of CDR, RR, PPV, SEN, SPEC and workload savings. Statistical testing showed a combination of non-inferior or superior outcomes for some workflows, while others yielded superior outcomes, across all measured metrics.

## CONCLUSION

This evaluation presents the advantages and challenges of different workflow options for integrating AI into breast screening. The primary workflow and multiple other variations emerge as particularly promising strategies, offering superior clinical outcomes and operational gains. These findings underscore the importance of tailoring AI integration to specific clinical contexts to optimise its impact on breast screening.

## CLINICAL RELEVANCE/APPLICATION

This evaluation shows that different AI implementation strategies provide improved CDR and workload savings with varied trade-offs. Some may provide superior performance across all metrics assessed. The optimal method of implementing AI into breast screening pathways will need to be considered prior to its use in clinical practice according to local requirements.

## S5-SSCA02-2 INFLUENCE OF THE DENOISING ALGORITHM ON PERICORONARY ADIPOSE CT ATTENUATION: COMPARISON BETWEEN ADAPTIVE STATISTICAL ITERATIVE RECONSTRUCTION AND DEEP LEARNING IMAGE RECONSTRUCTION

Ning Pan (*Abstract Co-Author*) Nothing to Disclose
Jianxin Guo (*Abstract Co-Author*) Nothing to Disclose
Jianying Li, PhD (*Abstract Co-Author*) Employee, General Electric Company
Lihong Chen (*Abstract Co-Author*) Nothing to Disclose
Tingting Qu (*Presenter*) Nothing to Disclose

### PURPOSE

Pericoronary adipose tissue CT mean attenuation (PCATMA) is a marker of coronary artery inflammation. The influence of deep learning image reconstruction algorithm (DLIR) on PCATMA is still unknown, which was investigated in this study in comparison with adaptive statistical iterative reconstruction veo (ASIR-V) algorithm.

### METHODS AND MATERIALS

Twenty-one patients with confirmed or suspected coronary artery disease who underwent CT coronary angiography were included. All scans were reconstructions with both low and high strength of ASIR-V and DLIR. PCATMA of the left anterior descending artery (LAD), left circumflex artery (LCX), and right coronary artery (RCA) were calculated using a dedicated software. The differences of PCATMA between the low and high strength of ASIR-V and DLIR algorithms were compared by Wilcoxon rank sum test and Bland-Altman plot.

### RESULTS

The PCATMA significantly increased when higher strength of ASIR-V or DLIR was used (Fig.1). However, Bland-Altman plot showed that the mean difference between the low and high strength of DLIR for LAD, LCX, and RCA (-1.2±0.9 HU, -1.7±0.9 HU and -1.1±0.8 HU, respectively) was significantly smaller than the difference (-4.1±5.9, -4.5±6.0 and -3.9±5.5, respectively) of ASIR-V (all $P<0.05$) (Fig.2 and Fig.3).

### CONCLUSION

The PCATMA increased significantly with higher strength of ASIR-V or DLIR. However, comparing with ASIR-V, the magnitude of change in PCATMA was significantly smaller for DLIR compared with ASIR-V.

### CLINICAL RELEVANCE/APPLICATION

Because PCATMA changes only slightly with the progression of coronary atherosclerosis, and because PCATMA is more robust to different strengths of DLIR, it is better to use DLIR for denoising when applying PCATMA in clinical practice to reduce bias.

## S5-SSCA02-3 PHOTON-COUNTING CT: HOW THE GENERATION OF CT CHANGE THE RESULT OF COMPUTED ASSISTANCE DIAGNOSTIC (CAD)?

Yiran Wang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To explore whether the artificial intelligence-aided diagnosis results of the new generation photon counting CT will be affected by the image quality.

### METHODS AND MATERIALS

A total of 50 patients who underwent CCTA imaging in photon counting CT were included. The acquisition scheme selected high-resolution imaging mode, only 0.2mm and 0.6mm images were selected for reconstruction, and Bv72 and Bv48 were used for convolution kernals. The two groups of images were deliverd to the coronary post-processing module of the artificial intelligence assistant diagnosis software, and the subjective score of the image judged by the software and the degree of stenosis of the three main coronary arteries were recorded. The results of invasive coronary angiography were also recorded at the same time.Qualitative image analysis was performed by four radiologists. The statistical significance of the difference between groups was evaluated by Friedman test, and the Kappa consistency score was used to compare the results of AI-assisted diagnosis between the two groups. If there is a significant difference, the pairwise post-test corrected by Bonferroni is used.

### RESULTS

Compared with standard reconstruction, the image of High-Difination reconstruction algorithm was more consistent with invasive coronary angiography in AI software-assisted diagnosis (Kappa=0.874;p < 0.001). Of the 12 moderate stenosis segments initially scored in the standard reconstruction, 4 segments (30%) were reclassified as mild stenosis, while only 1 of the 7 severe stenosis segments was reclassified as moderate stenosis, while no change in AI determination of stenosis was found in mild stenosis and normal segments. However, using this algorithm will reduce the subjective score of the image judged by the software (3.64 vs.4.23 p < 0.001).

### CONCLUSION

Photon counting CT coronary artery HD imaging can improve the accuracy of AI-assisted diagnosis.

### CLINICAL RELEVANCE/APPLICATION

Photon counting CT coronary artery HD imaging can improve the accuracy of AI-assisted diagnosis.

## S5-SSCA02-4 DIAGNOSTIC PERFORMANCE OF AI-DRIVEN ANALYSIS OF CORONARY ARTERY STENOSIS IN CARDIAC CTA

Kristina Hallam (*Abstract Co-Author*) Employee, Siemens AG
Ronald M. Peshock, MD (*Abstract Co-Author*) Stockholder, General Electric Company;Researcher, Siemens AG;Researcher, Aidoc Medical

Christopher Fan (*Abstract Co-Author*) Nothing to Disclose
Fernando U. Kay, MD, PhD (*Presenter*) Research Grant, Edwards Lifesciences Corporation

### PURPOSE

This study aims to evaluate the diagnostic performance of an Artificial Intelligence (AI) algorithm prototype in automatically analyzing coronary artery stenosis using the CAD-RADS 2.0 system on cardiac computed tomography angiography (CTA).

### METHODS AND MATERIALS

We included all cardiac CTA studies performed between 2017 and 2021 at a single academic center. Studies were included under a waiver for informed consent. Exclusions were non-diagnostic studies (CAD-RADS category N), coronary anomalies, and patients post coronary artery bypass graft (CABG) or stenting. CAD-RADS categories extracted from structured clinical radiology reports served as the reference standard. All available CTA series were processed independently by the AI algorithm (ACA Prototype, Siemens Healthineers). None of these CTA scans were used in the development of the algorithm. Discrepancies exceeding one CAD-RADS category between the radiological report and the ACA CAD-RADS prompted adjudication by two independent expert readers, who were blinded to both the clinical and AI-based scores.

### RESULTS

Out of 1,128 studies initially screened, 87 were excluded (3 CABG, 7 stents, 23 coronary anomalies, 54 CAD-RADS N), leaving a total of 1,041 studies from 1,033 patients (56% female, median age 62 years; interquartile range: 54 - 69). The studies originated from five models across three manufacturers (Siemens, Philips, and Canon). The weighted kappa coefficient for agreement between the ACA prototype and the reference CAD-RADS scores was 0.73 (95% CI: 0.69 - 0.76). The area under the receiver operating characteristic curve for detecting maximum stenosis of = 50% and = 70% was 0.90 (95% CI: 0.88 - 0.92) and 0.90 (95% CI: 0.87 - 0.92), respectively.

### CONCLUSION

The AI algorithm prototype demonstrates high diagnostic accuracy in assessing coronary artery stenosis using the CAD-RADS 2.0 system on cardiac CTA across a large, diverse sample of scans from multiple vendors in an academic center.

### CLINICAL RELEVANCE/APPLICATION

Its substantial agreement with the clinical reference standard and ability to detect significant stenosis highlight its potential for improving clinical workflows. Future research studies are required to investigate how AI-preliminary read strategies impact patient management by assessing their safety, as well as their influence on turnaround time.

## S5-SSCA02-5 DEEP LEARNING-BASED CT MYOCARDIAL BLOOD FLOW QUANTIFICATION AND RISK STRATIFICATION OF CORONARY ARTERY DISEASE

Yarong Yu (*Presenter*) Nothing to Disclose

### PURPOSE

To train and validate an AI-model that carry out fully automatic quantification of MBF and ischemic myocardial volume, enable accurate diagnosis of hemodynamically significant stenosis with reference to invasive FFR, and particularly to investigate the prognostic value of AI-MBF.

### METHODS AND MATERIALS

This multi-center study involved 3 cohorts from 3 hospitals. We gathered 268 patients underwent CT-MPI + CCTA retrospectively to develop the AI model. These patients were randomly divided into 8:2 ratio: training dataset (211 patients) and tuning dataset (57 patients). Subsequently, we collected 90 patients for external validation. 90 symptomatic patients with stable angina were prospectively enrolled. These patients underwent dynamic CT-MPI initially and then took ICA or invasive FFR measurement within a 1-month interval for the purpose of diagnostic performance assessment, with invasive FFR serving as the reference standard. Finally, we evaluated the prognostic value of AI-MBF for major adverse cardiovascular events (MACEs) in 660 patients from 3 distinct hospitals, using multivariable Cox regression analysis.

### RESULTS

In the test set, there was excellent agreement, between AI model and manual measurements of both segment and patient-based MBF. Ninety participants with 116 target vessels were included for final analysis. AI-based MBF had lager AUC (using 93 mL/100 mL/min as a cutoff) than diameter stenosis (DS) (AUC = 0.970 vs 0.789, P<0.001, in per-vessel level; AUC = 0.963 vs 0.797, P<0.001, in per-patient level). Over a median follow-up of 35 months, MACEs occurred in 126 (19%) of 660 patients in this study. Multivariate Cox regression analysis revealed that AI-based ischemic myocardial volume (HR 1.13, p=0.019), presence of obstructive CAD (HR 2.04, p<0.001) and low attenuation plaque (HR=2.03, p=0.020) were the independent predictors for MACEs. Furthermore, the model with ischemic myocardial volume had higher global chi-square test result and improved reclassification than the model

without ischemic myocardial volume. For per-patient, the mean CT-MPI postprocessing time of AI-model was 8s (SD=1s) versus 403s (45s) taken manual reconstruction.

**CONCLUSION**

AI-model enabled fast, fully automatic CT-MBF quantification and accurate diagnosis of ischemic coronary stenosis. The ischemic myocardial volume percentage derived from AI-model improved risk stratification of CAD.

**CLINICAL RELEVANCE/APPLICATION**

AI-model enable accurate diagnosis of hemodynamically significant stenosis, precisely guiding treatment strategy for purpose. The model with ischemic myocardial volume derived from AI-model had better risk stratification for CAD patients. AI-model significantly improved clinical workflow.

### PURPOSE

To establish a strong baseline for peri-pancreatic edema detection with deep learning and conventional machine learning approaches and to provide a unique dataset for the public.

### METHODS AND MATERIALS

We develop a new deep learning algorithm for automatic detection of peri-pancreatic edema from CT scans. Our method is based on a combination of segmentation algorithms for ROI determination of the pancreas, radiomics (XGBoost), and transformer-based (Swin-tiny) combined classifier for detection/diagnosis. We also introduce a novel CT dataset sourced from 255 patients with acute pancreatitis, featuring annotated pancreas segmentation masks and corresponding diagnostic labels for peri-pancreatic edema condition, publicly available for reproducible research and transparency. With this novel dataset, we both evaluate the efficacy of the segmentation model (LinTransUNet), a linear Transformer-based segmentation algorithm, as well as a classification model for predicting peri-edema existence. The Dice score was used for segmentation evaluation, and accuracy and precision were used for classification (diagnostic) experiments.

### RESULTS

LinTransUNet for the segmentation mask generation of CT pancreas images, yielding a commendable dice coefficient of 80.85%. We also evaluated different deep learning backbones in this study for classification (diagnosis). The best deep learning model (Swin-tiny) demonstrates robust accuracy rates averaging 97.95%. While the radiomics-based model exhibited a lower score in every indicator, it achieved an accuracy of 79.61% and a precision of 81.91%.

### CONCLUSION

In this study, we established a unique dataset comprising CT images from 255 patients with acute pancreatitis, categorized into classes indicative of the presence or absence of peri-pancreatic edema. LinTransUNet was employed for segmentation, showing promising results. By evaluating various deep learning and radiomics-based models, we established a new baseline for peri-pancreatic edema detection.

### CLINICAL RELEVANCE/APPLICATION

Early and accurate detection of peri-pancreatic edema is crucial for diagnosis and predicting the prognosis of pancreatitis. Our algorithm could potentially improve diagnostic accuracy by automatically detecting subtle signs of edema that might be missed by radiologists on visual inspection alone.

## S5-SSGI03-2 IDENTIFYING RADIOLOGICAL PREDICTORS FOR THE EVOLUTION OF ACUTE PANCREATITIS INTO RECURRENT AND CHRONIC FORMS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Endre Botond Gagyi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The progression of acute pancreatitis (AP) to its recurrent (RAP) and chronic (CP) forms involves significant clinical and radiological challenges, necessitating detailed imaging studies to understand the morphological changes that predict disease progression. This systematic review and meta-

analysis aimed to identify radiological risk factors and imaging biomarkers associated with the progression of AP to RAP and CP.

**METHODS AND MATERIALS**

Following the protocol registration on PROSPERO (CRD42022368931), we searched Medline, Embase, and Cochrane databases up to December 19th, 2023, for studies examining risk factors for the evolution of AP into RAP or CP. Pooled odds ratios (OR) with 95% confidence intervals (CI) were calculated using the random effects model. Heterogeneity was evaluated using the $I^2$ statistic. The risk of bias assessment was performed using the Quality in Prognostic Studies (QUIPS) tool.

**RESULTS**

A total of 124 articles were included in the meta-analysis, and several risk factors were identified for the progression of AP into RAP and CP. We found the following radiological risk factors of AP recurrence: pseudocyst, acute peripancreatic fluid collections (APFC), anatomic abnormality etc. The pooled OR for pseudocyst was 2.19 (95% CI: 1.53-3.14, $I^2$ = 0%), for APFC was 2.15 (95% CI: 1.00 - 4.62, $I^2$ = 6%), for anatomic abnormality was 9.77 (95% CI: 1.16 - 82.29, $I^2$ = 78% . The risk of bias was moderate in the majority of the included studies.

**CONCLUSION**

Radiological features such as pseudocysts, acute peripancreatic fluid collections, and anatomic abnormalities are crucial predictors of the transition from AP to its recurrent and chronic forms. Recognizing these features early through imaging can guide clinical interventions to prevent disease progression, highlighting the essential role of radiology in managing pancreatitis.

**CLINICAL RELEVANCE/APPLICATION**

This study underscores the importance of imaging in the management of acute pancreatitis. Identifying radiological features like pseudocysts, acute peripancreatic fluid collections, and anatomic abnormalities early can critically inform treatment strategies, potentially preventing the progression of AP into RAP and CP and improving patient outcomes.

## S5-SSGI03-3 ASSOCIATION OF RADIOMIC FEATURES WITH GEOLOCATION-BASED ALLOSTATIC LOAD AND OUTCOMES IN ACUTE PANCREATITIS

Abraham Fourie Bezuidenhout, MD (*Abstract Co-Author*) Nothing to Disclose
Manisha Bohara, MBBS, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Investigate the association of radiomics with geolocation-based allostatic load measured by food access and social vulnerability index (SVI) (based on 16 attributes in 4 domains: socioeconomic status, household composition and disability, minority status and language, and housing type and transportation), and also with outcomes in patients with acute pancreatitis (AP).

**METHODS AND MATERIALS**

This study included all AP-related hospitalizations from 2008-2018. We recorded clinicoradiologic information and geocoded physical addresses to determine food access (normal vs low), and SVI (divided into quartiles; IV being the most vulnerable). Radiomic indices included visceral (VA) subcutaneous adiposity (SA), visceral/total adiposity ratio (VA/TA), and sarcopenic imaging marker, psoas muscle Hounsfield Unit Average Calculation (HUAC).

**RESULTS**

Among 486 patients with 592 AP-related hospitalizations, we noted median (IQR) VA of 159.5(159), SA of 203(168), VA/TA of 42.85(23) HUAC of 52.4(14). Higher severity of AP was associated with higher VA (mild AP: 137.5(148), moderate: 159(150), severe: 223.5(163); P=0.001) and lower HUAC (mild: 53.74(14), moderate:51.3(13), severe: 47.17(13); P=0.001). AP recurrence was associated with higher VA [single AP: 149(156) vs. recurrent AP: 177(148); p=0.04] and sarcopenia [single AP: 54.5(12) vs. recurrent AP: 53.6(13); p=0.04]. Also, higher VA/TA ratios were associated with active smoking [36.3(21) vs. 45.8(23); p=0.001] and alcohol consumption [38.0(23) vs. 45.8(22); p=0.001]. Geospatial analysis showed lower VA among patients with higher SVI: (I: 176(149), II: 145.5(168), III: 174(149), IV: 38.4(25); P=0.038). By regression analysis, VA had significant association with SVI [-47.24(-77- -18); P =0.002] and SVI subindices: socioeconomic status [-49.5(95%CI: -81 - -18); P=0.002], Minority status and Language [-59.3(95%CI: -92- -27); P<0.001], Housing type and transportation [-42(95%CI: -75- -9); P=0.002].

**CONCLUSION**

Severity of AP and recurrent AP, were associated with higher VA and sarcopenia, while SA was associated with smoking and alcohol. Geospatial analysis of radiomics in AP showed significant association of residence in socially vulnerable areas with lower VA which may protect against recurrent and severe AP.

**CLINICAL RELEVANCE/APPLICATION**

This is the first study investigating epidemiology of radiomics among patients with variable geospatial allostatic load. We noted higher VA and lower sarcopenia in regions with relatively preserved social determinants of health, which have significant association with AP severity and recurrence. Health interventions in visceral obesity are imperative to improve outcomes of patients with AP, regardless of social vulnerability.

## S5-SSGI03-5 CHRONIC PANCREATITIS MRI SCORE (CP-MRI): A NEW PROPOSAL FOR DIAGNOSIS AND DISEASE SEVERITY USING PARENCHYMA AND DUCTAL FEATURES

Evan L. Fogel (*Abstract Co-Author*) Nothing to Disclose
Dhiraj Yadav, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Temel Tirkes, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Generate a new diagnostic scoring system for chronic pancreatitis (CP) using MRI parameters in the well-phenotyped PROCEED study population. We aimed to generate a semi-quantitative composite score that would fulfill the need for a more accurate and early diagnosis of CP.

**METHODS AND MATERIALS**

The MINIMAP study prospectively imaged and analyzed 46 control, 45 suspected, and 46 definite CP patients enrolled at seven clinical centers in the USA from February 2019 to May 2021. Suspected and definite CP diagnoses were established based on imaging findings, symptomatology, and clinical presentation. MRI was performed using a standard imaging protocol on 1.5T Siemens and GE scanners. Logistic regression analysis generated multiparametric CP-MRI score, which included fat fraction (FF), arterial-to-venous enhancement ratio (AVR), and pancreatic tail diameter (PTD). If secretin-enhanced MRCP was performed, pancreatic ductal elasticity (PDE) was added to generate the CP-SMRI score. Lin's concordance correlation coefficient was used for interobserver agreement.

### RESULTS

All MRI and MRCP parameters were significantly different between the control and definite CP cohorts: FF ($p<0.001$), AVR ($p<0.01$), PTD ($p<0.001$) and loss of PDE ($p<0.001$). Using a multiparametric score yielded better diagnostic performance than the individual parameters. CP-MRI and CP-SMRI had cross-validated AUCs of 0.84 and 0.86, respectively. The score of 2.6 was 87% sensitive, 68% specific using CP-SMRI and 89% sensitive, 67% specific using CP-MRI for the diagnosis of CP. Interobserver agreement for both scores was 0.74.

### CONCLUSION

The multiparametric approach to diagnose CP yields higher diagnostic performance than individual parameters. Larger population studies with multiple observers and longitudinal analyses are warranted.

### CLINICAL RELEVANCE/APPLICATION

We propose new diagnostic criteria that combine three parenchymal MRI features and an optional dynamic secretin-enhanced MRCP feature.

## S5-SSGI03-6 CORRELATION BETWEEN FAT AND IRON CONTENT, PARENCHYMAL STIFFNESS, GLAND VOLUME, AND PANCREATIC FUNCTION

Mirko D'Onofrio, MD (*Abstract Co-Author*) Speaker, Bracco Group;Speaker, Siemens AG;Consultant, Siemens AG;Speaker, Hitachi, Ltd
Carlo Giuseppe Licata (*Abstract Co-Author*) Nothing to Disclose
Rachele Zibbra (*Abstract Co-Author*) Nothing to Disclose
Anna Garofano (*Abstract Co-Author*) Nothing to Disclose
Flavio Spoto, MD (*Abstract Co-Author*) Nothing to Disclose
Riccardo De Robertis, PhD, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate correlations between pancreatic fat and iron content assessed by 3D multi-echo Dixon MRI, gland volume, parenchymal stiffness assessed by US point shear wave elastography (pSWE), and pancreatic function.

### METHODS AND MATERIALS

117 subjects prospectively underwent 3D multi-echo Dixon MRI and transabdominal US pSWE evaluation on the same day. Volumes of interest encompassing the whole pancreas were segmented on MRI images to calculate median proton density fat fraction (PDFF), median R2* values, and gland volume. The median value of nine pSWE measurements was calculated for each subject. Measurements were compared between subjects with normal pancreatic function and those with pancreatic insufficiency using the Mann-Whitney U test. P values =0.05 were considered statistically significant.

### RESULTS

93 subjects were included (50 men and 43 women; mean age 61 years, range 18- 85); 28 subjects (30.1%) had pancreatic insufficiency. MRI-PDFF was the only parameter with a significant difference between groups, being significantly higher in subjects with pancreatic insufficiency than in those with a normal pancreatic function (median 7% vs. 3.1%, $p=0.008$).

### CONCLUSION

Pancreatic fat content assessed by MRI-PDFF may be correlated with pancreatic insufficiency.

### CLINICAL RELEVANCE/APPLICATION

The pancreatic fat content, as determined by MRI-PDFF, demonstrates reliability and holds clinical significance in enhancing diagnostic precision for the detection of pancreatic insufficiency and it could potentially be incorporated into the screening process for patients presenting with risk factors.

Aaditeya Jhaveri, BS (*Presenter*) Nothing to Disclose

### PURPOSE

The spleen is the most commonly injured organ in blunt abdominal trauma with high grade injuries having a high mortality rate due to hemorrhagic shock. Multi-detector contrast enhanced CT is the gold-standard diagnostic imaging tool for the detection of such injuries, and the rapid identification of splenic injuries is crucial. However, turnaround time from presentation to image interpretation can be delayed, especially at non-trauma centres. Machine learning (ML) models have potential to accelerate this through automatic detection and grading of splenic injuries. We externally validated an open source ML model using the largest validation dataset in the literature for such a purpose.

### METHODS AND MATERIALS

The second place ML model from the RSNA 2023 Abdominal Trauma Detection AI Challenge was modified and retrained to focus on splenic injuries. External validation of the model was performed using a dataset of 1,216 split bolus protocol trauma CT scans performed between January 1, 2005 and July 31, 2021 on adult patients (= 18 years) at a level 1 trauma centre. Ground truth labels were established by 5 abdominal radiologists using the AAST splenic injury scoring scale. The dataset consisted of 608 positive (172 female, 438 male; age range 18-97 years; mean age 44.4 ± 19.9 years) and 608 negative cases (154 female, 456 male; age range 18-103 years; mean age 46.6 ± 19.5 years). There were 455 low (AAST I-III) and 153 high (AAST IV and V) grade splenic injuries.

### RESULTS

The model demonstrated an overall AUC of 0.930 (95% CI: 0.917, 0.944), sensitivity of 0.766 (95% CI: 0.730, 0.797), specificity of 0.957 (95% CI: 0.940, 0.969), positive predictive value (PPV) of 0.936 (95% CI: 0.911, 0.954), and negative predictive value (NPV) of 0.832 (95% CI: 0.806, 0.856) for the detection of splenic injuries. For the detection of high-grade injuries, the model demonstrated an AUC, sensitivity, specificity, PPV, and NPV of 0.959 (95% CI: 0.945, 0.974), 0.942 (95% CI: 0.893, 0.969), 0.857 (95% CI: 0.836, 0.876), 0.459 (95% CI: 0.405, 0.514), and 0.991 (95% CI: 0.984, 0.995) respectively.

### CONCLUSION

The ML model demonstrated robust performance in both the 3-class splenic injury classification and detection of high-grade injuries. Overall, performance metrics either met or surpassed those reported in existing literature. These findings demonstrate the potential for ML in automatic splenic injury detection. This will ultimately enhance patient care by prioritizing radiologist worklists and facilitate early trauma intervention.

### CLINICAL RELEVANCE/APPLICATION

Rapid detection and accurate grading of splenic trauma is critical due to the high mortality risk. We externally validated an ML model that demonstrated robust performance and high potential for clinical deployment.

## S5-SSGI04-2 PREDICTING LIVER SHEAR STIFFNESS WITH A MULTI-CHANNEL DEEP LEARNING MODEL USING MULTIPARAMETRIC ABDOMINAL MRI AND CLINICAL DATA IN CHILDREN AND ADULTS

**PURPOSE**

To develop multi-channel transformer-based deep learning (DL) models for predicting liver shear stiffness in children and adults diagnosed or suspected of chronic liver disease, using multiparametric abdominal MRI images and clinical data.

**METHODS AND MATERIALS**

In this IRB-approved retrospective multi-site study, we identified all children and adults who underwent abdominal MRI with MR elastography (MRE) for liver stiffness assessment between 2011 and 2022 from four sites. From each site, we collected axial T1-weighted (T1w), T2-weighted (T2w), and diffusion-weighted (DWI) MR images as well as relevant clinical data (e.g., age, sex, laboratory values). Mean liver shear stiffnesses (kPa) measured by MR elastography (MRE) were extracted from the electronic health record as ground truth. Our proposed multi-channel model utilized a pre-trained Swin Transformer model to capture latent features for regression (Figure 1). Model performance was evaluated using Pearson's correlation coefficient (PCC) and Mean Absolute Error (MAE) with 95% confidence intervals, assessed through internal multi-site 10-fold cross-validation (CV) and external validation experiments.

**RESULTS**

3,691 MRI examinations were acquired from 3,296 patients (mean [SD] age=50.3 [16.5] years; mean BMI=29.1 [6.6] kg/m2; 1,735 [52.2%] females). The initial cohort, consisting of 2,467 exams acquired between 2011 and 2020, was utilized for internal CV, while a second cohort, consisting of 1,224 exams obtained between 2021 and 2022, served as an external validation dataset. Our integrated multiparametric MRI and clinical model achieved a mean (95% CI) PCC of 0.75 (0.71, 0.77) and MAE at 0.83 kPa (0.79, 0.86) during internal validation. External validation yielded a mean PCC of 0.73 (0.69, 0.76) and MAE at 0.86 kPa (0.82, 0.89). The model's performance excluding cases of fatty liver disease reached 0.76 (0.72, 0.79).

**CONCLUSION**

The proposed multi-channel transformer-based DL model demonstrated strong prediction capability on predicting liver stiffness using multiparametric MR images on a large, multi-site, multi-vendor dataset.

**CLINICAL RELEVANCE/APPLICATION**

Our AI model can predict liver shear stiffness using multiparametric abdominal MRI data in children and adults, showing strong correlation with MR elastography measurements. Model refinements may further increase performance.

## S5-SSGI04-3 NON-INVASIVE IMAGING ASSESSMENT OF TERTIARY LYMPHOID STRUCTURES AND IMMUNOTHERAPY RESPONSE IN GASTRIC CANCER: A MULTI-CENTER RETROSPECTIVE AND PROSPECTIVE STUDY

Yuming Jiang, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Tertiary lymphatic structures (TLSs) are associated with improved survival and enhanced response to anti-cancer immunotherapy. However, assessing TLSs relies on substantial tissue samples, which is limited by access to tissue, spatial heterogeneity, and temporal evolution. This study aimed to develop a computed tomography (CT) imaging-based approach for non-invasive assessment of TLSs and immunotherapy response.

**METHODS AND MATERIALS**

This study involved 3,155 patients with gastric cancer (GC) from twelve cohorts spanning six hospitals. TLSs were classified into four stages (absence, Agg, FL-I, FL-II) according to their maturation based on immunohistochemistry staining. A CT imaging-based TLSs scoring model (ctTLSs) was developed to assess TLSs status, subsequently classified into four classes (ctTLSs-0/1/2/3). We next evaluated the model's associations with prognosis and immunotherapy response. To enhance the model's interpretability, we analyzed multi-omics data and employed the Shapley value strategy to provide its biological insights and order of importance.

**RESULTS**

The ctTLSs model achieved high accuracies in predicting TLSs status in the internal validation (AUC range: 0.809-0.872) and external validation (0.801-0.856) cohorts. In retrospective and prospective validation cohorts, ctTLSs exhibited significant associations with both disease-free and overall survival (HR range: 0.206-0.634, all $P < 0.01$). Shapley value analysis highlighted ctTLSs as the strongest predictor of TLSs status. Upon analyzing multi-omics data, we found that higher ctTLSs levels positively correlated with tumor immune activation and apoptosis signaling, while displaying a negative correlation with tumor proliferation and metabolism signaling. Intriguingly, patients with high ctTLSs (but not low ctTLSs) exhibited substantial benefits from immunotherapy ($P < 0.0001$). The objective response rate of four ctTLSs classes was 16.7% in ctTLSs-0, 35.5% in ctTLSs-1, 45.8% in ctTLSs-2, and 53.8% in ctTLSs-3.

**CONCLUSION**

The ctTLSs model could noninvasively assess TLSs status, enabling improved prognosis evaluation and informed decisions regarding immunotherapy.

**CLINICAL RELEVANCE/APPLICATION**

The imaging model has the potential for non-invasive prediction of prognosis and immunotherapy response, which will allow the optimization of individual decision-making.

## S5-SSGI04-4 COMPUTATIONAL ALGORITHM FOR AUTOMATED PATTERN RECOGNITION DIFFERENTIATING BILIARY AND PORTAL VENOUS GAS IN COMPUTED TOMOGRAPHY

Shri Krishna Jayanthi, MD (*Abstract Co-Author*) Nothing to Disclose
Mateus Esmeraldo, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The primary aim of this study is to develop and evaluate the efficacy of a novel computer program designed to automatically distinguish between biliary and portal venous gas observed on Computed Tomography (CT) scans. By using imaging analysis techniques with a theoretically based approach based on different branching pattern and gas distribution between biliary and portal venous gas, our program seeks to provide an accurate, fast and automated solution that enhances diagnostic accuracy and optimizes clinical outcomes, thereby reducing the potential for misdiagnosis and improving patient care in acute settings.

**METHODS AND MATERIALS**

A retrospective analysis of 40 abdominal CT scans was performed, comprising 20 cases of portal venous gas and 20 cases of biliary gas. For each case, the slice showing the maximum gas presence in the liver parenchyma was selected post multiplanar reconstruction with a minimum intensity projection of 20 mm. This slice underwent pixel binarization, converting to a binary image using a window setting of Width: 1 and Level: -20 HU on a standard DICOM (Digital Imaging and Communications in Medicine) viewer. The binary image was then processed by our program to produce 1-pixel wide representations, and the ratio of these representations to the amount of gas (represented by black pixels) was calculated.

**RESULTS**

The program demonstrated a sensitivity and specificity of 100% in differentiating between biliary and portal venous gas in the tested sample. Compared with the radiologist reports, in four cases the report was either incorrect (misidentifying pneumobilia as portal venous gas) or inaccurate (failing to distinguish between the two conditions), resulting in a sensitivity of 100% and a specificity of 84% for correct portal venous gas identification by radiologists.

**CONCLUSION**

The developed algorithm achieved 100% accuracy in differentiating between biliary and portal venous gas in the tested sample, demonstrating its potential as a valuable diagnostic tool for radiologists and in settings where a radiologist is not available.

**CLINICAL RELEVANCE/APPLICATION**

Distinguishing between portal and biliary gas is crucial due to their associated clinical implications. Portal venous gas often indicates severe conditions that may require urgent intervention, such as bowel ischemia, whereas biliary gas more frequently arises from benign causes like surgical manipulation of the biliary tract. Current diagnostic practices heavily rely on subjective assessments by generalist physicians, surgeons and radiologists, who frequently make errors in this differentiation. Our tool aims to improve patient outcomes by significantly reducing the rate of misdiagnosis.

## S5-SSGI04-5 DEEP LEARNING-BASED AUTOMATIC DETECTION OF PANCREATIC DUCTAL ADENOCARCINOMA SMALLER THAN 2 CM USING HIGH-RESOLUTION COMPUTED TOMOGRAPHY AND INDIRECT INDICATORS

Mizuki Ozawa, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Pancreatic ductal adenocarcinoma (PDAC) has very poor prognosis, with a 5-year survival rate of 6%, but small PDACs (=2 cm, T1 stage, UICC 8th edition) have relatively higher survival rates (20-40%). Detecting small PDACs is challenging, with 40% of PDACs missed by computed tomography (CT). Although deep learning-based automated detection of PDACs has been developed, sensitivity on detecting small PDACs is modest at 75%. Small PDACs are difficult to detect as tumor mass, and indirect findings such as dilatation of main pancreatic duct (MPD), parenchymal atrophy may be the key to their diagnosis. High-resolution CT (HR-CT) has good low-contrast detectability, and may improve PDAC diagnosis. This study assessed diagnostic performance of an automatic small PDAC detection system using a three-dimensional convolutional neural network with HR-CT with indirect indicators.

**METHODS AND MATERIALS**

Contrast-enhanced pancreas protocol HR-CT scans of 181 patients diagnosed with PDAC between January 2018 and December 2023 were identified. The inclusion criteria were PDAC diameter = 2cm and age = 18 years. The exclusion criteria were history of surgery or chemotherapy for PDAC and lack of appropriate thickness of CT images. Among those patients, 101 were included; 104 patients with no pancreatic abnormalities were chosen as controls. We identified the ratio of the cross-sectional area of MPD and pancreatic parenchyma (D/P ratio) as a value of indirect indicator of PDAC. Our proprietary software for automatic tumor mass and D/P ratio detection blindly analyzed clinical data from the 205 patients. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were evaluated to detect tumor mass, D/P ratio and combination of tumor mass and D/P ratio detection. A receiver operating characteristic (ROC) curve analysis was performed.

**RESULTS**

The overall sensitivity, specificity, PPV and NPV of tumor mass detection were 0.75, 0.76, 0.75 and 0.76, respectively; those for D/P ratio detection were 0.85, 0.94, 0.93 and 0.87, respectively and those for both tumor mass and D/P ratio detection were 0.94, 0.70, 0.75 and 0.92, respectively. The area under the ROC curve for tumor mass and D/P ratio detection were 0.85 and 0.95, respectively.

**CONCLUSION**

Adding indirect indicator evaluation to automatic tumor mass detection can improve the accuracy of small PDAC detection using HR-CT.

**CLINICAL RELEVANCE/APPLICATION**

Our high-sensitivity detection software can help physicians and radiologists avoid non-detection of small PDACs.

## S5-SSGU02-1 REEVALUATING DIAGNOSTIC CONFIDENCE: THE IMPACT OF DELAYED EXCRETORY PHASE IMAGING IN CT-IVP ON DETECTING RENAL AND URINARY TRACT ABNORMALITIES

Sung Yoon Park, MD (*Abstract Co-Author*) Nothing to Disclose
Arash Mahdavi, MD (*Abstract Co-Author*) Nothing to Disclose
Antonio C. Westphalen, MD, PhD (*Abstract Co-Author*) Shareholder, ScanMed, LLC;Research funded, BotImage, Inc
Deepashri Basavalingu, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Rajat Bhargava, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Rozita Jalilianhasanpour, MD (*Abstract Co-Author*) Nothing to Disclose
Christopher A. Mejias, MD (*Abstract Co-Author*) Nothing to Disclose
Negar Firoozeh, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the value of delayed excretory phase imaging when combined with non-contrast and nephrographic phase images in enhancing diagnostic consistency and radiologist confidence.

### METHODS AND MATERIALS

This HIPAA compliant, IRB approved retrospective, single institution cross sectional study, granted a waiver for informed consent, included 100 randomly selected CT-IVP done to investigate hematuria between 01/01/2012 and 03/11/2023. Using MIM Software, six readers (2 radiologists with over 10 years of experience, 3 fellows, 1 resident) reviewed 2 sets of images, with a 3-week washout period between sessions. The first set included non-contrast and nephrographic images, while the second also had delayed excretory images. At least 3 readers reviewed each pair of sets. Data were collected using Redcap, addressing the presence or absence of renal parenchymal, collecting system and ureteral, and vesical abnormalities, along with assessments of diagnostic confidence levels. Statistical analyses were done using Stata 18. The McNemar test was selected because it is used for paired dichotomous data and is suitable for 'before-and-after' studies. A mixed-effects model analyzed the influence of the interpretation session and reader specific variations on lesion detection. The Wilcoxon signed-rank test assessed changes in radiologists' confidence levels between interpretation sessions.

### RESULTS

There were no statistically significant differences in the rate of detected abnormalities involving the renal parenchyma, collecting system and ureters, and bladder between the two sessions. For brevity, only the mixed-effects model for the detection of ureteral lesions is provided, but the results were similar for all abnormalities. The analysis reveals that different imaging sessions, one of which included delayed phase images, do not significantly influence the detection of ureteral lesions ($p = 0.61$). Statistical analysis showed significant changes in diagnostic confidence for readers 4 and 5 ($p = 0.04$ and $p < 0.001$, respectively), but not for other readers (all $P > 0.05$). However, the direction of the ranks shows that both readers were more confident on session 1, rather than session 2. (R4, positive ranks sum = 501, negative ranks sum = 974; R5, positive ranks sum: 272.5, negative ranks sum: 966.5).

### CONCLUSION

Our results suggest that the delayed excretory phase images do not significantly enhance the diagnostic detection of lesions nor affect the confidence of radiologists in detecting abnormalities, underscoring a need to evaluate its clinical utility further.

### CLINICAL RELEVANCE/APPLICATION

The exclusion of delayed excretory phase may improve scanning and interpretation efficiency and decrease exposure to radiation.

## S5-SSGU02-2 OPTIMIZING BLADDER MRI: ACCELERATING SCAN TIME AND IMPROVING IMAGE QUALITY THROUGH DEEP LEARNING

Gu Mu Yang Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Lili Xu (*Abstract Co-Author*) Nothing to Disclose
Qianyu Peng (*Abstract Co-Author*) Nothing to Disclose
Li Chen (*Abstract Co-Author*) Nothing to Disclose
Hao Sun, MD (*Abstract Co-Author*) Nothing to Disclose
Erjia Guo, MS, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of deep learning on T2-weighted imaging (T2DL) of the bladder regarding acquisition time (TA), image quality and diagnostic confidence as compared to standard T2-weighted TSE imaging (T2S).

**METHODS AND MATERIALS**

In total, 28 consecutive patients for the evaluation of bladder cancer were prospectively enrolled in this institutional review board approved study. T2S and T2DL sequences in three planes were performed for each participant. Acquisition time was compared between the two acquisition protocols. The image evaluation was performed by two radiologists independently using a 5-point Likert scale for artifacts, noise, bladder wall clarity, bladder trigone clarity, lesion edge sharpness, tumor-to-bladder muscle layer contrast, overall image quality, and diagnostic confidence, with 5 indicating the best quality. Additionally, T2 scoring based on VI-RADS were performed by two readers. The intergroup comparisons were performed using the Wilcoxon signed rank test.

**RESULTS**

The mean patient age was 66 ± 13 years (range, 33-85 years). Compared to T2S, acquisition time of T2w TSE imaging in T2DL could be reduced by 49.4% in axial orientation and 43.8% in coronal and sagittal orientations. Inter-reader agreement for image quality parameters was substantial. The severity and impact of artifacts was evaluated to be superior in T2DL versus T2S in axial imaging by Reader 2 ($p<0.05$). Noise levels were rated significantly superior in T2DL compared to T2S ($p < 0.05$) in axial imaging for both readers. For both readers, the lesion edge sharpness in all planes was rated to be signi& 7;cantly higher in T2DL compared to T2S ($p < 0.05$). The tumor-to-bladder muscle layer contrast was also signi& 7;cantly higher in T2DL with a median of 5 (4-5) as compared to T2S with a median of 4 (4-5) for both readers in axial and sagittal imaging. Overall image quality in T2DL was evaluated to be higher compared to T2s in axial (4 (IQR 4-5) vs. 4 (IQR 3-4)) and sagittal imaging (4 (IQR 4-4.75) vs. 4 (IQR 3-4)) (both $p < 0.05$). Additionally, there was no signi& 7;cant difference regarding the diagnostic confidence and T2 scoring of both sequences in all planes ($p > 0.05$).

**CONCLUSION**

Our findings demonstrated the feasibility of using T2DL of the bladder in reducing acquisition time, enhancing image quality, and improving the detectability of lesions compared to T2s. Meanwhile, there is no significant difference in diagnostic confidence and T2 score between the two sequences.

**CLINICAL RELEVANCE/APPLICATION**

Our results indicated that T2DL might be able to replace conventional T2S with a significant reduction of acquisition time, superior lesion detectability and overall image quality while maintaining diagnostic confidence.

## S5-SSGU02-3 DIAGNOSTIC SIGNIFICANCE OF PERITUMORAL ENHANCEMENT IN DISTINGUISHING BETWEEN MUSCLE-INVASIVE AND NON-MUSCLE-INVASIVE BLADDER CANCER

Atsushi Higaki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mitsuru Takeuchi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akira Yamamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuichi Kojima (*Abstract Co-Author*) Nothing to Disclose
Tsutomu Tamada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Takuma Maruhisa (*Abstract Co-Author*) Nothing to Disclose
Hiroyuki Watanabe (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the prevalence of peritumoral enhancement (PTE) in muscle-invasive bladder cancer (MIBC) and non-MIBC (NMIBC) and propose a Modified Vesical Imaging-Reporting And Data System (VI-RADS) diagnostic criterion incorporating PTE.

**METHODS AND MATERIALS**

This retrospective study included 95 patients (pathologically confirmed 36 MIBCs and 59 NMIBCs; age, 71+/-11; 77 men) who underwent MRI between 2011 and 2023. The images were interpreted by four radiologists. T2-weighted imaging, diffusion-weighted imaging and dynamic contrast-enhanced imaging (DCEI) were performed. DCEI was acquired using a 3D T1-weighted gradient echo sequence with fat suppression. After acquisition of pre-contrast imaging, contrast medium (Magnescope, Guerbet) was injected using a power injector system at a dose of 0.1 mmol/kg body weight at a rate of 3.0 ml/s, followed by a saline flush. DCEI was acquired 7-8 times every 15 seconds after contrast administration. The readers categorized the images into three patterns, based on the presence or absence of PTE: Absent, Possibly present, or Definitely present. In this study, PTE was defined as a linear structure convex outward from the normal bladder wall (more curved than bladder wall) and contrasts more than the normal muscle layer and tumor. The frequency of PTE was calculated for each of the MIBC and NMIBC. A Modified VI-RADS was proposed, with Definitely present PTE assigned to VI-RADS category 5 and Possibly present PTE to VI-RADS category 4, regardless of DWI category. Sensitivity and specificity were compared with the Original VI-RADS using McNemar test. Pathologic diagnosis was used as the reference standard.

**RESULTS**

PTE was Possibly present in 6%-31% (2/36-11/36) and Definitely present in 50%-64% (18/36-23/36) of MIBC. PTE was absent in 92%-98% (54/59-58/59) of NMIBC. The sensitivity and specificity of Original VI-RADS was 41.7% to 55.6% (15/36-20/36) and 98.3% to 100% (58/59-59/59) for MIBC (cutoff = category 4), respectively. The sensitivity and specificity of the Modified VI-RADS was 72.2% to 86.1% (26/36-31/36) and 91.5% to 98.3% (55/59-58/59), respectively. The sensitivity of Modified VI-RADS was higher than that of Original VI-RADS ($p < 0.01$) in all readers but specificity was not significantly different.

**CONCLUSION**

Modified VI-RADS incorporating PTE, which is highly specific for MIBC, can correctly diagnose MIBC underdiagnosed by the Original VI-RADS.

**CLINICAL RELEVANCE/APPLICATION**

Modified VI-RADS can correctly classify MIBC that are underestimated as Category 2 or 3 by Original VI-RADS as Category 4 or higher, and can contribute to treatment decisions of bladder cancer.

## S5-SSGU02-4 EFFECT OF HISTOLOGICAL VARIANT PROPORTION ON THE DIAGNOSTIC EFFICACY OF THE VESICLE IMAGING-REPORTING AND DATA SYSTEM IN BLADDER UROTHELIAL CARCINOMA WITH VARIANT HISTOLOGY: A MULTI-INSTITUTIONAL, MULTI-READER RADICAL CYSTECTOMY COHORT STUDY

Yuki Arita, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Recent studies showed the VI-RADS's high accuracy in diagnosing muscle-invasive bladder cancer (MIBC). Nonetheless, the diagnostic efficacy of VI-RADS in bladder urothelial carcinoma (UC) with variant histology remains contentious. This research aimed to examine the diagnostic value of VI-RADS in assessing muscle invasion in variant UC according to the proportion of histological variants using a radical cystectomy (RC) cohort.

**METHODS AND MATERIALS**

Multi-institutional retrospective analysis of 81 treatment-naļve patients with pathologically confirmed variant UC who underwent bladder multiparametric MRI (mpMRI) before RC without receiving neoadjuvant chemotherapy between 2011 and 2021. Two sets of images, biparametric MRI (bpMRI) and mpMRI including DCE-MRI, were independently reviewed by three board-certified radiologists based on VI-RADS. The RC-based histological results served as the reference standard for all included patients. Receiver operating characteristic curve analysis, Z-test, and Wald test were used to assess diagnostic accuracy.

**RESULTS**

Among the 81 patients, 55 (67.9%) and 26 (32.1%) were diagnosed with MIBC and non-MIBC, respectively. The area under the curves (AUCs) of mpMRI in the entire cohort was significantly higher than that of bpMRI for readers 1 and 2 (0.919/0.900/0.882 vs 0.881/0.850/0.850, p=0.006/0.041/0.099 for Reader 1/2/3). In the subgroup analysis for predominant variant histology (histological variant>50%), the sensitivity of mpMRI was significantly higher than that of bpMRI for all readers (82.8/82.8/79.3% vs. 65.5/62.1/62.1%, p=0.025/0.014/0.025 for Reader 1/2/3), using the VI-RADS cut-off score of 4. No significant differences were observed between mpMRI and bpMRI in terms of specificity for all readers (91.7/91.7/91.7% vs 91.7/83.3/83.3%, p=0.99/0.317/0.317 for Reader 1/2/3). For non-predominant variant histology (histological variant<50%), no significant differences were detected between mpMRI and bpMRI in terms of sensitivity and specificity for all readers (sensitivity: 84.6/76.9/73.1% vs 69.2/69.2/69.2%, p=0.056/0.157/0.317; specificity: 92.9/92.9/85.7% vs 92.9/85.7/85.7%, p=0.99/0.317/0.99, for Reader 1/2/3).

**CONCLUSION**

In this treatment-naļve patient cohort with RC, mpMRI's diagnostic accuracy was superior to bpMRI's in evaluating muscle invasion in variant UC. The presence of predominant variant histology may decrease bpMRI's diagnostic performance.

**CLINICAL RELEVANCE/APPLICATION**

mpMRI including DCE-MRI is recommended for the assessment of muscle invasion in variant UC patients, particularly those with predominant variant histology (who are known to potentially exhibit resistance to chemotherapy, warranting immediate surgical interventions).

## S5-SSGU02-5 MULTIPARAMETRIC MRI TO PREDICT COMPLETE RESPONSE AFTER NEOADJUVANT RADIOIMMUNOTHERAPY OF LOCALLY ADVANCED BLADDER CANCER - RADIOLOGIC ASPECTS OF THE PROSPECTIVE, MULTICENTER, PHASE II TRIAL RACE IT

Marcus R. Makowski (*Abstract Co-Author*) Nothing to Disclose
Andreas Sauter, MD (*Abstract Co-Author*) Nothing to Disclose
Stefan Reischl, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Neoadjuvant therapy, including radioimmunotherapy (RIT), is being evaluated within trials for locally advanced bladder cancer (BC) patients who may not be candidates for surgery. Predicting complete tumor response (CR) after neoadjuvant therapy is crucial for determining the feasibility of bladder-sparing strategies. This study aims to evaluate the utility of multiparametric magnetic resonance imaging (mpMRI) using the Vesical Imaging-Reporting And Data System (VI-RADS) criteria in predicting CR in BC patients after neoadjuvant RIT.

**METHODS AND MATERIALS**

This tertiary-center, retrospective study analyzed mpMRI data of patients treated by neoadjuvant RIT for locally advanced BC within the prospective RACE IT trial. The imaging protocol and tumor-staging followed the VI-RADS guidelines and was performed by two radiologists of different experience levels (expert / resident). Histopathological examination of tumor stage served as ground truth for the evaluation of the diagnostic accuracy of mpMRI.

**RESULTS**

Twenty-one patients with muscle-invasive BC were included, of which 15 underwent post neoadjuvant-RIT mpMRI and subsequent cystectomy. Intrareader agreement was moderate to substantial, with the expert reader demonstrating better agreement 0.74 ($p < 0.001$). Interreader agreement was moderate. Post-RIT mpMRI sensitivity/specificity for detection of residual tumor (>ypT0) was 100%/33% for the expert and 89%/33% for the resident at a cut-off VI-RADS > 0, the corresponding AUROC values were 0.86 (expert) and 0.78 (resident). For residual muscle-invasive tumor AUROC values were 0.78 (expert) and 0.88 (resident), resulting at a sensitivity/specificity of 100%/30% (expert) and 100%/50% (resident) for a cut-off VI-RADS = 2.

**CONCLUSION**

This study suggests that VI-RADS criteria can be valuable tools for evaluating tumor response in mpMRI of BC patients after neoadjuvant RIT. Sensitivity for residual tumor was high, even though at the cost of a low specificity, compared to what was reported in the literature for cases without neoadjuvant treatment and potentially caused by postradiogenic tissue alterations.

**CLINICAL RELEVANCE/APPLICATION**

This is the first report on the use of mpMRI to evaluate the outcome after neoadjuvant RIT in bladder cancer. Our findings could open the door to expanding bladder-sparing strategies for a broader patient population, pending validation in larger studies.

## S5-SSGU02-6 EVALUATING VI-RADS SCORE PERFORMANCE IN THE POST-TURBT SETTING: EXPLORING THE NEED FOR MODIFICATION

Martina Pecoraro, MD (*Abstract Co-Author*) Nothing to Disclose
Marco Bicchetti (*Abstract Co-Author*) Nothing to Disclose

Giuseppe Martina (*Abstract Co-Author*) Nothing to Disclose
Carlo Catalano, MD (*Abstract Co-Author*) Nothing to Disclose
Valeria Panebianco, MD (*Abstract Co-Author*) Nothing to Disclose
Antonella Borrelli, MD (*Abstract Co-Author*) Nothing to Disclose
Ailin Dehghanpour, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The vesical imaging reporting and data system (VI-RADS) was introduced to standardise bladder MRI protocol. VI-RADS is not recommended post-TURBT due to potential inflammatory changes. Moreover, certain tumor characteristics, such as the presence of a stalk and inner layer enhancement, may be lost after TURBT. However, in routine clinical practice, bladder MRI is often performed post-diagnostic or therapeutic TURBT to achieve more accurate local staging.The aim of this study was to assess the diagnostic accuracy of the VI-RADS score and its individual MRI categories, structural (T2W), diffusion (DWI), and contrast-enhanced (DCE) after diagnostic TURBT. The primary objective was to determine the optimal dominant sequence. Additionally, we aimed to evaluate inter-reader agreement in scoring VI-RADS.

**METHODS AND MATERIALS**

This retrospective study utilized a prospectively maintained cohort. Two experienced uroradiologists, with 4 and 6 years of expertise in bladder imaging, independently and blinded to clinico-pathological information evaluated 150 mpMRI bladder scans. For each scan, besides assigning the final VI-RADS score and individual VI-RADS scores for each sequence, a separate VI-RADS score was assigned, once considering DWI and once considering DCE as the dominant sequence. This approach aimed to compare the diagnostic predominance and accuracy between these functional sequences in a post-TURBT setting. Exclusion criteria included intravesical local treatment and a temporal distance of less than 2 weeks between TURBT and mpMRI.

**RESULTS**

The performance of VI-RADS assessment in detecting muscle-invasive bladder cancer after TURBT showed an AUCs of 0.94 (95% CI 0.91-0.99) for the most experienced reader. On a per-sequence analysis, overall DWI showed the highest AUC compared to the single sequences (T2WI: 0.90 [95% CI 0.86, 0.94]; DWI: 0.96 [95% CI 0.90, 0.98]; DCE: 0.92 [95% CI 0.88, 0.96]).Inter-reader agreement between the more and less experienced radiologists using k statistics was 0,83 for overall VI-RADS assessment.

**CONCLUSION**

MRI, particularly VI-RADS, demonstrates high diagnostic accuracy in local staging of bladder cancer when performed at least two weeks after TURBT. The inflammatory changes resulting from the procedure make DWI the more accurate sequence compared to DCE. Therefore, DWI should be considered as the dominant sequence when scoring VI-RADS post-TURBT.

**CLINICAL RELEVANCE/APPLICATION**

Accurate local staging of bladder cancer patients undergoing TURBT is crucial for effective patient management. By preventing under- or over-staging due to inflammatory changes, it significantly impacts therapeutic decisions.

Wenyi Yue (*Presenter*) Nothing to Disclose

### PURPOSE

The transition from FIGO 2008 to FIGO 2023 introduces molecular classification, which included POLEmut, MMR-D, NSMP and P53abn, for endometrial cancer (EC) staging, aiding in prognostic risk assessment and treatment decisions. Our objective was to explore a pioneering radiogenomics method leveraging MRI, clinicopathological and genetic data to create a gene expression signature for EC patients across three institutions.

### METHODS AND MATERIALS

Between January 2020 and March 2024, we included 526 patients with histopathologically confirmed EC. These patients were recruited from three medical centers: 292 individuals from the Institution 1, 154 from Institution 2 and 80 from Institution 3. We collected clinicopathological data, preoperative MRI and genomic DNA from these patients. The MRI examinations were conducted utilizing either 1.5T MR scanners or 3.0T MR scanners. The ROIs were delineated and reviewed by two radiologists on T2WI images, and matched to corresponding areas on T1WI, T1CE, and DWI. The data were used as training and test sets respectively. Radiomics features were extracted using the IBSI-compliant Pyradiomics 3.0. Features that were robust to image preprocessing parameters, contour variations (ICC > 0.8) and equipment differences (P > 0.05) were retained for subsequent analysis. Recursive feature elimination was used for feature selection. The final discrimination model was an ensemble of four multivariate logistic regression models based on the one-vs-all strategy. The minority class was upsampled during the training. ComBat and z-score were used to normalize the feature matrix. The most effective hyperparameter were determine based on a 5-fold cross-validation.

### RESULTS

The clinical and pathological characteristics of the three institutions are summarized. The clinical-radiomics combined model achieved a macro-average AUC of 0.771. The class-wise AUCs were 0.79, 0.70 and 0.76 for POLEmut; 0.70, 0.67 and 0.68 for MMR-D; 0.79, 0.69 and 0.73 for NSMP; 0.80, 0.76 and 0.76 for P53abn in the internal test, external test set 1 and 2, respectively. Histograms of the distribution of the most important features of each sub-model were plotted to reflect the heterogeneity within the ROIs.

### CONCLUSION

Our results demonstrate that the predictive model derived from MRI imaging features holds significant promise in identifying molecular subtypes in EC.

### CLINICAL RELEVANCE/APPLICATION

This model has the potential to guide clinicians in tailoring individualized treatments for EC patients.

## S5-SSOB01-2 PRENATAL LINK BETWEEN CEREBRAL BLOOD FLOW AND CARDIAC FUNCTION IN CHD ASSESSED BY FETAL MRI

Sophia Stoecklein, MD (*Abstract Co-Author*) Nothing to Disclose
Gloria Biechele, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Congenital heart defects (CHD) are common severe birth defects. This condition also impacts on brain development with biometric and neurocognitive consequences from the neonatal period onwards. Recent technologies allow in-utero evaluation of cerebral perfusion using MRI-based arterial spin labelling (ASL) as well as the dynamic assessment of cardiac function using DUS (Doppler Ultrasound) gating. We therefore investigated brain perfusion in CHD as well as healthy control (HC) fetuses in relation to cardiac anatomy and function.

### METHODS AND MATERIALS

52 singleton pregnancies (n=38 HC, n=14 CHD) underwent fetal MRI (1.5T) after US examination at 29 weeks onwards. Cerebral blood flow (CBF) was quantified by flowsensitive alternating inversion recovery ASL (FAIR-ASL) sequences of the fetal brain in all patients and cardiac anatomy and function were assessed by DUS-gated cine-sequences of the fetal heart and thoracic vessels in a subgroup (n=8 HC, n=14 CHD) of the patients. Readouts' courses over gestation and associations were evaluated and compared between the groups.

### RESULTS

Mean gestational age (GA) was similar between the groups (HC: 33.4 [range 29-36] weeks vs. CHD: 32.7 [range 30 - 36] weeks, p=0.31). In 52 pregnancies, mean total CBF was 89.4 ± 29.9 ml/min/100g and mean regional CBF in basal ganglia was 93.0 ± 25.4 ml/min/100g, both increasing over gestation. There was no difference in mean total CBF between HC and CHD (87.9 ± 3.8 ml/min/100g vs. 93.7 ± 11.0 ml/min/100g, p=0.52), whereas mean regional CBF in basal ganglia was significantly increased in CHD (88.8 ± 3.8 vs. 105.4 ± 7.7, p=0.04). In addition, basal ganglia CBF revealed an inverse correlation with right ventricular shortening fraction in HC (p=0.003), but not in CHD.

### CONCLUSION

Although limited in sample size and very preliminary, our results suggest differences in cerebral perfusion between HC fetuses and those affected by CHD, as assessed by our novel ASL-based approach. More precisely, modified cardiac function related to CHD may particularly affect perfusion of the basal ganglia. Further studies should confirm these findings reflecting on potential roots of altered fetal gyration patterns and neonatal brain biometrics, that have been reported in individuals affected by CHD.

### CLINICAL RELEVANCE/APPLICATION

Given the substantial number of CHD cases, the heart-brain interplay is of importance for parental counceling.

## S5-SSOB01-3 DETECTING FETAL GERMINAL MATRIX AND INTRAVENTRICULAR HEMORRHAGE IN BRAIN MRI USING LABEL-FREE DEEP LEARNING

Haoxiang Li (*Abstract Co-Author*) Nothing to Disclose
Zhu Juncheng (*Abstract Co-Author*) Nothing to Disclose
Hongjia Yang (*Abstract Co-Author*) Nothing to Disclose
Zihan Li (*Abstract Co-Author*) Nothing to Disclose
Mingxuan Liu (*Abstract Co-Author*) Nothing to Disclose
Qiyuan Tian (*Abstract Co-Author*) Nothing to Disclose
Jialan Zheng (*Abstract Co-Author*) Nothing to Disclose
Ziyu Li (*Abstract Co-Author*) Nothing to Disclose
Zechen Zhou (*Presenter*) Nothing to Disclose

### PURPOSE

Germinal matrix and intraventricular hemorrhage (GMH-IVH) is the most common fetal intracranial hemorrhage. MRI is pivotal for the early detection of subtle prenatal GMH-IVH lesions, which manifest as hypointense signals in T2-weighted MRI. Deep learning emerges as a powerful tool for detecting such lesions from MRI. However, supervised learning methods are limited by the amount of training data due to the disease rarity (0.5-0.9 per 1000 pregnancies). To address the challenge, a fetal GMH-IVH detection method based on synthetic training data with anomalies is proposed to achieve accurate hemorrhage detection without the need for GMH-IVH labels.

### METHODS AND MATERIALS

The study used MRI data from 84 pregnant women, with 74 normal fetal brains and 10 brains with GMH-IVH lesions. 2D T2-weighted TSE image data were acquired in axial, coronal, and sagittal directions. The NiftyMIC method was used for slice-to-volume motion correction and reconstruction of a single super-resolved fetal brain volume at 0.8 mm isotropic resolution. Experienced radiologists manually annotated the hemorrhage regions. Generating pseudo MRI data with GMH-IVH from normal fetal brain images involved four steps: 1) extracted brain regions of interest (ROIs, e.g., ventricles and thalamus) using a pre-trained deep learning model for brain segmentation; 2) created random-shaped masks by generating uniform noise, applying Gaussian blur, stretch and thresholding; 3) created hemorrhage regions by dilating ROIs (30%), removing ventricles and thalamus from ROIs (30%), and directly selecting brain white matter regions (10%); 4) computed the intersection of masks from step 2 3, randomly decreased signal values, and applied Gaussian blur. The Swin-Unet was trained using 370 pseudo hemorrhage images synthesized from 74 normal fetal brains, or using 10 images from 2 GMH-IVH brains. The remaining 40 slices from 8 GMH-IVH brains were used to evaluate hemorrhage detection results.

### RESULTS

Swin-Unet trained with limited empirical data yielded segmentation dice similarity coefficient (DSC) of 0.169 ± 0.189 and mean intersection over union (MIOU) of 0.107 ± 0.134. In contrast, Swin-Unet trained with synthetic pseudo hemorrhage data achieves substantially higher segmentation accuracy with DSC of 0.635 ± 0.138 and MIOU of 0.479 ± 0.144.

### CONCLUSION

The proposed fetal brain GMH-IVH detection method based on pseudo anomaly synthesis can accurately segment hemorrhage regions without the need for annotated hemorrhage images.

### CLINICAL RELEVANCE/APPLICATION

The proposed label-free deep learning method achieves accurate and efficient detection and localization of fetal brain hemorrhages potentially for early diagnosis and improved treatment for GMH-IVH.

## S5-SSOB01-5 USING DIFFUSION WEIGHTED IMAGING AND BLOOD INFLAMMATORY MARKERS TO PREOPERATIVELY DIFFERENTIATE BETWEEN LEIOMYOSARCOMA AND ATYPICAL LEIOMYOMAS

Nishat Bharwani, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Miriam Salib, MBBS (*Abstract Co-Author*) Nothing to Disclose
Andrea L. da Silva, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Andrea G. Rockall, FRCR, MRCP (*Abstract Co-Author*) Nothing to Disclose
Kavita Shapriya, MBBS, FRCR (*Presenter*) Nothing to Disclose

**PURPOSE**

The preoperative differentiation of leiomyosarcoma (LMS) from atypical benign leiomyoma (LM) poses a diagnostic challenge. Diffusion-weighted imaging and low ADC values have been found in LMS, but there is overlap with LM. There is increasing evidence that inflammation and malignancy are inherently linked. This study's purpose was twofold: to review ADC values of histologically proven LMS compared to LM, with a focus on comparative assessment of the most restricted portion of the lesion, and to compare preoperative haematological markers in both groups.

**METHODS AND MATERIALS**

Patients with atypical myometrial lesions on MRI who underwent surgery were identified from surgical, imaging, and pathological databases over a 10-year period (2013-2023). From these, patients with histologically proven LMS and LM were included. For all patients, the pre-operative full blood count was analysed, focusing on white cell counts and the neutrophil: lymphocyte ratio (NLR). A subset of patients with DWI MRI sequences were identified for imaging analysis where readers manually segmented the whole lesion on the ADC map to give a volume of interest (VOI) and a mean ADC value for the whole lesion. VOIs were visually analysed to pick out the most restricted parts, with up to 3 regions of interest (ROI) identified, and a mean calculated over the 3 ROIs. Segmentations and ROIs were checked by 2 readers independently. Haematological markers and ADC values between the two groups were compared using Mann Whitney U tests and ROC curves.

**RESULTS**

A total of 235 patients with atypical myometrial lesions were identified, with 195 with histologically proven LM and 24 with LMS. Blood parameters of 191 LM and 20 LMS patients were available. A total of 64 patients had imaging with both DWI and ADC maps (52 LM and 12 LMS).Blood analysis found higher NLR correlated with LMS, with a median of 3.32 versus 1.72 for LM ($p<0.001$). A Youden index cut off of =2.10 was suggested for LMS. The VOI mean ADC value for LMS 1.18 x10-3 mm2/sec (+/-0.24 SD) was found to be significantly lower than for LM 1.49 x10-3 mm2/sec (+/-0.36 SD) ($p=0.006$). The mean ADC value generated on the ROIs was significantly lower for LMS than for LM at 0.82 versus 1.10 x10-3 mm2/sec ($p=<0.001$). The specificity of ROI ADC values was 65.4% with a sensitivity of 83.3% and a NPV of 94.4%.

**CONCLUSION**

ADC, particularly with the use of a focal ROI, is a useful diagnostic tool for improving preoperative diagnostic prediction of LMS in atypical LM. The NLR is higher in the LMS cohort, suggesting an inflammation-malignancy relationship.

**CLINICAL RELEVANCE/APPLICATION**

Future considerations involve modelling a predictive scoring system that combines imaging characteristics with biomarkers to improve diagnostic certainty and differentiate between LM and LMS.

## S5-SSOB01-6 ASSESSING JOINT HUMAN-AI SYSTEMS BASED ON UNCERTAINTY ESTIMATION

Elisabeth Epstein (*Abstract Co-Author*) Nothing to Disclose
Filip Christiansen, MSc, BSc (*Abstract Co-Author*) Nothing to Disclose
Robert Welch (*Abstract Co-Author*) Nothing to Disclose
Kevin Smith, MSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Emir Konuk (*Presenter*) Nothing to Disclose

**PURPOSE**

Collaborative human-AI systems that leverage notions of confidence and uncertainty have the potential to surpass the effectiveness of both doctors or AI working in isolation. However, we currently lack meaningful metrics to evaluate the performance of such joint systems. In this study, we proposed a novel and meaningful performance measure for joint human-AI systems and aimed to identify the best uncertainty or confidence estimation methods for such joint decision making systems.

**METHODS AND MATERIALS**

We utilized a retrospective dataset comprising 17,119 ultrasound images from 3,652 patients with an ovarian tumor, gathered from 20 centers in 8 countries using 21 different devices. The ground truth for model training and evaluation was histological diagnosis. The exams were assessed by 66 doctors. We developed neural network classifiers using 7 different methods, including temperature scaling and deep ensembles. These methods either calibrate the confidence of the classifier or impart a notion of uncertainty to the AI. We estimated confidence by maximum classifier response and utilized the entropy of the estimated probabilities for measuring uncertainty, further decomposed into aleatoric and epistemic components. We evaluated human-AI systems' joint risk and F1 score both with in domain (InD) data which is an internal dataset where the AI is trained and evaluated, and out of domain data where the AI is evaluated on external hospitals it did not see before (OoD-H), or unseen devices (OoD-D).

**RESULTS**

We found that all joint human-AI confidence-based decision-making systems surpassed both standalone doctors or AI. For OoD-D, joint systems achieved a boost in F1 score of 0.04 over both AI and doctors, while demanding 25% less of doctors' time. For OoD-H, a joint human-deep ensemble achieved an F1 of 0.79 vs. 0.73 of the doctors' while demanding 40% less time. For unseen (OoD) data, most joint systems required more doctor oversight to perform optimally, indicating the ability of the decision-making system to defer to human judgment when encountering unfamiliar data patterns.

**CONCLUSION**

Our findings reveal a 'sweet spot' of human involvement in the joint human-AI system, beyond which additional human oversight harms performance. In joint decision-making systems, the expertise of the doctors has a higher impact on overall clinical performance than the choice of AI method, especially in OoD data.

**CLINICAL RELEVANCE/APPLICATION**

Existing metrics do not consider the efficiency impact of AI on healthcare resource utilization. Our framework allows hospitals to tailor AI usage to align with available resources, optimizing both performance and resource allocation. Our framework can be extended to various reading strategies, including unblinded double reading.

## S5-STCE1-1 DIAGNOSTIC EFFICACY AND JUSTIFICATION OF ADJACENT AND CONCURRENT X-RAY IMAGING

Dania Abu Awwad, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Injuries to extremities are common presentations to emergency departments and there is no limit to the number of X-rays that can be requested. While multiple fractures or concurrent injuries are possible, justification for each requested region is needed as this impacts workflow efficiency and radiation dose to patients. There have been limited studies on the efficacy of concurrent imaging, most of which have focused on paediatric populations alone or on forearm injuries. Hence, this study aims to assess the diagnostic efficacy of X-ray requests for all patients presenting for multiple adjacent body regions.

### METHODS AND MATERIALS

Data was extracted from two hospitals over a six-month period. All patients who presented for X-ray examinations and had multiple adjacent regions X-rayed within 24 hours were included in the study. X-ray examinations were restricted to upper and lower extremities. The main region of interest or the first X-ray taken was referred to as the initial X-ray, while any other X-ray taken after was considered adjacent imaging. The clinical history of each imaging request was collected and compared to the radiology reports.

### RESULTS

There were 3589 X-rays taken for 1514 patients, ranging from two to six imaging requests. In total, 60% of X-rays showed no new findings, 24% had other findings such as osteoarthritis or swelling, 2% had suspicious findings, and only 15% had new findings such as fractures. 92% of all new findings were found in the initial X-ray, meaning that 32% of initial X-rays had a new finding but only 2% of adjacent X-rays had new findings. Of all the included X-rays, only 59% had symptoms for the requested body regions, which drops to 51% for X-ray examinations that led to no findings but increases to 76% for X-rays that reported new findings.

### CONCLUSION

Adjacent imaging had low diagnostic efficacy for both upper and lower limb regions. While many request forms had limited clinical history provided, it was much higher for imaging requests that reported no findings. While the clinical history in imaging requests does not encompass the full patient story or presenting issue, there has been a correlation between clinical history and imaging results. The vast difference between the percentage of fractures detected in initial versus adjacent imaging highlights a need to re-evaluate how and when X-ray imaging is used, particularly when multiple regions are requested.

### CLINICAL RELEVANCE/APPLICATION

The findings underscore the importance of adopting a value-based approach to radiology. By ensuring that imaging requests are clinically justified and based on individual patient needs, healthcare providers can optimize resource use and reduce unnecessary procedures, which in turn helps minimize patient exposure to radiation.

## S5-STCE1-2 THREE INTERVENTIONS, THREE VILLAGES, ONE GOAL - HEALTH EQUITY

Komal Verma Saluja, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

Breast cancer is the most prevalent cancer and second-leading cause of cancer death among women across all ages, ethnicities, and socioeconomic backgrounds. The potential benefits of mammography screening in early detection of breast cancer continue to be underutilized. Major factors contributing to breast imaging disparities include lack of awareness, cultural and linguistic barriers, social inhibitions, poor access to imaging services, financial constraints and lack of insurance support. This study was aimed to comparatively assess the impact of various health equity interventions in improving breast cancer diagnostics.

### METHODS AND MATERIALS

Study population comprised of women aged 40-75 years, from three neighboring villages A (n=331), B (n=297), C (n=316), with similar socio-cultural, demographic, geographical and economic characteristics. The adopted health equity interventions were those recommended and proven effective by previous researchers. These included (1) periodic community education sessions consisting of contact sessions and special events for village A, (2) breast health volunteers selected from local communities and trained for village B and (3) mobile mammography van for village C. The impact of the interventions was measured in terms of percentage of women who underwent screening mammography over a two-year period, with a secondary objective to identify shifts in awareness, attitude and perception about breast cancer screening mammography, which was explored through a structured, validated questionnaire administered to the women within target population.

**RESULTS**

Percentage of women in target population undergoing mammography screening in villages A, B and C was 57.4%, 65.5% and 68.8% respectively ($p < 0.009$). Mobile van by addressing financial, transport and time barriers established itself as the most effective intervention. Health volunteer approach statistically proved superior in improving awareness and reducing stigma. Based on input output analysis, education emerged as the most efficient tool. The biggest barrier faced by women was stigma followed by finance, transport, and time. The graph displays the impact of different interventions on the barriers perceived by the study population.

**CONCLUSION**

Mobile mammography van is the most effective tool to address breast imaging inequities however in a resource poor setting, community education remains a more efficient tool.

**CLINICAL RELEVANCE/APPLICATION**

Gauging the efficacy of various health equity interventions allows efficient implementation of tailor-made programs according to population characteristics.

## S5-STCE1-3 FUTURE OF RADIOLOGY: CLINICAL AND ENVIRONMENTAL ADVANTAGES OF DIGITAL CARBON NANOTUBE X-RAY SOURCES - 75% SMALLER SIZE, 17% LESS ENERGY CONSUMPTION, 40% LESS RADIATION DOSAGE FOR PATIENT SAFETY, WITH FLUOROSCOPY AND EXTREMITIES IMAGING INSIGHTS COMPARED TO CONVENTIONAL X-RAY SOURCES

Taewon Kim (*Abstract Co-Author*) Nothing to Disclose
Amar P. Gupta, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

With the advent of nanotechnology, it has transformed and digitalized many fields of medical imaging. One such example is digital X-ray detectors which have many advantages over X-ray films. Similar paradigm shift is seen in X-ray sources, where Carbon Nanotubes (CNTs) based digital X-ray sources are outperforming the conventional analogue filament-based X-ray sources. In this paper, we have shown that CNT X-ray tubes are 75 % smaller in size, 17% less energy consumed and produces 40% less radiation dose in fluoroscopic setting rated for similar use and specifications. Not only this, shifting to Digital-CNT X-ray tube has substantial impact on environment considering the manufacturing process compared to conventional X-ray sources which signifies that CNT X-ray sources are future of radiology.

**METHODS AND MATERIALS**

We compared the CNT and Filament X-ray tubes bought from different vendors. Both tubes were rated for 70 kV, 3 mA and 0.4 Focal spot. The Tubes' physical dimensions were measured and compared. Tubes were operated in pulsed mode at 50 kV, 1 mA by digitally switching with MOSFET circuit for a pulse of 40 ms with 50% duty cycle for fluoroscopic patient dosage measurement. The cadaver hand was imaged using Varex Flat panel at different kVps but constant 2mAs using both tubes and the image qualities were compared in 2× and no magnification mode. Lastly, we interviewed the vendors about manufacturing process of these tubes and compared the environmental impact during the production.

**RESULTS**

Digital CNT X-ray source was ~75 % less small in volume size, ~ 50% less in weight and consumes 17% less energy for producing the X-ray of same energy and current. Moreover, in the fluoroscopic setting, where the X-rays are continuous the CNT X-ray tube performed ~44% less radiation dosage due to perfect digital switching. The cadaver hand imaging at different magnification and kVps shows similar quality for both X-ray tubes. When compared to their manufacturing process, we found that CNT X-ray tubes can have less carbon emissions because they are produced in simple vacuum ovens in huge quantities whereas filament X-ray tubes are manufactured one by one individually using flammable gases which can have bad environmental impact.

**CONCLUSION**

Digital CNT X-ray tubes are the future of radiological imaging and sustainable in production. For the same rating and usage, the digital X-ray source outperforms the conventional one in every aspect which shows that it is better for patient, medical practitioners and X-ray manufactures to shift to this technology.

**CLINICAL RELEVANCE/APPLICATION**

Digital CNT X-ray source produces 40% less radiation than conventional sources in fluoroscopic setting and can perform better in cardiac and respiratory-gated imaging due to faster switching and better synchronization with detector.

## S5-STCE2-1 UTILIZING PET RADIOMICS FOR PREDICTING CANCER-ASSOCIATED CACHEXIA RISK: A PROMISING APPROACH

Xin-Gui Peng, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Yang Jiang, PhD, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to assess if a model constructed from radiomics features extracted from PET images can predict cachexia risk in cancer patients undergoing [18F]fluoro-2-deoxy-D-glucose (18F-FDG) PET/CT scans.

### METHODS AND MATERIALS

Cancer patients who underwent 18F-FDG PET/CT scans from April 2017 to October 2021 were included. Radiomics feature extraction and model construction utilized the FeAture Explorer Professional Edition (FAE, Version 0.5.3) on PET images of the liver, pancreas, visceral fat, subcutaneous fat, psoas muscle, and sacrospinal muscle. Feature selection employed Pearson correlation, recursive feature elimination, and support vector machine methods. Logistic regression identified clinical features associated with cancer-associated cachexia and constructed a clinical-radiomics model.

### RESULTS

A total of 626 patients were analyzed, divided into training (n=438) and testing (n=188) datasets. In the training dataset, the AUC for the clinical-radiomics model (0.802) surpassed clinical (0.741) and radiomics (0.772) models. The clinical-radiomics model also outperformed the clinical model ($P < 0.001$) and the radiomics model ($P = 0.012$). In the validation dataset, AUCs were 0.759, 0.772, and 0.796 for clinical, radiomics, and clinical-radiomics models, respectively, with no significant differences observed.

### CONCLUSION

PET radiomic features extracted from the liver, pancreas, visceral fat, subcutaneous fat, and erector spinae muscles are beneficial for identifying cancer patients at higher risk of developing cachexia.

### CLINICAL RELEVANCE/APPLICATION

The integration of radiomics features from specific organs and tissues into a predictive model offers clinicians a powerful tool for early identification of cachexia risk in cancer patients, facilitating personalized management strategies and potentially improving treatment outcomes.

## S5-STCE2-2 THE RATIO OF VISCERAL TO SUBCUTANEOUS FAT IS A PREDICTIVE FACTOR FOR CYTOKINE RELEASE SYNDROME GRADE IN GASTRIC CANCER PATIENTS RECEIVING CLAUDIN18.2-TARGETED CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY

Changsong Qi (*Abstract Co-Author*) Nothing to Disclose
Lei Tang, MD (*Abstract Co-Author*) Nothing to Disclose
Meng He, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Cytokine release syndrome (CRS) has a significant impact on survival and functional recovery in patients after chimeric antigen receptor (CAR)-T cell therapy, and the identification of its determinants is still challenging. We analysed the impact of body composition parameters from CT images and serum inflammatory markers on the severity of CRS in patients with advanced gastric cancer (GC) treated with CLDN18.2-targeted CAR-T cells.

### METHODS AND MATERIALS

Forty-five advanced GC patients treated with CLDN18.2-targeted CAR-T cells were enrolled in the study. The skeletal muscle index, skeletal muscle density, subcutaneous fat area (SFA), visceral fat area (VFA) and VFA-to-SFA ratio (VSR) on baseline CT were automatically segmented and calculated by using a deep learning-based tool that we have previously proposed. The relationship between body composition and CRS severity was investigated by using univariate and multivariate binary logistic regression analyses.

### RESULTS

Patients with CRS grade 2 had a significantly higher VSR than did patients with CRS grade 1 (1.07 vs. 0.23, respectively; P=0.003). Furthermore, the SFA was slightly higher in patients with CRS grade 1 than in those with CRS grade 2 (80.95 vs. 52.71 cm2, respectively; P=0.051). However, skeletal muscle-related parameters and body mass index (BMI) were not significantly different between the two groups. The area under the ROC curve (AUC) showed that patients with SFA < 77.19 and VSR = 0.21 had a greater probability of developing CRS grade 2, with AUCs of 0.660 (0.491-0.829) and 0.762

(0.620-0.905), respectively. Binary logistic regression analysis demonstrated that SFA < 77.19 and VSR = 0.21 were significantly associated with an increased likelihood of CRS severity (P=0.005 and 0.002, respectively).

**CONCLUSION**

The baseline ratio of visceral to subcutaneous fat area correlated with the severity of CRS in advanced GC patients treated with CLDN18.2-targeted CAR-T cells.

**CLINICAL RELEVANCE/APPLICATION**

The fat parameters from CT images are associated with the severity of cytokine release syndrome (CRS) in patients treated with CLDN18.2-targeted CAR-T cell therapy. The CT-based VSR exhibits potential for clinical application in early prediction of CRS grade and perhaps directing interventions.

## S5-STCE2-3 SAFETY OF LU-PSMA WITH PRIOR RADIUM-223 TREATMENT FOR METASTATIC PROSTATE CANCER

John Wang (*Abstract Co-Author*) Nothing to Disclose
Matthew Labriola (*Abstract Co-Author*) Nothing to Disclose
Hannah McManus (*Abstract Co-Author*) Nothing to Disclose
Valeria Maldonado Grijalva (*Abstract Co-Author*) Nothing to Disclose
Terence Z. Wong, MD, PhD (*Abstract Co-Author*) Consultant, General Electric Company
Colm Kelleher, MD (*Abstract Co-Author*) Nothing to Disclose
Marybeth A. Nedrud, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Lu177-PSMA-617 (LuPSMA) is approved for the treatment of metastatic castration resistant prostate cancer (mCRPC). There is limited real-world safety data for this radioligand therapy in the setting prior treatment with radium-223.

**METHODS AND MATERIALS**

Retrospective chart review was completed for the first 100 mCRPC patients who received =1 dose of LuPSMA at a single institution from June 2022 to July 2024. Demographics, clinical history, including prior lines of therapy before LuPSMA, and baseline laboratory studies were collected. Clinical outcomes pertaining to LuPSMA, including the total doses received, the presence of dose reductions/treatment holds, and post-treatment blood counts/renal function were reviewed. Student's t and chi-squared tests analyzed differences between outcomes for those who completed prior treatment with radium-223 and those who did not.

**RESULTS**

Ninety-eight participants were included, with 2 excluded due to prior receipt of LuPSMA on clinical trial. Of those included, 17% (17/98) received radium-223 prior to LuPSMA administration. The mean age and baseline PSA, Hgb, WBC, and Cr, did not differ between those who received prior radium-223 (n=17) and those who had not (n=81, p>0.05). The mean number of prior lines of therapy was greater for those who received radium-223 (n=5.2) than those who had not (n=3.7, p=0.0006). The mean number of LuPSMA doses received per participant did not differ between the two groups (3.7 doses with radium-223 vs. 4.1 doses without radium-223, p>0.05). In addition, there were no differences in number of treatment holds or dose reductions (p>0.05). Early termination of LuPSMA therapy for both groups was most often due to clinical disease progression (4/10, 40%, with radium-223 vs. 28/47, 59%, without radium-223, p>0.05). There were numerically higher rates of LuPSMA discontinuation secondary to cytopenias in the radium-223 group (3/10, 30%) when compared to those without radium-223 (8/47, 17%), but no statistical differences between the two (p>0.05). There was no difference in mean Hgb, WBC, or Cr between the two groups at the end of LuPSMA treatment (p>0.05).

**CONCLUSION**

For a small group with prior radium-223 treatment, there was no difference in mean number of LuPSMA doses received, post-treatment blood counts, or rates of early termination secondary to cytopenias when compared to those who had not received prior radium-223. Although limited by small sample size, this data suggests that prior radium-223 treatment does not interfere with the ability to safely administer LuPSMA.

**CLINICAL RELEVANCE/APPLICATION**

Our results build upon the current literature and provide further support for the real-world safety of LuPSMA therapy in the setting of prior radium-223.

## T1-SSCH05-1 IMPACT OF IMMEDIATE AI ENABLED PATIENT TRIAGE TO CHEST CT ON THE LUNG CANCER PATHWAY: LUNGIMPACT

Madava G. Djearaman, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
David Baldwin (*Abstract Co-Author*) Nothing to Disclose
Arjun Nair, MD, FRCR (*Abstract Co-Author*) Advisory Board, Aidence BV
Indrajeet Das, FRCR (*Abstract Co-Author*) Nothing to Disclose
Neal Navani (*Abstract Co-Author*) Nothing to Disclose
Nick Woznitza, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Lung cancer is the leading cause of cancer deaths worldwide. Early detection and rapid diagnosis of lung cancer is essential to improve outcomes for patients. Despite introduction of lung cancer screening, the majority of patients present through the symptomatic route when a chest X-ray (CXR) is the most common first investigation. Rapid diagnosis is facilitated by correct identification of patients who would benefit most from an urgent CXR report and progression to urgent CT where indicated. Artificial intelligence (AI) may play a role in improving the process of identifying abnormalities suspicious of lung cancer and thus accelerating entry onto the diagnostic pathway. This has to be achieved in the context of services that are often at maximum capacity and there needs to robust scientific evidence for important clinical benefits that outweigh any extra activity.

### METHODS AND MATERIALS

The study was approved by the East of England Research Ethics Committee. It is a prospective, block randomised controlled trial of AI prioritisation of abnormal CXRs for clinician review vs. standard reporting (with AI available). It is underway across 5 geographically diverse distinct hospital sites in England, UK. All patients who are referred for a chest X-ray from primary/family care at each site are included. The study commenced 17 July 2023 and will conclude 31 July 2024. Co-primary outcomes are time from CXR to diagnosis of lung cancer and time from CXR to CT chest. Secondary outcomes include concordance between clinician report and AI, and stage of lung cancer diagnosis. A health economic evaluation will estimate the cost-effectiveness of CXR AI in lung cancer diagnosis including the difference in costs per patient screened, cost per patient diagnosed, and costs per percentage increase in early diagnosis.

### RESULTS

To date (April 2024) we have randomised 46,360 CXRs and are projected by trial close to have randomised 78,220 CXRs. The full results will be published in late 2024 or early 2025 and will be available at the RSNA meeting.

### CONCLUSION

LungIMPACT is measuring the impact of immediate AI-based prioritisation of CXRs for reporting and is measuring an important clinical impact (the speed of diagnosis of lung cancer). A positive result may change practice (inclusion of AI) whilst a negative result will prompt better evaluation of AI products before introduction into routine practice. The study was identified as one of the "11 clinical trials to shape medicine in 2024" by Nature Medicine.

### CLINICAL RELEVANCE/APPLICATION

Adoption of AI in clinical practice requires robust evidence of clinical and cost-effectiveness. The LungIMPACT trial is the largest multisite randomised trial of CXR AI for lung cancer and will provide answers to both.

## T1-SSCH05-2 AI-RAD COMPANION MEETS LUNG-RADS: DIAGNOSTIC VALUE OF A DEEP-LEARNING BASED PROTOTYPE FOR AUTOMATED PULMONARY NODULE CLASSIFICATION ON CHEST CT

Ismail M. Kabakus, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Parker Anderson, MD (*Abstract Co-Author*) Nothing to Disclose
Adrienn Toth, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study was to investigate the performance of a prototype, fully automated AI decision support tool (AI-Rad Companion, "AIRC") in classifying benign and malignant pulmonary nodules on chest CT scans with histopathologic confirmation or 2-year radiographic stability as the reference standard.

**METHODS AND MATERIALS**

282 patients were enrolled in this multicenter retrospective study, who previously underwent clinically indicated chest CT. 167 had biopsy proven lung cancer, while 115 had at least one benign pulmonary nodule. Diagnostic, baseline, and follow-up CT exams were evaluated using a prototype software (AIRC Research, Chest CT Explore V1.3.4, Siemens Healthineers), which provided automated image analysis, quantification, and visualization of lung nodules. By combining the information about lesion size, its temporal change, and lesion characteristics, a Lung-RADS score (1, 2, 3, 4A, 4B, 4X) was computed according to the guidelines by the American College of Radiology. Lung nodule validation was performed with the histopathologic result or stability for 2 years confirmation as the ground truth. A true positive nodule was defined as a nodule confirmed to be malignant by biopsy and reported as Lung-RADS 4B/X by the AIRC. The diagnostic performance was tested on the diagnostic CT exams, while follow-up exams were used to assess the intra-rater reliability. Baseline scans were analyzed to evaluate the clinical usefulness of AIRC in the early detection of high-risk pulmonary nodules.

**RESULTS**

Overall diagnostic accuracy for lung nodule classification (benign or malignant) was 0.762 (95% CI 0.783 - 0.811). Sensitivity and specificity of nodule classification were 0.749 (95% CI 0.676 - 0.812) and 0.783 (95% CI 0.696 - 0.854), respectively, with positive and negative predictive values of 0.833 (95% CI 0.778 - 0.877) and 0.682 (95% CI 0.619 - 0.739). 21 lung cancer patients had the lung cancer present as a much smaller nodule, an average of 17 months prior to the diagnostic scan. 80% of these 'baseline' nodules were detected and rated as Lung-RADS 4A or higher by AIRC. Furthermore, AIRC accurately characterized and classified the same nodules on subsequent scans within 7 days of the diagnostic CT with high (> 95 %) intra-rater reliability.

**CONCLUSION**

AIRC showed promising performance in malignancy risk categorization of benign and malignant lung nodules, showcasing its potential for early detection, and indicating its reliability for longitudinal monitoring.

**CLINICAL RELEVANCE/APPLICATION**

These findings suggest that AIRC holds promise as a valuable tool for clinicians in the accurate classification and early detection of high-risk pulmonary nodules, potentially improving patient outcomes through timely intervention and management.

## T1-SSCH05-3 STREAMLINING PRE-DEPLOYMENT VALIDATION AND BENCHMARKING OF MULTIPLE AI SYSTEMS FOR PULMONARY NODULE DETECTION: A CONCORDANCE-DISCORDANCE BASED APPROACH?

Catherine M. Jones, MBBS (*Abstract Co-Author*) Researcher, Annalise-AI Pty Ltd
Shraddha Mittal (*Abstract Co-Author*) Nothing to Disclose
Vasantha Kumar Venugopal, MD (*Presenter*) Officer, CARPL.AI Inc

**PURPOSE**

To streamline pre-deployment validation of AI tools for lung nodule detection and characterization on CT, using inter-AI concordance as a surrogate for traditional ground truth. We evaluated the efficacy and efficiency of this novel validation method against standard practices.

**METHODS AND MATERIALS**

The study employed a structured multi-phase approach to benchmarking AI solutions for lung nodule detection. 142 CT studies were processed via two distinct AI algorithms to identify lung nodules and assess malignancy risks. Studies were classified based on AI agreement: Concordant, where all AIs agree on nodule location, bypassing radiological evaluation; Discordant, prompting detailed radiologist analysis due to varied nodule locations flagged by AIs; and Partially concordant, involving a combination of agreement and discrepancy in AI findings within the same case. Kappa statistics quantified inter-AI concordance, and radiologist-AI agreement metrics were calculated for discordant and partially concordant cases to validate the efficiency and reliability of using AI concordance as a surrogate ground truth. A Thoracic Radiologist reviewed the discordant and partially concordant cases to evaluate the AI outputs of the nodule locations.

**RESULTS**

The study achieved an inter-AI concordance rate of 44.46%. AI1 detected 290 nodules, while AI2 detected 342, with only 68 nodules unmatched, indicating substantial agreement on detected nodules. Among the studies, 103 (72.54%) were fully concordant, requiring no further radiologist review. The total reading time for the dataset was 3,778 seconds, with an average of approximately 63 seconds per study. Discordant cases, which exclude fully concordant cases, accounted for 19.30% of the total reading time, suggesting a potential significant reduction in time spent on reviews if concordance rates improve. The AI solutions demonstrated a Kappa of 0.261 for nodule detection concordance, indicating fair agreement.

**CONCLUSION**

Employing inter-AI concordance as a surrogate for ground truth validation demonstrates a promising approach to optimize the pre-deployment validation process for lung nodule detection AI, enhancing efficiency and potentially accelerating the integration of reliable AI tools into clinical workflows.

**CLINICAL RELEVANCE/APPLICATION**

This study's innovative approach of employing inter-AI concordance as a surrogate for ground truth in pre-deployment validation holds promise for quicker integration of reliable AI solutions into clinical practice without compromising on safety and trust.

## T1-SSCH05-4 WORKFLOW EFFICIENCY BENEFITS OF A LUNG NODULE DETECTION AI PROGRAM

Paras Lakhani, MD (*Abstract Co-Author*) Nothing to Disclose
Matt Deng, PhD (*Abstract Co-Author*) Employee, Infervision Inc
Vijay M. Rao, MD (*Abstract Co-Author*) Nothing to Disclose

Ryan K. Lee, MD, MBA (*Abstract Co-Author*) Bayer, Speaker's BureauPhilips, Speaker's BureauBracco, Advisor
Adam E. Flanders, MD (*Abstract Co-Author*) Nothing to Disclose
Christopher G. Roth, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Richard M. Beck, MD (*Abstract Co-Author*) Nothing to Disclose
Avishkar Sharma, MD (*Abstract Co-Author*) Nothing to Disclose
Baskaran Sundaram, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

One of the earliest clinical applications of deep learning in radiology was automated detection of lung nodules from CT of the chest. The adoption of AI for this purpose has been slow, partly due to the insufficient evidence of the inherent value when integrated into the clinical workflow. This study directly addresses whether adoption of the technology augments radiologist efficiency.

**METHODS AND MATERIALS**

We performed an IRB approved pilot research study evaluating the interpretation times of nine community-based radiologists before and after deployment of a PACS integrated, FDA cleared lung nodule detection algorithm (InferRead Lung CT.AI) . This software automatically detects lung nodules from chest CT, and reports nodule characteristics such as diameter and volume. We recorded the reading time (report launch to report final time) for all chest CT interpreted over a ninety-day time period before and after implementing the detection tool. Aggregate mean reading time intervals for the nine radiologists were generated before and after deployment. Reading times greater than 60 min were excluded from this study. Participating radiologists also completed a survey.

**RESULTS**

During the trial period, a total of 1,192 chest CT were interpreted without the detection tool, and 738 scans were read with it. The reading time distributions are shown in the attached bar plots. Overall, the utilization of AI software resulted in a statistically significant reduction in reading times (Mann-Whitney U-test, p value = 0.032). The average reading time was 16.5±11.4 minutes without AI, with the peak time between 8-10 minutes, while the reading time was 14.8±10.0 minutes with AI and a peak time between 6-8 minutes. A reduction of reading time with AI was observed in eight out of the nine participants. In addition, eight anonymous responses were collected from the survey. Radiologists felt more confident reporting lung nodules using the AI system with an average score of 4.5/5. Subjective average reading experience score with the tool was 4.75/5. The AI software alleviates anxiety with an average score of 4.5/5.

**CONCLUSION**

Deployment of the lung nodule detection AI system was shown to significantly reduce the radiologist reading time interval for the nine community based radiologists in this pilot project. The deployment of the tool not only significantly reduced reading times but also bolstered radiologists' confidence in reporting lung nodules, diminished anxiety, and enhanced the overall reading experience.

**CLINICAL RELEVANCE/APPLICATION**

This study demonstrates a soft benefit of adopting a lung nodule detection system into clinical workflow. It is perhaps one rationale that can be used to justify clinical adoption of a specific AI system.

## T1-SSCH05-5 DIFFERENTIATION BETWEEN INVASIVE ADENOCARCINOMA AND FOCAL INTERSTITIAL FIBROSIS AMONG PERSISTENT PULMONARY PART-SOLID NODULES: WITH EMPHASIS ON THE CT MORPHOLOGIC ANALYSIS

Jung Han Woo (*Abstract Co-Author*) Nothing to Disclose
Yoon Ki Cha, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Min Hyuk Yu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Focal interstitial fibrosis (FIF) manifesting as persistent part-solid nodule (PSN) has been mistakenly treated surgically due to similar imaging features to invasive adenocarcinoma (ADC). The purpose of this study was to observe predictive imaging features correlated with FIF through CT morphologic analysis.

**METHODS AND MATERIALS**

From January 2009 to December 2020, 44 patients with surgically proven FIF in a single institution were enrolled and compared with 88 ADC patients through propensity score matching. Patient characteristics and CT morphologic analysis of persistent PSNs were used to identify predictive imaging features of FIF. Receiver operating characteristic (ROC) curve analysis was used to quantify performance of imaging features.

**RESULTS**

Total of 132 patients with 132 PSNs (44 FIF, 88 ADC; mean age, 67.7 ± 7.58; 75 females) were involved in our analysis. Multivariable analysis demonstrated that preserved peritumoral vascular margin (preserved vascular margin), preserved secondary pulmonary lobule margin (preserved lobular margin), lower coronal to axial ratio (C/A ratio; cut-off: 1.005) were significant independent predictors of FIF ($p < 0.05$). ROC curve analysis to evaluate the predictive value of the logistic model based on the imaging features of FIF, and the AUC value was 0.881.

**CONCLUSION**

CT imaging features of preserved vascular margin, preserved lobular margin, and lower C/A ratio (cut-off, < 1.005) might be helpful imaging features in discriminating FIF over ADC, among persistent PSN in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

The clinical relevance of our study lies in its contribution to improving the diagnostic accuracy for patients with persistent part-solid nodules (PSNs). By identifying specific CT imaging features—such as preserved vascular and lobular margins, and a lower coronal to axial ratio—that are indicative of focal interstitial fibrosis (FIF) rather than invasive adenocarcinoma (ADC), clinicians can reduce the likelihood of unnecessary surgical interventions.

### PURPOSE

To assess influence of contrast attenuation (air, dark borosilicate contrast material [DBCM], water, and iodine solutions) on visualization of thin structures at photon-counting CT (PCCT) and dual-source CT (DSCT).

### METHODS AND MATERIALS

A line pair phantom with 6 groups of alternating acrylic bars (120 HU at 120 kVp) and slits of equal width at increasing line pair frequencies (3.0 to 9.0 LP/cm) was serially filled with 8 different contrast materials (air; DBCM -400, -160, and -60 HU; water; iodine 140, 240, and 540 HU). Phantom was placed in a body-shaped phantom (40x30 cm, Gammex) and scanned on Siemens PCCT (NAEOTOM Alpha) and DSCT (SOMATOM Force) with similar acquisition and reconstruction parameters (512 or 1024 matrix, 400 or 200 mm FOV, soft [BR44] or sharp [BR68/69] kernel, at 1 mm slice thickness). Two radiologists readers (MH and TA) assessed on a 5-point Likert scale for each group of bars at standard abdominal window levels (W=400, L=40): 1) Number of acrylic bars visible (0 to 4); 2) Accuracy of bar width (0=not visible, 4=bars and slits equal width); and for each acrylic bar 3) Clarity of bar (0=cannot distinguish from noise, 4=entire bar clearly seen). For analysis, the three DBCMs were pooled, and iodine 140 HU was omitted for poor bar delineation.

### RESULTS

When grouping all agents, number of bars visible was significantly higher with sharp kernel compared to soft (2.1 vs 1.3, p=0.002) but not between 1024 vs 512 matrix size (1.7 vs 1.8, p=0.76). Accuracy and clarity scores were also higher between sharp and soft kernels (1.3 vs 0.7, p=0.01; and 1.1 vs 0.6, p=0.02) but not for matrix size. Number of bars, accuracy, or clarity scores were not different between PCCT vs DSCT (1.5 vs 1.9, p=0.12; 0.9 vs 1.1, p=0.29; 0.7 vs 1.0, p=0.16). Between agents, at PCCT with soft kernel and both matrix sizes, pooled DBCMs had highest scores for number of bars (1.7, p=0.02), accuracy (1.0, p=0.001), and clarity (0.9, p<0.001) than air (0.8, 0.6, 0.5), water (1.5, 1.0, 0.6), iodine 240 (1.5, 0.5, 0.4) and iodine 540 HU (0.7, 0.2, 0.2). Comparing all reconstructed datasets (n=6), there was a significant difference between contrast agents for accuracy (p=0.007) and clarity (p=0.009) but not number of bars (p=0.17), with DBCMs performing better than iodine 240 and 540 HU for both accuracy (1.5 vs 0.5 and 0.6, p=0.001 and p=0.009), and clarity (1.2 vs 0.3 and 0.6, p<0.001 and p=0.04).

### CONCLUSION

Use of sharp kernel improves visualization of thin structures at PCCT and DSCT irrespective of matrix size. At standard soft kernel, DBCM performs best for delineating thin bars compared to air, neutral, or positive contrast agents.

### CLINICAL RELEVANCE/APPLICATION

Oral DBCM could improve delineation of fine bowel folds and potentially pathology at both conventional and PCCT. Clinical testing is warranted.

## T1-SSGI08-2 SPECTRAL CT IODINE CONCENTRATION FOR NORMAL LIVER AND HEPATIC STEATOSIS

Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation

Matthew N. Nazarian, MD (*Abstract Co-Author*) Nothing to Disclose

Tom Brosch (*Abstract Co-Author*) Researcher, Koninklijke Philips NV
Mahati Mokkarala, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Spectral CT offers a wide range of potential applications, utilizing various quantitative parameters for analysis by radiologists and scientists. Currently, consensus normal values for liver iodine concentration do not exist. This study aims to assess whether spectral CT can provide reliable quantitative data for normal livers and those with steatosis.

**METHODS AND MATERIALS**

A retrospective PACS search identified 174 portal venous phase examinations on 174 patients performed on a spectral CT (Spectral CT 7500, Philips Healthcare) at an urban academic center. These examinations were analyzed using spectral data, including virtual monoenergetic images, iodine maps, and virtual non-contrast images. Abdominal organs and the abdominal aorta were segmented. Radiology reports were reviewed. Out of the 174 examinations, 134 total examinations had normal livers by radiology report and 24 had hepatic steatosis as the only remarkable liver finding. Excluded from the study were 7 examinations with other diffuse liver diseases such as cirrhosis and 11 examinations with liver lesions > 1.0 cm. Mean liver iodine concentrations were obtained via liver segmentation. Iodine concentration obtained from adequate segmentation of the abdominal aorta was used to normalize liver iodine concentration for each examination. Mean absolute and normalized iodine concentration in normal livers (n=130) and those with hepatic steatosis alone (n=24) were calculated. Statistical analyses were performed using Excel (Office 365, Microsoft) and R (R Core Team).

**RESULTS**

Normal livers had a mean liver iodine concentration of 2.57 mg/mL (SD=0.39), and a normalized liver iodine concentration of 0.54 (SD=0.13). Livers with hepatic steatosis alone had a mean liver iodine concentration of 2.33 mg/mL (SD=0.54) and a normalized liver iodine concentration of 0.40 (SD= 0.14). There was a statistically significant difference between the normalized iodine concentrations in the normal livers when compared to the group of hepatic steatosis alone ($p<0.0001$).

**CONCLUSION**

Livers with hepatic steatosis alone showed decreased iodine concentration compared to normal livers. Additional quantitative spectral CT data can help define abnormal and normal liver parameters.

**CLINICAL RELEVANCE/APPLICATION**

The initial clinical integration of spectral CT enables the utilization of additional information, such as quantitative iodine maps. However, for successful clinical integration, it will be necessary to determine a consensus regarding iodine concentrations in hepatic steatosis and other diffuse liver diseases.

## T1-SSGI08-3 OPTIMIZING PHOTON-COUNTING CT VIRTUAL MONOENERGETIC IMAGING WINDOW SETTINGS IN THE ABDOMEN

Richard W. Ahn, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Anish Goel (*Abstract Co-Author*) Nothing to Disclose
Vasantha Vasan, MD (*Abstract Co-Author*) Nothing to Disclose
Lakshmi Ananthakrishnan, MD (*Abstract Co-Author*) Nothing to Disclose
Xinhui Duan, PhD (*Abstract Co-Author*) Nothing to Disclose

Yin Xi, PhD (*Abstract Co-Author*) Nothing to Disclose
Darren M. Imphean (*Abstract Co-Author*) Nothing to Disclose
Xunbo Xu, ARRT (*Abstract Co-Author*) Nothing to Disclose
Liqiang Ren, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To optimize window settings and display contrast to noise ratio (dCNR) on photon-counting CT virtual monoenergetic images (VMIs) for improved soft tissue and liver visualization.

**METHODS AND MATERIALS**

Institutional IRB approval was obtained. CT data was retrospectively collected from 39 patients scanned on a clinical photon-counting CT (NAEOTOM Alpha, Siemens) with an abdomen-pelvis dual-phase (arterial and portal venous) protocol. For each phase, axial VMIs (Br44 kernel and 5mm thickness) were reconstructed at 60 and 70 keV, resulting in four image series in total for each patient. First, 3 radiologists defined optimal window center/width (C/W) soft tissue and liver settings by manually adjusting windows for optimal soft tissue and liver visualization. The median C/W across all readers and 39 patients were used. Next, for each phase, dCNR was quantified for 5 window settings: default soft tissue (40/400 HU), default liver (50/250 HU), optimal soft tissue, optimal liver, and a vendor-recommended soft tissue setting for 60 keV (FAST-WINDOW: 65/470 HU), and in 3 structures: portal vein, aorta, and muscle. The soft tissue window setting was evaluated by calculating the dCNR of aorta against muscle whereas that for liver window evaluation was done by calculating the dCNR of portal vein against muscle. Percent change in dCNR from the reference C/W settings (default) were reported. Paired t-tests were used to test the percent change against 0.

**RESULTS**

The optimal soft tissue window C/W settings were determined as 100/600 and 60/480 HU for 60 and 70 keV at arterial phase, and 75/500 and 45/400 HU for 60 and 70 keV at portal venous phase. The optimal liver settings were 120/350 and 100/280 HU for 60 and 70 keV at arterial phase, and 130/300 and 105/250 HU for 60 and 70 keV at portal venous phase. For soft tissue windows, display CNR increased by up to 51% when viewing images using the reader-determined optimal C/W settings compared to default C/W settings. Compared to 70 keV images at default liver window, the 60 keV with default window decreased the display CNR by 10% (arterial) and 14% (venous) but increased by 57%/92% (arterial) and 43%/75% (venous) for 70/60 keV images with optimal liver windows. All comparisons were statistically significant with a $p < 0.01$.

**CONCLUSION**

Optimal window settings for both soft tissue and liver can significantly improve the display CNR on PCCT virtual monoenergetic images with more improvements on 60 keV compared to 70 keV images.

**CLINICAL RELEVANCE/APPLICATION**

Low keV images have the potential benefit of increased CNR but inappropriate window settings result in lower display CNR. Viewing images at the determined optimal window settings can achieve higher display CNR and improve image interpretation.

## T1-SSGI08-4 DEEP LEARNING IMAGE RECONSTRUCTION REDUCES NOISE, IMPROVES CONTRAST AND SHARPNESS, AND MAINTAINS TEXTURE FOR ROUTINE LOW-KILOELECTRON VOLT VIRTUAL MONOENERGETIC IMAGE

## RECONSTRUCTION TO MELIORATE DIAGNOSTIC ACCEPTANCE AND LESION CONSPICUITY: A PROSPECTIVE STUDY WITH FIVE READERS

Huan Zhang (*Abstract Co-Author*) Nothing to Disclose
Lingyun Wang (*Abstract Co-Author*) Nothing to Disclose
Weiwu Yao (*Abstract Co-Author*) Nothing to Disclose
Jingyu Zhong, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare image quality and diagnostic acceptance of low-kiloelectron volt virtual monoenergetic image (VMI) to adaptive statistical iterative reconstruction (Asir-V).

### METHODS AND MATERIALS

We prospectively include portal-venous phase scans in contrast-enhanced abdomen dual-energy CT from 109 participants (66 men, mean age ± standard deviation, 57.3 ± 13.1 years) with 152 lesions (median, 12, range, 3 to 107 mm). The raw data of each participant was reconstructed into four image series: VMI at 50-keV using Asir-V at 50% blending (AV-50), and VMI at 40-keV using AV-50 and DLIR at medium (DLIR-M) and high strength (DLIR-H). The CT number values of nine anatomical sites (liver, spleen, pancreas, kidney, abdominal aorta, main portal vein inferior vena cava, paraspinal muscle, and fat tissue) and their standard deviations were measured, and the corresponding (SNR), and (CNR) were calculated. Noise power spectrum (NPS) using homogenous region of liver, and edge rise slope (ERS) at five edges (liver-fat, spleen-fat, kidney-fat, liver-portal vein, and pancreas-splenic vein) were measured. Five radiologists rated image quality in terms of image noise, image contrast, image sharpness, image texture, small structure visibility, and diagnostic acceptability, and evaluated the lesion conspicuity.

### RESULTS

The CT number values in 50-keV images were significantly different from those in 40-keV images, in all anatomical sites (all $p<0.001$). The SD, SNR and CNR values, and noise and noise peak in NPS measurements, were significantly lower in DLIR images than AV-50 images in all anatomical sites (all $p<0.001$). The ERS values were significantly higher in 40-keV images than 50-keV images at all edges (all $p<0.001$). The difference of the peak and average spatial frequency among the four algorithms were significant (both $p<0.001$) but relatively small. The 40-keV images were rated higher in image contrast and sharpness than 50-keV images (both $p<0.001$). The 40-keV AV-50 images showed most severe image noise, but were reduced by DLIR (both $p<0.001$). The 40-keV DLIR-M images were rated higher than 40-keV and 50-keV AV-50 images for diagnostic acceptability and lesion conspicuity (both $p<0.001$).

### CONCLUSION

Our study evaluated the low-keV VMIs, and proved that DLIR can provide lower noise, higher contrast and sharpness, and nature texture to allow 40-keV as a new standard for routine VMI reconstruction. The DLIR-M may gain higher diagnostic acceptance than DLIR-H in abdomen.

### CLINICAL RELEVANCE/APPLICATION

DLIR can improve images quality to allow 40-keV as a new standard for routine VMI reconstruction in abdomen, and the DLIR-M may provide a better trade-off among noise, contrast, sharpness, and texture, for higher diagnostic acceptability and lesion conspicuity.

## T1-SSGI08-5 HEPATIC FAT QUANTIFICATION USING DUAL-ENERGY COMPUTED TOMOGRAPHY:A REGION-OF-INTEREST EVALUATION ON PATIENTS SUSPECTED OF MILD HEPATIC STEATOSIS

Guozhi Zhang (*Abstract Co-Author*) Nothing to Disclose
Baozhi Liu (*Abstract Co-Author*) Nothing to Disclose
Shidan Dou (*Abstract Co-Author*) Nothing to Disclose
Xiaojian Li (*Abstract Co-Author*) Nothing to Disclose
Tianhui Wu (*Abstract Co-Author*) Nothing to Disclose
Dongbo Li (*Abstract Co-Author*) Nothing to Disclose
Liying Peng, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the potential of dual-energy computed tomography (DECT) for fat quantification on patients suspected of mild hepatic steatosis, by using a fine-grained region-of-interest (ROI) evaluation, with magnetic resonance imaging (MRI) serving as the reference.

### METHODS AND MATERIALS

Ten patients who were suspected of mild hepatic steatosis in ultrasonography and had also undergone a recent MRI exam were enrolled in this prospective study, where non-contrast DECT was performed <30 days after the MRI. A total of one hundred ROIs were defined by one fellowship-trained abdominal radiologist on the MRI proton density fat fraction (MRI-PDFF) map, where for each patient three ROIs were positioned on the left liver lobe and seven were positioned on the right liver lobe. Another radiologist was asked to delineate one hundred ROIs at corresponding locations on the DECT fat fraction (DECT-FF) map, expressed in fat percentage ranging from 0 to 100%, which was acquired through dual-material decomposition using fat and normal liver parenchyma as basis materials, on a routinely available post-processing workstation (uOmnispace.CT). The agreement between DECT-FF and MRI-PDFF (reference) was analyzed with the intraclass correlation coefficient (ICC) and the Bland-Altman plot.

### RESULTS

The mean hepatic fat fraction for the left lobe, the right lobe, and the whole liver was 7.5%, 7.7%, and 7.6%, respectively, with DECT-FF, and 7.2%, 8.1%, and 7.8%, respectively, with MRI-PDFF. Good agreement was found between DECT-FF and MRI-PDFF for the left lobe (ICC, 0.81; 95% CI 0.64-0.90). The agreement was slightly lower for the right lobe (ICC, 0.71; 95% CI 0.57-0.81) and the whole liver (ICC, 0.73; 95% CI 0.63-0.81). The Bland-Altman analysis showed a mean difference of 0.3% (95% LoA, -4.5%-5.2%), -0.4% (95% LoA, -7.1%-6.2%), and -0.2% (95% LoA,-6.4%-6.0%), for the left lobe, the right lobe, and the whole liver, respectively, between DECT-FF and MRI-PDFF.

### CONCLUSION

Overall, DECT-FF exhibited fairly acceptable agreement with MRI-PDFF, in hepatic fat quantification for mild steatosis.

### CLINICAL RELEVANCE/APPLICATION

DECT shows potential in hepatic fat quantification for the patients suspected of mild hepatic steatosis, which might be useful for early diagnosis of hepatic steatosis.

## T1-SSGI08-6 SPECTRAL HU CURVE EVALUATION OF LIVER LESIONS IN PANCREATIC CANCER

Corey T. Jensen, MD (*Abstract Co-Author*) Research Grant, General Electric Company
Gauruv S. Likhari, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the accuracy of CT spectral HU curve assessment of hypodense liver lesions.

### METHODS AND MATERIALS

In this retrospective Health Insurance Portability and Accountability Act-compliant study (January 2016 through May 2023), patients with biopsy-proven pancreatic adenocarcinoma and a biopsy-proven indeterminate liver lesion underwent a DECT abdominal CT scan in the late arterial phase. Spectral HU curves were provided for each hypodense liver lesion 0.5 cm and larger and the curve slopes were calculated. Lesion Hounsfield units were recorded on virtual non-contrast, 40 keV, and 70 keV imaging. Lesion iodine concentrations and enhancement were also recorded. A diagnosis of benign versus malignant was determined based on a spectral curve slope cutoff of 1.4, iodine concentration of 7.1 mg/mL, and virtual enhancement of 10.

### RESULTS

The final study group included 36 patients consisting of 19 men and 17 women with a mean age of 63 years ± 9 (standard deviation), a mean height of 170.9 cm ± 9.5, a mean weight of 69.8 kg ± 14.5, and body mass index of 23.9 kg/m2 ± 3.5. Reference standard assessment identified 92 liver lesions (50 metastases, 24 cysts, 2 hemangiomas, 3 regions of inflammation) with a mean size of 1.1 cm ± 0.5. The mean number of days between CT scan and liver lesion biopsy was 24. There were a total of 145 follow-up imaging exams performed for the study group related to indeterminate liver lesions (119 CTs, 12 MRIs, 8 PET-CTs, 6 U/S). Diagnosis by use of spectral curve slope, iodine concentration, and virtual enhancement resulted in accuracies of 0.92, 0.92, and 0.89, respectively.

### CONCLUSION

Spectral HU curves provide highly accurate differentiation of benign from metastatic hypodense liver lesions, most useful in the determination of cyst versus necrotic metastasis.

### CLINICAL RELEVANCE/APPLICATION

Hypodense liver lesions are a challenging issue at staging, often requiring further imaging, follow-up, and/or biopsy. The additional information from multienergy CT can provide useful additional information in this setting and may reduce the need for costly additional evaluation.

## T1-SSGI09-1 DETECTION OF CYSTIC LESIONS OF THE PANCREAS: IMAGE QUALITY AND DIAGNOSTIC ACCURACY OF PHOTON-COUNTING DETECTOR CT VS. CONVENTIONAL ENERGY-INTEGRATING DETECTOR CT

Fabian Bamberg, MD, MPH (*Abstract Co-Author*) Speakers Bureau, Bayer AG;Speakers Bureau, Bracco Imaging;Speakers Bureau, Siemens AG;Research Grant, Siemens AG

Balazs Bogner, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Rau, MD (*Abstract Co-Author*) Nothing to Disclose
Stephan Rau, MD (*Presenter*) Nothing to Disclose

### PURPOSE

MR imaging is the modality of choice for the diagnosis and characterization of cystic pancreatic lesions as diagnostic accuracy of CT is limited, especially if lesions are small. Photon-counting detector (PCD) CT with its higher resolution and lower image noise compared to conventional energy-integrating detector (EID) CT may have the potential to improve diagnosis. Here, we investigated image quality and diagnostic accuracy of PCD-CT for the detection of cystic pancreatic lesions compared to EID-CT in clinical routine datasets.

### METHODS AND MATERIALS

In this prospective IRB-approved study, we included consecutive patients who underwent clinically indicated contrast-enhanced PCD-CT of the abdomen. For all patients an additional EID-CT with a comparable imaging protocol was available for comparison. Multiparametric MRI served as reference standard. CT images were assessed in a blinded reading by three independent radiologists for the presence of pancreatic cystic lesions. In addition, image quality, lesion conspicuity, and diagnostic confidence were rated on 5-point Likert scales (5=excellent). As quantitative measures, the coefficient-of-variation (CV) and the contrast of cystic pancreatic lesions to the parenchyma were calculated. Radiation doses were compared via CTDIvol [mlGy].

### RESULTS

Among 106 included patients (age 62.7±12.6 years; 45 [42.5 %] male), 46 MRI-confirmed cystic lesions (mean size 8.7±7.4 mm; range: 2-45 mm) were present. Sensitivity for the detection of cystic lesions was significantly higher for PCD-CT vs. EID-CT across all readers (50.7% vs. 41.3%; p=0.05, respectively). Image quality, lesion conspicuity, and diagnostic confidence were rated superior for PCD-CT vs. EID-CT (5.0 [4.66-5.00] vs. 4.0 [3.67-4.33]; 4.0 [3.0-4.33] vs. 3.0 [2.33-3.67] and 5.0 [4.33-4.66] vs. 4.0 [3.67-4.33], respectively). Quantitative analyses revealed a significantly lower CV of 0.18 vs. 0.24 (p=0.002) at lower radiation doses of 7.13 vs. 8.68 mGy (p<0.001). Contrast of cystic lesions to pancreas parenchyma was significantly higher for PCD-CT vs. EID-CT (103.2 ± 29.9 HU vs. 77.6 ± 19.5 HU p<0.001).

### CONCLUSION

PCD-CT provides superior image quality and diagnostic accuracy for the detection of cystic pancreatic lesions compared to EID-CT at lower radiation dose.

### CLINICAL RELEVANCE/APPLICATION

Cystic pancreatic lesions are a frequent incidental finding in routine abdominal CT examinations. PCD-CT provides significantly higher diagnostic accuracy compared to EID-CT and can improve diagnosis of cystic pancreatic lesions that may otherwise go unnoticed. In addition, multispectral data of PCD-CT may further help in lesion characterization.

## T1-SSGI09-3 AN EXPLAINABLE PREDICTION MODEL OF LYMPHOVASCULAR INVASION& ITS PROGNOSTIC VALUE IN RESECTABLE PDAC:A MULTICENTER STUDY

Linxia Wu (*Abstract Co-Author*) Nothing to Disclose
Ziwei Jin (*Presenter*) Nothing to Disclose

**PURPOSE**

Lymphovascular invasion (LVI) is an independent factor for early recurrence, metastases and poor prognosis in pancreatic ductal adenocarcinoma (PDAC). Early identification and prediction of LVI are crucial. This study aimed to establish and validate an explainable prediction model based on the machine learning (ML) approach for LVI and assess its prognostic value in patients with PDAC.

**METHODS AND MATERIALS**

Patients who underwent radical surgical resection and were pathologically proven with PDAC were recruited retrospectively from two centers. The derivation cohort, consisting of 202 PDAC patients admitted to Center 1 from January 2014 to November 2021, was separated for training and internal validation, and an external dataset of 60 patients with PDAC admitted to another center was employed for external validation. LVI was defined based on pathological reports. With 16 medical characteristics easily obtained or evaluated before surgery, 10 ML algorithms were used to construct prediction models. Several evaluation indexes, including the area under the receiver operating characteristic curve (AUC), were used to compare the predictive performance. The Shapley Additive explanation method was used to rank the feature importance and explain the final model. A probability threshold for the final model was identified for LVI prediction. Subsequently, the association of the model's risk stratification with disease-free survival (DFS) and overall survival (OS) was then statistically examined using Cox regression analysis and the log-rank test.

**RESULTS**

The LightGBM model performed best in discriminative ability among the 10 ML models. After reducing features according to feature importance rank, an explainable final LightGBM model was established with 10 features. The final model could accurately predict LVI in both internal (AUC=0.814) and external (AUC=0.790) validations. The model's risk stratification was an independent predictor of DFS (all $P < 0.001$) and OS (all $P < 0.001$). Furthermore, patients in the high-risk group stratified by the model consistently had a significantly shorter DFS and OS in all patients (all $P < 0.001$).

**CONCLUSION**

Our explainable ML model was not only successfully developed to accurately predict LVI but was also highly relevant to shorter DFS and OS in early resectable PDAC patients, and it mitigated the concern of the “black-box” issue with an undirect interpretation of the ML technique.

**CLINICAL RELEVANCE/APPLICATION**

The final LightGBM model aims to assist clinicians in identifying patients at high risk of recurrence and with poor prognoses at the molecular biological level. It provides clinicians with a novel perspective for making effective diagnoses and treatment strategies for patients with PDAC.

## T1-SSGI09-5 IMPACT OF REPORTED MEASUREMENT VARIABILITY ON PANCREATIC CYST SURVEILLANCE: 40% INCREASE IN DIAGNOSTIC AND INVASIVE PROCEDURES OVER 15 YEARS

Yameng Deng (*Abstract Co-Author*) Nothing to Disclose
Fiona Kolbinger (*Abstract Co-Author*) Nothing to Disclose
Thoa Tran (*Abstract Co-Author*) Nothing to Disclose
Edward Jackson (*Abstract Co-Author*) Nothing to Disclose
C. Max Schmidt, MD, PhD (*Abstract Co-Author*) Consultant, RedPath Integrated Pathology, Inc;Consultant, RedPath Integrated Pathology, Inc;Scientific Advisory Board, Asuragen, Inc;Speaker, Asuragen, Inc;Founder, B9, Inc
George Ralli, DPhil (*Abstract Co-Author*) Employee, Perspectum Diagnostics Ltd
Fatih Akisik, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Surveillance of pancreatic cysts imposes a significant burden on healthcare systems. While several healthcare-economic studies have explored this aspect of pancreatic cyst surveillance, none account for variability in radiological measurement. To assess the additional costs this imposes, we extend a published surveillance model to include measurement variability.

**METHODS AND MATERIALS**

We used a previously established approach to simulate pancreatic cyst progression and resultant clinical pathways for a cohort of 10,000 patients (starting age 55, 50% female) managed under the international consensus guidelines of the International Association of Pancreatology (IAP) for 15 years. To examine the effect of varying rates of interobserver measurement variability, at each time-point where a patient received an MRI scan, random Gaussian noise was added to the diameters of the cyst and main pancreatic duct, for a range of noise levels. At each level of noise, the simulation was conducted 30 times.

**RESULTS**

After incorporating reported rates of interobserver variability for cyst measurement (6.4 mm) and a conservative estimate of pancreatic duct variability (1 mm) the mean number of surgeries for benign cysts rose from 530 [95% CI 488, 571] to 964 [915,1013]. The entirety of these additional surgeries was caused by error in cyst diameter, as benign cases were unlikely to have sufficiently dilated pancreatic ducts to trigger surgery. MRI studies/patient rose from 9 [8.9, 9.1] to 11.9 [11.8, 12], EUS studies/patient from 4.6 [4.5, 4.8] to 7.3 [7.2, 7.4], total deaths/ 10,000 patients from 44.5 [35.7, 57.2] to 55.6 [42.6, 68.7]. Total surveillance costs/patient from $ 19,853 to $ 28,845, compared to an error-free case. The rate of correct cancer diagnoses remained stable (123.4 [101.6, 145.1] vs 123.9 [102.2, 145.7]).

**CONCLUSION**

Incorporating previously reported levels of interobserver variability into models of patients undergoing pancreatic cyst surveillance significantly increases unnecessary procedures.

**CLINICAL RELEVANCE/APPLICATION**

Pancreatic cyst guidelines heavily depend on threshold-based decision-making, yet measurement variability in examinations can significantly alter clinical decisions and care trajectories.

## T1-SSGI09-6 EXTRACELLULAR VOLUME FRACTIONS DETERMINED BY EQUILIBRIUM CONTRAST-ENHANCED CT TO PREDICT POSTOPERATIVE PROGRESSION-FREE SURVIVAL IN PANCREATIC DUCTAL ADENOCARCINOMA

Hajime Sakuma, MD, PhD (*Abstract Co-Author*) Research Grant, Eisai Co, Ltd;Research Grant, FUJIFILM Holdings Corporation;Research Grant, Guerbet SA;
Motonori Nagata, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kensuke Domae, MD (*Abstract Co-Author*) Nothing to Disclose
Satoshi Nakamura, MD (*Abstract Co-Author*) Nothing to Disclose

Yutaka Toyomasu, MD (*Abstract Co-Author*) Nothing to Disclose
Yasutaka Ichikawa, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Extracellular volume (ECV) fractions determined by equilibrium contrast-enhanced CT have recently emerged as an imaging biomarker for predicting survival in patients with pancreatic ductal adenocarcinoma (PDAC). The aim of this study was to evaluate the utility of the ECV fractions for predicting postoperative recurrence in patients with resectable or borderline resectable PDAC.

**METHODS AND MATERIALS**

The study cohort included 53 patients (mean age, 72±9 years) who underwent radical resection for resectable or borderline resectable PDAC and who underwent dynamic contrast-enhanced CT preoperatively. On non-contrast and equilibrium phase CT, changes in mean CT values in the tumor and aorta were measured by placing regions of interests, and corrected for hematocrit to calculate the ECV fraction of the tumor as follows: ECV (%) = (1 - hematocrit) × (?HUtumor / ?HUaorta) × 100. Using the cutoff value of ECV determined by the Contal-O'Quigley method, the Kaplan-Meier method with log-rank test was used to evaluate ECV in relation to progression-free survival (PFS). The incremental prognostic value of ECV over tumor size (long diameter) was evaluated using the global chi-square test.

**RESULTS**

Mean observation period was 507 days (interquartile range, 177-1521 days). Recurrence of PDAC occurred in 32 (60%) of 53 patients. The optimal cutoff values of tumor ECV fraction was 55.6% for PFS. In the Kaplan-Meier method with log-rank test, patients with lower tumor ECV fraction showed poorer PFS than that with higher tumor ECV (p=0.037) when stratified by the cutoff value (Figure 1). The 5-year survival rate for the lower and higher ECV group was 24% and 75%, respectively. The number of patients in the favorable prognosis group with ECV above the cutoff value was 9 (17%) of the patients included in this study. There was no significant linear correlation between ECV and tumor size (p=0.7). Global chi-square test showed that ECV was of significant incremental prognostic predictive value to tumor size (p=0.046).

**CONCLUSION**

The ECV fraction (the cut-off value, approximately 56%) obtained from equilibrium contrast-enhanced CT is a promising quantitative indicator for predicting postoperative recurrence in patients with resectable or borderline resectable PDAC and has incremental prognostic value relative to tumor size.

**CLINICAL RELEVANCE/APPLICATION**

The ECV fraction derived from equilibrium contrast-enhanced CT has the potential as an imaging biomarker for predicting postoperative recurrence in patients with PDAC.

### PURPOSE

To determine the diagnostic performance of 4-minute DL-reconstructed 6-fold parallel imaging (PI) and simultaneous multislice (SMS) accelerated knee MRI in children and adolescents.

### METHODS AND MATERIALS

Pediatric patients with painful knee conditions who underwent DL-reconstructed 6-fold PI-SMS-accelerated knee MRI and arthroscopic knee surgery between October 2022 and December 2023 were retrospectively identified. Nine fellowship-trained musculoskeletal radiologists independently scored the MRI studies for image quality and the presence of ligamentous, meniscal, tendinous, and osteocartilaginous abnormalities. Cartilage defects were divided into partial and full-thickness defects and assessed for each joint compartment individually. Intraarticular fractures were assessed separately for all osseous structures (femur, tibia, patella). Kappa-based interreader agreements and diagnostic performance parameters with arthroscopic surgery as the reference standard were computed (significance level p <.05).

### RESULTS

Forty-four children and adolescents (mean age: 15±2 years; range: 9-17 years; 24 boys) who underwent 3T knee MRI and arthroscopic surgery within a median of 22 days (range: 2-133 days) were analyzed. Overall image quality was rated very good (median: 5 [95% CI: 4;5]) without degradation by motion artifacts (median: 5 [5;5]). Arthroscopy-verified structural abnormalities were detected with good to very good agreement (? = 0.66 [0.61-0.71]). Consensus sensitivities/specificities/accuracies were 100%/84-100%/93-100% for the diagnosis of anterior (n=25) and posterior (n=1) cruciate ligament tears, 65-71%/97-100%/86-93% for the diagnosis of medial (n=7) and lateral (n=17) meniscus tears, 100%/100%/100% for the diagnosis of discoid lateral menisci (n=5), 100%/95%/96% for the diagnosis of medial patellofemoral ligament tears (n=3), and 55-60%/100%/98-99% for the diagnosis of cartilage defects (n=11) and fractures (n=3).

### CONCLUSION

DL-enhanced clinical 4-minute knee MRI has excellent image quality and high diagnostic performance for diagnosing internal derangement in children and adolescents with a good-to-very-good interreader agreement.

### CLINICAL RELEVANCE/APPLICATION

Deep learning augmented ultra-fast musculoskeletal MRI adds value to pediatric radiology by maximizing scan efficiency, potentially decreasing the need for sedation or general anesthesia without negatively affecting diagnostic accuracy.

## T1-SSPD03-2 GADOLINIUM DEPOSITION IN MULTIPLE ORGANS/TISSUES IN MOTHER AND PUP MOUSE: EXPOSURE DURING PREGNANCY, LACTATION

Kai Xu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shi Qiu (*Abstract Co-Author*) Nothing to Disclose
YING KONG (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the effects of pregnancy, lactation, and repeated administration of GBCAs on gadolinium deposition in multi-organ/tissue of mother and pup mice.

**METHODS AND MATERIALS**

Two hundred and seventy ICR mice were divided into three groups (non-pregnant, pregnant, and lactating; n=90/group) and received Gadodiamide, Gadoterate meglumine, or saline intravenously (2.5 mmol Gd/kg once every two days for a total of 10 doses) throughout the entire gestation or lactation period. Gadolinium concentration detection, histological analyses, and transmission electron microscopy were performed on mothers and pup mice at corresponding time points (the completion of the injection, one month later, and three months later).

**RESULTS**

(i)Gadolinium deposition exhibits analogous patterns in non-pregnant, pregnant, and lactating mice: gadodiamide exhibited more gadolinium retention in multi-organ/tissue and showed faster accumulation and regression speed in examined tissues versus gadoterate meglumine; gadolinium deposition decreased more rapidly in the first month in all tissues examined, exception of skin where it decreased at a near-uniform rate over 3 months; gadolinium deposition was found to be lower in the kidneys of both pregnant and lactating mice than in non-pregnant mice, and was more pronounced in gadodiamide.(ii)Exposure to GBCAs during pregnancy resulted in gadolinium deposition in the organs of the fetus, with the greatest deposition observed in the kidneys. Gadolinium deposition was observed to be higher in fetuses due to gadodiamide, and the administration of gadodiamide also resulted in a reduction in litter rates in pregnant mice. A noteworthy observation is the substantial proportion of gadolinium deposits in the fetal body that were metabolized after 1 month.(iii)Exposure to GBCAs during lactation did not result in detectable gadolinium deposition in the organs/tissues of their unweaned pups.

**CONCLUSION**

Exposure to GBCAs during pregnancy resulted in gadolinium deposition in multiple organs/tissues in their fetuses, with significant gadodiamide, and the deposited gadolinium was almost completely metabolized within 1 month, with no significant organ toxicity found in the fetus.

**CLINICAL RELEVANCE/APPLICATION**

The utilization of GBCAs in pregnant women is discouraged, and if clinically necessary, only the more stable, less-deposited macrocyclic GBCAs are recommended.Continued breastfeeding after exposure to GBCAs during lactation does not pose a risk of gadolinium deposition to the pups.

## T1-SSPD03-3 VIRTUAL 3D MODEL FOR MEASURING SUPRA- AND INFRATROCHANTERIC FEMORAL TORSION IN CEREBRAL PALSY: COMPARISON TO A MATCHED CONTROL GROUP

Michael B. Millis, MD (*Abstract Co-Author*) Nothing to Disclose
Ata Kiapour, PhD (*Abstract Co-Author*) Nothing to Disclose
Sarah D. Bixby, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Jade Iwasaka-Neder, MD, MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

Cerebral palsy (CP) leads to complex torsional abnormalities in the femur due to muscle spasticity, which is often corrected by derotational osteotomy. The level of torsion, either supra- or infratrochanteric, is still not known and could guide pre-surgical planning of osteotomy site. Axial measurements on 2D imaging do not capture the complex anatomy of the proximal femur on this population. This study evaluated a novel measurement technique for assessing the supra- and infratrochanteric components of femoral torsion in virtual 3D models, comparing these measurements in patients with cerebral palsy and in a matched control group.

**METHODS AND MATERIALS**

This IRB-approved prospective study included patients < 18 years old with a diagnosis of CP referred for hip/femur CTs and a matched control group of patients with healthy femurs referred for hip/femur MRI. CT scans were performed according to standard protocols on state-of-the art multidetector scanners with submillimeter resolution. Subjects in the control group were scanned on a 3 Tesla MRI scanner according to standard department protocol, including a fast 3D gradient echo sequence (T1 VIBE). CT scans and T1 VIBEs were reconstructed in virtual 3D femur models and reviewed by three pediatric musculoskeletal radiologists who measured the supra- and infra-trochanteric femoral torsions. Statistical analysis included the independent t test, Mann-Whitney U test, and intraclass correlation coefficient (ICC).

**RESULTS**

The study cohort consisted of 52 femurs from patients with CP (10.2 ± 4.5 years, range 4-17; female=30) and 52 control femurs (11.9 ± 2.5 years, range 8-17; female=20). Intra- and inter-reader correlations on both groups were good to excellent (ICC=0.80). The supra- and infratrochanteric torsion values of the control femurs were 28.5° ± 9.6° (mean ± SD) and -5° ± 7.3°, respectively. On the CP group, supratrochanteric torsion was 35.1° ± 13.3° and infratrochanteric torsion was -1.6° ± 15.9°. On both groups, the supratrochanteric torsion is the main contributor to the overall femoral torsion. In comparison with the controls, patients with CP had significantly higher supratrochanteric torsion values ($p = 0.05$). There is no statistical difference in infratrochanteric torsion between the two groups, but infratrochanteric torsion had a wider range and right skew of values in the CP group.

**CONCLUSION**

The 3D femur model technique is a reliable technique to measure supra- and infratrochanteric femoral torsions. Patients with CP have predominantly increased supratrochanteric torsion.

**CLINICAL RELEVANCE/APPLICATION**

Quantification of supra- and infratrochanteric femoral torsion angles allows a more detailed analysis of cerebral palsy and may influence treatment planning.

## T1-SSPD03-4 SOLID BREAST MASSES DETECTED BY ULTRASOUND IN ADOLESCENT PEDIATRIC POPULATION: FREQUENCY AND DIAGNOSTIC OUTCOMES

Teresa Victoria, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Christian A. Barrera, MD (*Abstract Co-Author*) Nothing to Disclose
Michael S. Gee, MD, PhD (*Abstract Co-Author*) Researcher, General Electric Company Researcher, Siemens AG Researcher, Motilent LLC
Valeria Pena-Trujillo, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the prevalence and outcome of breast masses with ultrasound evaluation and biopsy in the adolescent pediatric population

**METHODS AND MATERIALS**

In this retrospective study, all female patients aged 13 - 18 years with a breast ultrasound between 2018 and 2024 were identified. Thirteen years of age was used as a lower limit as this is the average menarche age in the United States. Eighteen years of age was used as an upper limit as patients older than 18 years are seen by the Adult Breast Imaging Center instead of Pediatric Radiology. Demographic information was registered. Patients who had an ultrasound-guided biopsy and subsequent surgical excision were collected. The pathology results for both procedures were recorded.

**RESULTS**

773 breast ultrasounds were performed. 78 (10%) ultrasound-guide breast mass biopsies were performed. Fibroadenoma (49/78, 63%) was the most common diagnosis, followed by fibroepithelial lesion (15/78, 19%). 29 out of 78 (37%) patients underwent surgical excision. 9 patients were upgraded from fibroepithelial lesion to fibroadenoma and 2 patients to Phylloides tumor. 3 patients were diagnosed with a hamartoma, 3 patients with intraductal papilloma, and 1 with nodular fasciitis. No malignant pathology results were identified.

**CONCLUSION**

The number of breast masses detected by ultrasound in adolescent girls is low. Fibroadenoma is the most common breast mass in girls and the prevalence of malignancy is extremely rare.

**CLINICAL RELEVANCE/APPLICATION**

Pediatric breast masses in adolescent patients aged 13-18 years are benign. Small pediatric departments embedded in larger adult hospitals may opt for their dedicated breast center overseeing the adolescent population. We argue that given that the likelihood of benignity is high, that these patients are seen and diagnosed in a pediatric center, cared for by pediatric specialists, rather than in an adult center, which may be overwhelming for the young patient.

## T1-SSPD03-5 RADIOLOGIC GROWTH CHART OF FEMORAL HEAD OSSIFICATION CENTER AND ACETABULAR INDEX IN NORMAL KOREAN CHILDREN USING DEEP LEARNING-BASED AUTOMATIC MASUREMENT

MOON KI RYUM (*Abstract Co-Author*) Nothing to Disclose
Byoung-Dai Lee, PhD (*Abstract Co-Author*) Nothing to Disclose
Musook Lee (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a deep learning (DL)-based algorithm using a vast amount of hip anteroposterior (AP) radiographs of Korean children, and to utilize it for establishing a growth chart of the femoral head ossification center (FHOS) and the acetabular index (AI) in normal Korean children."

**METHODS AND MATERIALS**

A total of 4,560 hip AP radiographs were used to develop the DL-based algorithm for automatic measurement of FHOS sizes and AI. Additionally, 1,200 hip AP radiographs of normal Korean children were collected to evaluate the variation in the size of FHOS and the AI as they relate to growth. The agreement between the reference standard and the outputs of the DL-based algorithm was determined using Pearson correlation coefficient (r), intraclass correlation coefficient (ICC), mean absolute error (MAE), and root mean squared error (RMSE). Linear regression analysis was employed to assess the correlations between FHOS size and age.

**RESULTS**

The FHOS sizes measured by the DL-based algorithm demonstrated excellent agreement with the reference standard for all evaluation data (left, r = 0.95; ICC = 0.95; MAE = 2.73 mm; RMSE = 3.53 mm; right, r = 0.95; ICC = 0.95; MAE = 2.70 mm; RMSE = 3.45 mm). Similarly, the AI measurements obtained through the DL-based algorithm also exhibited outstanding agreement with the reference standard (left, r = 0.90; ICC = 0.90; MAE = 2.11°; RMSE = 2.99°; right, r = 0.90; ICC = 0.90; MAE = 2.03°; RMSE = 2.80°). The correlation between age and FHOS size was significant, with high R2 correlation coefficient of 0.91 for the left and right femoral heads, respectively.

**CONCLUSION**

The DL-based algorithm developed in this study successfully achieved accurate detection and measurement of the FHOS size and the AI in hip radiographs. Consequently, it enabled the establishment of reference values for the development of hip joints of normal Korean children.

**CLINICAL RELEVANCE/APPLICATION**

This growth chart may provide foundational data on the various developmental stage of femoral head size and acetabular index in normal Korean children by age. Consequently, it could be instrumental in the diagnosing and managing a range of developmental disorders.

## T1-SSPH06-1 APPLICATION OF AI-BASED SEQUENCES FOR SIGNIFICANT REDUCTION OF ENERGY CONSUMPTION OF MRI

Meinrad J. Beer, MD (*Abstract Co-Author*) Nothing to Disclose
Stefanie Lorenz (*Presenter*) Nothing to Disclose

### PURPOSE

Strategies to reduce energy consumption by imaging modalities in healthcare are an essential topic in the era of climate and energy crises. Here, MRI scanners have the highest energetic impact. The advent of AI-based sequences allows a significant reduction in measurement times, which might have also a positive impact on energy consumption. Real-world energy measurements of MRI systems are largely lacking, especially regarding reduction by the application of AI-sequences.

### METHODS AND MATERIALS

During a two-weeks period power consumption, log files were collected of one 1.5T and one 3T MRI system (Magnetom SOLA and Magnetom VIDA fit, Siemens Healthineers, Germany) in a tertiary hospital. Times for procedure, standby and turn-off were tracked, as well as the number and type of procedures, sequence type, application of AI-based sequences, and energy used. In all measurements, the apparent power was determined according to the units VA or VAh. Values were calculated for energy consumption of three main clinical szenarios (MRI of Head, Knee, Abdomen) without and with AI-application, extrapolating these for one year.

### RESULTS

Comparing the mean electrical power of both devices during measurements and in standby/idle mode, the 1.5T system consumed less energy during measurements (27.32 kVA vs. 29.99 kVA, $p<0.001$), while the 3T system consumed less energy in standby/idle mode (9.01 kVA vs. 9.89 kVA, $p<0.001$). Energetic cost for most frequent clinical scenarios were on average 15.04 kVAh for Head MRI, 10.24 kVAh for Knee MRI and 15.80 kVAh for Abdominal MRI. Highest mean energetic costs were measured for CISS -sequences (3.34 kVAh), lowest for FLASH 3D sequences (0.17 kVAh). AI-based sequences were applied for Head MRI (33.0 %) and Pelvis MRI (52.4 %). This yielded in a reduction of the respective measurement times of 2.3 min ($p=0.371$) and 2.5 min ($p=0.376$), accompanied by a reduction of energy consumption by 2.32 kVAh ($p=0.125$) and 3.07 kVAh ($p=0.065$), extrapolated to one year of 5860.55 kVAh and 1674.94 kVAh.

### CONCLUSION

Application of AI-based sequences does not only reduce measurement times but also significantly reduces energy consumption in MRI scanners, regardless of field strength (1.5T and 3T). Sequences technologies with the highest energy consumption such as CISS and EPI would profit most from AI-technologies. A broad application of AI-sequences could reduce energy consumption by 15-20 %.

### CLINICAL RELEVANCE/APPLICATION

MRI scanners consume significant amounts of energy. Optimization is mandatory in times of climate and energy crises. Application of AI-based sequences will have a major impact to be a carbon-reduced healthcare provider.

## T1-SSPH06-2 WHICH DIELECTRIC PAD TO USE AT 7T CLINICAL NEUROIMAGING. BARIUM TITANATE OR CALCIUM TITANATE?

Wendy Elvendahl (*Abstract Co-Author*) Nothing to Disclose
Zuzan Cayci, MD (*Abstract Co-Author*) Nothing to Disclose
James Joers (*Abstract Co-Author*) Nothing to Disclose
Bhargavi Goduguchinta (*Abstract Co-Author*) Nothing to Disclose
Young Woo Park, PhD (*Abstract Co-Author*) Nothing to Disclose

Matthew White (*Abstract Co-Author*) Nothing to Disclose
Jeffrey B. Rykken, MD (*Abstract Co-Author*) Nothing to Disclose
Can Ozutemiz, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Transmit B1 inhomogeneities and susceptibility artifacts limit the usefulness of 7T MRI for assessing structures near the skull base. Dielectric pads composed of high-permittivity materials such as barium titanate ($BaTiO_3$) or calcium titanate ($CaTiO_3$) can reduce these effects. Our purpose was to

compare these pads regarding imaging quality in clinical neuroimaging.

**METHODS AND MATERIALS**

BaTiO3 and CaTiO3 dielectric pads with matching size (2x6.5x10cm2, 1x18×10cm2, 1x36x10cm2) and thickness (5.5mm) were produced with deuterated water in our center following literature guidance. Pads were double heat sealed and double bagged for safety. Five healthy volunteers underwent 7T MRI with an FDA-approved clinical MRI system (Siemens Terra, 1TX/32RX Nova head coil) with BaTiO3 and CaTiO3 pads. Pads were placed in the suboccipital, frontal and bitemporal regions. Clinically used standard sequences, 3D-T2-SPACE, 3D-FLAIR, oblique coronal T2-TSE, oblique coronal 2D-FLAIR, and coronal T1-TSE were applied in each volunteer in addition to B1 mapping. Two board-certified neuroradiologists assessed each image blindly and scored image quality (1: excellent, 2: reasonably good, 3: adequate, 4: suboptimal, 5: poor) and artifacts (1: none, 2: mild, 3: moderate, 4: moderate/severe, 5: severe) using a 5-point Likert scale and were asked which exam they preferred. The scores for 5 subjects, across 2 observers, were pooled, and paired comparison was made with Wilcoxon signed rank test between BaTiO3 and CaTiO3 pads.

**RESULTS**

Significantly more artifacts were noted with BaTiO3 compared with CaTiO3 in posterior fossa (3D-T2-SPACE, 3D-FLAIR), orbitofrontal gyri (3D-T2-SPACE, 3D-FLAIR) and temporal lobes (3D-FLAIR) ($P < 0.05$). The BaTiO3 pads also showed increased right/left side differences in posterior fossa and orbitofrontal gyri over CaTiO3. Image quality was higher in the skull base structures with CaTiO3 pads in 3D-T2-SPACE and 3D-FLAIR ($P < 0.05$).

**CONCLUSION**

For the pad compositions and geometries used in this study, CaTiO3 pads provided better imaging quality and fewer artifacts in the skull base compared with BaTiO3 pads when placed in suboccipital, bitemporal and frontal regions.

**CLINICAL RELEVANCE/APPLICATION**

BaTiO3 pads create a stronger B1 shift, leading to more magnetic inhomogeneity than CaTiO3 pads. When placed in suboccipital, bitemporal, and frontal regions, CaTiO3 pads provide more homogeneous imaging with relatively fewer artifacts and higher imaging quality. Use of CaTiO3 pads is recommended for optimal homogeneity in clinical neuroimaging at 7T.

## T1-SSPH06-3 INTERROGATION OF GLIOBLASTOMA FATTY ACID SYNTHESIS AND METABOLISM WITH DEUTERIUM METABOLIC IMAGING

Xia Ge (*Abstract Co-Author*) Nothing to Disclose
Joseph E. Ippolito, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kevin Cho (*Abstract Co-Author*) Nothing to Disclose
Elena Nunez (*Abstract Co-Author*) Nothing to Disclose
Andrew L. Chang, MD,PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Glioblastoma, an invariably lethal brain tumor, undergoes marked metabolic alterations during tumorigenesis and is extraordinarily difficult to treat. Detecting recurrence after treatment and understanding metabolic alterations within the tumor microenvironment is extremely challenging. An exciting and emerging imaging method called deuterium metabolic imaging (DMI) detects metabolic adaptations via non-radioactively labeled deuterated substrates. This study developed approaches to image lipid synthesis with deuterium oxide (D2O) and metabolism with d31-palmitic acid (d31-PA) in glioblastoma.

**METHODS AND MATERIALS**

A fatty acid phantom was generated for characterization of lipid DMI signal performed at 12 T. DMI was performed in mice orthotopically implanted with GL261 glioblastoma utilizing either orally administered d31-PA or D2O and was correlated with pharmacokinetic metabolic measurements from mouse serum. Mice were either orally gavaged with an emulsion of d31-PA prior to imaging or provided dilute D2O for ad libitum consumption following tumor implantation. Following imaging, tumor, brain, and other organs were harvested for ex vivo DMI or conventional and imaging mass spectrometry to characterize spatial metabolism of deuterated tracers.

**RESULTS**

Although D2O administration resulted in robust enrichment of lipid signal in GBM, d31-PA uptake and metabolism was not significantly detected within intracranial tumors. Interestingly, d31-PA uptake and metabolism was detected in normal tissues, indicating preferential utilization of fatty acids in non-neoplastic tissues. These findings suggest de novo lipogenesis within GBM is a preferential pathway for cellular lipids rather than uptake of administered long chain fatty acids.

**CONCLUSION**

DMI can assist in interrogating GBM fatty acid synthesis and metabolism, as well as further our understanding of lipid distribution within the body by providing a non-invasive scaffold for dynamic interrogation of fatty acid distribution in an oncologic model.

**CLINICAL RELEVANCE/APPLICATION**

Developing a non-invasive method for characterization of tumor fatty acid synthesis and metabolism may improve our understanding of tumor metabolism and could dynamically guide selection of patient-tailored metabolic therapies in the future.

## T1-SSPH06-4 NEWLY DEVELOPED CONJUGATE GRADIENT AND DEEP LEARNING RECONSTRUCTIONS: UTILITY FOR LUNG MRI WITH ULTRA-SHORT TE TO REDUCE ACQUISITION TIME WITH KEEPING IMAGE QUALITY AND NODULE DETECTION CAPABILITY

Yoshiharu Ohno, MD, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

Takahiro Ueda, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Kaori Yamamoto (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Yoshiyuki Ozawa, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Conjugate gradient reconstruction (CG-recon) and deep learning reconstruction (DLR) for lung MRI with ultra-short TE (UTE-MRI) are newly developed to reduce acquisition time without decreasing image quality and nodule detection capability. The purpose of this study was to determine utilities of CG-recon and DLR for reducing acquisition time with keeping image quality and nodule detection capability on UTE-MRI.

**METHODS AND MATERIALS**

35 patients with lung nodule underwent UTE-MRI obtained with CG-recon and grid-reconstruction (Grid-recon) by original (UTEoriginal), 1/2 (UTE1/2) and 1/4 (UTE1/4) sampling spoke numbers at 1.5T and 3T systems. Then, each UTE-MRI was reconstructed with and without DLR. Standard protocol in this study was UTEoriginal obtained by Grid-recon and reconstructed without DLR. In each patient, standard reference for nodule was determined by thin-section CT. To determine the influence of sampling spoke number reduction and reconstruction method differences, signal-to-noise ratios (SNRs) of lung and nodule, overall image quality and nodule presence probability were assessed by ROI measurements or 5-point scales. SNRs and overall image quality were compared between each UTE-MRI and standard protocol by Student's t-test or Wilcoxon's signed rank test. Then, ROC analysis was performed to compare nodule detection capability between each UTE-MRI and standard protocol.

**RESULTS**

DLR was significantly improved SNRs of all UTE-MRIs as compared with standard protocol ($p<0.05$). Overall image qualities of each UTE1/4 and all UTE1/2s except UTE1/2 obtained by CG-recon and reconstructed with DLR were significantly lower than that of standard protocol ($p<0.05$). Area under the curve (Az) of standard protocol (Az=0.966) was significant larger than that of UTE1/4 obtained by Grid-recon (with DLR: Az=0.913, $p<0.0001$; without DLR: Az=0.824, $p<0.0001$) and CG-recon (with and without DLR: Az=0.913, $p<0.0001$) and UTE1/2 obtained by Grid-recon and reconstructed without DLR (Az=0.944, $p=0.03$), and significantly smaller than that of UTEoriginal obtained by CG-recon (with DLR: Az=0.98, $p=0.008$; without DLR: Az=0.977, $p=0.03$).

**CONCLUSION**

CG-recon and DLR were useful for reducing acquisition time without degradation of image quality and nodule detection on UTE-MRI.

**CLINICAL RELEVANCE/APPLICATION**

CG-recon and DLR are useful for reducing acquisition time without degradation of image quality and nodule detection on UTE-MRI.

## T1-SSPH06-5 UNIFORM: A UNIFIED DEEP LEARNING FRAMEWORK FOR MULTI-ORGAN AND MULTI-CONTRAST MRI RECONSTRUCTION

Jan-Jakob Sonke, PhD (*Abstract Co-Author*) Royalties, Elekta AB;Royalties, Precision X-Ray, Inc;Research Grant, Elekta AB
Ritse M. Mann, MD, PhD (*Abstract Co-Author*) Researcher, Siemens AG;Consultant, Siemens AG;Researcher, Bayer AG;Consultant, Bayer AG;Researcher, Medtronic plc;Consultant, Medtronic plc;Researcher, Becton, Dickinson and Company;Consultant, Becton, Dickinson and Company;Researcher, ScreenPoint Medical BV
Jonas Teuwen, MSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Nikita Moriakov (*Abstract Co-Author*) Nothing to Disclose
Jonatan Ferm (*Abstract Co-Author*) Nothing to Disclose
George Yiasemis, MSc, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate UNIFORM, a unified deep learning framework designed for reconstructing MRI images from undersampled data across different organs and contrasts. This approach aims to speed up MRI procedures and reduce the need for multiple specialized reconstruction algorithms.

**METHODS AND MATERIALS**

We optimized the state-of-the-art vSHARP algorithm —a top contender from the CMRxRecon challenge at MICCAI 2023—this physics-based deep learning model employs variable half-quadratic splitting with ADMM unrolled optimization to reconstruct images from undersampled multi-coil k-space data. The model was trained on a broad dataset that included multi-coil k-space data from various organs sites and contrasts, such as fastMRI knee (proton density, with and without fat suppression), fastMRI brain (T1-weighted, both pre and post-contrast, T2-weighted, FLAIR), fastMRI prostate (T2-weighted), and CMRxRecon cardiac (cine - short and long-axes, T1 and T2-weighted) MRI. Training was executed over 420,000 iterations on two A100 80GB Nvidia GPUs, using data retrospectively undersampled at different acceleration factors (2x, 4x, 6x, 8x) with diverse undersampling strategies. Additionally, zero-shot training was performed on prospectively undersampled data for an unseen organ (breast, T1-weighted) at higher accelerations (10x, 17x) using a self-supervised learning (SSL) method.

**RESULTS**

Evaluation of the model's performance on test data undersampled at various accelerations (2x, 4x, 6x, 8x) used fidelity metrics such as the structural similarity index measure (SSIM) and peak signal-to-noise ratio (pSNR). The results displayed robust performance across various organs and contrasts with high image quality maintained even at higher acceleration factors SSIM/pSNR: 2x: 0.9774 ± 0.0306/46.10 ± 3.49, 4x: 0.9678 ± 0.0347/42.82 ± 2.78, 6x: 0.9583 ± 0.0359/40.44 ± 2.57, 8x: 0.9469 ± 0.0376/38.41 ± 2.76. Zero-shot experiments on the unseen breast data lead to reconstructions with significantly fewer artifacts (sharper anatomical details, reduced background noise) compared to the zero-filling reconstruction.

**CONCLUSION**

The UNIFORM framework shows substantial promise in multi-organ and multi-contrast MRI reconstruction, potentially providing a robust solution for clinical MRI regardless of the data type, provided sufficient training data is available. Challenges remain in the availability of fully-sampled data for certain organs, which are vital for supervised training but can be partially mitigated by self-supervised learning methods.

**CLINICAL RELEVANCE/APPLICATION**

UNIFORM offers a promising approach for significantly reducing MRI scan times while ensuring high fidelity in image reconstruction across a range of organs and contrasts.

## T1-SSPH07-1 A NOVEL VIRTUAL NON-CONTRAST ALGORITHM ON PHOTON-COUNTING-DETECTOR CT: IMPROVED CT NUMBER ACCURACY AND VISUALIZATION OF ADIPOSE AND SOFT TISSUES

Rainer Raupach, PhD (*Abstract Co-Author*) Employee, Siemens AG
Bernhard Schmidt, PhD (*Abstract Co-Author*) Employee, Siemens AG
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Kevin J. Treb, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Virtual non-contrast (VNC) images generated from spectral CT data might obviate the need to acquire a separate true non-contrast image. However, due to assumptions behind VNC algorithms, CT numbers of materials besides water and iodine might be inaccurate. The purpose of this work was to demonstrate the improvement in CT number accuracy and visual distinguishability of adipose and other soft tissues using a new VNC algorithm on a photon-counting-detector CT (PCD-CT) system.

### METHODS AND MATERIALS

Phantoms were scanned on two clinical PCD-CT scanners with identical hardware (NAEOTOM Alpha, Siemens Healthineers): One scanner was equipped with a classic VNC algorithm and the other with the new VNC algorithm. For each scanner, both low-energy threshold ("T3D") and VNC images were reconstructed from the same set of acquisition parameters using a clinical abdomen protocol with a quantitative reconstruction kernel (Qr44). Two phantoms were scanned: An adult abdomen phantom (Multi-Energy CT Phantom, Sun Nuclear) with a uniform solid water background and several quantitative material inserts (adipose, liver, blood, 2-5 mg/mL iodine), and an ex vivo porcine tissue phantom injected with approximately 15 mg/mL iodine contrast.

### RESULTS

CT numbers of the adipose insert in the multi-energy phantom were -71 HU in the T3D images, and were -57 HU and -75 HU in the classic and new VNC images, respectively. CT numbers of the liver insert were 53 HU and 59 HU for the classic and new VNCs, compared to 64 HU in T3D images. CT numbers of 2 and 4 mg/mL iodine + blood inserts and a 5 mg/mL iodine + water insert agreed within +/- 5 HU between the classic and new VNC images. The image noise magnitudes of the two VNC algorithms were within 1 HU of each other in all material inserts, and the contrast-to-noise ratio (CNR) between adipose and liver inserts improved by 22% with the new VNC. In the porcine tissue phantom, boundaries between the muscle, adipose, and virtually-removed contrast bolus were readily distinguishable along a muscle-adipose interface in the new VNC images, but were more ambiguous with the classic VNC.

### CONCLUSION

The new VNC algorithm improves the CT number accuracy and CNR of adipose and other soft tissues while retaining the ability to remove iodine signal and preserve accurate CT numbers of water.

### CLINICAL RELEVANCE/APPLICATION

VNC images with accurate CT numbers for tissues of interest might be utilized in place of true non-contrast CT images to reduce radiation dose and streamline clinical workflow. Improving the accuracy of CT numbers and the CNR of adipose and other soft tissues can extend the practical range of clinical applications where VNC imaging is viable.

## T1-SSPH07-2 RELIABLE IODINE MEASUREMENT IN SMALL LUMEN DIAMETERS FOR CORONARY ARTERY DISEASE ASSESSMENT VIA PHOTON-COUNTING CT

Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation
Harold I. Litt, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV
Pooyan Sahbaee, PhD (*Abstract Co-Author*) Employee, Siemens AG
Leening Liu (*Abstract Co-Author*) Nothing to Disclose
Martin Rybertt, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

The recent deployment of the first-generation clinical dual-source photon-counting CT (PCCT) addresses existing challenges in both visualization and quantification of iodine within the coronary arteries, a critical factor disease assessment. This study evaluates the capability of PCCT to quantify iodine accurately in small lumen diameters, across different phantom sizes and iodine concentrations.

**METHODS AND MATERIALS**

To characterize the effect of lumen diameter on iodine quantification, phantom inserts for a body phantom (Multi-energy CT phantom, Gammex) containing a U-shaped constant diameter tube that can be filled with iodinated contrast agents were 3-D printed with a calcium-based filament (StoneFil, Formfutura). Phantoms with different lumen diameters (4, 6, 8, 10, 12 mm) were filled with solutions of different iodine concentrations (2, 5, 10 mg/mL). They were then scanned with PCCT (Naeotom Alpha, Siemens Healthineers) at four different patient sizes (20x20 (S), 25x25 (M), 30x40 (L), and 40x50 cm (XL)) and four radiation dose levels (CTDIvol 5, 10, 15, 20 mGy). Regions of interest (ROIs) were placed on virtual monoenergetic images (VMI) at 70 keV and iodine density maps (ID). Mean and standard deviation were calculated along the length of the tube. Measurements of a 12 mm lumen diameter at a CTDIvol of 20 mGy on the small body phantom served as the reference value for calculating absolute differences between lumen diameters.

**RESULTS**

At lumen diameters greater than 6 mm, ID maps showed good performance at smaller patient sizes (S, M) with maximum absolute differences of 0.8 mg/mL at 20 mGy. With the L phantom, ID demonstrated average differences of 0.5±0.5, 0.5±0.6, and 0.1±0.3 mg/mL for iodine 2, 5, and 10 mg/mL, respectively. Radiation dose had a minimal effect on lumen diameters of 4 mm at S, M, and L phantoms with maximum variance of 0.5, 0.2, and 0.1 mg/mL for 2, 5, and 10 mg/mL of iodine, respectively. Similarly, VMI 70 keV performance was consistent across all patient sizes for lumen diameters greater than 6 mm, exhibiting absolute differences of VMI 70 that averaged 3.8, 5.6, and 6.8 HU for iodine concentrations of 2, 5, and 10 mg/mL respectively.

**CONCLUSION**

Spectral quantification with PCCT demonstrated consistency between lumen diameters greater than 6 mm across patient sizes for different iodine concentrations. By exploiting the combination of high resolution and spectral quantification, small structures can be characterized to improve diagnostic evaluation of diseases, such as coronary artery disease.

**CLINICAL RELEVANCE/APPLICATION**

Consistent quantification at different lumen diameters and phantom sizes with PCCT may facilitate accurate quantitative evaluation of coronary arteries and other clinically relevant small structures.

## T1-SSPH07-3 TECHNICAL EVALUATION OF A DUAL-SOURCE DUAL-ENERGY MODE ON PHOTON-COUNTING DETECTOR CT FOR MUSCULOSKELETAL IMAGING

Francis I. Baffour, MD (*Abstract Co-Author*) Nothing to Disclose
Andrea Ferrero, PhD (*Abstract Co-Author*) Nothing to Disclose
Elisabeth Shanblatt, PhD (*Abstract Co-Author*) Employee, Siemens AG
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Kishore Rajendran, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the performance of an investigational dual-source dual-energy mode on photon-counting detector (DS-PCD) CT for bone imaging.

**METHODS AND MATERIALS**

Hydroxyapatite inserts (HA 100, 200 and 300 mg/cc) were placed in water phantoms (30 cm [S], 40 cm [M], and 50 cm [L] diameter) and scanned on clinical PCD-CT (Siemens NAEOTOM Alpha) using DS-PCD mode (Quantum Peak). Two kV-pairs were used (70/Sn150 kV and 90/Sn150 kV) for S and M phantoms with CTDIvol range 11-24 mGy, and 90/Sn150 kV for L phantom at 41 mGy CTDIvol. The phantoms were also scanned on single-source PCD-CT with two energy thresholds (SS-PCD) at 120 kV and 140 kV, and on a dual-source energy-integrating detector (DS-EID) CT (SOMATOM Force). Dual-energy images (low/high for DS-PCD and DS-EID, threshold-low / threshold-high for SS-PCD) were reconstructed using Qr40 kernel at 2 mm section thickness. Spectral separation was quantified using HA dual-energy ratio (DER), difference in effective energies between low and high images, and mean absolute percent error (MAPE) of HA mass density obtained from HA/water basis decomposition. To demonstrate clinical feasibility, two patients (a 46-year-old male and 24-year-old male) were scanned using DS-PCD under IRB approval. Bone edema maps were reconstructed and compared with clinical imaging reference standards (MRI or DS-EID).

**RESULTS**

For S and M phantoms, DS-PCD at 70/Sn150 kV showed the highest mean DER (S: 2.43 and M: 2.47), followed by DS-EID at 70/Sn150 kV (S: 2.38 and M: 2.34), and SS-PCD at 120 kV showed the lowest mean DER (S: 1.66 and M: 1.67). For L phantom, DS-PCD at 90/Sn150 kV showed highest mean DER (1.89) compared to SS-PCD (1.68 to 1.71) and DS-EID at 90/Sn150 kV (1.80). Across phantom sizes and kV pairs, the difference in effective energies for DS-PCD were slightly lower than the DS-EID at matching kV pair (average percent difference 5.2%). Despite this, the DER was higher on DS-PCD compared to DS-EID for all sizes at matching kV pair which can be attributed to the uniform photon-weighting benefit from PCDs. The MAPE values for DS-PCD were consistently lower across all phantom sizes (MAPE max. of 1.44%) compared to SS-PCD (MAPE max. 3.97%) and DS-EID (MAPE max. 3.68%). Qualitatively, patient wrist and knee images showed bone edema on DS-PCD comparable to clinical MR images, and more precise edema depiction compared to DS-EID images at the site of fractures with fewer artifacts.

**CONCLUSION**

The investigational dual-source dual-energy configuration on clinical PCD-CT showed superior spectral performance for bone imaging task compared to single-source multi-energy PCD-CT and dual-source EID-CT.

**CLINICAL RELEVANCE/APPLICATION**

Accurate material decomposition reduces artifacts and improves bone edema visualization associated with bone pathology.

## T1-SSPH07-4 ULTRA HIGH-RESOLUTION SPECTRAL IMAGING USING CZT-BASED PHOTON-COUNTING CT: A PHANTOM STUDY FOR EVALUATION OF SPATIAL RESOLUTION AND IODINE QUANTIFICATION ACCURACY

Xiaohui Zhan, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Thomas Labno, BS (*Abstract Co-Author*) Employee, Toshiba Corporation
Richard Thompson, PhD (*Abstract Co-Author*) Employee, Canon Medical Research, USA

Steven Ross, PhD (*Abstract Co-Author*) Nothing to Disclose

Ruoqiao Zhang, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Zhou Yu, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Shobhit Sharma, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the ultra high-resolution spectral (spectral-UHR) imaging capabilities of CZT-based photon-counting CT (PCCT) using a custom phantom enabling simultaneous evaluation of spatial resolution and iodine quantification accuracy.

**METHODS AND MATERIALS**

A custom phantom containing known iodine concentrations (0.1-20 mgI/ml) and 3D-printed microfluidic channels simulating line pairs (10, 20, and 30 lp/cm) filled with high concentration of iodine (170 mgI/ml) was placed inside a ballistic gel frame to simulate realistic patient sizes. The phantom was scanned in axial mode on a prototype CZT-based PCCT at 120 kVp using a small focal spot (0.4x0.5 mm) and exposures of 50, 100, and 200 mAs (CTDIvol = 3.2, 6.4, and 12.8 mGy, respectively). Spectral-UHR mode was used to perform projection-domain two-material decomposition and UHR virtual monoenergetic images (VMIs) at 60 and 90 keV (pixel size/slice thickness: 0.2/0.2 mm) were reconstructed using the filtered-backprojection (FBP) with a sharp bone kernel (FC30) and iterative denoising. Iodine maps were generated using the 60 and 90 keV VMIs in the image domain. For line pairs, iodine maps with pixel size/slice thickness of 0.015/0.2 mm were also generated. To assess spectral-UHR performance, the following evaluations were done: (1) visual comparison of line pairs in iodine maps between spectral-NR (spectral normal-resolution) and spectral-UHR images at 200 mAs (slice thickness = 1.2 mm), and (2) Bland-Altman analysis for iodine measurements across all exposures (slice thickness = 3.0 mm).

**RESULTS**

Spectral-UHR mode showed improved visualization of iodine-filled line pairs, with the ability to resolve frequencies between 20-30 lp/cm for the chosen kernel. Iodine concentration measurements in spectral-UHR mode showed strong agreement with true concentrations across all exposures, with the 95% confidence intervals (mgI/ml) of [-0.40, 0.82]/[-0.44, 0.86]/[-1.24, 0.58] (<2 mgI/ml) and [-0.47, 1.07]/[-0.74, 0.88]/[-2.50, 0.46] (>2 mgI/ml) and minimal bias (mgI/ml) of 0.21/0.21/-0.33 (<2 mgI/ml) and 0.30/0.07/-1.02 (>2 mgI/ml) at 200/100/50 mAs. A slight increase in bias and reduction in precision for iodine measurements was found with decreasing exposure levels.

**CONCLUSION**

Spectral-UHR imaging with CZT-based PCCT enables visualization of high-resolution features while preserving spectral information as indicated by good iodine quantification accuracy across all exposures.

**CLINICAL RELEVANCE/APPLICATION**

Iodine quantification accuracy is important for all contrast-enhanced CT exams, especially in cardiovascular and oncological domains. The ability to visualize finer structures while preserving iodine accuracy would remarkably improve the diagnostic performance of CT images.

## T1-SSPH07-5 ACCURATE SIMULATION OF LOWER-DOSE DATA AND SPECTRAL CORRELATION IN PHOTON-COUNTING-DETECTOR CT

Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Timothy Winfree, BS, MS (*Abstract Co-Author*) Nothing to Disclose
Lifeng Yu, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a projection domain lower-dose simulation algorithm for PCD-CT that accurately emulates spatial and spectral correlations in measured data.

**METHODS AND MATERIALS**

Performing noise insertion of PCD-CT data to simulate lower-dose exams requires careful considerations of spectral and spatial correlations in the projection data that could arise due to effects unique to photon counters such as charge sharing and pulse pileup. First, to determine the extent to which charge sharing and pulse pileup affect the data, repeated scans of a 10cm water phantom were acquired over the available mA range and subtracted to obtain noise only projections - from which the correlation between energy channels and adjacent pixels were measured. To accurately simulate the spectral correlation, we assume that the energy bins (B1 and B2), obtained by subtracting the measured threshold data, are independent and insert Poisson noise in each of the bin data. Subsequently, the noisy bins are summed together to form the noisy threshold data (T1 and T2).Quarter dose data at 22, 90, and 214 mA were simulated for comparison with measured data at each corresponding mA condition. The correlation between T1 and T2, B1 and B2, as well as the image-domain spatial 3D NPS were compared for validation.

**RESULTS**

Excellent agreement in NPS between simulated and measured lower-dose data was achieved, differing by a maximum of 5.0%, 6.3%, 4.1%, and 6.1% for half-dose (HD) T1, HD T2, quarter-dose (QD) T1, and QD T2 images, respectively. Spatial correlation between adjacent detector pixels was very small (0.002-0.1) for both energy thresholds regardless of mA, indicating that charge sharing can be neglected for the purpose of noise insertion. Simulated lower dose data underestimates the spectral correlation (T1 and T2) at the target dose when the mA in the reference scan increases. As the mA of the reference scan decreases (less pileup), the correlation in the simulated data converges to that of the measured data (0.586 vs. 0.588 at 22 mA).

**CONCLUSION**

The proposed noise insertion algorithm can synthesize lower dose images with realistic spatial and spectral correlations in PCD-CT when the reference scan is not significantly affected by pileup.

**CLINICAL RELEVANCE/APPLICATION**

This tool enables accurate simulation of lower-dose data from existing PCD-CT exams, which can be used to optimize radiation dose and train AI-based denoising algorithms.

## T1-SSPH07-6 EVALUATION OF CORONARY STENOSIS, PLAQUES, AND STENTS IN A PHANTOM USING THE SUPER HIGH RESOLUTION SPECTRAL MODE FROM A PROTOTYPE CZT-BASED PHOTON COUNTING CT SYSTEM

Ruoqiao Zhang, PhD (*Presenter*) Employee, Canon Medical Systems Corporation

## PURPOSE

Compared with conventional scintillator-based energy-integrating detectors (EIDs), photon counting detectors can be made with smaller pixel sizes with reduced pixel crosstalk and measure the spectral information with multiple energy bin output simultaneously. In this work, we compared the image quality between normal-resolution (NR) and super-high-resolution (SHR) spectral modes provided by a full-size PCCT clinical prototype system in phantom studies.

## METHODS AND MATERIALS

The prototype PCCT is built based on a Aquilion Precision system. The CZT-based PCCT system covers the full 50cm FOV in the fan angle and 39.6mm in the cone angle. Summation of 3x3 detector pixels is used for NR image reconstruction, while 1x1 detector pixel is used for SHR reconstruction. The counting mode generates images based on events with energy greater than 30keV, and the spectral mode generates images using 5 energy bin counts with data-domain decomposition. In this study, scans were acquired in axial mode at 120 kVp, 200 mA, 1 sec rotation, with a focal spot size of 0.4mm*0.5mm. Both NR and SHR Spectral images were reconstructed with FBP and AIDR3D methods using a standard body kernel. The modulation transfer function (MTF) was measured at the Teflon rod in Catphan CTP682 module for resolution evaluation. Different tubes mimicking various degrees of coronary stenosis and plaques were placed inside a water-filled phantom to compare the performance of PCCT NR Spectral and SHR Spectral with respect to coronary stenosis, plaques, and stents.

## RESULTS

MTF result shows that SHR Spectral provides similar spatial resolution as SHR Counting and is much sharper than NR Spectral. Coronary stenosis phantom results show that SHR Spectral can resolve different types of stenosis and plaques by evaluating the trend of CT number across different keVs, providing better material differentiation than SHR Counting. SHR Spectral delineates small in-stent stenosis and plaques much more clearly and improves the visualization of the stent significantly than NR Spectral thanks to the reduction of blooming artifacts.

## CONCLUSION

We compared image quality between NR and SHR Spectral modes on a full-size PCCT prototype system. Result demonstrated that SHR Spectral improved the spatial resolution significantly than NR Spectral while retaining spectral information for material discrimination.

## CLINICAL RELEVANCE/APPLICATION

The SHR Spectral mode in our PCCT system can potentially provide more accurate evaluation of different types and degrees of in-stent stenosis and plaques than conventional scanners in cardiac imaging.

### PURPOSE

Point-of-care portable MRI (pMRI) is a novel technology that allows bedside brain imaging, potentially eliminating the risks and resource demands associated with transporting patients to conventional stationary CT and MRI units. We reviewed our institutional experience with pMRI in hospitalized and emergency department (ED) patients in the first two years after acquiring this technology.

### METHODS AND MATERIALS

We retrospectively reviewed all portable MRI brain scans performed on hospitalized and ED patients at our institution between March 30, 2022 and March 29, 2024. Radiology reports were reviewed and categorized as having new findings not previously documented on imaging, incremental interval changes, or stable/normal findings. The subset of cases with new findings were compared with subsequent conventional stationary CT or MRI brain scans for accuracy.

### RESULTS

194 pMRI scans were performed in hospitalized and ED patients, 192 of which were considered diagnostic quality. Nearly half of the scans had either new findings (30/192 or 16%) or incremental interval changes (58/192 or 30%) that could potentially lead to changes in patient management. The most common new findings not previously documented on imaging were infarcts, hemorrhages, and contusions. The most common incremental interval changes were changes in ventricular size, changes in extra-axial collection size, and changes in mass effect (changes in midline shift, brain herniation, or ventricular compression). Within the subset of patients with new findings that had subsequent conventional stationary CT/MRI brain (0-6 days later), the vast majority (24/26, 92%) were true positives, one was a false positive, and one was indeterminate.

### CONCLUSION

In this largest patient series to date in a real-world setting, pMRI shows promise as a valuable new tool for neuroimaging in hospitalized and ED patients at the bedside that provided actionable information for guiding patient care.

### CLINICAL RELEVANCE/APPLICATION

In this largest patient series to date in a real-world setting, pMRI shows promise as a valuable new tool for neuroimaging in hospitalized and ED patients at the bedside that provided actionable information for guiding patient care.

## T2-STCE1-2 EVALUATING BRONCHODILATOR RESPONSE USING FREE-BREATHING OXYGEN AND COMPLIANCE MAPPING WITH 0.55T MRI

Adrienne Campbell (*Abstract Co-Author*) Nothing to Disclose
Rajiv Ramasawmy (*Abstract Co-Author*) Nothing to Disclose
Pierre Daude, PhD (*Abstract Co-Author*) Nothing to Disclose
Ahsan Javed (*Abstract Co-Author*) Nothing to Disclose
Joseph W. Plummer, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Mid-field MRI is particularly well suited to lung imaging techniques including oxygen mapping. Here, we utilize a self-calibrating, motion-compensating, reconstruction technique to generate lung images at several points throughout the breathing-cycle. Not only does this provide a novel insight to oxygen-uptake throughout the breathing-cycle, but it also provides a bonus view of lung compliance.

### METHODS AND MATERIALS

Five healthy-volunteers (HV) and ten patients with asthma were imaged on a 0.55T MRI scanner (MAGNETOM Free.Max, Siemens Healthineers AG, Erlangen, Germany) using a T1-weighted free-breathing stack-of-spirals ultrashort echo time sequence (TE/TR=0.55/7.6ms; FA=12°, resolution=(3.0mm)3, FOV=480x480x240 mm3, scan-duration=6min). Free-breathing data were acquired while under 100% oxygen, followed by a 6-minute break, then under room air. Asthma patients were imaged before and after receiving albuterol bronchodilator treatment (within 1 hour). Data were retrospectively divided into six bins, corresponding to their position within the breathing-cycle, and reconstructed into six respiratory-resolved 3D images using a custom motion-compensated low-rank reconstruction pipeline. Percent signal enhancement (PSE) maps were calculated from the fractional-difference between the oxygen and room air images following registration and volume correction. Specific ventilation (SV) maps were estimated by fractional-difference between the oxygen images at each respiratory phase, registered to end expiration. Mean PSE and SV were measured at end-inspiration for each subject.

### RESULTS

The figure demonstrates the free-breathing PSE and SV maps for a HV and a patient with asthma before/after bronchodilator treatment. For the HV, the PSE distributed evenly throughout the lungs and across the breathing-cycle; while the SV distributed evenly across space but increased towards end-inspiration, as would be expected with the alveolar expansion. Across five HVs, mean PSE=(11.84±2.10)% and SV=(9.49±2.03)%. The asthma patient example (pre-bronchodilator) showed extensive regions of low PSE throughout the breathing-cycle, with less-uniform SV. Across ten asthma patients, mean PSE=(5.46±3.21)% and SV=(7.34±3.66)%. However, the PSE increased post-bronchodilator throughout the lungs (10.10±4.81)%, indicating improved oxygen uptake. Furthermore, the SV increased (9.01±3.85)% post-bronchodilator, indicating improved gas intake following treatment.

### CONCLUSION

Our proposed method enables a dynamic assessment of oxygen uptake and lung compliance during tidal breathing. In principle, PSE maps are sensitive to dissolved oxygen in the tissue and blood, while SV maps correspond to the local lung compliance throughout the breathing-cycle, and therefore provide complementary insights into lung function. Notably, the gained-temporal resolution is obtained without extra data acquisition and provides clinicians a novel insight into bronchodilator response.

### CLINICAL RELEVANCE/APPLICATION

We propose a free-breathing low-field MRI method that generates both oxygen-enhancement and compliance maps dynamically throughout the respiratory cycle. This method enables novel insights of the spatio-temporal response to bronchodilator treatment in asthma without acquiring additional data.

## T2-STCE1-3 QUALITY OF MOBILE MRI IN EMERGENCY AND TRAUMA RADIOLOGY

Waqas Ahmad I, MBBS (*Abstract Co-Author*) Nothing to Disclose
Quratulain Sahi, MBBS, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

Mobile MRI units are increasingly being adopted due to their portability and cost-effectiveness. This study aims to assess the diagnostic performance, comparative effectiveness, and overall impact of mobile MRI in the context of emergency and trauma radiology.

### METHODS AND MATERIALS

This prospective study was conducted in the emergency departments (EDs) of 3 major trauma centers over one year. 200 patients with acute trauma or other emergency conditions were included, and randomly assigned to imaging with traditional high-field MRI or mobile low-field MRI unit. The mobile MRI units used were equipped with low-field magnets (0.2-0.5 Tesla). Diagnostic performance was evaluated by comparing the image quality, diagnostic accuracy, and time to diagnosis. Primary outcomes measured were: 1. Image quality, rated on a standardized scale by a panel of radiologists. 2. Diagnostic accuracy, by comparing findings with final clinical diagnoses. 3. Time to diagnosis and treatment. 4. Patient and clinician satisfaction. Secondary outcomes included technical feasibility of deployment, logistical challenges and cost-effectiveness.

### RESULTS

The study found that mobile low-field MRI units provided diagnostic images of sufficient quality for most cases, which was deemed acceptable for clinical decision-making in 92% of cases. The diagnostic accuracy of mobile MRI was comparable to high-field MRI, with a concordance rate of 95%. On average, the mobile MRI group had a 30% shorter time to imaging and a 25% faster time to definitive Patient outcomes showed no significant differences in recovery times, complication rates or overall treatment efficacy. Patients and clinicians reported high satisfaction levels with the process. Mobile MRI units were successfully deployed and operated in all three EDs with minimal logistical issues. Cost-effectiveness analysis revealed that mobile MRI units, reduced overall imaging costs by decreasing the need for patient transportation and improving efficiency of the diagnostic process.

### CONCLUSION

Mobile low-field MRI offers acceptable image quality and high diagnostic accuracy, comparable to traditional high-field MRI, while significantly reducing time to diagnosis and treatment. The convenience and rapid deployment of mobile MRI units make them particularly valuable in acute care settings.

### CLINICAL RELEVANCE/APPLICATION

Mobile MRI units provide a flexible and efficient solution that can be used in a variety of clinical scenarios, from busy urban trauma centers to remote or resource-limited locations. Future research should focus on further optimizing mobile MRI technology, exploring its use in other clinical settings, and developing guidelines for its integration into standard emergency and trauma care protocols.

## T2-STCE2-1 DEVELOPMENT AND VALIDATION OF MRI-BASED ON DEEP LEARNING RADIOMIC SIGNATURES TO PREDICT EIGHT CORE MOLECULAR BIOMARKERS IN ADULT DIFFUSE GLIOMA: A MULTICOHORT STUDY

Junjie Li (*Abstract Co-Author*) Nothing to Disclose
Zhizheng Zhuo (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to develop a Deep Learning and Radiomics signature (DLR) model and a combined DLRC (Deep Learning and Radiomics with Clinical signature) model using MRI to predict eight core molecular pathological biomarkers for adult diffuse glioma.

### METHODS AND MATERIALS

A retrospective study was conducted on 1151 adult diffuse glioma patients in our hospital. Multi-parameter MRI images (T2 and T1C) and pathological information, including IDH mutation, 1p/19q co-deletion, MGMT methylation, TERT mutation, EGFR amplification, +7/-10, and KI67 expression were collected. Patients were randomly divided into a training set (n=805) and an internal test set (n=346). Subsequently, 3562 radiomics features and 4096 DL features were extracted. After feature reduction and selection, the MLP was used to build radiomics and DL model. The DLR model base on radiomics and DL results from MLP. Finally, logistic regression was used to integrate the DLR and clinical prediction model to build the DLRC prediction model. The DLR model and DLRC models were tested in external test sets from JL Hospital (n=118), TCGA (n=237), and UCSF (n=477).

### RESULTS

The DLR model showed AUCs of 0.829 to 0.927 for predicting IDH mutation in internal, JL, TCGA, and UCSF test sets, AUCs of 0.805 to 0.880 for predicting 1p/19q co-deletion, AUCs of 0.531 to 0.714 for predicting MGMT methylation, and AUCs of 0.725 to 0.761 for predicting TERT mutation. In the internal test set, the DLR model showed an AUC of 0.753 for predicting EGFR amplification, an AUC of 0.832 for predicting +7/-10, an AUC of 0.792 for predicting CDKN2A/B co-deletion, and an AUC of 0.883 for predicting KI67 expression. In the internal, JL, TCGA, and UCSF test sets, the DLRC model showed AUCs of 0.899 to 0.966 for predicting IDH mutation, AUCs of 0.825 to 0.896 for predicting 1p/19q co-deletion, AUCs of 0.530 to 0.716 for predicting MGMT methylation, and AUCs of 0.620 to 0.844 for predicting TERT mutation. In the internal test set, the DLRC model showed an AUC of 0.775 for predicting EGFR amplification, an AUC of 0.849 for predicting +7/-10, an AUC of 0.815 for predicting CDKN2A/B co-deletion, and an AUC of 0.890 for predicting KI67 expression.

### CONCLUSION

This study developed and validated a DLR model to preoperatively predict eight core molecular pathological biomarkers in ADG patients, combining with additional clinical-available variable could facilitate their clinical application.

### CLINICAL RELEVANCE/APPLICATION

The study verified the DLR and DLRC demonstrated high diagnostic performance in identifying eight molecular biomarkers with adult diffuse glioma patients at MRI. Our approach has the potential to facilitate timely diagnoses and management of adult diffuse glioma patients encountered in routine clinical practice.

## PURPOSE

To assess and improve the quality of anatomical annotations in public multicenter radiological image datasets.

## METHODS AND MATERIALS

Massive multicenter datasets are essential for elevating medical AI quality and inter-hospital generalization. By combining multiple public datasets, enormous databases are being created, but ensuring their quality is not easy. We propose an automatic tool to generate comprehensive profiles of radiology datasets, identifying same patient data, duplicates, data leakage, and label noise. By assessing image similarity, it avoids images from the same patients from being shared between training and validation scripts, removes duplicate data and ensures rigorous external validation, by checking for data leakage in test datasets. Additionally, the tool finds potential low-quality per-voxel annotations, by analyzing labels from two perspectives: (I) annotation deviation from anatomical priors, and (II) samples that are exceedingly difficult for AI algorithms to overfit during training. Label error detection is especially important considering the rise of AI-annotated datasets. The profiler flags problematic cases for manual revision and automatically corrects some errors, leveraging anatomical priors and AI-generated pseudo-labels. We used the profiler to analyze AbdomenAtlas 1.0, a multicenter public dataset with 5,195 CT scans fully annotated for 9 anatomical structures, collected from 16 public databases.

## RESULTS

The profiler identified overlaps in the public datasets, i.e., AbdomenAtlas, and removed 436 duplicated CT volumes. It grouped same-patient samples, tracing 221 CT volumes to a group of 90 patients. Label error detection identified 32.4% of the aorta and 2.6% of the kidney annotations as noisy, due to diverging annotation standards in public data. Moreover, 30% of the errors identified derived from inadequate CT scan quality. With the profiler's help, radiologists assisted by AI revised problematic annotations.

## CONCLUSION

The profiler effectively prevents duplicates when merging public databases, avoids data leakage and improves per-voxel annotations, facilitating the creation of high-quality large-scale multicenter databases.

## CLINICAL RELEVANCE/APPLICATION

Massive datasets revolutionized computer vision, and the same is expected for medical AI. By improving these datasets’ quality, our profiler can help the multiple models that learn from them, including AI models that accelerate the radiologist workflow by segmenting organs and tumors.

### PURPOSE

To present interim findings from the 'COMBO TRIAL,' a prospective intraindividual study evaluating the performance of Contrast-Enhanced Mammography (CEM) compared to Digital Mammography (DM) for the surveillance of women with a personal history of breast cancer (BC).

### METHODS AND MATERIALS

Between January 2023 and April 2024, 1150 asymptomatic women who underwent breast-conserving surgery for BC within the last 10 years were invited to undergo CEM instead of DM for routine surveillance. Exclusion criteria included: suspicious symptoms of BC, allergy to iodinated contrast agents, renal failure and breast implants. For each patient, one reader reported CEM (Low energy [LE] + Recombined), while a second reader, independent and blinded, evaluated only LE images equivalent to DM. Both readers assigned independent BI-RADS scores for DM and CEM. The reference standard was 1-year follow-up for negative cases and biopsy/surgery for BI-RADS 4 and 5. The primary endpoints included the Cancer Detection (CD) rate for both DM and CEM, along with the incremental CD rate for CEM. Secondary endpoints included sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy for each test. We evaluated differences in diagnostic performance between DM and CEM using the McNemar test for paired data ($p<0.05$ significant) and assessed the statistical significance examining the overlap of the confidence intervals.

### RESULTS

Overall, 607 patients met the inclusion criteria and 600 were included in the analysis. Of these, 59 women were recalled for assessment, resulting in a recall rate of 9.8%. Among them, 14 cases of BC were detected: 8 (5 Ductal Carcinoma In Situ [DCIS]+3 invasive) were identified by both DM and CEM, while CEM detected 6 additional cases (1 DCIS+5 invasive). Three cases were missed by both DM and CEM but subsequently detected by US, resulting in a global recurrence rate of 2.8%. The CD rate for CEM was 23 per 1000, compared to 13 per 1000 for DM, indicating an incremental CD for CEM of 10 per 1000 compared to DM ($p=0.014$). Compared to DM, CEM demonstrated significantly higher sensitivity (82.4% vs. 47.1%), slightly lower specificity (96.4% vs. 97.6%), slightly higher PPV (40.0% vs. 36.4%), slightly higher NPV (99.5% vs. 98.4%), and similar accuracy (96.0% vs. 96.2%).

### CONCLUSION

Implementation of CEM in BC surveillance was associated with a significant increased detection of invasive cancers. Final results and the collection of interval cancers are awaited for comprehensive evaluation.

### CLINICAL RELEVANCE/APPLICATION

Women with history of breast cancer face higher risks of recurrence or new cancers. CEM in surveillance protocols enables earlier detection compared to DM, potentially improving overall survival.

## T3-SSBR05-2 GENERATING IODINE-ENHANCED MAMMOGRAPHY FROM LOW-ENERGY IMAGES USING DEEP LEARNING

Konstantinos Zormpas-Petridis, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Contrast-enhanced mammography (CEM) is an invaluable tool for the diagnosis, monitoring and screening of breast cancer (BC) patients, including those with high-breast density, offering great sensitivity and high spatial resolution. We show that deep learning can be used to generate clinically-equivalent iodine-enhanced images from low-energy images. Due to the similar appearance of low-energy to non-contrast digital mammography (DM), this could alleviate the need for contrast media, thus sparing patients from potential side effects and making CEM more accessible.

**METHODS AND MATERIALS**

We retrospectively selected 140 CEM examinations in patients with suspicious imaging findings, who underwent histologic verification or follow-up of at least 12 months. We trained a 2D CycleGAN on 100 patients in a supervised manner by using paired low-energy and iodine-enhanced images as input and output (ground-truth) respectively. We utilized a ResNet architecture for the generator, patch-based (128x128 pixels) training and a perceptual cycle-loss function to generate the iodine-enhanced images. We quantitatively validated our approach in 40 test patients (63 breasts - 37 positive and 36 negative for malignancy) by calculating the contrast-to-noise ratio (CNR), the mean-absolute-error (MAE) and the SSIM between the low-energy and clinical/synthetic iodine-enhanced images. Additionally, two trained radiologists (> 6 and > 2 years' experience) blindly scored the 40 test patients for background parenchymal enhancement (BPE; score 1-4) and potential malignancy detection (yes/no).

**RESULTS**

Our method showed high correlation to the clinical images regarding the changes from low-energy (CNR: Mean=-0.015/-0.16, standard deviation=0.23/0.05 for clinical/synthetic respectively, MAE: r=0.99, SSIM: r=0.8). Upon visual inspection a "halo" artifact present in above 50% of the clinical images was corrected in the synthetic. The two radiologists on average estimated the BPE from the synthetic images by grouping scores as mild (1-2) and marked (3-4) with 90% accuracy and identified potential malignancies with 89.6/78.6 % accuracy, 87.8/70.2 % sensitivity and 94.4/93.1 % specificity for clinical/synthetic respectively.

**CONCLUSION**

Deep learning can generate clinically usable iodine-enhanced mammography images. We demonstrated proof-of-concept that radiologists can perform the same clinical tasks, such as malignancy detection and BPE calculation, paving the way for the evaluation of our approach directly on DM images.

**CLINICAL RELEVANCE/APPLICATION**

The possibility of avoiding the use of contrast media in large scale examinations and the reduction of image artifacts would improve BC diagnosis and make CEM more available to intermediate risk patients.

## T3-SSBR05-3 COMPARISON OF THE CLINICAL, IMAGING, AND HISTOPATHOLOGIC FEATURES OF BREAST CANCERS DETECTED ON LOW ENERGY VS RECOMBINED IMAGES ON SCREENING CONTRAST ENHANCED MAMMOGRAPHY

**PURPOSE**

To compare the clinical, imaging, and histopathologic features of breast cancers detected on low energy vs recombined images on screening contrast enhanced mammography (CEM) in women at increased risk for breast cancer.

**METHODS AND MATERIALS**

This is a retrospective, HIPAA-compliant, and IRB-approved review of our CEM database from 01/2015-12/2021. Medical records were reviewed for age at diagnosis, breast density, background parenchymal enhancement (BPE), and tumor histopathology. The clinical, imaging, and histopathological features were compared for cancers detected on the low energy images (LE) with or without associated enhancement vs those detected due to enhancement only on recombined images (RI). LE images were considered equivalent to 2D full field digital mammography (FFDM).

**RESULTS**

7661 screening CEM were performed in 2820 women during the study period. Eighty-two cancers were diagnosed, including 51 (62%) invasive cancers, 5 (6%) microinvasive cancers, and 26 (32%) cases of ductal carcinoma in situ (DCIS). Median age at diagnosis was 52 years for women whose cancers were seen on LE +/- enhancement, and 54 years for those with cancers detected due to enhancement only on RI. There was no statistically significant difference in breast density (p=0.74) or BPE (p=0.44) between the two groups. Thirty-one (38%) were detected on LE +/- enhancement, and 51 (62%) on RI only. 6/10 (60%) cancers detected as calcifications on LE only were DCIS. 39/51 (76%) of cancers detected due to enhancement only on the RI were either invasive cancers or DCIS with microinvasion.

**CONCLUSION**

In women undergoing screening CEM, 62% of cancers detected are due to enhancement alone on RI. The cancers detected due to enhancement alone are more likely to be invasive cancers compared to those detected on the LE images.

**CLINICAL RELEVANCE/APPLICATION**

CEM increases the number of cancers detected by 165% compared to a 2D FFDM. The additional cancers detected due to enhancement alone are predominantly invasive cancers, highlighting the benefit of vascular based screening in women without access to breast MRI.

## T3-SSBR05-4 EFFECTIVENESS OF CONTRAST ENHANCED MAMMOGRAPHY FOR EVALUATION OF ARCHITECTURAL DISTORTION DETECTED ON SCREENING MAMMOGRAPHY

Vandana M. Dialani, MD (*Abstract Co-Author*) Research Consultant, Hologic, Inc;Research Consultant, Intrinsic Imaging LLC
Alexander Brook, PhD (*Abstract Co-Author*) Nothing to Disclose
Shutao Wang, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Contrast enhanced mammography (CEM) is an emerging technology utilizing iodinated intravenous contrast media to evaluate breast lesions. Architectural distortion (AD) is a common concerning finding on screening mammography, resulting in recalls and biopsies. Here, we hypothesize that CEM can be used as an effective diagnostic imaging tool for further evaluation and management of patients with AD.

### METHODS AND MATERIALS

This retrospective study was conducted under an IRB approved protocol. Clinical data from adult patients who were recalled for AD and underwent diagnostic CEM were collected. Patients without a biopsy or a 2-year follow-up were excluded from the study. Patients with no cancer on biopsy or subsequent follow up imaging for at least 2 years were considered negative.

### RESULTS

Among the 148 patients with age ranging from 40 to 87 years old, 89 patients had no positive findings on CEM (60%) while 59 patients (40%) had either enhancing mass/focus or non-mass enhancement. All CEM positive cases were biopsied, among which 45/59 (76%) were cancers. All the 89 cases with negative CEM findings were negative based on either tissue sampling (10/89;11%) or 2-year imaging follow-up (79/89;89%). Correlating to the biopsy/surgical pathology results, CEM demonstrates a sensitivity of 1.00 (95% CI 0.92-1.00) and specificity of 0.86 (95% CI 0.78-0.92). The negative predictive value of CEM was 1.00 (95% CI 0.96-1.00). The positive predictive value of CEM was 0.76 (95% CI 0.63-0.86). Majority (8/14;71%) of the false positive CEM cases with benign biopsies had radial scars on pathological examination.

### CONCLUSION

In this study, contrast enhanced mammography demonstrated excellent sensitivity and negative predictive value when used as a diagnostic tool for patients who had a recall for architectural distortion on routine screening mammograms.

### CLINICAL RELEVANCE/APPLICATION

High negative predictive value of CEM may allow this technique to be the new confirmatory diagnostic study, thus potentially avoiding unnecessary biopsies in patients with architectural distortion.

## T3-SSBR05-5 THE CLINICAL SIGNIFICANCE OF LESION CONSPICUITY ON CONTRAST ENHANCED MAMMOGRAPHY

Janice S. Sung, MD (*Abstract Co-Author*) Research Grant, General Electric Company
Christopher E. Comstock, MD (*Abstract Co-Author*) Speakers Bureau, Bracco Group;Advisory Board, Guerbet SA;Consultant, Bayer AG;Speaker, Northwest Imaging Forums, Inc
Sarah Eskreis-Winkler, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Maxine S. Jochelson, MD (*Abstract Co-Author*) Speaker, General Electric Company
Carol H. Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Tali Amir, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine if lesion conspicuity on contrast enhanced mammography (CEM) is associated with likelihood of malignancy

### METHODS AND MATERIALS

This was a retrospective, IRB approved study. From January 1, 2020 through December 31, 2021 a total of 3,427 CEM examinations were performed. Cases of known cancer, those done for short interval follow-up, and those without adequate follow-up were excluded. There were a total of 473 enhancing lesions among 436 women. Conspicuity was assigned by one of two radiologists who were blinded to the outcome of the case. Conspicuity was assigned as low, moderate, or high as defined by the Breast Imaging and Data System (BI-RADS) lexicon. All cases had tissue confirmation and/or at least two years of imaging follow-up.

### RESULTS

Among the 473 lesions, 248 (52.4%) were low conspicuity, 181 (38.3%) showed moderate conspicuity, and 44 (9.3%) were high conspicuity. There were 31 cancers among the 473 cases (6.5/1000)of which 13 (42% of cancers) were low conspicuity, 16 (52% of cancers) were moderate conspicuity, and 2 (6% of cancers) were high conspicuity. The positive predictive value (PPV) of low conspicuity for cancer was 5.3% (95% confidence interval [CI] 2.8% to 8.9%). PPV of moderate conspicuity was 8.8% (95% CI 5.1% to 13.9%). For high conspicuity, PPV was 4.5% (95% CI 0.5% to 15.5%)There was no statistically significant difference of PPV of low versus high conspicuity (p= 0.99) or moderate versus high conspicuity (p = 0.52).

### CONCLUSION

Lesions conspicuity on CEM is not reliably associated with malignancy and is not helpful for discriminating benign from malignant findings. Lesions should not be discounted based on low conspicuity alone.

### CLINICAL RELEVANCE/APPLICATION

Lesion conspicuity is not a useful criterion for differentiating benign from malignant enhancing lesions on CEM.

## T3-SSBR05-6 BREAST MAGNETIC RESONANCE IMAGING AND CONTRAST-ENHANCED MAMMOGRAPHY INTER-READER AGREEMENT FOR BREAST CANCER DIAGNOSIS: A MULTI-READER RETROSPECTIVE STUDY

Serena Carriero (*Abstract Co-Author*) Nothing to Disclose

Sonia Santicchia (*Abstract Co-Author*) Nothing to Disclose
Ottavia Battaglia, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Early Breast cancer (BC) detection and exact tumoral extent evaluation are of pivotal importance for successful treatment and to improve survival rate.Breast magnetic resonance imaging (MRI) and contrast-enhanced mammography (CEM), represent the most effective techniques for BC local staging, depicting tumoral neovascularization and providing functional information.We aimed to assess intra-patient concordance between readers of varying experience in CEM and breast MRI for breast cancer diagnosis.

**METHODS AND MATERIALS**

Breast MRI and CEM exams performed in a single center (09/2020-09/2021) for an IRB-approved study were retrospectively and independently evaluated by four radiologists of two different centers with different levels of experience who were blinded to the clinical and other imaging data. The reference standard was the histological diagnosis or at least 1-year negative imaging follow-up. Inter-reader agreement was examined using Cohen's and Fleiss' kappa (?) statistics and compared with the Wald test.

**RESULTS**

Of the 750 patients, 395 met inclusion criteria (44.5 ± 14 years old), with 752 breasts available for CEM and MRI. Overall agreement was moderate (? = 0.60) for MRI and substantial (? = 0.74) for CEM. For expert readers, the agreement was substantial (? = 0.77) for MRI and almost perfect (? = 0.82) for CEM; for non-expert readers was fair (? = 0.39) for MRI and moderate (? = 0.57) for CEM. Pairwise agreement between expert readers and non-expert readers was moderate (? = 0.50) for breast MRI and substantial (? = 0.74) for CEM and it showed a statistically superior agreement of the expert over the non-expert readers only for MRI (p = 0.011) and not for CEM (p = 0.062).

**CONCLUSION**

The agreement of CEM was superior to that of MRI (p=0.012), including for both expert (p=0.031) and non-expert readers (p = 0.005).

**CLINICAL RELEVANCE/APPLICATION**

Despite both breast MRI and CEM have been showed to improve diagnostic accuracy in the diagnosis and staging of primary breast cancer, the lack of standardization in the interpretation of imaging findings with a wide range of inter-reader agreement rate remains a key issue.Identifying a diagnostic approach that is both accurate and associated to a high agreement is of pivotal importance to ensure optimal and equal patient's management. Furthermore, consistency enhances confidence in the diagnostic findings and reduces the potential for diagnostic errors or discrepancies that could occur with individual interpretations. Finally, the inter-reader agreement is crucial to assess the reproducibility and generalizability of findings across multiple readers and institutions.

## T3-SSCA05-1 T2 MAPPING RATIO OF THE RIGHT-LEFT VENTRICULAR BLOOD POOL AS A MARKER TO EVALUATE THE SEVERITY OF DISEASE IN PATIENTS WITH PRIMARY PULMONARY HYPERTENSION AND LEFT HEART FAILURE

Carlo Catalano, MD (*Abstract Co-Author*) Nothing to Disclose
Nicola Galea, MD (*Abstract Co-Author*) Nothing to Disclose
Giulia Cundari, MD (*Abstract Co-Author*) Nothing to Disclose
Martina Giannetti, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The ratio between blood T2 mapping measured in the right (RV) and left (LV) ventricular cavity by Cardiac Magnetic Resonance (CMR) was proven to be correlated to the level of blood oxygenation. The aim of the study was to demonstrate the modifications of RV/LV-ratio in patients with heart failure (HF) and primary pulmonary hypertension (PAH), as conditions characterized by a reduction in pulmonary oxygen exchange.

### METHODS AND MATERIALS

44 patients with HF, 32 with PAH on therapy and 30 controls who underwent CMR were retrospectively enrolled. The protocol included GRE T2 mapping, native MOLLI T1 mapping and cine-SSFP sequences. The volumes of both ventricles and the blood T1 and T2 mapping values, delineating two circular regions of interest (ROI) in the cavity of the RV and LV blood pool, were evaluated. Then, the ratio (RV/LV-T2 ratio) was assessed.

### RESULTS

The difference between RV/LV-T2 ratio was statistically significant among patients with HF (ratio:0.59 ± 0.12) and PAH (ratio: 0.75 ± 0.16) and between HF and controls (ratio: 0.79 ± 0.12, $p< 0.0001$), but not between PAH and controls. A significant linear correlation was found between the RV/LV-T2 ratio and the RV ejection fraction (EF) (Pearson:0.259, $p<0.05$), the LV EF (Pearson:0.508, $p<0.0001$), all volumetric parameters of the LV (Pearson: -0.473/-0.408, $p<0.0001$) and the blood T1 mapping in the RV (Pearson: -0.439, $p<0.0001$).

### CONCLUSION

In patients with HF, the RV/LV-T2 ratio decreased in relation to the reduced oxygenation capacity of the blood.

### CLINICAL RELEVANCE/APPLICATION

The RV/LV-T2 ratio correlates with biventricular systolic function and may represent a marker to evaluate the severity of the disease in patients with HF or PAH.

## T3-SSCA05-2 GENDER-SPECIFIC IMPACTS OF ASYMPTOMATIC HYPERURICEMIA ON CARDIAC STRUCTURE AND FUNCTION IN HYPERTENSIVE PATIENTS: INSIGHTS FROM CARDIAC MAGNETIC RESONANCE IMAGING

Xinyuan Zhang (*Abstract Co-Author*) Nothing to Disclose
Si-shi Tang (*Abstract Co-Author*) Nothing to Disclose
Xue-Ming Li (*Abstract Co-Author*) Nothing to Disclose
Zhongqin Zhou (*Abstract Co-Author*) Nothing to Disclose
Yue Gao, MD (*Abstract Co-Author*) Nothing to Disclose
Wei-Feng Yan, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study uses cardiac magnetic resonance (CMR) to explore how asymptomatic hyperuricemia (HU) affects left ventricular (LV) function and structure in patients with essential hypertension and examines gender differences in these effects.

### METHODS AND MATERIALS

We included 225 patients with essential hypertension (125 males and 100 females), divided into 93 with asymptomatic hyperuricaemia (HU+ group) and 132 without (HU- group), along with 65 normotensive controls. Conventional LV function parameters and global myocardial strain measures—radial (GRPS), circumferential (GCPS), and longitudinal peak strain (GLPS)—were assessed using CMR. Pearson correlation and regression analyses evaluated the links between serum uric acid levels and CMR parameters across different genders.

### RESULTS

Ejection fraction remained stable across groups, but left ventricular global longitudinal peak strain (LV GLPS) decreased progressively from normotensive controls to the hypertensive without hyperuricemia (HU-) group, and further in the hypertensive with hyperuricemia (HU+) group. Additionally, both left ventricular global circumferential peak strain (LV GCPS) and global radial peak strain (LV GRPS) were lower in the HU+ group compared to controls. Left ventricular mass index (LVMI) and remodeling index (LVRI) increased progressively from controls, through the HU- group, to the HU+ group. Serum uric acid levels were significantly correlated with GRPS, GCPS, and GLPS. Furthermore, after adjusting for clinical factors, serum uric acid was independently associated with LV GLPS. In male patients, multiple regression analyses revealed independent associations of serum uric acid with LVMI and LVRI, whereas such associations were not observed in female patients.

### CONCLUSION

Asymptomatic hyperuriceamia is linked to a further decline in LV function in hypertensive patients, with significant associations between increased serum uric acid levels and decreased myocardial strain. Moreover, the impact of elevated uric acid on LV remodeling appears to be gender-specific.

### CLINICAL RELEVANCE/APPLICATION

Patients with essential hypertension and coexisting asymptomatic hyperuricaemia demonstrate more pronounced decreases in left ventricular motor function and structural changes compared to those without hyperuricaemia. These findings underline the significant correlation between elevated serum uric acid levels and myocardial strain impairments. It has been observed that elevated uric acid levels may have gender-specific pathophysiological effects on cardiac structure, suggesting the need for gender-tailored approaches in managing hypertensive patients with hyperuricaemia.

## T3-SSCA05-4 COMPARISON OF ECG GATING VERSUS PERIPHERAL PULSE GATING IN QUANTIFYING MYOCARDIAL IRON USING T2* MRI IN PATIENTS WITH THALASSEMIA MAJOR

Geetanjali Nanda, MD (*Abstract Co-Author*) Nothing to Disclose
Abhishek Suman, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Madhuri Barnwal (*Abstract Co-Author*) Nothing to Disclose
Kabir Mahajan, MBA (*Abstract Co-Author*) Nothing to Disclose
Vineeta Ojha, MD (*Presenter*) Nothing to Disclose

### PURPOSE

T2* MRI is the current non-invasive gold standard for myocardial iron quantification. As recommended in major societal guidelines (including SCMR), ECG gated T2* acquisition is standard of practice. The ECG gating entails additional time in attaching ECG electrodes on the chest before the scan. Sometimes, this is cumbersome in smaller children who are non-cooperative. The aim of this study was to compare the accuracy of ECG-gating versus peripheral pulse (PP) gating in estimating the T2* mapping values for myocardial iron quantification in Thalassemia Major patients.

### METHODS AND MATERIALS

109 thalassemia major patients referred for T2* MRI were prospectively recruited to undergo T2* MRI of heart and liver using both ECG -gating and peripheral pulse gating for heart. Images were analyzed using a dedicated cardiac MRI software by two independent observers and myocardial T2* was calculated by drawing a single septal ROI as previously described.

### RESULTS

The mean age of the study population was 22.72 y (range - 3-49 years) with male predominance (67 males). The median T2* of heart using ECG and PP gating was 34.35 ms; IQR: 16.43 and 32.91 ms; IQR:11.93, respectively. There was excellent intra-class correlation between the T2* of the heart using ECG gating and PP gating (ICC 0.97, $p<0.001$). There was excellent agreement (weighted kappa=0.988, 95% CI-0.902 to 1) between the ECG gating and PP gating methods for accepted T2* classification (>20 ms as normal, 10-20 ms as mild to moderate, and <10 ms as severe iron overload), with only one patient with normal T2* on ECG gating being classified as mild-moderate category on PP gated T2* MRI. Bland- Altman analysis revealed that the difference between the values obtained by two methods was more in those with higher T2* values (>30 ms) where it did not reclassify the patients (all normal myocardial iron).

### CONCLUSION

There is high degree of accuracy and agreement between ECG and PP-gated T2* MRI in quantifying myocardial iron in Thalassemia Major patients and in classifying them into normal, mild to moderate and severe groups using T2* MRI, which defines the recommended chelation therapy.

### CLINICAL RELEVANCE/APPLICATION

1. The findings suggest that PP gating can serve as a reliable alternative to ECG gating for myocardial iron quantification in Thalassemia Major patients, especially in situations where ECG gating is impractical or challenging.2. If incorporated into protocol, PG T2* MRI, may have the potential to expedite the imaging process. 3. This might also mean a step in the direction of sustainable MRI by not only decreasing overall scanner time per scan but also reduce wastage of raw materials like metallic electrodes, especially pertinent in LMIC countries like ours with huge Thalassemia burden.

**PURPOSE**

Metabolic Syndrome (MetS) encompasses a set of cardiometabolic risk factors that elevate the risk of cardiovascular diseases. This study investigates whether MetS in middle-aged individuals, who are initially free of coronary artery calcium (CAC), is predictive of incident CAC a biomarker of subclinical coronary artery disease (CAD).

**METHODS AND MATERIALS**

The study participants were part of The Coronary Artery Risk Development in Young Adults (CARDIA) Study, a community-based study with initial recruitment in 1985. Based on ATP-III criteria, we coded MetS positive when 3 or more of the following were present: waist circumference >102 cm in men or >88 cm in women; fasting triglyceride =150 mg/dl; HDL-cholesterol <40 mg/dl in men or <50 mg/dl in women; blood pressure =130/85 or treatment; fasting glucose =100 mg/dl or treatment at the year 25 exam(baseline, 2010-11). This report is a subset of 513 participants (347 females, 202 Black) all with CAC scores of zero at the 2010-11 exam who participated in the chest CT exams in 2020-22. The chest CT exams were analyzed using a deep-learning algorithm with additional expert review for the presence and amount of CAC. We evaluated the association between baseline MetS status and incident CAC using logistic regression models adjusted for study field center, age, race, sex, smoking status, alcohol intake, physical activity, and education.

**RESULTS**

At baseline (mean age 49.8 ± 3.6 years), 18.9% of participants had MetS. A decade later, 32.7% had incident non-zero CAC scores. Presence of MetS at baseline was associated with incident CAC, with unadjusted and adjusted odds ratios of 2.2 (95% CI, 1.4-3.4, $p<0.001$) and 2.3 (95% CI, 1.5-3.8, $p<0.001$), respectively.

**CONCLUSION**

Ten-year Incidence of CAC was almost 33% during middle-age and those with MetS had more than twofold increased risk of subclinical CAD. This finding underscores the importance of early cardiometabolic risk management in the prevention of subclinical atherosclerosis.

**CLINICAL RELEVANCE/APPLICATION**

Our findings indicate that community dwelling middle-aged adults with MetS are over twice as likely to develop incident subclinical CAD within ten years, highlighting the necessity of addressing cardiometabolic abnormalities early and across the lifespan.

### PURPOSE

Elder self-neglect, defined as the inability to perform essential self-care, is an emerging global public health problem. We hypothesize that older adults experiencing self-neglect have higher medical and imaging needs. We aimed to evaluate imaging patterns, and outcomes over four years in these patients compared to matched controls at Emergency Department (ED) visits, particularly comparing adherence to the self-neglect mandate.

### METHODS AND MATERIALS

This IRB-approved retrospective study, conducted at two major academic medical centers, utilized the enterprise data warehouse to identify patients of >60 years receiving a self-neglect mandate in the ED during 2019. Our study cohort consisted of 111 cases and 108 matched controls by age, gender, race, and time of ED presentation. An emergency radiology fellow systematically reviewed chart notes and imaging reports at the time of mandate (index visit) and for subsequent follow-up periods.

### RESULTS

The imaging utilization was higher among cases for radiographs ($p<0.001$), CT studies ($p<0.0002$) and overall imaging studies ($p<0.0001$). Additionally, cases who did not follow discharge recommendations had higher use of imaging during the initial visit ($p=0.018$) and on subsequent visits or readmissions ($p=0.02$). There was also a higher prevalence of substance use ($p=0.02$) and mental health disorder ($p=0.001$) among cases. Mortality rates were higher in the self-neglect patients (44%) compared to controls (6.5%; $p=0.0001$), and among self-neglect patients who did not follow discharge recommendations (52.1% vs. 30.2%; $p=0.02$). Nearly half of the patients in both groups showed no acute imaging findings on index visit. Pneumonia was more common in self-neglect patients (7.2% vs 1%; $p=0.05$) (Table 3)

### CONCLUSION

Imaging utilization, pneumonia, and mortality were significantly high in the self-neglect patients; particularly for those who did not follow recommendations.

### CLINICAL RELEVANCE/APPLICATION

Identifying at-risk patients and employing early intervention strategies can support this vulnerable population and decrease the strain on the already overwhelmed healthcare system.

## T3-SSER01-2 RADIOLOGIC ASSESSMENT ENABLES EARLY DETECTION OF INTIMATE PARTNER VIOLENCE

Alejandra Duran-Mendicuti, MD (*Abstract Co-Author*) Nothing to Disclose
Tatiana C. Rocha, MD (*Abstract Co-Author*) Nothing to Disclose
Bharti Khurana, MD, MBA (*Abstract Co-Author*) Consultant, General Electric Company;Editor, Wolters Kluwer nv;Author, Cambridge University Press;Consultant, ROKIT Healthcare, Inc
Patrick Lenehan, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Intimate partner violence (IPV) is a serious public health concern but can be difficult to detect in the clinical setting. Previous work has demonstrated that radiologists can raise suspicion for IPV before it is self-reported. We aimed to validate this observation on an expanded cohort and to assess the prevalence of radiologically suspected IPV among a group of patients who have never self-reported.

### METHODS AND MATERIALS

The study population consisted of females reporting physical IPV to our institution's violence prevention support program between 2013 and 2018 ("cases"; N = 1437 patients with 48792 imaging studies) and age- and race-matched females who did not report IPV ("controls"; N = 6693 patients with

102752 imaging studies). Reports were retrospectively reviewed in chronological order for each patient by two Emergency Radiologists who were blinded to case-control status. For each study, the radiologist indicated whether IPV was suspected based on observed injuries and overall findings. Rates of suspected IPV between cases and controls were compared using a crude odds ratio and Fisher-exact test. Potential for early detection was assessed by summarizing the distribution of time between the date of initial self-reporting and the date on which a radiologist first raised suspicion for IPV.

**RESULTS**

Suspicion of IPV was raised on a total of 433 out of 151,544 (0.29%) radiology reports reviewed, including 250 reports from cases and 183 reports from controls. At the patient-level, IPV was suspected by radiologists at any time for 159 of 1437 cases versus 129 of 6693 controls (11.1% vs. 1.9%; OR=6.3; p<0.0001). Upper and lower extremity fractures were among the most common injury patterns that raised suspicion for both groups, while facial fractures contributed disproportionately for cases (17 of 250 reports, 6.8%) compared to controls (2 of 183 reports, 1.1%) (OR=6.6; p=0.004). Among the 159 cases for whom IPV was suspected by a radiologist, the first radiologic evidence occurred a median of 1 day before initial self-reporting (IQR: 1865 days), and 64 of these cases (40.3%) were suspected by radiologists at least six months prior to self-reporting.

**CONCLUSION**

In a blinded retrospective review of radiology reports, suspicion for IPV was raised for a significantly higher fraction of cases than controls. Radiologic evidence of IPV was often present several months or years before it was first self-reported.

**CLINICAL RELEVANCE/APPLICATION**

Awareness of characteristic imaging patterns can help radiologists detect IPV before disclosure and facilitate earlier interventions to reduce the resultant cycles of physical and psychological harm.

## T3-SSER01-3 EVALUATING THE UTILITY OF PELVIC ULTRASOUND FOLLOWING A NEGATIVE CT PELVIS IN WOMEN PRESENTING TO THE EMERGENCY ROOM WITH ABDOMINAL PAIN

Tamanna Hossin (*Abstract Co-Author*) Nothing to Disclose
Joseph J. Cavallo, MD, MBA (*Presenter*) Nothing to Disclose

**PURPOSE**

Evaluate the utility of pelvic ultrasound (US) performed within 24 hours after a CT of the abdomen and pelvis (CTAP) in the emergency department (ED) for finding emergent pelvic gynecological pathology in instances where CT Pelvis did not report significant findings.

**METHODS AND MATERIALS**

We extracted imaging reports of patients seen across 9 EDs of a large northeast health system between 2017 and 2020 who received a pelvic US within 24 hours of having a CTAP. We established criteria for determining pelvic pathology in CTAP via expert author consensus between emergency medicine and radiology physicians, and used the criteria to screen out cases with abnormal CT pelvis findings. We reviewed US reports for the remaining cases to determine if pelvic US revealed any new information. Notable pelvic US findings were categorized into the following three groups: (1) incidental finding with no follow up needed, (2) significant finding that may need non-emergent outpatient follow up, and (3) emergent finding that may affect acute management.

**RESULTS**

Out of 1569 cases evaluated, 651 (41.5%) patients had negative pelvic findings on CTAP. Of these 651 cases, 433 (66.5%), 205 (31.5%), and 13 (2%) had US had findings that met criteria for group 1, 2, and 3, respectively. Group 3 US findings consisted of 1 case with gonadal vein thrombosis for which aspirin was started, 5 cases with pelvic inflammatory disease which required antibiotics, 5 cases with tubal abnormalities (i.e. hematosalpinx, hydrosalpinx) which did not affect ED management, and 2 cases with suspected retained products of conception (RPOC), one of which was ruled out clinically, and the other underwent dilation and curettage with subsequent pathology revealing no RPOC. Negative predictive value of a negative CT Pelvis for emergent pathology (group 3) was 98%. Looking at the broader dataset of 1569 cases, no cases of tubo-ovarian abscess (TOA) or torsion suggested on US were missed when using the criteria we established to identify abnormal CT Pelvis studies.

**CONCLUSION**

Pelvic ultrasound within 24 hours following a negative CT of the pelvis is unlikely to alter immediate management in the acute setting.

**CLINICAL RELEVANCE/APPLICATION**

In women presenting to the ED with abdominal pain, a pelvic ultrasound following a CTAP that shows no significant findings is unlikely to reveal emergent conditions such as tubo-ovarian abscess or ovarian torsion. The findings of this study suggest that over 98% of subsequent ultrasound examinations do not influence immediate clinical decisions. Therefore, limiting follow-up ultrasounds in these scenarios in the ED could decrease healthcare costs and reduce ED lengths of stay, thereby enhancing care efficiency and generating cost savings.

## T3-SSER01-4 THE FREQUENCY OF IMAGING MARKERS ADJUSTED FOR TIME SINCE SYMPTOM ONSET IN INTRACEREBRAL HEMORRHAGE: A NOVEL PREDICTOR FOR HEMATOMA EXPANSION

Xiaoming Qiu (*Abstract Co-Author*) Nothing to Disclose
Lei Song (*Presenter*) Nothing to Disclose

**PURPOSE**

Hematoma expansion (HE) is common in patients with intracerebral hemorrhage (ICH) and associated with a worse outcome. Imaging makers and shorter time from symptom onset are both associated with HE, but prognostic scores based on these parameters individually have not been satisfactory. We hypothesized that a score including both imaging markers of expansion, and time of onset, would improve prediction.

**METHODS AND MATERIALS**

Patients with supratentorial ICH within 6 h after onset were consecutively recruited from six centers between January 2018 and August 2022. Three markers were used: hypodensities, the blend sign, and the island sign. We first defined frequency of imaging markers (FIM) as the relationship between the number of imaging markers and onset-to-CT time (OCT). The time-adjusted FIM was defined as the ratio of the number of imaging markers to the onset-to-initial imaging time. Multivariate analysis was performed to determine the relationship between FIM and HE. Receiver operating curve analysis was used to identify potential threshold values of FIM that optimally predict HE. In addition, the sensitivity, specificity, positive and negative predictive values (PPVs and NPVs), and the area under the curve (AUC) of the optimal cut-off in predicting HE were calculated.

**RESULTS**

In total, 1488 patients were eligible for inclusion, of whom 418 had incident HE. Multivariate analysis showed that age, male sex, baseline Glasgow Coma Scale score, presence of intraventricular hemorrhage, and FIM were independent predictors of HE (odds ratio (OR) = 0.98, 95% confidence interval (CI) = 0.97-0.99; OR = 1.73, 95% CI = 1.28-2.35; OR = 0.87, 95% CI = 0.83-0.92; OR = 0.42, 95% CI = 0.28-0.62; OR = 7.82, 95% CI = 5.86-10.42, respectively). The optimal cut-off point for FIM in predicting HE was 0.63, with sensitivity, specificity, PPV, NPV, and AUC values of 0.69, 0.89, 0.71, 0.88, and 0.83, respectively.

**CONCLUSION**

The FIM adjusted for time since symptom onset is a significant predictor of HE. Its use may allow improved prediction of those patients with ICH who develop HE, and the score may be clinically applicable in the management of patients with ICH.

**CLINICAL RELEVANCE/APPLICATION**

FIM may be useful to further identify ICH groups with high-risk HE and optimize clinical decision-making.

## T3-SSER01-5 REDUCING PHYSIOLOGICAL ACUTE ADVERSE REACTIONS BY DE-EMPHASIZING RISK NOTIFICATION BEFORE IODINATED CONTRAST INJECTION IN CONTRAST-ENHANCED COMPUTED TOMOGRAPHY: A RANDOMIZED STUDY

Jia Xiaoqian, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To demonstrate the reduced physiological acute adverse reactions (PAAR) by de-emphasizing the potential risks of iodinated contrast media (ICM) to patients before ICM injection in contrast-enhanced computed tomography (CT).

**METHODS AND MATERIALS**

This was a prospective, randomized study and was approved by the Institutional Ethics Committee of our hospital. Prospectively enrolled 51884 patients undergoing contrast-enhanced CT from August 16, 2018 to December 16, 2019. Patients were divided into two groups based on their reservation methods. Patients who had in-person reservation were enrolled into the traditional group (Group A) where detailed risk factors of ICM were explained by a dedicated nurse before contrast injection; and patients with online reservation were enrolled in the de-emphasizing group (Group B) where patients obtained and signed an informed consent form including risk notification online without having detailed risk notification by a dedicated nurse before CT examination. After CT examination, patients were asked to stay for 30 minutes before leaving. The differences of PAAR and other clinical impact between the two groups were statistically analyzed.

**RESULTS**

There is no statistically significant difference in the incidence of ICM related hypersensitivity reactions (HSRs) between the two groups (0.17% vs. 0.16%, P = 0.766). Group B had reduced incidence rate of PAAR (0.22% vs. 0.40%, P<0.001), lower rate of patients experiencing anxiety (0.87% vs. 2.67%, P<0.001), and lower rate of refusing CT due to concerns about the risks of using ICM (0.23% vs. 1.33%, P<0.001); Additionally, Group B required no prep time for risk notification just before CT examinations (0 vs. 14 min) and saved 2 nurses per shift.

**CONCLUSION**

De-emphasizing the potential risks of using ICM to patients can minimize patient anxiety and ICM-related PAAR, reduce examination time and hospital staffing requirement.

**CLINICAL RELEVANCE/APPLICATION**

De-emphasizing the potential risks of using ICM to patients can minimize patient anxiety and ICM-related PAAR. In addition, this risk notification method can reduce examination time and demand for nursing requirement.

## T3-SSER01-6 SHATTERED BUT NOT OVERLOOKED: RADIOLOGICAL INSIGHTS INTO ABDOMINOPELVIC INJURIES FROM BOMB BLASTS IN A WAR-HIT COUNTRY

Zohaib Mallick, MBBS (*Abstract Co-Author*) Nothing to Disclose
Zahra Rahmatullah (*Presenter*) Nothing to Disclose

**PURPOSE**

Abdominopelvic injuries resulting from bomb blasts represent a critical area of concern, requiring detailed radiological assessment for effective management. This study analyzes the radiological and clinical findings from such incidents to provide insights into the most common injuries and subsequent diagnostic strategies.Objective: To delineate the patterns and implications of abdominopelvic injuries in bomb blast victims through comprehensive radiological and clinical profiling.

**METHODS AND MATERIALS**

We reviewed 160 patients with abdominopelvic injuries for first and second radiology investigations, including computed tomography (CT), ultrasound (US), X-ray (XR), and additional specialized procedures. Clinical parameters such as systolic and diastolic blood pressure and pulse rates were also examined to correlate physiological responses with injury severity. The demographic data of the patients involved in the study were analyzed to understand the distribution across different age groups and genders.

**RESULTS**

Among 160 bomb blast victims, initial radiological findings identified hemoperitoneum in 15 cases and abdominal wall injuries in 7, highlighting severe internal trauma. Vascular injuries were less common, reported in only 2 patients. Notably, visceral injuries were rare with only one case detected. The cohort was predominantly male (91.8%), aged 30-40 years, with systolic blood pressure peaks at 120 and 140 mmHg, and pulse rates around 110 bpm. Primary investigations predominantly utilized CT and US, essential for diagnosing and monitoring these injuries.

**CONCLUSION**

This study provides comprehensive insights into the radiological and clinical profiles of bomb blast victims with abdominopelvic injuries, highlighting the importance of immediate and sequential radiological evaluations. This research underscores the critical role of tailored diagnostic pathways in improving clinical outcomes for bomb blast victims.

## CLINICAL RELEVANCE/APPLICATION

The clinical relevance of this project lies in enhancing trauma care for bomb blast victims by improving diagnostic accuracy and treatment protocols.Key applications include:Refined Diagnostic Protocols: Data from this study supports the prioritization of CT and ultrasound in detecting critical conditions.Enhanced Trauma Management: Insights on common injury patterns can inform standardized emergency responses and training, optimizing care in mass casualty events.Policy and Preparedness: The findings can guide public health policies and preparedness strategies, particularly in conflict-prone areas.Overall, this project contributes to better patient outcomes through informed medical practices and emergency preparedness.

### PURPOSE

High spatial resolution is required for CT imaging of the small (sub-millimeter) middle ear prostheses, which is vital for determining complications after stapedectomy and ossiculoplasty and informing potential revision surgery. This study aims to evaluate the impact of spatial resolution for the visualization of stapes and ossicular replacement prostheses using photon counting detector (PCD) CT, energy integrating detector (EID) CT, and comb filters.

### METHODS AND MATERIALS

A collection of 21 common middle ear prostheses of various shapes and materials were placed within a head phantom and scanned on a PCD-CT (NAEOTOM Alpha, Siemens) and 3 EID-CT: 2 dual source CTs with comb filters (Flash and Force, Siemens), and a dual-layer CT without comb filter (7500, Philips). Scanning and reconstruction were performed following the clinical temporal bone protocols for each scanner, with a matched 120 kV and 80 mm field of view; sharp kernels/algorithms of Qr89, Ur77, Ur77, and YD; and minimal allowable slice thickness of 0.2, 0.4, 0.5, and 0.67 mm, respectively. Qualitative and quantitative assessments were performed for image quality, including visual inspection, volume rendering, line profiles, and full-width half measurement (FWHM) of the prostheses.

### RESULTS

PCD-CT provided images with the highest spatial resolution and detail, allowing clinically relevant assessment of prosthesis position relative to the coupled ossicular chain - rivaling that of direct visualization. The EID-CT scanner with comb filter provided good results, but had noticeable loss of detail compared to PCD-CT. For the EID-CT without a comb filter, a substantial loss of spatial resolution was observed, and characterization of prosthesis details became unfeasible. This was also quantitatively validated by the line profiles and FWHM measurements, which were 0.55 mm for PCD-CT, 0.78 mm and 0.94 mm for EID-CT with comb filters, and 1.09 mm for the EID-CT without comb filter. PCD-CT result showed a 49.54% improvement in FWHM compared to the EID-CT without comb filter. Among the 3 scanners with ultra-high-resolution (UHR) capabilities, PCD-CT had lower radiation dose (CTDIvol: 31.5 vs 46.7 and 51.4 mGy) and lower image noise (81.3 vs 93.0 and 274.8 HU) compared to the two EID-CTs with comb filters.

### CONCLUSION

PCD-CT provides dose-efficient UHR imaging for visualization and characterization of sub-millimeter structures of middle ear prostheses, which were degraded for the EID-CT with comb filters and undifferentiable for EID-CT without comb filters. Compared to EID-CT with comb filters, PCD-CT images show higher resolution and lower noise at lower radiation dose due to its high dose efficiency.

### CLINICAL RELEVANCE/APPLICATION

UHR PCD-CT provides accurate evaluations of stapes prostheses.

## T3-SSHN02-3 VALUE OF DUAL-LAYER SPECTRAL DETECTOR CT IN DIFFERENTIATING MIDDLE EAR CHOLESTEATOMA AND CHRONIC SUPPURATIVE OTITIS MEDIA

Wenguang Liu (*Abstract Co-Author*) Nothing to Disclose
Yiwen Sun (*Abstract Co-Author*) Nothing to Disclose
Xiaomin Liu (*Abstract Co-Author*) Nothing to Disclose
Shuangyuan Zhou, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the potential value of dual-layer spectral detector CT (DLCT) in differentiating middle ear cholesteatoma and chronic suppurative otitis media.

### METHODS AND MATERIALS

This prospective, institutional review board-approved study included sixty-six patients who were preliminary diagnosed as cholesteatoma or otitis media, and received DLCT scanning before surgery. Thirty-four patients were finally diagnosed cholesteatoma based on intraoperative or pathological findings. The conventional CT value, virtual mono-energetic images (VMIs) at 40keV and 70keV, slope of the spectral attenuation curve in Hounsfield units (?HU), electron density (ED), and effective atomic number (Zeff) were measured to quantitatively differentiate cholesteatoma and otitis media. Mann-Whitney test was used for comparison and the receiver operator curves (ROCs) was used to find out the best parameters.

### RESULTS

The VMI 40keV, and Zeff of cholesteatoma were significantly lower than that of the otitis media while ED was significantly higher ($p<0.001$), but conventional CT value and VMI 70keV were not significant difference. The spectral attenuation curve of cholesteatoma was arched upward, which was consistent with the curve of subcutaneous fat, while the curve of middle ear mastoiditis was down or relatively flat. The optimal cutoff values for VMI 40keV, ED, Zeff, ?HU were 45.9HU, 99.6, 7.0, and 0.67, with AUCs of 0.989 (sensitivity=100%; specificity=90.6%), 0.812 (sensitivity=97.1%; specificity=59.4%), 1.00 (sensitivity=97.1%; specificity=100%), and 1.00 (sensitivity=97.1%; specificity=100%), respectively.

### CONCLUSION

Spectral CT improved both quantitative and qualitative determination of cholesteatoma versus otitis media.

### CLINICAL RELEVANCE/APPLICATION

The preferred treatment and surgical methods of cholesteatoma and otitis media are different. Conventional CT is limited in differentiating these two diseases. Our result demonstrates spectral CT can distinguish the two diseases excellently and help clinicians make reasonable treatment plans effectively.

## T3-SSHN02-4 UNLOCKING THE FULL POTENTIAL OF ULTRA-HIGH-RESOLUTION PHOTON-COUNTING-DETECTOR CT WITH A DEDICATED DENOISING CONVOLUTIONAL NEURAL NETWORK FOR ENHANCED TEMPORAL BONE IMAGING

Matthew Carlson, MD (*Abstract Co-Author*) Nothing to Disclose
John I. Lane, MD (*Abstract Co-Author*) Nothing to Disclose
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Joseph R. Swicklik, RT, BS (*Abstract Co-Author*) Nothing to Disclose

Michael R. Bruesewitz, RT (*Abstract Co-Author*) Nothing to Disclose
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
John C. Benson, MD (*Abstract Co-Author*) Nothing to Disclose
Emily Koons (*Abstract Co-Author*) Nothing to Disclose
Shaojie Chang, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Ultra-high-resolution (UHR) photon-counting-detector (PCD) CT improves image resolution but also increases image noise. This requires use of smoother kernels, which yield resolution below the system's capability (0.125 mm in-plane). This work developed a denoising convolutional neural network (CNN) to reduce noise while preserving high spatial resolution for enhanced temporal bone visualization.

### METHODS AND MATERIALS

With IRB approval, a CNN was developed and trained on clinical temporal bone images (n=1885) to reduce noise and tested on 20 independent patient cases. All exams were conducted using the UHR mode on a dual-source PCD-CT (NAEOTOM Alpha, Siemens Healthcare). Images were reconstructed using iterative reconstruction at strength 3 (QIR3), slice thickness of 0.2 mm, clinical routine (Hr84) and the sharpest available kernel (Hr96). The trained CNN was applied to the 0.2 mm images reconstructed with the Hr96 kernel and QIR1. For each of the 20 test cases, three image series (Hr84-QIR3, Hr96-QIR3, and Hr96-CNN) were displayed side-by-side in a randomized order for blinded review by two experienced neuroradiologists to assess overall image quality and the delineation of three key anatomical structures: the modiolus, stapes footplate, and incudomallear joint. Images were ranked from 1 to 3, with 1 being the most preferred and 3 the least preferred; equal ranking was permitted.

### RESULTS

The trained CNN significantly reduced image noise—by approximately 80% compared to the highest resolution commercial images (Hr96-QIR3), and 50% relative to clinical routine images (Hr84-QIR3), while maintaining the ultra-high resolution. For overall image quality, Hr96-CNN images were ranked significantly higher than both Hr84-QIR3 ($p<0.001$) and Hr96-QIR3 ($p<0.001$). Both readers preferred the CNN denoising images for visualization of all three anatomical structures: the modiolus (Hr96-CNN/Hr84-QIR3/HR96-QIR3: 1/1.8/2.8, $p<0.001$), the stapes footplates (Hr96-CNN/Hr84-QIR3/HR96-QIR3: 1/1.94/2.88, $p<0.001$), and the incudomallear joint (Hr96-CNN/Hr84-QIR3/HR96-QIR3: 1/1.64/2.53, $p<0.001$).

### CONCLUSION

The proposed CNN significantly reduced image noise in UHR PCD-CT, enabling the use of the sharpest kernel with acceptable noise levels. UHR PCD-CT combined with CNN denoising significantly enhanced diagnostic image quality and improved visualization of key anatomy.

### CLINICAL RELEVANCE/APPLICATION

The resulting high-resolution images feature acceptable noise levels that not only improve anatomical delineation but also more precisely define the interfaces between metal prostheses and surrounding structures, enhancing temporal bone visualization.

## T3-SSHN02-5 PHOTON-COUNTING CT TEMPORAL BONE IMAGING CAN ACHIEVE BOTH HIGH SPATIAL RESOLUTION AND LOW RADIATION DOSE

Feng Feng, MD (*Abstract Co-Author*) Nothing to Disclose
Zhuhua Zhang (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose
Tong Su, MD (*Abstract Co-Author*) Nothing to Disclose

Yu Chen, MD (*Abstract Co-Author*) Nothing to Disclose
Jiajing Tong (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of photon-counting CT combined with tin-filter technology for high spatial resolution imaging in temporal bone imaging, especially in detail display and radiation dose reduction advantage.

### METHODS AND MATERIALS

This study included 30 healthy volunteers who underwent both photon-counting CT and conventional EID CT for high spatial resolution imaging of the inner ear in the recent past. Photon-counting CT imaging was performed with sn100kV, collimation of 120*0.2mm, IQ set at 110, and the thinnest reconstructed slice thickness was 0.2mm with 0.1mm increment. EID-CT was performed with conventional parameters: 120kV, 200mAs, collimation of 96*0.6mm, and reconstructed image slice thickness of 0.6mm. Two experienced radiologists conducted a double-blind assessment on the delineation, details, and overall image quality of structures including stapes, incudomalleolar joint, cochlear foramen, and vestibular aqueduct using a 5-point scale. In addition, radiation doses between the two groups were also comparably analyzed.

### RESULTS

Twenty-seven patients were finally included in the study (35.19±16.38 years, 17 females). Photon-counting CT was superior to EID-CT for all observed structures (stapes 4.63±0.56 vs. 3.37±0.56 , incudomalleolar joint 4.53±0.51 vs. 3.87±0.57, cochlear foramen 4.97±0.18 vs. 4.40±0.50, and vestibular aqueduct 4.37±0.72 vs. 3.93±0.74, $P<0.05$ for all). At the same time, the radiation dose was significantly reduced by 64% (0.33±0.05 VS 0.92±0.28, $P<0.001$).

### CONCLUSION

Photon-counting CT ultra-high-resolution imaging combined with tin-filter technology can achieve higher image quality under less radiation dose conditions.

### CLINICAL RELEVANCE/APPLICATION

Photon-counting CT provides high spatial resolution inner ear imaging at ultra-low radiation doses, which is expected to expand the application of this examination and even be applied to routine physical examinations for the elderly population.

## T3-SSHN02-6 PHOTON-COUNTING-DETECTOR CT OUTPERFORMS STATE-OF-THE-ART CONE-BEAM CT IN ASSESSMENT OF DENTAL ROOT CHANNEL IMAGING

Markus Altenburger (*Abstract Co-Author*) Nothing to Disclose
Maximilian Russe, MD (*Abstract Co-Author*) Nothing to Disclose
Martin Peter Pichotka (*Abstract Co-Author*) Nothing to Disclose
Fabian Bamberg, MD, MPH (*Abstract Co-Author*) Speakers Bureau, Bayer AG;Speakers Bureau, Bracco Imaging;Speakers Bureau, Siemens AG;Research Grant, Siemens AG
Wiebke Semper Hogg (*Abstract Co-Author*) Nothing to Disclose
Alexander Rau, MD (*Abstract Co-Author*) Nothing to Disclose
Stephan Rau, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Accurate treatment of dental root canals profits from sufficient imaging of the root canals. Especially untreated accessory root canals can lead to a persistence of symptoms. Therefore, high-resolution imaging of dental structures improves the outcome and is frequently warranted. This study systematically compared cone beam computed tomography (CBCT), energy-integrating CT (EID), and photon counting detector (PCD) CT scanners regarding their potential in dental high resolution imaging. For this, we employed a dental phantom with small artificial bore holes to simulate dental root channels.

### METHODS AND MATERIALS

In this experimental phantom study, bore holes of different sizes (diameters: 1000µm, 600 µm, 400 µm, 300 µm and 200 µm) were drilled into three bovine teeth mounted on a bovine rib as a jaw substitute. Subsequently, the phantom was scanned in a dental CBCT, a third generation EID-CT scanner and a first-generation PCD-CT scanner using established ultra-high-resolution protocols from clinical routine. Scans from a micro CT served as reference standard. Spatial resolution of the scans was evaluated via line profiles through the bore holes, whereby visibility compared to surrounding noise (signal = 2*SD) as well as width compared to the ground truth were assessed.

### RESULTS

PCD-CT was able to reliably delineate all bore holes in each of the three teeth down to 200 µm diameter. In contrast, in CBCT and EID-CT the bore holes could only be detected until 300 µm, whereby in EID-CT only two of three teeth, bore holes at 300 µm and 400 µm could be delineated. In addition, the PCD-CT shows a considerably smaller divergence of the bore hole width compared to the ground trough with 3.7% at 1000 µm and 10.6% at 300 µm compared to CBCT (12.6% and 22.3%) and EID-CT (11.0% and 38.2%).

### CONCLUSION

PCD-CT provided superior resolution, more accurate size measurement, and enhanced detection of dental root channels, thereby offering improvements in diagnostic capabilities compared to CBCT and EID-CT systems.

### CLINICAL RELEVANCE/APPLICATION

Clinical PCD-CT allows for detailed dental anatomy visualization superior to CBCT, potentially improving patient outcomes via more precise treatment planning and the possibility of opportunistic assessment of dental structures in routine examinations of the head.

Matthias M. Stechele, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To comprehensively elucidate the transcriptional activation of hepatic cell populations following RF ablation.

### METHODS AND MATERIALS

Single cell RNA sequencing (scRNAseq) was performed on 8-10w old male C57/Bl6 mice 7d following standardized RF ablation (70Cx5min) of normal liver and appropriate controls. >6,000 cells/sample were analyzed using Seurat5.0.1 on R4.3.0. Normalized datasets were subject to unbiased analysis of >4000 highly variable genes to identify those elevated in ten major cell populations including hepatocytes, macrophages, stellate cells, lymphocytes, and endothelial cells. These genes were further evaluated by string-db pathway analysis (https://string-db.org/) including clustering by Markov Cluster Algorithm (MCL) methodology to define key active pathways and interactions.

### RESULTS

311 genes had 4-fold transcriptional elevation 7d post-ablation, with 171 genes showing 4-fold expression in >4 cell types. Hepatocytes, Kupffer cells, and macrophages had 311, 158, 127 genes activated, respectively. Activated genes clustered into 14 major pathways; the largest, most-central pathways included cytokines (n=47, including Ccl2 and Ccl7), immunomodulators (n=33, including Il-6, Il-10, Ctla-4, and Pdcd-1), and growth factors (n=40, including Egf, Pdgf, and Fgf). All 10 cell types showed activation of these three pathways. Additionally, genes of angiogenesis pathways were seen in endothelial cells and hepatocytes, and increased genes for collagen production were noted for hepatic stellate cells and cholangiocytes. T-cells had notable increases in Ccl2 and Ccl7, whereas NK-cells in Il-10 and Cd86.

### CONCLUSION

RF ablation can induce persistent activation of hepatic cellular processes throughout the entire liver. Factors that can promote tumorigenesis and immunologic pathways, potentially amenable to immunomodulation, are simultaneously activated.

### CLINICAL RELEVANCE/APPLICATION

Systemic effects of hepatic RF ablation can include immune-stimulation, as well as the generation of unwanted pro-tumorigenic growth factors that can negatively impact ablation outcomes, both when used as a standalone treatment or in combination with immunotherapy. Transcriptional scRNAseq analysis following RF ablation of normal liver permits a better understanding of the microenvironment of most metastases. This technology enables the development of targeted therapies and predictive biomarkers together, which will enable tailoring personalized interventional oncology for maximum efficacy

## T3-SSIR02-2 RECALCITRANT PELVIC PAIN- EFFECTIVENESS OF PULSED RADIOFREQUENCY ABLATION FOR PUDENDAL NEUROPATHY MANAGEMENT

Yin Xi, PhD (*Abstract Co-Author*) Nothing to Disclose
Sarah Attia, BS (*Abstract Co-Author*) Nothing to Disclose

Avneesh Chhabra, MD, MBA (*Abstract Co-Author*) Consultant, ICON plc;Consultant, Treace Medical Concepts, Inc;Author with royalties, Wolters Kluwer nv;Author with royalties, Jaypee Brothers Medical Publishers Ltd;Speaker, Siemens AG;Medical Advisor, ImageBiopsy Lab;Research Grant, ImageBiopsy Lab
Zuhair Zaidi, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Pudendal neuropathy, a disabling chronic pelvic pain condition, poses challenges for patients in obtaining lasting relief and functional improvements. Surgical intervention carries risks of iatrogenic nerve injury and perineural scarring while physical therapy has shown varying efficacy and requires many sessions to achieve benefits. Alternative therapeutic options include perineural injection or pulsed radiofrequency ablation (pRFA), currently described only in case reports. This study systematically evaluated pRFA's effectiveness against perineural steroid injections alone, aiming to provide clearer insights into lasting pain management for such patients.

**METHODS AND MATERIALS**

A retrospective review was conducted on 78 pudendal neuropathy patients who were diagnosed using clinical findings, responses to perineural injections, and MR neurography (MRN). These patients underwent a total of 149 standardized CT-guided pudendal nerve pRFAs at 42 degrees Celsius for 120 seconds, between October 2020 and April 2024. This study analyzed demographic data, pain levels, quality of life, analgesic usage, duration of pain relief, and responses to personal pain relief questionnaires to evaluate functional improvements following the pRFA treatment.

**RESULTS**

There were 78 patients with pudendal neuropathy, consisting of 37 males and 41 females with an average age of 58 years and an average BMI of 27.37. The pudendal pRFA provided pain relief for 17.2 ± 26.7 weeks, significantly longer than the 6.7 ± 8.9 weeks from anesthetic injections ($p<0.05$), with a similar post-pRFA average pain score of 1.4 ± 1.9 as with injections (1.7 ± 1.5; 1.8 ± 1.8) ($p=0.9$). No complications were observed except transient urinary incontinence, lasting for 2 hours in one patient. No correlations were observed between symptom onset and treatment efficacy; however, subjective quality of life improvements ($p<0.0001$) and less analgesic use were reported post-pRFA by 6-weeks ($p<0.05$).

**CONCLUSION**

pRFA provides more sustained pain relief for patients suffering from pudendal neuropathy than perineural steroid injections alone suggesting a potential advancement in treatment options that could significantly improve the functional ability and quality of life for those affected by this condition.

**CLINICAL RELEVANCE/APPLICATION**

Clinicians are encouraged to consider pRFA for pudendal neuropathy in treatment plans, particularly for those who have not found relief with traditional methods or perineural injections alone.

## T3-SSIR02-3 EFFICACY OF GELATIN SPONGE EMBOLIZATION IN REDUCING POST-RENAL BIOPSY HEMORRHAGE AND PREDICTORS FOR BLEEDING COMPLICATIONS FOLLOWING PERCUTANEOUS RENAL BIOPSY

Bedros Taslakian, MD (*Abstract Co-Author*) Nothing to Disclose
Tarub Mabud, MD,MSc (*Abstract Co-Author*) Nothing to Disclose
Mikhail Silk, MD (*Abstract Co-Author*) Nothing to Disclose
Frederic Bertino, MD (*Abstract Co-Author*) Nothing to Disclose
Andrew Ma, BA (*Abstract Co-Author*) Nothing to Disclose
Tommy Pan, MD, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

Percutaneous renal biopsy (PRB) is the gold-standard for diagnosing kidney pathology. However, PRB carries a risk of clinically significant bleeding. This study aims to investigate the effectiveness of gelatin sponge embolization in reducing post-biopsy bleeding and highlight risk factors for bleeding complications following PRB.

**METHODS AND MATERIALS**

We performed an Institutional Review Board-approved retrospective review of the electronic medical record from 2013 to 2023 and identified patients who underwent native PRB. All PRB were performed by board-certified Interventional Radiologists or supervised IR residents/fellows. Demographic data included: age, gender, body mass index (BMI), baseline antiplatelet and/or anticoagulant use and medical comorbidities. Pre-procedural labs included: effective glomerular filtration rate (eGFR), urine protein, protein-creatinine ratio, hemoglobin/hematocrit and platelet count. Procedural data included: coaxial needle size, the use or non-use of gelatin sponge, biopsy device, number of passes, and imaging modality. Statistical analysis was performed using a logistic regression model that compared bleeding complications with gelatin sponge usage and covariates (antiplatelet/anticoagulant usage, pass number, and renal pathology).

**RESULTS**

Four hundred ninety-eight patients were studied (256 male, 242 female). The mean age was 50.1 years (SD ± 18.0 years). Gelatin sponge was used in 144 (28.9%) of patients. The average number of passes was 3.0 (SD ± 1.2). There were 94 (18.9%) incidences of bleeding complications within 30 days of the procedure, of which 29 (5.8%) required intervention with CT angiogram and transcatheter arterial embolization. Our regression model suggests that gelatin sponge usage during biopsy tract closure is not significantly associated with reduced odds of bleeding complications ($p = 0.213$). The number of passes was significantly associated with increased odds of bleeding complications ($p = 0.022$).

**CONCLUSION**

While gelatin sponge is a rapid and inexpensive embolic material, our results suggest it does not significantly reduce the incidence of clinically significant hemorrhage after PRB. The number of biopsy passes was a significant predictor of increased bleeding risk.

**CLINICAL RELEVANCE/APPLICATION**

Life-threatening renal hemorrhage following PRB has been reported up to 16%. While gelatin sponge has been reported to decrease the risk of bleeding after other IR procedures, it did not significantly decreasing the risk of bleeding after PRB.

## T3-SSIR02-4 ASSESSING THE DIAGNOSTIC ACCURACY OF TRANSPERINEAL PROSTATE BIOPSY: A RETROSPECTIVE STUDY

Soraia Damiao, MD (*Abstract Co-Author*) Nothing to Disclose
Leticia Cavalcante (*Abstract Co-Author*) Nothing to Disclose
Mariana Galupo (*Abstract Co-Author*) Nothing to Disclose

Laura S. Lima, MD (*Abstract Co-Author*) Nothing to Disclose
Luiz H. Schiavon, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the accuracy of detecting prostate cancer (PCa) through the transperineal biopsy approach, assisted by multiparametric magnetic resonance imaging (mpMRI).

**METHODS AND MATERIALS**

Retrospective, single-center study through the analysis of medical records and images from transperineal prostate biopsy examinations of male patients between 2023 and 2024. All biopsies were performed after evaluating previous MRI exams; however, some were unavailable for analysis.

**RESULTS**

The study included 58 patients with an average age of 65 years and a mean PSA value of 15.3 ng/ml. Transrectal ultrasound examination identified lesions in 62.1% of patients (36), where 50% had a circumscribed lesion. In the peripheral zone, lesions were most commonly visualized (86.1%). Among those with lesions, 66.7% (24) were diagnosed with adenocarcinoma. Of those without lesions, 54.5% (12) were diagnosed as positive. Regarding the results of the anatomopathological analysis, 58 biopsies were analyzed, and it was found that 36 patients (37.9%) did not present affected fragments, while 22 patients (62.1%) were diagnosed with adenocarcinoma. Within this group diagnosed with adenocarcinoma, there were 13 patients (36.1%) with a Gleason score of 6 (3+3), 13 patients (36.1%) with a Gleason score of 7 (3+4), 4 (11.1%) with Gleason 9 (4+5), 3 patients (8.3%) with a Gleason score of 7 (4+3), 2 (5.6%) with a Gleason score of 8 (4+4), and 1 with a Gleason score of 10 (5+5). Among the 34 patients who had available information about the results of the prostate mpMRI, it was observed that the average prostatic weight was calculated at 49.5 grams, ranging from 5 to 111 grams. The distribution of findings in the PI-RADS score revealed that 41.2% of the sample (14) had a PI-RADS score of 4, while 23.5% (8) reached a PI-RADS score of 5, 17.6% (6) had a PI-RADS score of 2, and 11.8% (4) had a PI-RADS score of 3. 32 patients showed a correlation between the findings of the mpMRI study and the biopsy findings. Comparing the results of the mpMRI with the anatomopathological findings, it was found that, among the patients classified with a PI-RADS score of 2, 3 patients (40%) were diagnosed with adenocarcinoma, 3 patients with PIRADS 3, 9 patients with PIRADS 4, and 5 patients with PIRADS 5.

**CONCLUSION**

Tranperineal has proven to be a valuable approach for detecting prostate cancer. The importance of this strategy to improve diagnostic accuracy and treatment planning is emphasized.

**CLINICAL RELEVANCE/APPLICATION**

The study's results suggest that this method effectively identifies and characterizes prostate lesions, thus improving diagnostic accuracy and becoming an alternative in cases where transrectal biopsy has contraindications.

## T3-SSIR02-5 SOFTWARE-AIDED VERSUS VISUAL INSPECTION OF INTRAPROCEDURAL MINIMAL ABLATIVE MARGINS OF PATIENTS WITH LIVER TUMORS UNDERGOING PERCUTANEOUS THERMAL ABLATION (COVER-ALL): A RANDOMIZED, INTENT-TO-TREAT, PHASE 2, SUPERIORITY TRIAL

Bruno C. Odisio, MD, PhD (*Presenter*) Research Grant, Siemens AG;Consultant, Siemens AG;Speaker, Siemens AG;Research Grant, Johnson & Johnson;

**PURPOSE**

This study evaluates the use of a novel ablation confirmation (AC) method consisting of biomechanical deformable image registration (DIR) with AI-based autosegmentation and its impact on minimal ablative margins (MAM).

**METHODS AND MATERIALS**

Patients aged 18 or older with = 3 histology-agnostic liver tumors (1-5 cm) referred to percutaneous thermal ablation (PTA) at a quaternary cancer center were enrolled in this intent-to-treat, phase 2 clinical trial. All PTAs were performed with CECT imaging guidance, aiming to achieve MAM =5mm. Intraprocedural randomization (1:1) between experimental (AC method) and control (visual inspection) arms employed Pocock-Simon dynamic allocation to balance baseline covariates. Primary endpoint was MAM quantified by the AC method using intraprocedural pre- and post-ablation CECT images. The MAM quantified by AC method on the control arm was not disclosed to the operating physician. An interim analysis for superiority at 50% patient enrollment was performed to stop control arm enrollment. The MAMs were compared using a 2-sample t-test. Secondary endpoints included assessing 2-years oncological outcomes. Adverse events (AEs) were recorded with CTCAE v5.0. The study is registered with Clinicaltrials.gov: NCT04083378.

**RESULTS**

Between June 15, 2020, and October 05, 2023, 100 patients were enrolled (57.8 years [SD ± 13.2]; 61% male; 51% colorectal liver metastasis). At interim analysis with 50 patients, mean MAM (95% CI) was 5.87 mm (4.71-7.03) on the experimental arm (n = 24) vs 2.21 mm (1.08-3.34) on the control arm (n = 26), (P < 0.001). Control arm enrollment was then halted, with subsequent 50 patients enrolled in the non-randomized experimental arm, showing a mean MAM = 7.2 mm (95% CI 6.41-8.0). Categorical MAM evaluation for the entire experimental (n = 74) vs control (n = 26) arms demonstrated: MAM = 0 mm in 4% (3/74) vs. 46.2% (12/26); MAM > 0 - < 5 mm in 14.9% (11/74) vs. 38.5% (10/26); MAM = 5 mm in 81% (60/74) vs. 15.4% (4/26), respectively. After a median 24.7-month follow-up, local disease progression was noted in 15.4% (4/26) ablated tumors in the control arm vs 4% (1/24) in the experimental randomized arm (P = 0.34). Non-randomized group's 2-year follow-up is ongoing. Grade 1-3 AEs occurred in 5 patients (2 experimental, 3 control), with no Grade 4-5 AEs.

**CONCLUSION**

Intraprocedural use of our AC method significantly improved MAM and resulted in lower local disease progression rates, warranting its adoption as a standard-of-care for patients undergoing liver PTA.

**CLINICAL RELEVANCE/APPLICATION**

Intra-procedural AC methods' direct impact on ablation efficacy is underexplored, hindering widespread acceptance. This clinical trial findings endorse integrating our AC method into liver PTA practices.

## T3-SSIR02-6 Keynote Speaker: Elucidating the Cellular and Molecular Response to Tumor Ablation

## T3-SSMK04-1 HIGH-RESOLUTION 3D CT SYNTHESIS FROM ULTRA-SPARSE VIEW X-RAY IMAGES USING 3D DIFFUSION MODELS

Xiang Li, PhD (*Abstract Co-Author*) Nothing to Disclose
Matthew T. Tivnan (*Abstract Co-Author*) Nothing to Disclose
Wen-Chih Liu (*Abstract Co-Author*) Nothing to Disclose
Jayanth Pratap (*Abstract Co-Author*) Nothing to Disclose
Quanzheng Li, PhD (*Abstract Co-Author*) Nothing to Disclose
Siyeop Yoon (*Abstract Co-Author*) Nothing to Disclose
Dufan Wu, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Despite radiation exposure and cost concerns, 3D Computed Tomography (CT) scans are the benchmark for selecting patient-specific implants and surgical planning. On the other hand, bidirectional X-rays are already a primary diagnostic tool in everyday medical practice. Recent advancements have seen generative AI models, such as diffusion models, become powerful in creating high-quality images, although generating 3D images demands significant memory, restricting resolution. In our research, we present a new method to create 3D CT images from X-ray images using an efficient 3D diffusion model. This approach aims to lessen the reliance on CT scans, provide quick access to 3D data, and reduce healthcare expenses.

### METHODS AND MATERIALS

This study included 290 patients and utilized body-part segmentation to exclude any casts. The 3D CT scans had dimensions of 256 × 256 × 160, corresponding to a resolution of 0.5 $mm^3$. We used a diffusion model, a type of generative AI that applies a diffusion process. In this process, a slight amount of noise is iteratively added to an image during the forward diffusion phase, and the model is trained to estimate noise components. To enable training of the 3D diffusion model on a single GPU, sub-regions were extracted from the X-ray images along the superior and inferior directions, using regional coordinates as conditional inputs. This training method allows the neural network to refine 3D Gaussian noise while maintaining the data's characteristics, ultimately synthesizing an image with the desired visual properties.

### RESULTS

The synthesized 3D CT images, synthesized from two X-ray images, accurately displayed the fracture at the same location as observed in the original CT scans. The synthesized 3D CT had a resolution of 0.5 mm. The time required to reconstruct was approximately 5 minutes per patient. This demonstrates the potential of the proposed generative AI model to provide accurate 3D geometric relationships between bones and fragments

### CONCLUSION

Initial results indicate that our diffusion model is capable of effectively synthesizing 3D CT volumes from bidirectional X-rays, accurately capturing the complex 3D geometric relationships. This method is designed to be computationally efficient, allowing it to be trained on a single GPU and facilitating rapid 3D CT synthetization.

### CLINICAL RELEVANCE/APPLICATION

There are multiple benefits to patients, hand surgeons, health care systems, and health care economics: (1) Patients can avoid additional radiation from CT scans; (2) simulated CT for all fractures could improve our understanding of distal radius fractures in general; (3) workflows for complex distal radius fractures would be streamlined, avoiding the delay of an additional scan.

## T3-SSMK04-2 IS RADIOGRAPHY STILL SUITABLE FOR STAGING KIENBOECK'S DISEASE? - RETROSPECTIVE ASSESSMENT OF 281 CASES WITH CONVENTIONAL RADIOGRAPHY AND COMPUTED TOMOGRAPHY

Paul Reidler, MD (*Abstract Co-Author*) Nothing to Disclose
Rainer Schmitt, MD (*Abstract Co-Author*) Nothing to Disclose
Nina Hesse (*Abstract Co-Author*) Nothing to Disclose
Hannah Elena Gildein (*Presenter*) Nothing to Disclose

### PURPOSE

Comparison of diagnostic accuracy of conventional radiography (CR) and computed tomography (CT) for classifying Kienboeck's disease according to Lichtman.

### METHODS AND MATERIALS

Retrospective analysis of 278 patients (mean age 36.57 ± 12.61, 168 male) in a consensus reading by two musculoskeletal radiologists with 10 and 35 years of experience, respectively. A total of 281 lunate necroses were classified in CR and CT imaging based on the Lichtman classification (stages I, II, IIIa, IIIb, IIIc and IV corresponded to scores 1 to 6). Statistical analyses, including Wilcoxon signed-rank test, multinominal regression model, and weighted Cohen's kappa coefficient, were performed to evaluate scores for CR and CT.

### RESULTS

The most common rated stage in CR and CT imaging was stage IIIc with 122 (43.42%) and 171 (60.85%) cases, respectively, followed by stage IIIa (24.56%) for CR and stage IV (14.59%) for the CT assessment. In 188 out of 281 cases (66.90%), Kienboeck's disease was classified the same in both CR and CT imaging. Lichtman stage had to be upgraded in CT in 96 (34.16%) cases. Kienboeck's disease stage IIIa and IIIb were upgraded to stage IIIc after CT assessment in 24 (34.78%) and 23 (60.53%) cases, respectively. Overall, Kienboeck's disease was scored significantly higher in CT than in CR imaging (CT vs. CR: 4.66 (stage IIIc) ± 1.06 vs. 4.12 (stage IIIb) ± 1.23, $p < 0.001$). After adjusting for age, gender, affected hand side and time difference between CT and X-ray, there is a significant 2.05-fold increased likelihood for classifying Lichtman stage 3c with CT compared to CR.

### CONCLUSION

CT imaging is significantly more accurate than CR in determining the exact osseous stage of Kienboeck's disease.

### CLINICAL RELEVANCE/APPLICATION

In more than one third of the cases, the disease stage was upgraded in CT imaging, most commonly to stage IIIc, indicating a potential shift in therapy towards more destructive salvage procedures.

## T3-SSMK04-3 GANTRY-FREE CONE-BEAM CT ARTHROGRAPHY OF THE WRIST FOR FAST ONE-STOP-SHOP IMAGING OF SCAPHOLUNATE LIGAMENT TEARS

Henner Huflage, MD (*Abstract Co-Author*) Nothing to Disclose
Andreas Kunz, MD (*Abstract Co-Author*) Nothing to Disclose
Jan P. Grunz, MD (*Abstract Co-Author*) Research Consultant, Siemens AG
Theresa Sophie Patzer, MD (*Abstract Co-Author*) Nothing to Disclose
Karsten Luetkens, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Modern x-ray systems are capable of high-resolution cone-beam CT (CBCT) imaging in addition to radiography and fluoroscopy. Combining different modalities in a multi-purpose setup holds potential for musculoskeletal interventions like CBCT arthrography. This study investigates the diagnostic performance of CBCT arthrography in patients with suspected scapholunate ligament (SLL) tears.

### METHODS AND MATERIALS

In this retrospective investigation, consecutive patients with acute wrist trauma and suspected SLL injuries who underwent CBCT arthrography with a multi-use x-ray system were enrolled between June 2021 and March 2024. Three radiologists independently assessed all examinations for tears of the palmar and dorsal SLL segments. Surgical reports served as the reference standard for calculating indicators of diagnostic performance and interreader reliability was analyzed by computing Krippendorff a. Radiation dose and examination time were recorded.

### RESULTS

A total of 47 patients (mean age, 44.94 ± 15.77 [SD] years, 25 men) were included. Injuries of the palmar and dorsal SLL segment found recorded in 19 individuals (40%) and 5 patients (11%), respectively. CBCT arthrography facilitated good sensitivity (range for all readers, 79-89%) and excellent specificity (93-96%) in the diagnostic assessment of the palmar SLL. For the dorsal SLL, sensitivity (80-100%) and specificity (95-98%) were even higher. Substantial interreader agreement was determined for both the palmar (a = 0.78, 95% CI: 0.68, 0.89) and dorsal SLL segments (a = 0.81, 95% CI: 0.65, 0.94). The dose-area product for CBCT arthrography was established at 106.6 ± 48.0 mGy*cm2 and the volume CT dose index was 3.4 ± 1.4 mGy. Without patient repositioning in between required, the median time between the final contrast injection and CBCT was 3:07 min (2:32-3:50 min).

### CONCLUSION

CBCT arthrography allows for excellent diagnostic performance in the detection and exclusion of SLL tears with low radiation dose and short examination times.

### CLINICAL RELEVANCE/APPLICATION

The ability to alternate between fluoroscopy and 3D imaging without patient repositioning facilitates a "one-stop-shop" approach for CBCT arthrography of the wrist with minimal examination time.

## T3-SSMK04-4 SUPPRESSION OF IMMOBILIZATION DEVICE ON WRIST RADIOGRAPHY TO IMPROVE FRACTURE VISUALIZATION

Hyemin Park (*Abstract Co-Author*) Nothing to Disclose
Seung Eun Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Keum San Chun, PhD (*Abstract Co-Author*) Nothing to Disclose
Joon-Yong Jung, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Sungwon Lee, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study validates CycleGAN-generated splint-suppressed wrist radiographs, specifically focusing on fracture visualization.

### METHODS AND MATERIALS

We retrospectively collected 1748 patients who had wrist radiographs before and after immobilization device (splint) application. The dataset was divided into training (1696 patients with 5353 images) and testing sets (52 patients with 965 images). A CycleGAN-based model was trained to generate wrist radiographs with digitally removed splint densities (splint-suppressed wrist radiographs) from splint-applied radiographs. Two radiologists scored the generated splint-suppressed test set images for remaining splint density, hardware distortion, anatomical distortion, fracture clarity, and new artifacts using pre-defined semi-quantitative criteria. Subtraction images were created to quantify overall image alteration. A pre-trained YOLO8s fracture detection model was employed to assess fracture detection performance on three image groups of the test set: radiographs before splint application (original splint-less radiographs), splint-applied radiographs (original splint radiographs), and CycleGAN-generated splint-suppressed radiographs.

**RESULTS**

CycleGAN effectively generated splint-suppressed radiographs with minimal remaining splint density (97.99% had <10% remaining), hardware distortion (<10% in 100%), anatomy distortion (<10% in 99.63%), and fracture lesion changes (<10% in 100%). New artifacts were rarely introduced (absent in 97.54% of images). Importantly, the fracture detection model achieved improved precision (0.94 vs 0.92), recall (0.63 vs 0.5), and F1 score (0.75 vs 0.65) on the generated splint-suppressed images compared to the original splint radiographs, approaching the performance of the original splint-less radiographs (F1 0.71). Additionally, larger image alterations by CycleGAN corresponded to greater improvements in fracture detection.

**CONCLUSION**

CycleGAN successfully suppressed the density of splints from splint-applied wrist radiographs. Furthermore, the generated splint-suppressed radiographs enhanced the performance of wrist fracture detection in a pre-trained fracture detection model.

**CLINICAL RELEVANCE/APPLICATION**

This approach has the potential to improve fracture assessment in splint-applied patients.

## T3-SSMK04-5 ABSENCE OF T2 SIGNAL VOID IN VERTEBRAL ARTERY ON CERVICAL SPINE MRI IN TRAUMA PATIENTS: ASSOCIATED INJURIES AND OUTCOMES

Taeran Ahn, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the characteristics of cervical spine trauma patients with absence of T2 signal void in the vertebral artery (VA) on cervical spine MRI and evaluate the association between this finding and actual VA injury and subsequent brain infarction in the corresponding VA territory.

**METHODS AND MATERIALS**

This retrospective study analyzed 683 cervical spine MRI scans of acute trauma patients in a tertiary hospital with a regional trauma center from 2019 to 2023. Cases with absence of T2 signal void in the VA were identified, and injury characteristics were assessed. Angiography (CT angiography or conventional angiography) and brain MRI validated the absence of T2 signal void as an indicator of VA injury and brain infarction. Logistic regression analysis evaluated the relationship between injury characteristics and brain infarction, while descriptive statistics were used for bilateral VA involvement due to the small number of cases.

**RESULTS**

Forty-one patients (median age 60.0; 36 males) were included. Primary injury mechanisms were traffic accidents (48.8%), falls (36.5%), and being struck by an object (9.8%). T2 signal void absence was predominantly unilateral (95.1%). Most injuries were in the lower cervical spine (73.2%), with distraction being the most common morphology (26.8%). Coexisting disco-ligamentous complex (DLC) disruptions and cervical cord injuries occurred in 41.5% and 61%, respectively. VA occlusions and brain infarctions were confirmed in 43.9% and 29.3% of cases. Increased brain infarction risk was associated with distraction (OR=7.50, p=0.035), rotation/translation (OR=10.00, p=0.014), DLC disruption (OR=7.50, p=0.032), and spinal cord injury (OR=10.00, p=0.020). Bilateral VA involvement was observed in two patients, both developing brain infarction.

**CONCLUSION**

The absence of T2 signal void in the VA on cervical spine MRI is a notable indicator of vascular injury in trauma patients and is frequently associated with brain infarction. When accompanied by high-risk injury characteristics, such as severe injury morphology, DLC disruption, spinal cord injury, and bilateral VA involvement, focused consideration for brain MRI screening is warranted to assess for ischemic complications.

**CLINICAL RELEVANCE/APPLICATION**

Identifying the absence of T2 signal void in the VA on cervical spine MRI and recognizing high-risk injury patterns may help guide prompt treatment and prevent ischemic complications in trauma patients.

## T3-SSMK05-1 DIAGNOSTIC UTILITY OF PUBIC SYMPHYSEAL BIOPSY IN MALE PATIENTS WITH SUSPECTED OSTEOMYELITIS/SEPTIC ARTHRITIS

Jeremiah R. Long, MD (*Abstract Co-Author*) Nothing to Disclose
Motoyo Yano, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nicholas G. Rhodes, MD (*Abstract Co-Author*) Nothing to Disclose
Logan Haug, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the diagnostic utility of pubic symphyseal bone biopsy in the setting of suspected (PS) infection in male patients.

### METHODS AND MATERIALS

A multi-site retrospective study of male patients with pelvic CT or MR over a ten-year period within a single institution was performed. The radiology report database was searched for 13 key phrases such as “pubic symphyseal osteomyelitis” to identify suspected PS infections and puboprostatic fistulas (PPF). Findings were confirmed on imaging review by two musculoskeletal radiologists. All PS CT-guided and surgical biopsy culture results were recorded and considered positive based on growth of one or more organisms. Changes in clinical management were based on two criteria: 1) identification of an organism not seen in blood or urine within 1 month of biopsy and 2) change in the antibiotic regimen after sampling. Descriptive statistics, Fisher’s exact test and odds ratios were calculated using GraphPad Prism 10.

### RESULTS

69 of 112 patients underwent PS sampling: 37 CT-guided, 32 surgical, and 15 both. 22 patients had CT guided biopsy only, 9/22 (41%) with positive culture, 6 (27%) of which were management altering. 32 patients had surgical sampling only, 27/32 (84%) with positive culture, 22/32 (69%) of which were management altering. There is a nearly 8 times greater odds of obtaining a positive culture from surgical compared to CT guided sampling (OR 7.8, 95% CI 2.08-26.75, $p<0.01$). Surgical sampling results in nearly 6 times greater odds of management alteration (OR 5.9, 95% CI 1.8-17.6, $p<0.01$). Of the 15 patients undergoing both methods of sampling, 8 had negative culture with CT; 7/8 had subsequent positive culture with surgical sampling. 7/15 with positive culture on CT also had positive culture with surgical sampling. 6 of 37 patients had aspiration in addition to bone biopsy at the time of CT-guided sampling, 5 of which (83%) had positive cultures and 3 of which demonstrated pathogens not identified in bone. There was no significant association between PPF and culture positivity, however only 2/16 positive CT biopsies occurred in the absence of PPF.

### CONCLUSION

Surgical biopsies were significantly more likely to result in positive culture and lead to management change compared to CT guided biopsy. Aspiration at the time of CT guided procedure may increase yield of positive culture.

### CLINICAL RELEVANCE/APPLICATION

CT guided biopsy of PS infection has lower yield of organism identification than surgical sampling and may not be necessary if surgical intervention is planned.

## T3-SSMK05-2 UTILITY OF CALF MRI IN SUSPECTED LOWER EXTREMITY CELLULITIS

Andrew B. Ross, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Monica M. Cooley, MD (*Abstract Co-Author*) Nothing to Disclose
John S. Symanski, MD (*Abstract Co-Author*) Nothing to Disclose
Ian Kuckelman, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the yield of MRI of the calf for detecting complications of soft tissue infection and to identify risk factors predictive of MRI positivity.

### METHODS AND MATERIALS

We identified MRIs of the calf in adult Emergency Department and inpatients with suspected cellulitis between 01/01/2020 and 02/03/2024. The primary endpoint was identification of abscess or deep infection (fasciitis, myositis, or osteomyelitis). Data on clinical history, physical examination findings,

laboratory and culture results, imaging findings, and treatment were collected. Descriptive and secondary statistical analyses were performed to determine clinical and serologic factors associated with a positive MRI.

**RESULTS**

Our search identified 48 MRIs in 45 patients. The mean age was 60 (range 19-89) and 32 (71%) were male. Of the 48 studies, presenting complaints included pain (39/48, 81%), redness (36/48, 75%), fever (17/48, 35%), wounds or ulcerations (39/48, 81%), and/or evidence of sepsis (8/48, 17%). MRIs showed subcutaneous edema in 44 cases (92%) and were read as concerning for cellulitis in 32/48 cases (67%). 9/48 MRIs were positive (defined as showing suspected complications of infection, either a fluid collection or osteomyelitis); of those, fluid collections were found in 6 (13%) and suspected osteomyelitis in 3 (6%). 4/6 potential abscesses were sampled; of those, 3 were culture negative and one grew Citrobacter Koseri. Surgical biopsy was performed in 1/3 suspected osteomyelitis cases and was culture negative; the other two cases were unsampled and treated empirically. Only a history of ipsilateral surgery showed a significant association with a positive MRI (p=0.002). Specifically, a complicated infection was shown in 7/14 (50%) cases with ipsilateral surgery (3 cases of osteomyelitis and 4 cases of abscess) but in only 2/34 (6%) of cases without surgery (2 cases of abscess). Positive blood cultures and elevated serologies including WBC, ESR, and CRP were not significantly associated with a positive MRI. Almost all patients were treated with antibiotics(46/48, 95%) while surgical treatment of infection was rare (5/48, 10%) and occurred only in patients with a prior surgical history at the site.

**CONCLUSION**

In the absence of prior surgery, MRI of the calf is of low yield to detect abscess or deep infection in a patient with cellulitis.

**CLINICAL RELEVANCE/APPLICATION**

In patients with cellulitis and no history of prior surgery in the ipsilateral lower extremity, MRI of the calf is of low yield for identifying abscess or osteomyelitis.

## T3-SSMK05-3 ULTRASOUND-GUIDED HISTOTRIPSY FOR NON-INVASIVE TREATMENT OF SOFT TISSUE SARCOMA: FEASIBILITY STUDY

Steven B. Soliman, DO (*Abstract Co-Author*) Consultant, General Electric Company;Speaker, General Electric Company
Gunjan B. Malhotra, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose/objective is to assess the feasibility of using ultrasound (US)-guided histotripsy to treat various histotypes of excised human musculoskeletal benign masses and malignant soft tissue sarcomas (STS). Treatment was tracked with B-mode and shear wave elastography (SWE) imaging, then evaluated with hematoxylin and eosin (HE) histology. Analysis proved treatment of all samples.

**METHODS AND MATERIALS**

Histotripsy was delivered to 43 surgically excised human samples with a custom 1 MHz 8-element histotripsy US transducer using 1-cycle pulses at 100 Hz pulse-repetition frequency for 50 pulses per focal location and 0.5 mm spacings with peak negative pressure greater than 30 MPa. Histotripsy treatments were guided by B-mode US. SWE and B-mode were both collected pretreatment and posttreatment to evaluate the lesions. Following treatment, samples were processed for histologic analysis to evaluate damage generated by histotripsy.

**RESULTS**

Histotripsy created identifiable treatment across all histotypes, including liposarcomas, fibrous aggressive sarcomas, and various dedifferentiated sarcomas. B-mode imaging showed hypoechoic regions where treatment occurred and SWE measurement showed a 30-90% decrease in shear modulus of non-lipomatous tumors posttreatment, however, the shear modulus did not significantly change for lipomatous tumors. B-mode and SWE were shown to effectively identify the treatment by comparing pre and post treatment imaging.

**CONCLUSION**

US-guided histotripsy treatment resulted in effective STS necrosis in the treatment zone across multiple different sarcoma histotypes. There was an associated decrease in shear modulus measured by US SWE in histotripsy-treated non-lipomatous tumors, compared to no significant change in lipomatous tumors. Findings reflect differences in pre-treatment and post-treatment tissue stiffness based on the original tissue subtype.

**CLINICAL RELEVANCE/APPLICATION**

Currently, many STS histotypes are resistant to various forms of treatment including radiation, chemotherapy, and immunotherapy. Complete surgical excision is sometimes impossible. High Intensity Focused Ultrasound (HIFU) has limitations due to the off-target damage and slow treatment speed. Histotripsy utilizes microsecond-length, high-pressure ultrasound pulses to generate cavitation capable of mechanically liquefying tissue to acellular homogenate which the body then clears. Furthermore, histotripsy's precise targeting and tissue-selective ablation prevents off-target damage rendering it an ideal treatment method.

## T3-SSMK05-4 TRANSPEDICULAR-TRANSDISCAL CEMENT AUGMENTATION TECHNIQUE IN THE TREATMENT OF PROXIMAL JUNCTIONAL SPINAL FUSION HARDWARE FAILURE - A 5-YEAR FOLLOW UP

Mary E. Buchanan, MD (*Abstract Co-Author*) Nothing to Disclose
Corey K. Ho, MD (*Abstract Co-Author*) Nothing to Disclose
MK Lowry, MD (*Abstract Co-Author*) Faculty, Medtronic plc
David C. Gimarc, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Spinal deformity and degenerative disc disease can be surgically treated with fusion constructs, which can be extensive. Due to forced rigidity throughout the fused levels, the proximal junctional level is most prone to accelerated disc and endplate breakdown including hardware failure, and can cause pain, functional limitations, and the need for further revision. We report a novel technique describing a transpedicular-transdiscal approach of vertebral cement augmentation (VCA) at the proximal junctional level, and present a larger cohort over half a decade including longer-term follow-up and technical experience.

**METHODS AND MATERIALS**

We identified 45 patients undergoing 46 unique procedures of fluoroscopic-guided transpedicular-transdiscal VCA at the proximal junctional levels of their hardware fusion at our institution between 2016-2023. Cases were retrospectively reviewed in our EMR and PACS databases to identify their clinical presentation including timing of fusion and subsequent failure, procedure specifics, and follow-up course including the need for further spinal hardware revision.

### RESULTS

Cases were performed most commonly at the mid thoracic (n=34, 73.9%), and upper thoracic and lumbar regions (each n=6, 13.0%). Hardware failure was identified by imaging a median of 43.5 days after the surgical fusion (range 4-1250 days). Patients experienced an average VAS pain reduction of 2.2 between pre- and post-procedural assessments. Patients had an average of nearly 2 years of follow-up data (565 days; range 9-2480 days). 10 patients (21.7%) required further surgical revision 49-1178 days (mean 393, median 202 days) after the primary VCA procedure due to continued pain, kyphosis, and progressive junctional breakdown.

### CONCLUSION

Transpedicular, transdiscal VCA is a safe and effective procedure that can treat proximal junctional level failure in spinal fusion patients. This can delay and possibly avoid the need for subsequent revision surgery.

### CLINICAL RELEVANCE/APPLICATION

The early recognition of proximal junctional failure/kyphosis with spinal fusion constructs is an important diagnostic indicator of failing hardware, and can progress to further complications and revision. Our novel VCA technique has been shown to effectively treat symptoms and reduce further breakdown in many patients, avoiding or delaying the need for subsequent surgical revision.

## T3-SSMK05-5 CT-GUIDED PERINEURAL STEROID INJECTIONS AND CONTINUOUS FREQUENCY ABLATIONS FOR GENITOFEMORAL NEURALGIA WITH A HISTORY OF INGUINAL HERNIA: WHICH ONE IS BETTER?

Avneesh Chhabra, MD, MBA (*Abstract Co-Author*) Consultant, ICON plc;Consultant, Treace Medical Concepts, Inc;Author with royalties, Wolters Kluwer nv;Author with royalties, Jaypee Brothers Medical Publishers Ltd;Speaker, Siemens AG;Medical Advisor, ImageBiopsy Lab;Research Grant, ImageBiopsy Lab
Alex Iancau, BS (*Abstract Co-Author*) Nothing to Disclose
Flavio Duarte Silva (*Abstract Co-Author*) Nothing to Disclose
Sarah Attia, BS (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to evaluate the utility and efficacy of CT-guided perineural injections and continuous radiofrequency ablations (cRFA) for the treatment work-up for clinically suspected genitofemoral neuralgia confirmed on MR neurography (MRN) for patients with a history of inguinal hernia diagnosis and repair. Our hypothesis was that cRFA is therapeutically more effective than the perineural injection alone.

### METHODS AND MATERIALS

In this retrospective cross-sectional study, electronic medical records were searched for patients with a history of an inguinal hernia who had underwent MRN between the years of 2014 to 2024 for clinically suspected genitofemoral neuralgia. A consecutive series of 31 patients were included. Patient demographics, pain location/level/duration, previous work-up for the same indication, MRN imaging results, and work-up after MRN were noted. Patients who have a history of inguinal hernia diagnosis and repair as well as CT-guided perineural steroid injection or CT-guided cRFA treatment plus perineural steroid injection were included. Final diagnosis of genitofemoral neuropathy was made by multiple diagnostic criteria, including clinical symptoms and response to therapy. Treatment choice and their success rates were evaluated. Descriptive statistics were derived.

### RESULTS

Among 31 patients included, 7 (21.9%) were women and 24 were men (75%) of ages 55+/-16.31. All had good quality imaging studies without motion degradation. All 31 patients had inguinal hernia and all 31 had subsequent MRN work-up, yet only 27 (87.1%) of the patients had a history of inguinal hernia repair. All 31 (100%) patients were treated with CT guided perineural steroid injections and among them- 6 (19.4%) were followed up with cRFA. On average, it took 85.8+/- 112.6 days for the pain to return post perineural steroid injection. The pain improved significantly by -6.1+/-3.9 pain levels on a visual analogue scale of 1-10 (p-value = 6.72E-10). On an average, it took 117.8+/- 109.4 days for the pain to return post RFA. The pain improved significantly by -7.2 +/- 6.8 pain levels (p-value = 0.020) after RFA. There was not a statistically significant difference between the pain improvement (p-value = 0.59) or the time for the pain to return (p-value = 0.87) between CT guided perineural steroid injection and RFA.

### CONCLUSION

Both CT-guided perineural injection and RF ablation are similarly therapeutically effective for genitofemoral neuralgia related to inguinal hernia and its post-hernia repair complications.

### CLINICAL RELEVANCE/APPLICATION

Depending upon patient preferences, either CT-guided perineural injection or RFA can be used for targeted treatments for genitofemoral neuralgia related to inguinal hernia.

## T3-SSMK05-6 MSKI-RADS: AN MRI-BASED MUSCULOSKELETAL INFECTION REPORTING AND DATA SYSTEM FOR THE DIAGNOSIS OF EXTREMITY INFECTIONS

William B. Morrison, MD (*Abstract Co-Author*) Co-founder, Trace Orthopedics;Patent agreement, Trace Orthopedics;Consultant, AprioMed AB;Patent agreement, AprioMed AB;Consultant, Centinel Spine, LLC;Consultant, Medical Metrics, Inc

Karim Salhadar (*Abstract Co-Author*) Nothing to Disclose
Flavio Duarte Silva (*Abstract Co-Author*) Nothing to Disclose
Angela He, BS, BA (*Presenter*) Nothing to Disclose

### PURPOSE

Current terms used to describe MRI findings for musculoskeletal (MSK) infections are nonspecific and inconsistent. Thus, it is critical to create a RADS system for reporting them. The purpose of the study is to develop and validate a musculoskeletal infection classification and MRI-based scoring system.

### METHODS AND MATERIALS

In this retrospective cross-sectional internal validation study, Musculoskeletal Infection Reporting and Data System (MSKI-RADS) was designed. Adult patients of all genders with radiographs and MRI studies for suspected extremity infections between June 2015 and May 2019 were randomly included

with a known reference standard. The scoring categories included: 0 - incomplete imaging, I - negative for infection, II - superficial soft tissue infection, III - deeper soft tissue infection, IV - possible osteomyelitis (OM), V - highly suggestive of OM and/or septic arthritis, VI - known OM, NOS - nonspecific bony lesions. Twenty MSK readers from 13 institutions performed validation. Interreader agreement (intraclass correlation coefficient (ICC)), sensitivity of MSKI-RADS were calculated and accuracies of final diagnoses rendered by readers were compared using generalized estimating equations for clustered data.

**RESULTS**

Among 208 total radiographic and MRI image sets from 208 unique patients, male:female ratio was 63.9:36.1 with average age± SD of 55.1 ± 12.6 years and 55.1 ± 14.4 years, respectively. There was 20 Class I, 34 Class II, 35 Class III, 30 Class IV, 35 Class V, 18 Class VI, and 36 NOS. Moderate interreader agreement was observed among 20 readers (ICC: 0.7; 95% CI: 0.66, 0.75). There was no evidence of correlation between reader experience and overall accuracy (P = 0.94). Highest sensitivity was for MSKI-RADS I and NOS at 88.7% (95% CI: 84.6%, 91.7%). Sensitivity was 72.6% (95% CI: 63.4%, 80.1%) for MSKI-RADS V. Overall reader accuracy using MSKI-RADS across all patients was 64.9%±4.7%, higher than final reader diagnoses at 54.8%±6.8% (P<.001).

**CONCLUSION**

MSKI-RADS is a valid, reliable system for standardized terminology and recommended management of imaging findings of peripheral extremity infections across various MSK-fellowship-trained reader experience levels.

**CLINICAL RELEVANCE/APPLICATION**

By reducing confusion and minimizing usage of misleading terms, MSKI-RADS offers the potential to improve inter-disciplinary communication when treating patients with peripheral extremity infections. Its use can aid in efficient management decisions, improved patients outcomes, and better longitudinal collection of data for future research.

## T3-SSMS02-1 RADIOLOGY-PATHOLOGY CORRELATION: A SAFEGUARD AGAINST MISSED CANCER DIAGNOSIS IN CT-GUIDED OMENTAL AND MESENTERIC BIOPSIES

Francesca Rigiroli, MD (*Abstract Co-Author*) Nothing to Disclose
Olga R. Brook, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Alexander Brook, PhD (*Abstract Co-Author*) Nothing to Disclose
Lutfullah Sari, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze rate of malignancy on follow-up of concordant, discordant, and indeterminate non-malignant results of CT-guided mesenteric and omental biopsies.

### METHODS AND MATERIALS

In this retrospective, IRB-approved study, consecutive patients undergoing CT-guided omental biopsy between March 2005 and August 2021 were included. Concordance between pathology results and imaging findings was assessed by procedural radiologists. Definitions: concordant, for malignant biopsy results or benign pathology where imaging findings agree; discordant, if pathology results were not congruent with imaging; and indeterminate, if imaging could be explained by pathology, but could also reflect malignancy. Rate of malignancy and time to diagnosis were determined for each category. The tissue density was determined by drawing an ROI at the level of the targeted biopsy area encompassing the maximum possible area within the lesion.

### RESULTS

204 omental and mesenteric biopsies were included. Pathology showed non-malignant result in 41/204 (20%), further classified by radiology-pathology concordance evaluation as discordant in 24/41 (59%), indeterminate in 7/41 (17%), and concordant in 10/41 (24%). The prevalence of malignancy on follow-up was higher in discordant (13/24, 54%) and indeterminate (2/6, 33%) groups vs. concordant cases (0%), p<.001. There were 15/41 (37%) patients with final diagnosis of malignancy that would have been missed if radiology-pathology concordance evaluation had not been performed. The discordant and indeterminate groups demonstrated lower median lesion density (-63 HU, IQR -76- -41 and -53 HU, IQR -62- -46, respectively) and infiltration percentage (10%, IQR 10-10 and 10%, IQR 10-30, respectively) compared to the concordant group (-37 HU, IQR -48- -12 and 30%, IQR 10-35) (p= 0.02 and p= 0.01, respectively). Median time to diagnosis was shorter with repeat biopsy (18 days, IQR 9-34) and surgery (38 days, IQR 17-63) vs. imaging (185 days, IQR 107-239) and clinical follow-up (330 days, IQR 240-373), p<.001.

### CONCLUSION

The prevalence of malignancy was high in discordant (54%) and indeterminate (33%) cases of radiology-pathology concordance. Routine radiology-pathology concordance evaluation prevented missed cancer diagnosis in 37% of patients with non-malignant pathology result of the index CT-guided omental and mesenteric biopsies.

### CLINICAL RELEVANCE/APPLICATION

Implementing a standardized radiology-pathology concordance assessment can identify patients who are at risk for missed malignancy.

## T3-SSMS02-2 INDICATORS OF NEAR-INFRARED SPECTROSCOPY (NIRS) AND CT PERFUSION OF THE LIVER AFTER LIVING DONOR LIVER TRANSPLANTATION

Adham Ikramov (*Abstract Co-Author*) Nothing to Disclose
Ravshan Ibadov (*Abstract Co-Author*) Nothing to Disclose
Azimjon Usmonov (*Abstract Co-Author*) Nothing to Disclose
Khanum V. Abdukhalimova, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nigora Djuraeva, MD, PhD, DSc (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the relation between oxygenation parameters and CT perfusion of liver tissue in the early postoperative period in patients undergoing liver transplantation from living related donors.

**METHODS AND MATERIALS**

A single-center study was conducted from 2022 to 2024 on recipients of 96 liver transplantation from living related donors. All patients underwent continuous monitoring of regional liver tissue oxygen saturation (LSrO2) using NIRS (Equanox™ device with 3 and 4 wavelengths (Nonin Medical, Plymouth, Minnesota)) within the first 24 hours after surgery, with the NIRS sensor attached to the level of the liver allograft. One week after surgery, CT perfusion parameters of the liver (AF-arterial flow (ml/100ml³/min), PF-portal flow (ml/100ml³/min)) were determined using a 640-slice wide-detector computed tomography. To assess the correlation between the indicators, a Pearson correlation analysis was conducted.

**RESULTS**

The average LSrO2 value in all patients in the first hours of observation was 73±4.5, then by 24 hours of observation it reached 75±4.3. For the group of patients without postoperative complications, conditional normal levels of CT perfusion parameters were determined: AF - 34.47±9.27 ml/100ml³/min, PF - 153.55±4 ml/100ml³/min, which correlated with LSrO2 values at 24 hours (r=0.376 and r=0.437). After surgery, vascular complications were observed in 15 patients (15.6%), including arterial complications in 11 patients (11.4%) and venous complications in 3 patients (3.1%). The mean LSrO2 value in these patients was 48±3.2. CT perfusion parameters, expressed as AF and PF indexes, did not have significant correlation with LSrO2 at 24 hours (r=0.095 and r=0.059). However, within 1 week of the postoperative period, recipients with thrombotic complications experienced changes in perfusion parameters: the mean AF values were 21.8±0.6 ml/100ml³/min, PF - 185.6±4.7 ml/100ml³/min.

**CONCLUSION**

Reduction LSrSO2 levels in liver tissue may serve as a predictor of vascular complications in liver transplant recipients, confirmed by a decrease in AF perfusion and an increase in PF compared with without postoperative interventions.

**CLINICAL RELEVANCE/APPLICATION**

NIRS combined with CT liver perfusion is a new monitoring tool that provides valuable information on hepatic blood flow and oxygenation immediately after liver transplantation. It can be easily practiced and interpreted, but more research is still recommended for its use.

## T3-SSMS02-3 IMPLICATIONS OF VIRTUAL REALITY IN RADIOLOGY: PRESENT AND FUTURE APPLICATIONS - A SYSTEMATIC REVIEW

Hamid Chalian, MD (*Abstract Co-Author*) Nothing to Disclose
Seyedali Nabipoorashrafi, MD (*Abstract Co-Author*) Nothing to Disclose
Arash Bedayat, MD (*Abstract Co-Author*) Nothing to Disclose
Soheil Kooraki, MD (*Abstract Co-Author*) Nothing to Disclose
Christopher Zaki, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Virtual reality (VR) is ushering in a new era across various medical domains, offering promising applications ranging from education to treatment. As VR technology rapidly evolves, it's crucial to stay abreast of its implications, particularly in the field of imaging. This study systematically reviews the literature to assess the latest developments and potential impacts of VR in radiology.

**METHODS AND MATERIALS**

We conducted a systematic search of PubMed and Google Scholar using a predefined search string encompassing keywords related to "radiology" and "virtual reality." This search aimed to comprehensively gather relevant literature pertinent to our study objectives. Following predefined inclusion criteria, we conducted data extraction using structured sheets.

**RESULTS**

Our review revealed that VR is revolutionizing multiple aspects of radiology. It notably enhances education and training by simulation-based learning, thereby augmenting the skills of medical professionals. In procedural accuracy, particularly in interventional radiology, VR offers real-time guidance, ensuring precise navigation during complex procedures and ultimately improving patient outcomes.Moreover, VR facilitates connectivity and collaboration in healthcare by enabling telemedicine and remote consultations. This breaks down geographical barriers, promotes interdisciplinary teamwork, and facilitates knowledge exchange among professionals. Additionally, VR streamlines workstation tasks for radiologists, optimizing workflow efficiency and enhancing image interpretation and analysis speed and accuracy.

**CONCLUSION**

Our systematic review underscores the potential transformative impact of VR on various aspects of radiology. As VR technology continues to advance, it presents promising opportunities for further innovation and enhancement within the field, promises a future of improved patient care and outcomes.

**CLINICAL RELEVANCE/APPLICATION**

With the increasing demand for imaging and the need for radiologists, VR-dependent technology not only improves workstation efficacy but also potentially enhances accuracy and facilitates remote working.

## T3-SSMS02-4 COMPARING QIBA CTVOL CLASSIFICATIONS WITH RECIST RESPONSE CATEGORIES

Daniel C. Sullivan, MD (*Abstract Co-Author*) Nothing to Disclose
Lawrence H. Schwartz, MD (*Abstract Co-Author*) Nothing to Disclose
Nancy A. Obuchowski, PhD, MS (*Abstract Co-Author*) Research Consultant, Siemens AG;Research Consultant, IBM Corporation;Research Consultant, Elucid Bioimaging Inc;Research Consultant, Takeda Pharmaceutical Company Limited

Hao Yang (*Abstract Co-Author*) Nothing to Disclose
Binsheng Zhao, DSc (*Presenter*) Royalties, Varian Medical Systems, Inc;License agreement, Keosys SAS;License agreement, Hinacom Software and Technology, Ltd;

**PURPOSE**

CT volumetry provides more reproducible measurements of tumor size compared to unidimensional RECIST, enabling better estimation of changes in tumors over time. However, the lack of data validating tumor volumetry as a response assessment biomarker has hindered widespread adoption. The purpose of this study was to assess agreement between CT volumetry change classifications derived from QIBA Profile cut points (i.e., QIBA CTvol classifications) and the RECIST categories.

## METHODS AND MATERIALS

Target lesions in lung, liver, and lymph nodes were randomly chosen from patients in 10 historical phase III clinical trials for various cancer types, ensuring a balanced representation of lesion types, diameter ranges described in the QIBA Profile, and variations in diameter change magnitudes. Three radiologists independently segmented these lesions at baseline and follow-up scans using two different software tools. Two types of disagreements were assessed: (i) substantive disagreement, where the disagreement between QIBA CTvol classifications and RECIST categories could not be attributable to improved sensitivity with volumetry, and (ii) disagreement potentially due to improved sensitivity with volumetry. The proportion of lesions with disagreements between QIBA CTvol and RECIST, as well as type of disagreements, was reported along with 95% CIs, both overall and within subgroups representing various factors.

## RESULTS

2,390 measurements from 478 lesions (158 lung, 170 liver, 150 lymph node) in 281 patients were included. QIBA CTvol agreed with RECIST in 66.6% of interpretations, while 33.4% showed discrepancies, categorized as substantive disagreement (i) in 1.5% (95% CI: [0.8%, 2.1%]) and disagreement type (ii) in 31.9%. Scanner vendor (p=0.584), segmentation tool (p=0.331), and lesion type (p=0.492) were not significant predictors of disagreement. However, significantly more disagreements were observed for larger lesions (>=50mm, as per the large size category defined in the QIBA Profile).

## CONCLUSION

We conclude that QIBA CTvol classifications agree with RECIST categories.

## CLINICAL RELEVANCE/APPLICATION

Validation of QIBA CTvol classifications facilitates the use of precise CT volumetry, which is crucial for tracking tumor changes, improving treatment assessment, and guiding clinical decision-making.

## T3-SSNR07-3 WHITE MATTER ABNORMALITIES IN CHILDREN WITH TYPE 2 AND 3 SPINAL MUSCULAR ATROPHY: A DTI-BASED WHITE MATTER MICROSTRUCTURE AND NETWORK ANALYSIS

Yujian Liang (*Abstract Co-Author*) Nothing to Disclose
Pei Xiang (*Abstract Co-Author*) Nothing to Disclose
Yingqian Chen (*Abstract Co-Author*) Nothing to Disclose
Huirong Nie (*Presenter*) Nothing to Disclose

### PURPOSE

Spinal muscular atrophy (SMA) is an autosomal recessive disorder caused by a mutation in the survival motor neuron 1 (SMN1) gene on chromosome 5 that results in reduced expression of survival motor neuron (SMN) protein. Although this disease is characterized by progressive muscle weakness and atrophy, previous studies indicated SMA is a multisystem disease. Moreover, evidence from SMA patients and animal models suggests that it causes not only lower motor neuron degeneration but also extensive brain involvement. In this study, we aimed to investigate the changes in brain white matter microstructure and network by using diffusion tensor imaging (DTI) in children with type 2 and 3 SMA.

### METHODS AND MATERIALS

Forty-two type 2 and 3 pediatric patients and 42 age- and gender-matched healthy controls were enrolled in this study. The tract-based spatial statistics(TBSS) was used to assess white matter integrity and the structural network properties were calculated based on DTI white matter fiber tracking.

### RESULTS

TBSS analysis revealed widespread white-matter changes among a lot of brain white fiber groups, including projecting fibers, commissural fibers, association fibers, and limbic system fibers. Fractional anisotropy (FA) and axial diffusivity(AD) values were reduced and radial diffusivity(RD) value was increased in the SMA group and the difference was statistically significant ($P < 0.05$, TFCE and FWE correction). In the white matter network, compared to the HC group, SMA showed increased characteristic path length (Lp), normalized clustering coefficient (?), and small-world characteristic (s), and decreased global efficiency (Eglob)(all $P < 0.05$). In the node properties, after performing BenjaminiHochberg's procedure, only right supramarginal gyrus(SMG.R), right superior frontal gyrus, orbital part (ORBsup.R), right supplementary motor area(SMA.R), and left median cingulate and paracingulate gyri (DCG.L) were statistically significant ($P < 0.05$, FDR correction).

### CONCLUSION

This study discovered extensive brain white matter and DTI-based brain network alterations in types 2 and 3 pediatric SMA patients, which indicated that SMN protein deficit may cause abnormal development of white matter in the brain of SMA.

### CLINICAL RELEVANCE/APPLICATION

As the lifespan of SMA children is increasing as therapy becomes more effective, patients' changes in cognition and intellect are receiving more attention. Therefore, we should focus more on the changes of the disease on the brain and cognitive function of SMA children to improve their subsequent quality of life. An in-depth study of brain changes will help draw up a more comprehensive treatment plan to help patients reintegrate into society.

## T3-SSNR07-5 REGIONAL GLYMPHATIC DYSFUNCTION IN PATIENTS WITH SPINOCEREBELLAR ATAXIA TYPE 3

Manxi Xu (*Presenter*) Nothing to Disclose

### PURPOSE

Spinocerebellar ataxia type 3 (SCA3) involves neuroinflammation and imbalance between production and clearance of proteins which affects the glymphatic system, the lymphatic-like, fluid-transport system in the brain. However, it is unclear whether SCA3 is related to impairments in glymphatic function.

### METHODS AND MATERIALS

Using multimodal imaging data, 34 SCA3 patients and 36 age-, sex- and educational matched healthy controls (HCs) were compared using multiple glymphatic measurements, including choroid plexus (CP) and cerebrospinal fluid (CSF) volume, diffusion tensor imaging along the perivascular (DTI-ALPS) index, and coupling relationship between blood-oxygen-level-dependent signals and CSF flow (BOLD-CSF coupling). Then, we evaluated regional

glymphatic function by dividing DTI-ALPS and BOLD-CSF coupling into anterior, middle, posterior, and cerebellum regions, thereby identifying the spatial variation of glymphatic function in the two groups.

**RESULTS**

We demonstrated that compared with HCs, larger CP and CSF volumes were found in SCA3 patients. More importantly, for DTI-ALPS index and BOLD-CSF coupling, these surrogate markers for glymphatic clearance were weaker in SCA3 patients. Furthermore, altered regional glymphatic functions were most prominent in midbrain, cerebellum and middle regions. Crucially, the altered midbrain, cerebellum, middle and global glymphatic functions were accompanied by the severity of ataxia and other SCA3 symptoms. Similar to other neurodegenerative disorders, the association between multiple glymphatic indexes and SCA3 symptoms suggested that waste clearance is disrupted in SCA3 patients, which shed light on the pathogenesis of this disease from a glymphatic lens.

**CONCLUSION**

Our findings highlighted the dysregulated glymphatic function as a novel diagnostic marker for SCA3.

**CLINICAL RELEVANCE/APPLICATION**

These glymphatic dysfunctions correlate strongly with the severity of ataxia and other SCA3 symptoms, suggesting their potential as novel diagnostic markers for SCA3. This insight into glymphatic involvement provides a foundation for potential therapeutic strategies targeting enhanced glymphatic clearance in SCA3 treatment.

## T3-SSNR08-1 NORMATIVE AND INDIVIDUAL, NON-NORMATIVE INTRINSIC NETWORKS AND THE TRANSITION TO IMPAIRED COGNITION IN TEMPORAL LOBE EPILEPSY

Joseph Tracy (*Abstract Co-Author*) Nothing to Disclose
Sam Sharifzadeh Javidi (*Abstract Co-Author*) Nothing to Disclose
Qirui Zhang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Despite their temporal lobe pathology, a significant subgroup of temporal lobe epilepsy (TLE) patients are able to maintain normative cognitive functioning. Here, we identify TLE patients with intact versus impaired neurocognitive profiles, and interrogate for the presence of both normative and highly individual intrinsic connectivity networks (ICN) - all towards understanding the transition from impaired to intact neurocognitive status.

### METHODS AND MATERIALS

We retrospectively investigated data from 88 TLE patients and matched 91 healthy controls with resting-state functional MRI. Functional MRI data were decomposed using independent component analysis to obtain individualized ICNs. Here, we calculated the degree of match between individualized ICNs and canonical ICNs (e.g., Yeo et.al 17 resting-state network) and divided each participant's ICNs into normative or non-normative status based on the degree of match.

### RESULTS

We found that the individualized networks matched the canonical networks less well in the cognitively impaired compared to the cognitively intact TLE patients by two-way mixed measures ANOVA (Group effect: $F= 6.445$, $p = 0.002$, impaired vs. intact $p = 0.028$, intact vs. HC $p = 0.429$ and impaired vs. HC $p = 0.001$, Tukey's corrected). The cognitively impaired patients showed significant abnormalities in the profiles of both normative (Group effect: $F = 8.434$, $p < 0.001$, impaired vs. intact $p = 0.017$, intact vs. HC $p = 0.220$ and impaired vs. HC $p < 0.001$, Tukey's corrected) and non-normative networks (Group effect: $F = 12.01$ $p < 0.001$, Impaired vs. Intact $p = 0.033$, intact vs. HC $p = 0.014$ and impaired vs. HC $p < 0.001$, Tukey's corrected), whereas the intact patients showed abnormalities only in non-normative networks. At the same time, we found normative networks held a strong, positive association with the neuropsychological measures, with this association negative in non-normative networks.

### CONCLUSION

We provide the first data demonstrating that significant cognitive deficits are associated with the status of both canonical and highly-individual ICNs, making clear that the transition from intact to impaired cognitive status is not simply the result of disruption to normative brain networks.

### CLINICAL RELEVANCE/APPLICATION

Based on this, we conclude that non-normative brain networks may serve as early biological markers of forthcoming cognitive impairment.

## T3-SSNR08-3 FREQUENCY OF TEMPORAL THUMB SIGN IN ADULT PATIENTS WITH IDIOPATHIC SEIZURES WITH AND WITHOUT ELEVATED OPENING CEREBROSPINAL FLUID PRESSURE

Arash Kamali, MD (*Abstract Co-Author*) Nothing to Disclose
Kamand Khalaj, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

Temporal lobe epilepsy has been associated with structural anomalies such as temporal lobe encephaloceles. Research suggests that these structural skull base alterations may be linked with intracranial hypertension. Following to our most recent published study in pediatric patients, which unveiled a significant association between the Temporal Thumb sign (TTS), seizures, and elevated opening cerebrospinal fluid (CSF) pressure, we aimed to determine the frequency of TTS in adult patients with elevated and normal opening CSF pressure without and with diagnosis of idiopathic unprovoked seizures.

### METHODS AND MATERIALS

This IRB approved retrospective study analyzed adults aged 18-40 who underwent lumbar puncture and MRI or CT scan at our institution, resulting in four distinct groups. Group 1 (n=52) comprised patients with confirmed diagnosis of idiopathic intracranial hypertension (IIH) presenting with headaches

or visual changes without seizures. Groups 2 (n=27) and 3 (n=30 ) consisted of patients with idiopathic seizures, distinguished by elevated and normal CSF opening pressure (OP), respectively. Group 4 (n=38) comprised age- and sex-matched healthy controls with normal CSF exam and normal opening pressure who presented to emergency room with syncope or headaches. MRI and CT scans were re-evaluated, focusing on the TTS identified on coronal views, indicated by unilateral or bilateral protrusion of the inferior temporal gyrus into the skull base. The presence of TTS was independently assessed by two observers. In-house statistical analysis conducted.

**RESULTS**

The TTS was detected most frequently in patients with elevated OP and seizures at 92.6% compared to patients with IIH with no seizures and patients with normal OP and seizures (63.5% and 53.3%, respectively). The TTS had a frequency of 13.2% in the control group. The TTS had the highest combination of specificity and sensitivity (86.8% and 63.4%) for diagnosis of elevated OP between patients with elevated OP and without seizures (IIH) compared to healthy controls (P value < 0.001) (Table 2).

**CONCLUSION**

Our results suggest the "temporal thumb sign" could be used as a screening tool with high sensitivity (92.6%) and high negative predictive value of 90% to suggest possibility of elevated intracranial pressure in adult patients presenting with seizures to the emergency department.

**CLINICAL RELEVANCE/APPLICATION**

-- The TTS maybe used as an imaging screening tool on CT or MRI scans of adult patients in emergency department-- The presence of TTS may indicate intracranial hypertension in adult patients with idiopathic seizures by negative predictive value of 90%-- The presence of TTS may indicate possibility of seizures in adult patients diagnosed with elevated opening pressure by 92.6% sensitivity

## T3-SSNR08-4 INTELLIGENT OPTIMIZATION METHOD FOR SEEG-GUIDED RADIOFREQUENCY THERMOCOAGULATION TREATMENT PLANS BASED ON PET-MRI

Wei Qian (*Abstract Co-Author*) Nothing to Disclose
Shu Chang (*Abstract Co-Author*) Nothing to Disclose
Shouliang Qi (*Abstract Co-Author*) Nothing to Disclose
Haoming Zhuang (*Abstract Co-Author*) Nothing to Disclose
Bixuan Xia (*Abstract Co-Author*) Nothing to Disclose
Dianning He, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study is to localize stereotactic electroencephalography (SEEG) epileptogenic electrode sites based on magnetic resonance imaging (MRI) and positron emission tomography (PET) images of the brain in patients with refractory epilepsy (RE) and to combine them with the SEEG electrode point signal classification model to assist neurologists in the treatment of SEEG radiofrequency thermocoagulation (RF-TC).

**METHODS AND MATERIALS**

In this study, we initially obtained the 3D coordinates of the SEEG electrode locations in the patient's brain based on computed tomography (CT) images and clinical information. Subsequently, we registered the MRI and PET images with the CT images to obtain the electrode sites. Finally, the PET data for the specified locations was extracted. The SEEG signal was processed using EEGLAB, which enabled the extraction and selection of features from 1D time series and EEG signals. The information extracted from the image data regarding the coordinate positions of the electrode sites and the information extracted from the SEEG signals were utilized as the features of the electrode sites. The features extracted from the SEEG signals were subjected to feature selection by a t-test, and the 34 features with significant differences were retained. Subsequently, the eXtreme Gradient Boosting (XGBoost) machine learning model was employed to classify the electrode site and determine its categorization.

**RESULTS**

In this study, the prediction accuracy and performance of the ensemble model based on the fusion of SEEG signal features with PET image data features were found to be significantly improved compared to the unimodal model using only PET image data features. The area under the curve (AUC) of the ensemble model was 0.69, the sensitivity was 0.69, and the specificity was 0.52, while the AUC of the unimodal model was 0.56, the sensitivity was 0.55, and the specificity was 0.47.

**CONCLUSION**

The ensemble model based on the fusion of SEEG signal features with PET imaging data features demonstrates considerable potential and is anticipated to facilitate more effective assistance to physicians in the classification of SEEG electrode sites. This finding provides valuable insights for the precision surgical treatment of RE using the combination of imaging and signaling.

**CLINICAL RELEVANCE/APPLICATION**

The findings of our study are clinically significant in that they assist physicians in developing SEEG RF-TC treatment protocols that allow for faster and more precise localization of the electrode sites in the epileptogenic zone. This will prevent the failure to precisely localize and remove the epileptogenic zone during surgery, which may result in significant trauma and side effects to the patient.

Sue Mallett, DIPLPHYS,MS (*Abstract Co-Author*) Nothing to Disclose
Andrea G. Rockall, FRCR, MRCP (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the ability of imaging tests mpMRI and CT to correctly inform patient management in women being considered for up-front or interval debulking surgery (IDS) for ovarian cancer (OC) against a reference standard based on multidisciplinary tumor board review of all patient tests and treatment.

### METHODS AND MATERIALS

This prospective ethically approved observational study recruited women being considered for their initial surgery for suspected or confirmed OC in 18 gyneoncology cancer centres. Standard of care CT was reported on study proforma and treatment decision was recorded (benign surgery or follow-up, cancer surgery or chemotherapy). Patients underwent study mpMRI, for ORADS MRI score and peritoneal evaluation, reported by blinded radiologist, mpMRI alone followed by mpMRI/CT combined. Any significant mpMRI finding was conveyed to tumor board after CT plan was electronically submitted to ensure ethical patient management. Hypothetical treatment plans based on mpMRI alone and mpMRI/CT were completed months later, blind to the patient and their final management. All clinical events were recorded for 9 months. The joint primary outcomes were the difference between mpMRI and CT for agreement with the final reference standard for patient management, and classification of women as advanced or non-advanced ovarian cancer.

### RESULTS

647evaluable patients were included (mean age 61, SD 12). Patients entered the study for IDS (n=159, 24.6%) or pre treatment (n=488, 75.4%). Of these 488, borderline (n=55) and OC (n=296) were stage 1/2 in 36% (n=176), stage 3/4 in 35.9% (n=175), benign in 23.4% (n=114) and malignant non-OC in 4.7% (n=23). Actual treatment received was surgical in 86.4% (n=559), chemotherapy in 11% (n=71), follow-up in 0.6% (n=4) or other 2% (n=13). There was no significant difference in disease stage between the imaging paradigms. Based on 647 women, 6% more women were assigned correct treatment based on mpMRI compared to CT (95% CI 3 to 10). This significant difference benefit was due to women referred for primary surgery, where mpMRI had a 9.4% (n=46) higher accuracy than CT (95% CI 5 to 13); based on 18.2% (n=89) and 27.7% (n=135) incorrect decisions for mpMRI and CT respectively. For women imaged immediately prior to delayed surgery, decision making was not significantly different based on mpMRI or CT.

### CONCLUSION

Treatment planning based on mpMRI in suspected OC significantly reduced the number of incorrect treatment plans based on CT, with increased agreement with reference standard.

### CLINICAL RELEVANCE/APPLICATION

Pre-operative mpMRI may increase optimal initial treatment in suspected OC, with avoidance of inappropriate surgery, including over-extensive surgery for benign lesions or open-close/incomplete surgery in advanced OC.

## T3-SSOB02-2 THE ACCURACY OF COMPUTED TOMOGRAPHY IN PREDICTION OF THE PERITONEAL CANCER INDEX BEFORE CYTOREDUCTIVE SURGERY WITH HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY IN ADVANCED OVARIAN CANCER

Liu Jhe Hong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Among patients with advanced ovarian cancer, the addition of hyperthermic intraperitoneal chemotherapy (HIPEC) to interval cytoreductive surgery resulted in longer recurrence-free survival and overall survival. Computed tomography (CT) is routinely performed for optimal patient selection and surgical planning based on peritoneal cancer index (PCI). We aimed to investigate the accuracy of CT in prediction of the PCI in this setting.

**METHODS AND MATERIALS**

This retrospective study included 69 ovarian cancer patients underwent CT before cytoreductive surgery and HIPEC. Lesion size (LS) score was assigned from zero to three points: zero: no tumor; one: < 0.5 cm; two: up to 5 cm; and three: > 5 cm or confluent disease or matting to pelvic structures. LS score summation in the 13 abdominopelvic regions was the PCI. We calculated the accuracy of CT in the calculation of the PCI by the reference standard PCI at surgery. We also correlated the surgical PCI with the CT-PCI.

**RESULTS**

382 (42.6%) of the 897 regions had peritoneal deposits at surgery. The sensitivity were 60.7%, 52.1%, specificity 91.3%, 87.4%, PPV 68.1 %, 75.4%, NPV 88.3%, 71.1%, and accuracy 84.1 %, 72.4%, in comparison score 0,1 versus score 2,3, and in comparison score 0 versus score 1,2,3, respectively. The CT-PCI diagnostic performance is less accurate in pelvic and small intestinal regions. The CT-PCI (7.3 ± 6.1, mean ± standard deviation) and surgical PCI (9.8 ± 6.9) showed excellent correlation ($r = 0.83$, $p < 0.05$). Optimal cytoreduction was achieved in 65 (94%) patients.

**CONCLUSION**

CT seems to be effective in prediction of peritoneal carcinomatosis using the PCI score. Optimal cytoreduction with HIPEC could be achieved guided by CT even if implants < 0.5 cm.

**CLINICAL RELEVANCE/APPLICATION**

Dedicated MDCT protocol with routine use of a standardized PCI form may provide better comprehensive multiregional analysis that may help surgeons referring patients to the best treatment option.

## T3-SSOB02-3 PREDICTION OF PLATINUM RESISTANCE IN EPITHELIAL OVARIAN CANCER USING HABITAT RADIOMICS BASED ON MRI IMAGING

Jiejun Cheng (*Abstract Co-Author*) Nothing to Disclose
Lingling Lin, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the potential of using habitat radiomics as a novel tumour biomarker in predicting epithelial ovarian cancer (EOC) patients response to platinum-based chemotherapy.

**METHODS AND MATERIALS**

In this multicenter retrospective study, 258 EOC with preoperative MRI were included. Multivariable analysis was performed to identify independent risk factors for developing the clinical model. The entire primary tumor was partitioned into five spatial habitats through K-means clustering. The classical radiomics model and habitat radiomics model were developed using the features extracted from T2WI data. The area under the receiver operating characteristics curve (AUC) through the DeLong test, calibration curves, and decision curve analysis were used to compare the performance and clinical utility of models. The Spearman correlation test was used to assess the relationship between serum lipid and habitat radiomics features.

**RESULTS**

167 patients from A hospital were divided into train set (n = 116) and validation set (n = 51), 91 patients from B hospital were split into test set (n = 91). The multivariate regression analysis showed that P53 mutation is an independent risk factor for platinum resistance in EOC. The habitat radiomics model achieved a higher AUC than the classical radiomics model and clinical model in the test set (0.852 vs. 0.475 and 0.706). The habitat-based nomogram combined 9 habitat radiomics features with clinical features had an AUC of 0.867 in the test set, displaying improved calibration and clinical utility. Furthermore, the serum lipid (LDL, HDL, CHOL, and TG) had significant correlation with 9 habitat radiomics features in the test set.

**CONCLUSION**

The habitat-based nomogram could potentially help to predict platinum resistance in EOC patients treatment. The habitat radiomics features could reflect serum lipid situation.

**CLINICAL RELEVANCE/APPLICATION**

The habitat-based nomogram can offer precise predictions and valuable assistance to physicians in developing personalized treatment strategies. The correlation between habitat radiomics features and serum lipid explained the potential biological significance of habitat, and provided ideas for combining habitat with biological indicators to improve the prognosis of EOC.

## T3-SSOB02-4 OVARIAN-ADNEXAL IMAGING REPORTING AND DATA SYSTEM (O-RADS) ULTRASOUND (US) RISK ASSESSMENT SYSTEM: MORPHOLOGIC ANALYSIS OF BENIGN CASES IN O-RADS US 4 AND 5 CATEGORIES

Lisa Barroilhet, MD (*Abstract Co-Author*) Nothing to Disclose
Neha Antil, MD (*Abstract Co-Author*) Nothing to Disclose
Luyao Shen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine which imaging features result in benign lesions to be upscored to O-RADS US 4 and 5.

**METHODS AND MATERIALS**

This IRB-approved, multicenter, retrospective study included consecutive patients who underwent pelvic US in 2011-2014. Investigators blinded to the outcome recorded imaging features per the O-RADS US lexicon. Patients with O-RADS US 4 and 5 lesions were analyzed with a reference standard of benign pathology, benign on CT/MRI, or complete resolution on follow-up imaging. Morphologic features of benign lesions were analyzed comparing pathology with the O-RADS US score. Statistical significance was determined between O-RADS US 4 and 5 with $p<0.05$.

**RESULTS**

Of 1036 lesions in 935 subjects, 298 lesions were included: 200 O-RADS US 4 and 98 O-RADS US 5. 135 lesions were benign (112 O-RADS US 4 and 23 O-RADS US 5) and 84 were malignant. 79 other lesions met 2-year clinical or imaging stability criteria for benignity, however, were excluded due to a lack of pathology or definitive diagnosis on CT/MRI. Of 135 benign lesions, physiologic cysts, endometriomas, dermoid, or other benign non-neoplastic lesions comprised 51% (69/135) of total lesions: 53% (59/112) of O-RADS US 4 lesions, and 43% (10/23) of O-RADS US 5 lesions. The rest were benign tumors. Per lesion analysis demonstrated presence of solid-appearing components was the most common lexicon feature in benign lesions, overall (71%, 96/135) and in each pathologic category: physiologic cysts (57%, 20/35), endometriomas (80%, 12/15), dermoids (100%, 10/10), other benign tumors (70%, 46/66), and other benign non-neoplastic lesions (89%, 8/9). Multilocularity was the second most frequent feature overall (45%, 61/135) and in dermoids (50%, 5/10) and other benign tumors (53%, 35/66). Per O-RADS score analysis, presence of solid-appearing components was the most common lexicon feature for O-RADS US 4 (69%, 77/112) and O-RADS US 5 (83%, 19/23) ($p=0.216$). Multilocularity was the second most common feature and was more frequently seen in O-RADS US 5 (40%, 45/112, for O-RADS US 4 and 70%, 16/23, for O-RADS US 5, $p=0.012$).

**CONCLUSION**

Approximately half of benign lesions scored as O-RADS US 4 or 5 were physiologic cysts, endometriomas, dermoids, or other benign non-neoplastic lesions. Per lesion and O-RADS US Score analysis showed solid-appearing components and multilocularity to be frequently associated with benign lesions scored as O-RADS US 4 and 5.

**CLINICAL RELEVANCE/APPLICATION**

Presence of solid-appearing components and multilocularity can lead to upscoring of benign lesions into O-RADS US 4 and 5 risk scores. Critical assessment for solid-appearing components is key for O-RADS US risk assessment.

## T3-SSOB02-5 PREDICTIVE VALUE OF WHOLE-BODY DIFFUSION-WEIGHTED MRI IN THE PREOPERATIVE ASSESSMENT OF ADVANCED OVARIAN CANCER AFTER NEO-ADJUVANT CHEMOTHERAPY

Vincent Vandecaveye, MD,PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Predicting surgical outcome after neoadjuvant chemotherapy (NACT) for advanced ovarian cancer remains challenging. We aimed to evaluate the diagnostic utility of whole body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) after NACT to predict resectability at interval debulking surgery (IDS) and patient survival.

**METHODS AND MATERIALS**

In the framework of a prospective single-center clinical trial (NCT01657747), 105 patients undergoing NACT for non-primary resectable Fédération Internationale de Gynécologie et d'Obstétrique (FIGO) stage IIIC/IV ovarian cancer underwent WB-DWI/MRI prior to IDS from May 2011 to May 2015. WB-DWI/MRI was analyzed for predicting involvement of irresectable disease sites, complete IDS, progression-free (PFS) and overall survival (OS). Surgical exploration, biopsies of metastases beyond surgical reach and imaging follow-up served as reference standard. We recorded patient outcome with standardized imaging follow-up of at least 6.5 years and participants alive as censors.

**RESULTS**

IDS achieved complete resection in 78 of 105 patients (74%). Median PFS was 15 months; median OS was 33 months. WB-DWI/MRI showed 99.1% accuracy for detecting distant irresectable metastases, 94.3% accuracy for detecting irresectable deep upper abdominal disease and suprarenal lymphadenopathy and 96.1% accuracy for detecting irresectable multifocal intestinal metastases and/or SMA/mesenteric root involvement.WB-DWI/MRI predicted complete resection at IDS with 97.4% sensitivity, 81.5% specificity and 93.3% accuracy. Prediction of complete resection by WB-DWI/MRI correlated with improved PFS (median 18 versus 7 months) and OS (median 45 months versus 20 months); similar as complete resection at IDS (PFS: median 18 versus 7 months; OS: median 41 versus 21 months). MRI prediction of (in)complete resection, preoperative absolute CA-125 value and (in)complete resection status at IDS showed significant effects on PFS (MRI: Hazard ratio (HR) = 5.43, $p<0.01$; CA-125: HR = 1.00, $p<0.001$; IDS: HR = 4.19, $p<0.001$) and OS (MRI: HR = 4.24, $p<0.01$; CA-125: HR = 1.00, $p<0.001$; IDS: HR = 2.87, $p<0.001$). After multivariable analysis, only MRI prediction of complete resection and preoperative CA-125 remained significant (both $p<0.001$).

**CONCLUSION**

WB-DWI/MRI accurately predicts complete resection at IDS for FIGO stage IIIC/IV ovarian cancer. MRI prediction of complete resection was an independent predictor of PFS and OS and a stronger predictive factor than complete resection at IDS.

**CLINICAL RELEVANCE/APPLICATION**

WB-DWI/MRI is an effective tool for operability assessment of ovarian cancer patients treated with NACT and can aid to optimize patient selection for and outcome of IDS.

## T3-STCE1-1 MYOCARDIAL FIBROSIS QUANTIFIED BY T1 MAPPING PREDICTS OUTCOMES IN DIABETES MELLITUS PATIENTS WITH PRESERVED EJECTION FRACTION: A CARDIAC MRI STUDY

Lu Minjie, PhD (*Abstract Co-Author*) Nothing to Disclose
Wenjing Yang (*Presenter*) Nothing to Disclose

### PURPOSE

Cardiac magnetic resonance(CMR) could serve as a robust tool for the assessment of myocardial fibrosis in diabetes mellitus(DM). We aimed to evaluate the prognostic significance of CMR T1 mapping as a new noninvasive way to risk stratify patients with DM, with particular attention to its role in different clinical scenarios.

### METHODS AND MATERIALS

DM participants with preserved ejection fraction who completed CMR T1 mapping examinations between October 2016 and December 2022 were enrolled in this study. Extracellular volume fraction(ECV) was calculated from pre- and post-T1 mapping for the assessment of interstitial fibrosis. The primary composite outcome was cardiovascular death or heart failure hospitalization.

### RESULTS

A total of 377 DM participants (mean age, 56 years±13; 274 men) completed follow-up and were enrolled in the final analysis. During a median follow-up of 30.1 months, 58 DM patients experienced the primary outcome. In univariate Cox analysis, age, prevalent coronary heart disease, estimated glomerular filtration rate, NT-proBNP, cardiac index, LV end-diastolic volume index, global longitudinal strain, the presence of LGE, and ECV were all associated with the primary outcome(all $P<0.05$). In multivariate analysis, ECV remained significantly associated with outcome in two separate models incorporating clinical variables and CMR parameters. In a final model consisting of the strongest predictors overall, ECV(HR: 1.080, 95% CI: 1.007 to 1.159; $p=0.030$) remained an independent predictor along with age, LVEDVi and GLS. The final multivariate model predicted outcome with a C-statistic of 0.74. In addition, the prognostic value of ECV remained consistent in all subgroups of clinical interest, such as men and women, patients with or without other comorbidities(hypertension and obesity), and those with or without heart failure. In sensitivity analysis after excluding patients with LGE, ECV remained significantly associated the primary outcome in multivariate Cox analysis and subgroup analyses. Kaplan-Meier survival curves showed that patients without LGE but with ECV higher than or equal to 30.48% had no significant difference in survival probability compared to patients with LGE.

### CONCLUSION

ECV derived from CMR T1 mapping was significantly associated with the primary outcome in DM patients in different clinical scenarios. Notably, the myocardial fibrosis assessed by T1 mapping could provide prognostic value in patients without LGE.

### CLINICAL RELEVANCE/APPLICATION

Myocardial fibrosis is one of the key pathophysiologic findings in DM, which can be noninvasively evaluated by CMR. Our study showed ECV was significantly associated with the primary outcome in DM patients, particularly in various clinical scenarios. The prognostic value of ECV remained consistent in DM patients without LGE, supporting the clinical relevance of CMR T1 mapping for the assessment of interstitial fibrosis.

## T3-STCE1-3 DEEP LEARNING-BASED SUPERRESOLUTION RECONSTRUCTION FOR MR-GUIDED THERMOABLATION

Marcel D. Nickel (*Abstract Co-Author*) Employee, Siemens AG

Rudiger Hoffmann (*Abstract Co-Author*) Nothing to Disclose
Jens Kubler, MD (*Abstract Co-Author*) Nothing to Disclose
Moritz T. Winkelmann, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study investigates the effects of a deep learning-based super-resolution reconstruction approach for T1-weighted volume-interpolated breath-hold examinations (DL-VIBE) on image quality and intraprocedural parameters during MR-guided thermoablation of liver malignancies, compared to standard VIBE images (SD-VIBE).

## METHODS AND MATERIALS

Between September 2021 and February 2023, 34 patients (mean age: 65.4 ± 11.5 years, women: n=13) with liver malignancies were treated using MR-guided microwave ablation on a 1.5 T MR-scanner. Intraprocedural VIBE sequences (SD-VIBE) were acquired to monitor needle position and assess the ablation zone. The raw T1-weighted VIBE data were processed using a prototype deep learning algorithm to reduce noise and blurring while improving sharpness (DL-VIBE). Two experienced interventional radiologists independently evaluated the image data sets in a randomized, blinded manner, comparing DL-VIBE to unprocessed SD-VIBE images. Measurements included assessment of overall image quality, noise, artifacts, sharpness of liver and portal vein branches, detectability of needle artifacts, delineation of costodiaphragmatic recess, contrast of ribs, detectability of target lesion and antenna tip, confidence in needle position, and adequacy of ablation zone. Ratings were on a 5-point Likert scale, and interrater agreement was analyzed. Noise maps were created to demonstrate signal-to-noise ratio improvements.

## RESULTS

DL-VIBE images showed significantly higher overall image quality, lower artifacts and noise, and better sharpness of liver contours and portal vein branches compared to SD-VIBE ($P<0.001$). Interventional parameters, including real-time imaging of the interventional path, target lesion and needle tip detectability, confidence in needle positioning, and diagnostic confidence in the adequacy of the ablation zone, were significantly better with DL-VIBE ($P<0.001$). Interrater agreement was high (Cohen ? = 0.86). Quantitative noise maps indicated an improved signal-to-noise ratio with higher resolution using DL-VIBE. DL-VIBE reduced reconstruction time from 3.5 seconds to 1 second and decreased acquisition time per sequence by 14.4%, with an average of 24.7 sequences per patient (range: 9-69).

## CONCLUSION

DL-VIBE significantly improves the image quality and diagnostic reliability of MR-guided thermal ablation procedures while saving time compared to standard methods.

## CLINICAL RELEVANCE/APPLICATION

This integration of deep learning technology into theranostics promises improved patient outcomes through better image quality and procedural accuracy.

### PURPOSE

Strengthening environmental sustainability in radiology requires adaptation planning to prepare for climate-related adverse health effects. The purpose of this study was to determine short-term associations of climate-related environmental exposures with utilization of emergency medical imaging by stratified by patient age and sex.

### METHODS AND MATERIALS

In this retrospective, time-stratified, case-crossover study, daily imaging utilization counts from four local emergency departments from 2018-2023 were linked to local daily environmental data, including ambient heat and fine particulate matter (PM2.5) air pollution. Moving averages of ambient PM2.5 and temperature were calculated to account for lagged exposure effects. Conditional Poisson regression models were used to evaluate short-term associations of daily variations in ambient environmental exposures with daily utilization of emergency medical imaging stratified by sex and age group controlling for day-of-week, month, and year.

### RESULTS

A total of 738,084 emergency department imaging studies were included. A rise of 10°C in the 2-day moving average of mean daily temperature (representing average exposure to heat over the current and previous 1 day) was associated with overall imaging utilization increases of 4.5% (IRR 1.045; 95%CI 1.033, 1.057) in females, 6.7% (IRR 1.067; 95%CI 1.054, 1.080) in males, 5.8% (IRR 1.058; 95%CI 1.035, 1.080) in patients <18 years, 4.9% (IRR 1.049; 95%CI 1.037, 1.061) in patients =18 to <65 years, and 6.5% (IRR 1.065; 95%CI 1.050, 1.081) in those =65 years. A rise of 10 µg/m3 in the 3-day moving average of mean daily PM2.5 (representing average exposure of fine particulate air pollution over the current and previous 2 days) was associated with overall imaging utilization increases of 2.0% (IRR 1.020; 95%CI 1.010, 1.031) in females, 3.8% (IRR 1.038; 95%CI 1.027, 1.048) in males, 2.6% (IRR 1.026; 95%CI 1.007, 1.045) in patients <18 years, 2.4% (IRR 1.024; 95%CI 1.014, 1.034) in patients =18 to <65 years, and 3.9% (IRR 1.039; 95%CI 1.026, 1.052) in those =65 years.

### CONCLUSION

Ambient heat and particulate air pollution are associated with increased utilization of emergency department medical imaging across all age and sex groups. Effect sizes were larger in males compared to females with a bimodal effect by age, with largest effect sizes in older adults =65 years of age followed by pediatric patients <18 years of age.

### CLINICAL RELEVANCE/APPLICATION

These results advance our understanding of who is most at risk of climate related exposures and can be used to inform preparations in radiology departments to build resilience into existing systems. Readily available environmental data could provide early warnings about impending surges in imaging volumes.

## T3-STCE2-2 QUANTIFYING THE ENVIRONMENTAL SUSTAINABILITY OF LARGE LANGUAGE MODELS IN RADIOLOGY REPORTS ANALYSIS

Kate Hanneman, MD, MPH (*Abstract Co-Author*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*) Board of Directors, VoiceIt Technologies, LLC;Stockholder, VoiceIt Technologies, LLC;Board of

Directors, FLOWSIGMA Inc;Officer, FLOWSIGMA Inc;Stockholder, FLOWSIGMA Inc;Officer, Yunu Inc;Stockholder, Yunu Inc
Florence X. Doo, MD, MA (*Abstract Co-Author*) Nothing to Disclose
Sanaz Vahdati, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Natural language processing (NLP) in radiology has become increasingly important for efficient data extraction and analysis of medical reports. However, the growing use of large language models (LLMs) raises concerns about their environmental impact. This study aims to assess the performance and environmental footprint in the context of radiology report analysis, using two powerful state-of-the-art LLMs, LLaMA3-70B, and LLaMA3.1-70B to extract the presence of liver metastases from radiology reports.

**METHODS AND MATERIALS**

We collected radiology reports from 105 abdominopelvic CT scans, with 55 of 105 reports indicating liver metastases from our institution. We used two versions of powerful open-source large language models, LLaMA3 70B and LlaMA3.1 70B, to extract information from radiology reports and indicate the presence or absence of liver metastases. We employed few-shot pre-defined prompting to direct the model's generation of target outputs in accordance with specified parameters. The models' performance was measured by comparing model outputs with expert-annotated reference standards. To assess the environmental impact of LLM's operations, we used the "Carbon tracker" package. Our computations were performed on one local NVIDIA A100 GPU, allowing us to measure the energy consumption associated with processing each report as a distinct computational cycle.

**RESULTS**

The LlaMA3-70B and LLaMA3.1-70B models demonstrated high accuracy in extracting liver metastases, achieving 91% and 90%, respectively. For LLaMA3-70B, the positive predictive value (PPV) was 0.98 and the negative predictive value (NPV) was 0.86. LLaMA3.1-70B showed a PPV of 0.94 and an NPV of 0.87. Carbon footprint assessment of LLaMA3-70B inference determined an energy consumption of approximately 0.52 kWh, resulting in 187.33 g of CO2 equivalent emissions. LLaMA3.1-70B used approximately 0.62 kWh energy, producing 219.71g of CO2 equivalent (Table 1).

**CONCLUSION**

Our findings reveal that the LLaMA 3-70B model, though one iteration older, achieves comparable accuracy in extracting radiology report data while demonstrating a reduced environmental footprint compared to LLaMA 3.1-70B. This highlights the importance of conducting a comprehensive assessment of LLM models for radiology, balancing model performance with ecological considerations.

**CLINICAL RELEVANCE/APPLICATION**

Our work emphasizes considering both the performance and environmental aspects when selecting LLM models. This could lead to more eco-friendly radiology practices without compromising the quality of data extraction from reports. Integrating AI model evaluation with other departmental sustainability metrics is crucial to develop comprehensive eco-friendly innovations in radiology.

## T3-STCE2-3 MEASURING GEOGRAPHIC ACCESS TO IMAGING CENTERS IN URBAN AREAS

Claire Brookmeyer, MD (*Abstract Co-Author*) Nothing to Disclose
Preetham Bachina, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Current studies show that areas of extreme socioeconomic disadvantage have less access to accredited imaging facilities, mainly focusing on lung and breast cancer screening. Little has been done to evaluate geographic access to general outpatient radiological services, especially in urban settings. Imaging access via public transportation is particularly relevant as underserved populations are more likely to use public transport.

**METHODS AND MATERIALS**

Three cities of interest were chosen for our initial study: Baltimore, Chicago, and Houston. American College of Radiology (ACR) accredited facilities within each city's metropolitan area were identified from the ACR website. Each city was divided into census tracts. Isochrone maps from each census tract's centroid were generated using the TravelTime API to determine areas reachable within 20, 30, or 40 minutes by driving or public transportation. Tracts without an ACR imaging facility within the specified time were considered imaging access deserts. 2019 American Community Survey data was used to classify tracts by majority racial groups (>50%) and by income (poor vs. nonpoor at 200% of the federal poverty level). Odds ratios for access based on racial and income composition were calculated.

**RESULTS**

In all three cities, >99% census tracts are within a 20-minute drive of at least one imaging center. At the 30-minute public transit threshold, 23% of tracts in Baltimore, 32% in Chicago, and 74% in Houston are classified as imaging access deserts. In Baltimore, racial minority and poor census tracts generally have similar odds of being access deserts compared to White and non-poor tracts. In Chicago and Houston, at the 20-minute public transit threshold, Black, Hispanic, and poor tracts generally have significantly higher odds of being access deserts compared to White and non-poor tracts. However, at the 30-minute threshold, these differences become nonsignificant, and at the 40-minute threshold, Black and poor tracts have significantly lower odds of being access deserts than White and non-poor tracts.

**CONCLUSION**

While driving access to radiologic services is universally adequate in the studied cities, access via public transportation is notably limited. In Houston and Chicago, a shorter public transport threshold showed minority and poor census tracts generally having worse access which was reduced and eventually reversed with a longer transport time threshold.

**CLINICAL RELEVANCE/APPLICATION**

Inequities in imaging access lead to suboptimal outcomes for underserved communities. Radiology's current limitations in meeting these needs may be addressed by establishing imaging services in more accessible locations for underserved populations and individuals facing transportation barriers.

### PURPOSE

As the number of FDA-approved chest X-ray AI algorithms increases, there's still a lack of data on how they perform in real-world clinical settings. To address this gap, we conducted an international post-market surveillance study to evaluate a chest X-ray AI algorithm's performance in real-world clinical practice.

### METHODS AND MATERIALS

In our IRB-approved study, we included 2096 CXRs from 4 sites in India, 2 sites from Korea, and 1 site from Thailand. The inclusion criteria were the availability of CXR AI algorithm (Lunit.ai) outputs at the time of interpretation of CXRs as part of the standard of care workflow. All CXRs were deidentified and uploaded to an offline, secure annotation platform (Carpl.AI) for evaluation. Two thoracic radiologists, blinded to the AI outputs and radiology reports, independently reviewed the following AI-assessable CXR findings: pulmonary nodule, atelectasis, cardiomegaly, consolidation, fibrosis, mediastinal widening, nodule, pleural effusion, pneumothorax, and active tuberculosis. In addition, they also recorded the presence of any suboptimality for each CXR (incomplete anatomic coverage of thorax, under-/over-exposure, marked patient rotation, overlying external object, low lung volume, and artifacts impairing CXR evaluation). In cases of a disagreement between the two radiologists, a third radiologist independently reviewed the CXR to help establish a majority consensus ground truth. The sensitivity, specificity, and AUC with a 95% confidence interval were calculated to evaluate the performance of the reporting radiologist and standalone AI model. Chi-Square test was calculated to determine significant differences between reports and standalone model performance.

### RESULTS

The overall performance of AI-aided radiology reports was higher than the standalone AI algorithm. Table 1 summarizes the sensitivity, specificity, area under the curve, and the 95% confidence interval for the AI-aided radiology reporting as compared to the ground truth. There were small but significant differences in AI-aided radiology reports and standalone AI performance (p value<0.001) in suboptimal CXRs: incomplete anatomic coverage: 0.75, 0.667, low lung volume: 0.927, 0.899, over/under exposure: 0.895, 0.94, marked patient rotation: 0.939, 0.932, and more than one suboptimality, 0.879, 0.917, respectively.

### CONCLUSION

Compared to the multi-reader ground truth, our multicenter study demonstrates that real-world AI-aided radiology reporting results in extremely high sensitivity, specificity, and AUCs.

### CLINICAL RELEVANCE/APPLICATION

Our post-market surveillance of a chest x-ray AI algorithm supports the positive impact of AI on reporting of CXRs.

## T6-SSCH06-2 LOCAL VALIDATION OF A COMMERCIAL AI SYSTEM FOR AUTONOMOUS REPORTING OF CHEST RADIOGRAPHS: A LARGE-CENTRE UK RETROSPECTIVE ANALYSIS

Deborah J. Tattersall, MBChB (*Abstract Co-Author*) Nothing to Disclose
Benjamin J. Holloway, MBChB (*Abstract Co-Author*) Nothing to Disclose

Aditya Kale (*Abstract Co-Author*) Nothing to Disclose
Qasim Malik (*Abstract Co-Author*) Nothing to Disclose
Sonam Vadera, MBBS, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

The increasing burden of chest X-ray reporting calls for novel methods to streamline radiological assessment, whilst maintaining accuracy. This study aimed to evaluate the performance of ChestLink, a CE-marked Class IIb AI as a Medical Device tool developed by Oxipit (Vilnius, Lithuania), designed to autonomously report high-confidence normal chest X-ray studies.

**METHODS AND MATERIALS**

A retrospective analysis was undertaken at University Hospitals Birmingham NHS Foundation Trust, examining 82,761 chest X-rays across GP, AE, outpatient, and inpatient referral sources. A separately validated natural language processing (NLP) tool is provided by Oxipit to classify the clinician reports. The concordance between ChestLink's classifications and the clinician reports was calculated to evaluate accuracy and reliability.

**RESULTS**

Among the X-rays reviewed, 37,048 were normal scans based on clinician opinion. ChestLink was able to confidently report 9,821 (26.5%) of these as normal, effectively removing them from further assessment and expediting the workflow. The highest autonomous reporting rate was observed in the GP setting, with ChestLink correctly classifying 32% of studies as normal. Conversely, autonomous reporting rate was lowest among inpatients, where it identified 16.8% of normal chest X-rays. Overall, discordance was observed in 426 (4.3%) cases, whereby ChestLink classified the X-ray as normal while clinicians reported abnormalities. Among these discordant cases, 15 (0.15%) were deemed clinically significant.

**CONCLUSION**

ChestLink demonstrates promising accuracy in identifying normal chest X-rays, potentially reducing reporting workload. Nonetheless, the observed discordance warrants further investigation. A further 60,000 CXRs are currently being processed, and a case-by-case review by four consultant cardiothoracic radiologists is underway. Furthermore, a medical algorithmic audit and root-cause analysis are being conducted to identify potential failure modes and inform the decision to proceed to the prospective trial stage and subsequent deployment.

**CLINICAL RELEVANCE/APPLICATION**

The findings highlight the potential of AI tools like ChestLink in enhancing the efficiency of chest X-ray reporting. Integrating such AI tools into clinical workflows can aid radiologists in prioritising abnormal cases, thereby facilitating timely patient care, and enabling re-allocation of clinician time.

## T6-SSCH06-3 TOWARDS PHYSICIAN-LEVEL RADIOLOGIC REPORT GENERATION: COMPREHENSIVE EXPLORATION OF CLINICAL SIGNIFICANCE OF A NOVEL MULTIMODAL GENERATIVE ARTIFICIAL INTELLIGENCE MODEL

Eun Kyoung Hong, MD,PhD (*Abstract Co-Author*) Research Consultant, VUNO Inc
Byungseok Roh (*Abstract Co-Author*) Nothing to Disclose
Hae Won Kim (*Abstract Co-Author*) Nothing to Disclose
Woong Bae, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Generative AI is anticipated to significantly alter the landscape of medicine, especially in medical diagnostics. The aim of the study is to develop and comprehensively evaluate a novel, domain-specific multimodal generative AI model for Chest X-ray (CXR) report generation.

**METHODS AND MATERIALS**

Over 14 million CXR-report pair datasets were utilized in the study. After the model development, validation included: 1) Assessing the detection accuracy of the 13 most important CXR findings (RRDA), 2) Evaluating the acceptability rate, agreement, and quality scores of the generated reports, along with a comparative ranking analysis against radiologists' reports and outputs from a general-purpose Large-Language Model (GPT-4v), conducted independently by four radiologists (RRQE), 3) A multireader, multicase study was conducted, where CXRs were interpreted with and without the aid of AI-generated reports.

**RESULTS**

AI-generated reports demonstrated high sensitivities in detecting critical CXR findings, 95.26% for pneumothorax and 92.62% for subcutaneous emphysema. The acceptance rates by four evaluating radiologists were 70.48%, 73.29% and 29.56% for AI-generated, radiologists' and GPT-4v reports, respectively. The agreement and quality score analysis showed that AI-generated reports had higher agreement (Mean ± SD: 3.80 ± 1.32) and quality (3.87 ± 1.34) scores over radiologists' (3.45 ± 0.84 for agreement; 3.44 ± 1.17 for quality) and GPT-4v reports (2.12 ± 1.14 for agreement; 1.14 ± 0.27 for quality) ($p < .001$). From ranking analysis, AI-generated reports were most frequently ranked the highest (59.98%), GPT-4v reports lowest (73.58%), and radiologists' reports in the middle (54.73%). Results from the reader study demonstrated that when reporting with AI-generated reports, there was a significant reduction in reading time from 34.2 to 19.8 seconds ($p < .001$), and both report agreement and quality scores improved (4.47 ± 0.61 to 4.69 ± 0.46) and (4.31 ± 0.52 to 4.57 ± 0.44, respectively) (ps < .001).

**CONCLUSION**

The multimodal generative AI model can offer clinical value by assisting radiologists in generating radiologic reports with high precision, suggesting the potential to bring a positive impact on patient care.

**CLINICAL RELEVANCE/APPLICATION**

Our study demonstrates the potential of a novel multimodal generative AI model to achieve physician-level accuracy in radiologic report generation, by not only enhancing the clinical workflow by reducing reading times, but also improving the accuracy and quality of radiological reports. These results highlight the AI model's potential for clinical utility in medical imaging interpretation, suggesting future validation across various clinical settings is needed to fully demonstrate its benefits.

## T6-SSCH06-4 OPTIMIZING CHEST RADIOGRAPH WORKFLOW: EFFICIENCY GAINS OF AI-ASSISTED REPORTING IN A MULTI-ETHNIC COHORT

Akanksha Ojha (*Abstract Co-Author*) Nothing to Disclose
Charlene Liew, MBChB, FRCR (*Abstract Co-Author*) Nothing to Disclose

Ashutosh Pathak (*Abstract Co-Author*) Nothing to Disclose
Richa Pant (*Abstract Co-Author*) Nothing to Disclose
Siddhant Pardeshi (*Abstract Co-Author*) Nothing to Disclose
Yogesh Mantri (*Abstract Co-Author*) Nothing to Disclose
Amit T. Kharat, PhD,DMRD (*Presenter*) Co-founder, DeepTek.ai, Inc

**PURPOSE**

To evaluate the impact of an AI-powered PACS platform on report generation time (RGT) and turnaround time (TAT) for chest radiographs in a multi-ethnic patient cohort.

**METHODS AND MATERIALS**

The study included 1054 patients who visited Changi General Hospital, Singapore between November 2023 and January 2024. 8 board-certified radiologists, specializing in various fields, reported chest radiographs in two sessions. In Session 1, they used conventional PACS (Carestream Phillips VuePACS v12.2), while in Session 2, they used an AI-powered PACS (Augmento v1.4.6, DeepTek, India) integrated with Lunit INSIGHT CXR v3.1.5.0. There was a wash out period of 4 weeks between the two sessions to mitigate memory bias. The AI platform assigned a priority order (Normal, non-urgent, urgent, critical) to the chest radiographs as opposed to the conventional PACS which follows First In First Out worklist order. Mean and median were compared between sessions for RGT and TAT.

**RESULTS**

The median RGT was reduced from 2 minutes in Session 1 to 0.53 minutes in Session 2, resulting in a reduction of 1.47 minutes (73.33%). A statistically significant reduction in median RGT was observed across all notification levels in Session 2: normal (90% reduction), non-urgent (72.5% reduction), urgent (54.2% reduction) and critical (35.6% reduction). Even CXR's with 3 or more findings experienced a significant reduction in RGT (42.9%). Similarly, the median TAT was reduced from 675.87 minutes in Session 1 to 55.87 minutes in Session 2, resulting in the reduction of 620 minutes (91.73%). The effect of AI assistance on TAT reduction extended to all notification levels, prominently for critical CXRs where the median TAT decreased from 711.08 minutes to 41.56 minutes, resulting in 96.7% reduction. The improvement in the TAT was greater for chest radiographs with 3 or more findings (94.95%) compared to those with fewer findings.

**CONCLUSION**

Integration of an AI-powered PACS platform led to significant reductions in RGT and TAT for chest radiographs. These improvements were consistent across different notification levels of findings. The improvement in the TAT was greatest for chest radiographs with 3 or more findings, indicating the importance of AI powered workflow in reporting the critical scans first for making faster diagnostic decisions.

**CLINICAL RELEVANCE/APPLICATION**

The study demonstrates that AI assistance in radiology reporting significantly enhances efficiency, enabling faster diagnosis and treatment decisions. These findings are particularly relevant in clinical settings where timely diagnosis is crucial, highlighting the potential of AI technology to improve patient care in radiology departments.

## T6-SSCH06-6 ACCURACY OF ARTIFICIAL INTELLIGENCE-BASED PREDICTION OF OSTEOPOROSIS FROM CHEST RADIOGRAPHS AND ASSOCIATION WITH RISK OF LONG-TERM MORTALITY

Eui Jin Hwang, MD, PhD (*Abstract Co-Author*) Research Grant, Lunit Inc;Research Grant, Coreline Soft, Co Ltd;Research Grant, Monitor Corporation Inc
Ji Young Lee, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Osteoporotic fracture has become a big concern in elderly individuals. Identifying asymptomatic individuals with osteoporosis may help reduce this burden. We aimed to evaluate the accuracy of an artificial intelligence (AI) model to predict osteoporosis from chest radiographs (CXRs) and its association with long-term mortality.

**METHODS AND MATERIALS**

We retrospectively included consecutive adult (age =19 years) individuals who underwent CXRs and dual-energy x-ray absorptiometry (DEXA) scans on the same day for health checkups between 2014 and 2017 in a single institution. A commercialized AI tool (PROS® CXR: OSTEO, PROMEDIUS INC, Seoul, Korea) for predicting osteoporosis in the form of probability scores (0-100%) was retrospectively applied to CXRs. The accuracy of AI was evaluated based on osteoporosis diagnosis using DEXA as reference standards. We evaluated the area under receiver operating characteristic curves (AUCs) for the score provided by AI. We also evaluated the sensitivity and specificity of AI at two different thresholds: Predicted scores of 10% and 50%. We also investigated the association between the prediction of osteoporosis by AI and long-term all-cause mortality after adjustment of age, sex, and body mass index using Cox proportional hazard analysis.

**RESULTS**

A total of 10,412 CXRs from 8,618 asymptomatic individuals (mean age, 58 years; 2882 men) were included. The prevalence of osteoporosis by DEXA scan was 4.2% (440/10,412). The AI's prediction exhibited an AUC of 0.91 (95% confidence interval [CI], 0.90-0.92) for osteoporosis by DEXA scan. At a threshold predicted score of 10%, the sensitivity and specificity were 72.5% (319/440; 95% CI, 68.1-76.6%) and 89.4% (8,911/9,972; 95% CI, 88.7-90.0%), respectively. Meanwhile, at a score of 50%, the sensitivity and specificity were 61.1% (269/440; 95% CI, 56.4-65.7%) and 93.7% (9344/10,412; 93.2-94.2%), respectively. In multivariate Cox proportional hazard analyses of 8,167 individuals with available mortality information, a higher predicted score for osteoporosis by the AI was associated with a higher risk of long-term all-cause mortality (hazard ratio [HR], 1.01 per 1% point increase of score; 95% CI, 1.00-1.01; P=.016). Binary prediction results by both thresholds of 10% (HR, 1.40; 95% CI, 1.08-2.06; P=.014) and 50% (HR, 1.49; 95% CI, 1.05-2.12; P=.027) were also independently associated with long-term all-cause mortality.

**CONCLUSION**

Osteoporosis prediction from CXR using AI was accurate compared to DEXA scan, and was associated with risk of long-term mortality.

**CLINICAL RELEVANCE/APPLICATION**

An AI analysis of CXR can help opportunistic screening of asymptomatic osteoporosis, which can potentially provide a chance to reduce the risk of long-term mortality and morbidity.

### PURPOSE

Increasing number of patients with prostate cancer undergo assessment with multiparametric magnetic resonance imaging (mpMRI) and prostate-specific membrane antigen positron emission tomography/computed tomography (PSMA PET/CT). This approach offers comprehensive multimodality staging but can lead to discrepant findings. The objective of this study was to assess the frequency and types of discordances between mpMRI and PSMA PET/CT for primary prostate cancer assessment and explore their impact on treatment planning.

### METHODS AND MATERIALS

Consecutive men with diagnosed or suspected prostate cancer who underwent mpMRI and PSMA PET/CT in 2021-2023 were retrospectively included. mpMRI and PSMA PET/CT were interpreted using PI-RADS v2.1 and PRIMARY scores. Discordances between the two imaging modalities were categorized as “minor discordance” (e.g., larger or additional lesion seen on one modality) or “major discordance” (e.g., positive on only one modality or different index lesions between mpMRI and PSMA PET/CT).

### RESULTS

320 men (median age 69 years, interquartile range [IQR] 64-75) were included. Most had Gleason Grade Group =3 prostate cancer (68.1% [218/320]). Median PSA was 8.7 ng/mL (IQR 5.5-13.6). mpMRI and PSMA PET/CT were concordant in 164/320 (51.2%) and discordant in 156/320 (48.8%) patients among which 42/156 (26.9%) were "major discordances" and 114/156 (73.1%) were "minor discordances". Of 27 patients with lesions only seen on mpMRI, 85.2% (23/27) were clinically significant prostate cancer (csPCa). Of 23 patients with lesions only seen on PSMA PET/CT, 78.3% (18/23) were csPCa. Altogether, lesions seen on only one modality were csPCa in 80.0% (36/45).

### CONCLUSION

mpMRI and PSMA PET/CT were discordant in half of patients for primary prostate cancer evaluation, with major discrepancies seen in roughly one out of 8 patients.

### CLINICAL RELEVANCE/APPLICATION

For evaluating tumours in the prostate, mpMRI and PSMA PET/CT were discordant in about half of the patients. Furthermore, a non-negligible proportion of them showed major discordances such as lesions only seen on one imaging modality. Synergistic usage of mpMRI and PSMA PET/CT has the potential to result in better biopsy and treatment planning (e.g., focal boosting in radiation therapy, candidacy for focal therapy, etc.).

## T6-SSGU04-2 CLINICAL, PATHOLOGICAL AND IMAGING VARIABLES ASSOCIATED WITH PROSTATE CANCER DETECTION BY PSMA PET/CT AND MPMRI

**PURPOSE**

To assess differences in sensitivity and positive predictive value between pre-surgical PSMA-PET and mpMRI and characterize tumors detected and not detected by each imaging modality focusing on identifying the clinical, pathological and imaging variables associated with tumors detected by PSMA-PET and mpMRI invisible.

**METHODS AND MATERIALS**

This single-center, retrospective analysis included patients who underwent both PSMA-PET and mpMRI prior to radical prostatectomy with centralized imaging and pathology review. Two nuclear medicine physicians and 2 radiologists blindly and independently contoured PCa lesions on PSMA-PET and mpMRI, respectively. We used a majority rule (2:1) with a third reader for each modality in case of disagreement.We fused the PET/CT and MRI and assessed for agreement/disagreement visually, based on the overlapping lesion contours, and matched each lesion with the tumors delineated by a genito-urinary pathologist on WMHP. Logistic regression models explored associations between clinico-pathological variables and tumor detection on imaging

**RESULTS**

A total of 132 csPCa tumors from 100 patients were identified on surgical pathology. PSMA-PET and mpMRI identified 143 and 122 lesions, respectively. PSMA-PET showed higher sensitivity (87% vs 80%), but lower positive predictive value compared to mpMRI (87% vs 93%). Tumors correctly identified on each imaging modality had significantly higher ISUP GG, larger size, and were more likely to show large cribriform pattern (LCP) and intraductal carcinoma (IDC). Tumors detected by both imaging modalities were significantly larger and had higher ISUP grade groups than those invisible on one or both imaging modalities. On multivariable analysis, smaller tumor size on pathology and older age were associated with PSMA PET/CT not detecting csPCa. Whereas for mpMRI, smaller tumor size on pathology was associated with invisible PCa, while ISUP GG4/5 vs GG2 was associated with lower odds of non-detection. csPCa tumors invisible on mpMRI but detected by PSMA-PET were smaller in size compared to those detected by both modalities. Limitations include selection bias in a surgical cohort.

**CONCLUSION**

PSMA-PET tends to detect smaller csPCa not detected by mpMRI. Larger tumors on pathology with higher grade groups are more likely to be correctly detected by both imaging modalities. These findings provide insights for refining pre-surgical evaluation strategies in PCa.

**CLINICAL RELEVANCE/APPLICATION**

These findings provide insights for refining pre-surgical evaluation strategies in PCa.

## T6-SSGU04-3 IMPACT OF $^{18}$F-DCFPYL PSMA PET AND MP-MRI ON ACCURACY OF LESION DETECTION IN MEN ON ACTIVE SURVEILLANCE WITH LOW/INTERMEDIATE RISK PROSTATE CANCER

Shane A. Wells, MD (*Abstract Co-Author*) Consultant, Johnson & Johnson

Edward M. Lawrence, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Evaluate the value of prostate specific antigen (PSMA) PET imaging and multi-parametric MRI (mpMRI) in detection of clinically significant prostate cancer (csPC) in patients with low/intermediate risk prostate cancer on active surveillance.

**METHODS AND MATERIALS**

Prospective IRB-approved Phase II trial with 18F-DCFPyL PSMA PET and mpMRI obtained on a dedicated PET/MRI scanner (3.0T Signa, GE Healthcare). Planned accrual of 100 men on AS with biopsy-proven low or intermediate-risk PC and primary outcome of csPC (grade group(GG)/ISUP=2) detection. Pelvic PET and mpMRI of the prostate were performed 1 hour after injection of ~9mCi of 18F-DCFPyL PSMA. Prostate mpMRI and pelvic PET was interpreted independently by experienced GU radiologist and nuclear medicine physician, respectively, both blinded to results of the other modality followed by convened integrated review for biopsy lesion identification. Lesions were classified according to PI-RADS v2.1 (mpMRI), and 5-point visual Likert scale (PSMA PET). PET quantitative maximum standardized uptake value (SUVmax) was obtained for all PI-RADS and Likert lesions =3. Systematic (12 cores) as well as targeted MRI-US fusion biopsies (DynaCAD; UroNav) were performed by an experienced urologist for all MRI PI-RADS=3 (standard of care) with addition of a research PET+ Likert=3 lesion. Per lesion and per patient analysis were performed with prostate biopsy histopathology results.

**RESULTS**

Eighty patients recruited with imaging and biopsy completed on 57 [median age 68; mean PSA 8.1 ng/mL; time on active surveillance 25 months (IQR, 13-58 mo); 67% very low/low risk versus 28% intermediate risk]. One hundred sixty three lesions were targeted for biopsy (Gleason grade group 1, 28/163, 17%; Gleason grade group 2 or higher, 36/163, 22%). The addition of PSMA PET to mpMRI resulted in improved detection of csPC at a lesion level with AUC of 0.72 (95% CI 0.63-0.81), 0.70 (0.60-0.79), and 0.79 (0.71-0.88) for mpMRI, PSMA PET, and combined MRI/PET respectively. In the initial cohort of 18 lesions with csPC, 15/18 (83%) were positive on both modalities with 1/18 (6%) positive on mpMRI only, and 2/18 (11%) positive on PET only.

**CONCLUSION**

Combining PSMA PET and mpMRI improves diagnostic accuracy for csPC detection and offers complementary information.

**CLINICAL RELEVANCE/APPLICATION**

PSMA PET can add value to mpMRI in patients with low/intermediate risk prostate cancer on active surveillance, including detection of csPC that is missed by mpMRI and highlighting areas of disease that may be progressing to higher grade. Ongoing subset analysis will investigate which patients may benefit the most from this combined approach.

### PURPOSE

To compare the detection of Cr/IDC morphology PCa on multiparametric (mpMRI) targeted biopsy versus systematic biopsy in biopsy naive men at risk for PCa .

### METHODS AND MATERIALS

This study was a secondary analysis of a prospective randomized controlled trial which recruited participants with a clinical suspicion of PCa between April 2017 and November 2019 at 5 centers. Participants were randomized 1:1 either to MRI arm or systematic biopsy arm. Targeted biopsy was performed in participants with a Prostate Imaging-Reporting and Data System (PI-RADS) score =3.MRI features were recorded and biopsy slides and prostatectomy specimens were reviewed for the presence or absence of Cr/IDC histological patterns. Comparison of Cr/IDC patterns was performed using generalized linear mixed modeling.

### RESULTS

A total of 453 participants were enrolled, with 226 in the systematic biopsy arm (median age, 65 years [IQR: 59, 70]; 196 biopsies available for assessment) and 227 in the mpMRI targeted biopsy arm (median age, 67 years [IQR: 60, 72]; 132 biopsies available for assessment). Identification of Cr/IDC PCa was lower in the systematic biopsy arm compared to the mpMRI arm (31 of 196 [16%] vs 33 of 132 [25%]; P = .01). No evidence of a difference in mean cancer core length (CCL) (11.3 mm ± 4.4 [SD] versus 9.7 mm ± 4.5 [SD]; P=.09), apparent diffusion coefficient value (685 μm2/s ± 178 [SD] versus 746 μm2/s 245 [SD]; P=.52; P = .52) or dynamic contrast enhanced positivity (27 [82%] versus 37 [90%]; P = .33) for clinically significant PCa (csPCa) were observed between participants with or without Cr/IDC disease in the MRI arm. Cr/IDC positive histology overall had a higher mean CCL compared to negative Cr/IDC csPCa (11.1 mm ± 4.4 [SD] versus 9.2 mm ± 4.1 [SD]; P=.009).

### CONCLUSION

MRI targeted biopsy showed increased detection of Cr/IDC histological patterns compared to systematic biopsy. Clinical trial registration no. NCT02936258

### CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI (mpMRI) and targeted biopsy only are increasingly replacing systematic biopsy for diagnosis, risk stratification and monitoring. However, the evidence regarding MRI detection of Cr/IDC pattern PCa is contradictory. Our Phase 3 RCT trial demonstrated that Cr/IDC pattern PCa is more likely to be detected on mpMRI targeted biopsy compared with systematic biopsy

## T6-SSGU04-5 PROSTATE MRI USING THE PROSTATE IMAGING FOR RECURRENCE REPORTING (PI-RR) SCORING SYSTEM TO DETECT RECURRENT PROSTATE CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

### PURPOSE

The aim of this systematic review and meta-analysis was to assess the diagnostic performance of the PI-RR system in predicting the likelihood of local recurrence after whole-gland treatment.

### METHODS AND MATERIALS

The Preferred Reporting Items for Systematic Reviews (PRISMA) - Diagnostic Test Accuracy guidelines were followed. Relevant databases were searched through December 2023. Primary studies met eligibility criteria if they reported MRI diagnostic performance in prostate cancer recurrence using PI-RR. Diagnostic performance for MRI was performed using two different cut-off points (= 3 or = 4 as positive cases according to the PI-RR system). A meta-analysis with a random-effects model was used to estimate pooled sensitivity and specificity.

### RESULTS

Sixteen articles were reviewed with full-text reading, and six were considered eligible totaling 467 patients. Using a cutoff of PI-RR = 3 (4 studies) for recurrent disease, the sensitivity and specificity were 77.8% (95% CI: 69.9-84.1%) and 80.2% (95% CI: 58.2-92.2%), respectively. Considering a cutoff of PI-RR = 4 (4 studies), the sensitivity and specificity were 61.9% (95% CI: 35.6-82.7%) and 86.6% (CI: 75.1-93.3%), respectively. Overall, the inter-rater agreement varied from fair to excellent.

### CONCLUSION

PI-RR is accurate in detecting local recurrence after whole-gland treatment for prostate cancer and shows fair-to-good to excellent inter-reader agreement. Overall, the PI-RR cutoff = 3 showed high sensitivity and specificity.

### CLINICAL RELEVANCE/APPLICATION

In this systematic review we looked at MRI diagnostic performance in prostate cancer recurrence when following the PI-RR system. We found that it has good sensibility and specificity, with fair to excellent agreement between different radiologists.

## T6-SSGU04-6 MULTIPARAMETRIC MRI CHARACTERISTICS IN YOUNG MEN WITH NORMAL PSA

Kai Jannusch (*Abstract Co-Author*) Nothing to Disclose
Birte Valentin, MD (*Abstract Co-Author*) Nothing to Disclose
Peter Albers, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lars Schimmoeller, MD (*Abstract Co-Author*) Nothing to Disclose

Matthias Boschheidgen (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze multiparametric magnetic resonance imaging (mpMRI) appearance in young men (median age 50 years) with PSA below 3ng/ml.

### METHODS AND MATERIALS

In this prospective analysis within the PROBASE study consecutive men with PSA below 3 ng/ml and mpMRI were included. These men were screened with PSA-measurement at the age of 50 and underwent subsequent mpMRI. Occurrence of PI-RADS 4/5 would indicate MRI/TRUS-fusion and systematic biopsy. MRI findings in the peripheral zone (PZ) were characterized regarding changes in T2w, ADC value, and dynamic contrast enhancement (DCE).

### RESULTS

Between September 2021 and March 2022 fourty-seven men were analyzed. The median baseline characteristics were age 50 (50-51), PSA level 1.22 ng/ml (0.47 - 1.79), PI-RADS classification 2 (1-3), PI-QUAL 5 (3-5), prostate volume 27 ml (23-32), and PSA density 0.04 ng/ml2 (0.02-0.06). PI-RADS 3 occurred in 45% of men. No PI-RADS 4/5 was observed. Consecutively, no men underwent biopsy. But with more than two years f/u according to PROBASE no cancer case was reported. For PZ, diffuse T2w-hypointensities were present in 81% of men. Focal and accentuated T2w-lesions were detected in 11% and 40%, respectively. DCE enhancement of the PZ was partially and severely observed in 53% and 17%, respectively. The lowest and highest ADC values were 1230 ± 197 [×10-3 mm2/s] and 1819 ± 174 [×10-3 mm2/s], respectively. 30% of men had significant hyperplasia of TZ.

### CONCLUSION

In younger men with normal PSA levels, no instances of MRI suspicion for clinically significant prostate cancer were observed. However, diffuse T2w-hypointensities and DCE enhancement of the PZ were very common and resulted in PI-RADS 3 in 45%. That seems more likely to be age specific or inflammatory matching with the higher ACD values compared to PC.

### CLINICAL RELEVANCE/APPLICATION

Our study characterizes the “normal” imaging appearance of MRI in younger men with PSA values below 3 ng/ml in a screening setting. Nearly half of all men had PI-RADS classification of 3 which emphasizes the difficulties of the PI-RADS system for young subjects in a screening setting. However, no instances of MRI suspicion for clinically significant prostate cancer were observed and after more than 2 years f/u no cancer case was reported.

## T6-SSPH08-1 AUTOMATED ULTRASOUND IMAGING PERFORMANCE EVALUATION USING A RANDOMLY-DISTRIBUTED SPHERE VOID PHANTOM

Zheng Feng Lu, PhD (*Abstract Co-Author*) Nothing to Disclose
Cristel X. Baiu, MENG (*Abstract Co-Author*) Nothing to Disclose
Dufan Wu, PhD (*Abstract Co-Author*) Nothing to Disclose
Baihui Yu, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

IEC TS 62791:2022 specified a method to quantify the human-observer-related lesion detectability by measuring the lesion signal-to-noise ratio (LSNR) using randomly distributed sphere phantoms with mechanical scanning devices. We developed an automated analysis method for this task using freehand scanning. This study aims to apply it to various acquisition settings for computerized performance evaluation and preset optimization.

### METHODS AND MATERIALS

An ultrasound tissue-mimicking phantom that includes randomly distributed high-contrast spheres of 2 mm diameter and 20% volume fraction was scanned by moving the transducer freehand from one side to the other using a cine-loop acquisition. The volumetric image data were generated by stacking the elevational frames. After non-local mean denoising and N4 bias correction, the spheres were segmented with adaptive thresholds and watershed algorithm. Lesion detectability was quantified by LSNR for each sphere on the original image with the derived segmentation. LSNR was only calculated within the scanning plane where the maximum sphere cross-section was detected out of the elevational frames acquired by freehand scanning. The depth-dependent mean LSNR curve was then generated.The phantom was scanned by a GE Logiq E10 system with an ML6-15 linear array transducer. LSNR and the sphere count as functions of the depth were evaluated by changing the following factors one at a time: nominal frequency, imaging modes and compound techniques, dynamic range, transmit power, and gain. The focus was uniformly applied across the entire depth range.

### RESULTS

The best LSNR was observed around the 4cm depth for all settings except for B-mode, demonstrating the robustness of the method. The following acquisition settings led to better LSNR: higher nominal frequency, harmonic imaging with compound, decreased dynamic range, higher power, and higher gain. All factors contributed to more detected spheres except the dynamic range. The results agreed with the visual assessments. The reproducibility was verified by repeating the freehand scans under the same setting 11 times. The standard deviation of LSNR averaged along the depth was only 8.2%, while that of the sphere counts was up to 33.8% due to different hand motion speeds.

### CONCLUSION

The automated analysis method for sphere phantom by freehand scanning provides accurate and stable quantitative assessment of the lesion detectability for ultrasound performance evaluation.

### CLINICAL RELEVANCE/APPLICATION

The automated analysis tool using a low-cost sphere void phantom, along with the ease of freehand scanning, has simplified ultrasound performance evaluation and preset optimization, and can play a critical role in routine ultrasound QA/QC in a clinical environment.

## PURPOSE

To evaluate the feasibility of risk assessment of carotid plaques using 2D and 3D contrast-enhanced ultrasound (CEUS) with subharmonic-aided pressure estimation (SHAPE)

## METHODS AND MATERIALS

This prospective study enrolled 20 patients scheduled for carotid endarterectomy. Prior to their endarterectomy, subjects underwent 2D and 3D CEUS. The calcified plaque area, contrast-enhanced plaque area, and mean intensity of the contrast-enhanced plaque area were obtained from 2D CEUS. 3D SHAPE was used to estimate the pressure gradient between the carotid artery and plaque as well as the intraplaque pressure, utilizing the strong inverse linear relationship between subharmonic signal intensity from US contrast agents and ambient pressure. The subharmonic signal gradient i.e., the pressure gradient between the carotid artery and plaque as well as the mean subharmonic signal in the plaque were calculated from 3D SHAPE data. Four surrogate predictors of cardiovascular events were obtained from histological analysis of the plaque specimens collected after the endarterectomy: percentage lipid core, vascularity, intraplaque hemorrhage, and plaque cap thickness. The histology grades and US results were correlated using Spearman's correlation. The risk score combined from the histology predictors were compared to the US results independently or in combination.

## RESULTS

The contrast-enhanced plaque area and mean intensity of contrast-enhanced plaque area correlated moderately with the histological vascularity (? = 0.48-0.55). The pressure gradient between carotid artery and plaque had negative correlations with plaque vascularity (? = -0.31), cap thickness (? = -0.21), and intraplaque hemorrhage (? = -0.18). The plaque calcification showed negative correlation with cap thickness (? = -0.32). The intraplaque pressure by 3D SHAPE showed weak correlations with plaque vascularity (? = 0.28) and lipid core (? = 0.15). The mean intensity of contrast-enhanced plaque area showed the highest correlation with histology risk score combined from all 4 surrogate predictors (? = 0.35). When all US results were combined, correlation coefficients with the risk score based on all 4 surrogate predictors, based on plaque cap thickness, vascularity, and intraplaque hemorrhage, and based on vascularity and intraplaque hemorrhage were 0.56, 0.63, and 0.63, respectively.

## CONCLUSION

The plaque vascularity quantified by CEUS correlated well with the vascularity assessed by histology. Combined with the plaque calcification and vascularity from CEUS, the pressure estimates by 3D SHAPE showed the feasibility of risk assessment of carotid plaques.

## CLINICAL RELEVANCE/APPLICATION

CEUS with SHAPE showed potential to assess the risk of carotid plaques.

# T6-SSPH08-3 ULTRASOUND B MODE PERITUMORAL HETEROGENEITY OF LIVER METASTASES PREDICTS EARLIER OVERALL SURVIVAL FOR PATIENTS TREATED WITH IMMUNOTHERAPY

## PURPOSE

To evaluate the heterogeneity in the liver tumor and peritumoral area on B mode images to predict overall survival (OS) in metastatic patients who were treated with immunotherapy and had undergone an ultrasound (US) for the follow-up of their liver metastases irrespective of the cancer of origin.

## METHODS AND MATERIALS

This retrospective cohort included 49 patients who started their treatment from 2016. Patients who were followed up with a US of their liver tumor, after the onset of treatment at baseline, day 8 (D8) or day 14 (D14) and day 21(D21) were included.They eligible if they presented metastatic solid liver tumors, and were treated with immunotherapy, irrespective of their cancer of origin. The B Mode images of these patients were collected for each time point, totaling to 217 images. The liver and the lesion, regions of interest (ROI) visible on the images were outlined by a junior and a senior radiologist. The peritumoral mask was obtained by dilating the lesion ROI 1 cm. The images were normalized according to the gray levels of the fat mass. The heterogeneity index (H-index) for each lesion was calculated by clustering the ROI based on their gray level intensity and by quantifying the cluster's spatial heterogeneity(SH). The SH was based on the connectivity of the patches created by the clusters in the ROI and the cluster volume occupied with respect to the ROI volume. The end-point of the analysis was OS. Analyses were performed using the univariate Cox proportional hazard models, and the Kaplan Meir curves were used to visualize the separation between the populations with respect to the cut-offs found using maximally ranked selected statistics.

## RESULTS

Among the 49 patients, 42 patients, with availability of good quality images, were selected. The type of primary cancers included skin, colon, liver, rectal and breast cancers. The median OS was 12.33 months. Univariate cox analyses show that the H-index (p=0.009) of the peri tumoural region is an independent predictor of OS at D21. When normalized with respect to the area of the tumor, the H-index (p=0.01) still significantly predicts the OS at D21. Patients with a higher H-index (>0.109) have longer median OS (46.06 months) compared to those with a smaller H-index (=0.109) and a shorter OS (7.32 months). The analyses with the images at baseline, D8 and D14, did not yield a significant prediction of the OS.

## CONCLUSION

Tumor heterogeneity in the liver peritumoral region can be considered as a biomarker for liver metastases, irrespective of the origin of cancer.

## CLINICAL RELEVANCE/APPLICATION

B mode image brightness is related to the amplitude of the echo received from the boundaries of the tissues, using this method to measure heterogeneity can bring insights for better patient follow up and better survival prediction.

### PURPOSE

Periodic quality control (QC) testing of ultrasound (US) scanner systems is essential to ensure and maintain image quality. This study analyzes QC findings from medical physics annual surveys of modern clinical US systems.

### METHODS AND MATERIALS

QC results from annual surveys between 2018 and 2021 were retrospectively collected from 12 medical physicists from 10 institutions and one consulting company (hereafter referred to as sites). QC tests were classified as scanner- and transducer-related, evaluation of diagnostic workstation (DWS) display monitors, and review of routine QC programs. Test methodology and pass/fail criteria were established by each site. QC findings were defined as results requiring follow-up action by service engineers or other personnel. Items earmarked for future QC monitoring were not considered findings. When possible, the causes of physical and mechanical integrity (PMI) findings and transducer nonuniformity and artifact (NUA) findings were recorded. QC findings as the percentage of the equipment count per year were calculated and averaged for sites with multiple years of data.

### RESULTS

Among 11 sites, the maximum number of scanners and transducers tested per year totaled 349 and 1690, respectively. For scanners, all sites performed PMI inspections and visual assessments of scanner display monitors (SDM). The average percentage of scanner findings per year ranged from 0 to 40.8% (median 18.0%) across all sites. The most common QC findings were from PMI, followed by quantitative measurements of SDM. The top cause for PMI findings was faulty scanner brakes. Additional scanner findings, in decreasing order, stemmed from transducer port testing, visual testing of SDM, and overall system sensitivity (exhibited as reduced sensitivity of all transducers). For transducers, all sites tested PMI, NUA, and sensitivity. The average percentage of transducer findings per year ranged from 0.5% to 19.9% (median 7.2%) across all sites. The most common QC findings were due to NUA, followed by PMI issues. The top causes were weak/bad elements for NUA and transducer face issues for PMI. Other findings, in decreasing order, resulted from sensitivity in fundamental mode, lateral spatial resolution, sensitivity in harmonic mode (all identified in sensitivity in fundamental mode), and horizontal distance accuracy. 18.2% of sites conducted DWS monitor testing with one monitor showing findings and 18.2% of sites evaluated the QC program with no finding.

### CONCLUSION

Medical physics annual surveys revealed considerable actionable findings of modern US systems across 11 sites.

### CLINICAL RELEVANCE/APPLICATION

The survey results highlight valuable QC tests which yield actionable findings and can guide clinical QC activities to ensure image quality.

## T6-SSPH08-5 CONFOUNDERS OF ULTRASOUND ATTENUATION IMAGING IN A LINEAR PROBE USING THE CANON APLIO I800 SYSTEM: A PHANTOM STUDY

Alexander Martin, DPhil, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

There have been studies showing attenuation imaging (ATI) with ultrasound as an approach to diagnose liver diseases such as steatosis or cirrhosis. So far, this technique has only been used on a convex probe. The goal of the study was to investigate the feasibility of ATI measurements using the linear array on a canon Aplio i800 scanner on certified phantoms.

### METHODS AND MATERIALS

Three certified liver tissue attenuation phantoms were measured in five different positions using a linear probe. The effects of positioning and depth were explored and compared. The values were compared to the certified expected value for each phantom as well as the different measurement values for each measurement position.

### RESULTS

The ATI measurements on phantoms significantly affected the different probe positions and region of interest (ROI) depths. Values in the center with the probe perpendicular to the phantom were closest to certified values. Median values at 2.5-4.5 cm depth for phantoms 1 and 2 and 0.5-2.5 cm for phantom 3 were comparable with certified values. Measurements taken at a depth greater than 6 cm in any position were the least representative of the certified values ($p$-value $< 0.01$) and had the widest range throughout the sessions.

### CONCLUSION

ATI measurements can be performed with the linear probe in phantoms; however, careful consideration should be given to depth dependency, as it can significantly affect measurement values. Remaining measurements at various depths within the 0.5-6.0 cm range showed deviation from the certified values of approximately 25%.

### CLINICAL RELEVANCE/APPLICATION

Developing a protocol for using a linear probe for attenuation imaging with potential uses for superficial structures such as MSK, breast or thyroid, as well as possible uses in paediatric medicine.

## T6-SSPH08-6 PROTOACOUSTIC RADIOGRAPHY

Liangzhong Xiang, PhD (*Abstract Co-Author*) Nothing to Disclose
Yong Chen, PHD (*Abstract Co-Author*) Nothing to Disclose
Kristina Bjegovic, BS (*Abstract Co-Author*) Nothing to Disclose
Kaitlyn Kim, BS (*Abstract Co-Author*) Nothing to Disclose
Gilberto Gonzalez, PHD (*Abstract Co-Author*) Nothing to Disclose
Prabodh K. Pandey, PhD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Introducing "Protoacoustic Radiography" as a novel imaging method which leverages proton-induced acoustic (PrA) waves near the Bragg peak (BP) to enable 3D visualization from a single projection, addressing the limitations of traditional proton radiography, which requires multiple projections and precise proton tracking for 3D imaging. Protoacoustic Radiography streamlines the process, reducing procedure times and minimizing organ exposure to radiation. Additionally, Protoacoustic Radiography fully utilizes the superior contrast available near the Bragg peak. Experimental studies we performed. indicate its effectiveness in sensing materials contrast as well.

### METHODS AND MATERIALS

Experiment #1 involved the setup of three Cerrobend bars, spaced approximately 1 cm apart both axially and laterally within a water tank. Positioned around 6 cm from the central target, a 256-element ultrasonic transducer (UT) collected PrA signals generated by pulsed proton absorption. The choice of a proton energy level of 176MeV was made to align with the Bragg peak (BP) between the first two rods. PrA signals were captured for two additional energy levels, each shifting the BP by 1 cm. Image reconstructions were performed using a universal backprojection algorithm. In Experiment #2, a copper and a Cerrobend bar, separated by about 1 cm laterally, underwent irradiation. The energy deposition (ED) was reconstructed and subsequently refined for proton fluence correction using a regularized division method.

### RESULTS

Experiment #1: Using 176MeV proton excitation, only the first bar was imaged. At the second energy level (181 MeV), the first two bars could be seen while the third energy level (186 MeV) extended the imaging to include all the three bars within the proton range. Experiment #2: The reconstructed energy deposition map exhibited comparable values for both copper and Cerrobend rods. The fluence correction underscored the contrast variation between the two materials.

### CONCLUSION

A novel imaging method emerges from the synergy between protons and ultrasound, providing three-dimensional imaging from a single projection, depth selectivity based on proton range, and material contrast detection. This technique not only minimizes radiation exposure to organs along the proton path but also strategically shields deeper vital organs from radiation.

### CLINICAL RELEVANCE/APPLICATION

The proposed technique, Protoacoustic Radiography (PAR), has the capability to provide comprehensive 3D imaging of a targeted region from a single projection. By minimizing radiation exposure to organs in its path and effectively shielding deeper vital organs from harmful radiation by tuning proton energy, PAR has the potential to revolutionize medical imaging practices.

Simon Rickaby (*Abstract Co-Author*) Nothing to Disclose
Mathew Storey, MBChB (*Presenter*) Nothing to Disclose

### PURPOSE

Lung cancer is the leading cause of cancer mortality in the UK where five-year survival lags behind comparably developed nations. Improving early diagnosis is a national priority but is limited by the radiology workforce crisis and comparably low access to CT. We pilot the 'Artificial Intelligence triage to same day CT' (AI-CT) pathway using a 14 finding version of the Annalise CXR v2.3 model to improve access to CT for patients with suspected cancer and assess the diagnostic performance of the algorithm in this real-world project.

### METHODS AND MATERIALS

All chest radiographs between between January 2022 and October 2023 from 5 NHS centres in London, England. Time from chest radiograph acquisition to CT report (Time to CT), model findings, suspected cancer on CXR and CT were recorded before and after introduction of the AI-CT pathway . Survival analysis was performed using Time to CT and diagnostic performance metrics (including AUC-ROC and F1 scores) of the model were calculated using suspected cancer on CT as the ground truth.

### RESULTS

Data from 26,660 chest radiograph and 573 CT thorax examinations performed within 7 days were analysed. There was a significant improvement in the proportion of patients undergoing CT within 1 and 3 days of a suspicious chest radiograph (HR1.93 and 1.34 respectively, $p < 0.001$) following introduction of the AI-CT pathway. Same day CT was much more likely at sites with co-located CXR and CT facilities (HR 7.6, $p < 0.001$). The highest performing AI features were ‘single pulmonary nodule', 'multiple pulmonary masses' and 'single pulmonary mass' returning F1 scores of 0.47, 0.42 and 0.38 respectively. The combined 14-feature model sensitivity was 91% but specificity was 22% (F1 score 0.56).

### CONCLUSION

The custom model has high sensitivity but low specificity for cancer on chest radiographs and the AI-CT pathway improves the same day access to CT, but only at sites with co-located CXR and CT facilities.

### CLINICAL RELEVANCE/APPLICATION

The model can perform supervised triage to improve CT access for cancer while unsupervised deployment is limited by low specificity.

# Abstract Archives of the RSNA, 2024

Katrin Hostettler Haack (*Abstract Co-Author*) Nothing to Disclose
Martin Segeroth, MD, BSc (*Abstract Co-Author*) Nothing to Disclose
Maurice Pradella, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Accurate assessment of lung involvement is important for diagnosis and treatment planning in patients with sarcoidosis. Chest CT is the gold standard; however, low-field MRI promises to be a radiation-free alternative. This study aims to evaluate the inter-rater agreement between pulmonary MRI on a commercial low-field system with CT scans assessing lung parenchymal changes in sarcoidosis patients.

### METHODS AND MATERIALS

Patients with known pulmonary sarcoidosis were prospectively enrolled in this study. They underwent both CT (lung kernel reconstruction 1 mm3 resolution) and low-field MRI (commercial 0.55 T system; Free.Max, Siemens Healthineers). For MRI, a 3D radial balanced steady-state free precession (bSTAR) sequence with 1.3 mm3 isotropic resolution acquired during free-breathing was used; acquisition time was 6 min. Three cardiothoracic radiologists (experience: 20 years, 6 years, 1 year) independently reviewed first the CT scans and, after a blinding period of minimum 7 days, the MRI scans of all patients. Raters evaluated the presence or absence of reticulations, ground glass opacities, traction bronchiectasis, consolidations, and nodules. Inter-rater agreement for both MRI and CT reading sessions was quantified using Fleiss kappa (?). Furthermore, accuracy, sensitivity, and specificity using the CT readings as ground truth for the MRI readings were calculated.

### RESULTS

Fifteen patients were enrolled in this study, mean age: 50 years, 8 females. Mean accuracy, sensitivity and specificity between CT and MRI readings amounted to: consolidations (73%, 86%, 66%), traction bronchiectasis (73%, 27%, 96%), nodules (71%, 67%, 67%), ground glass opacities (64%, 70%, 59%), and reticulations (69%, 29%, 86%). Comparing inter-rater agreement between MRI and CT reading sessions, we found that agreement on MRI was higher for consolidations (?MRI = 0.62 vs. ?CT = 0.46), traction bronchiectasis (?MRI = 0.55 vs. ?CT = 0.30) and nodules (?MRI = 0.35 vs. ?CT = 0.17). On opposite, ground glass opacities (?MRI = -0.17 vs. ?CT = 0.73) and presence or absence of reticulations (?MRI = -0.29 vs. ?CT = 0.17) showed worse agreement in MRI readings.

### CONCLUSION

Our study suggests that commercial low-field MRI may offer new possibilities for pulmonary imaging. However, variance among raters identifying common lung parenchymal patterns was high. Technical and educational efforts are required to further improve imaging sequences and strengthen radiologists' confidence to enhance diagnostic accuracy and consistency in pulmonary MRI.

### CLINICAL RELEVANCE/APPLICATION

Commercial low-field MRI might be a radiation-free alternative to CT for lung imaging. Whilst dedicated MRI sequences might be improved further, radiologists should familiarize with pulmonary MRI, expanding its diagnostic potential for detection and management of lung diseases.

## T6-STCE2-2 EFFICACY OF FOLLOW-UP PORTABLE MRI COMPARED TO STANDARD FOLLOW-UP HEAD CT FOR INTERVAL EVALUATION OF TRAUMATIC INTRACRANIAL HEMORRHAGE

Ahmed Sayed Ahmed (*Abstract Co-Author*) Nothing to Disclose
Madonna Stotsenburg (*Abstract Co-Author*) Nothing to Disclose
Mario Rueda (*Abstract Co-Author*) Nothing to Disclose
Kaveh Asadi (*Abstract Co-Author*) Nothing to Disclose
Robert Borrego (*Abstract Co-Author*) Nothing to Disclose
Lauren Thompson (*Abstract Co-Author*) Nothing to Disclose
Faris Azar (*Abstract Co-Author*) Nothing to Disclose
Athina Yoham (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate and timely follow-up imaging is crucial for the effective clinical management of traumatic intracranial hemorrhage (TICH). The conventional follow-up modality is head computed tomography (CT), recognized for its widespread availability and rapid acquisition time. Portable magnetic resonance imaging (pMRI) presents several potential advantages, including enhanced portability, absence of ionizing radiation, and superior soft tissue contrast. This study seeks to evaluate the efficacy of follow-up pMRI relative to standard head CT in the assessment of TICH.

**METHODS AND MATERIALS**

From 02/23/2024 to 08/01/2024, patients with TICH at our level 1 trauma center were screened for eligibility to participate in our prospective study. Informed consent was obtained from all participants. Enrolled patients with TICH identified on head CT underwent pMRI on admission and pMRI images were then compared to CT images. The primary outcome was to evaluate pMRI's ability to identify and describe changes in TICH size and quality, compared to head CT. The secondary outcome was pMRI's impact on clinical decisions compared to head CT.

**RESULTS**

Twenty patients with a mean age of 63 years (±21 years), (14 males, 6 females) were included in this study. The mean interval between follow-up CT and pMRI was 10 hours (±5.7 hours). The study encompassed cases of subdural hematomas (n=11), subarachnoid hemorrhages (n=6), and intraparenchymal hemorrhages (n=3). pMRI exhibited superior performance in delineating intraparenchymal hemorrhages, subarachnoid hemorrhages, and the extent of hemorrhagic contusions, owing to its superior soft tissue contrast. Furthermore, pMRI identified detailed features of subdural hematomas that were not detected by CT, although certain subdural hematomas, such as tentorial hemorrhages, remained inconspicuous on pMRI. Both imaging modalities effectively assessed midline shifts and mass effects; however, pMRI provided a more comprehensive visualization of soft tissue involvement.

**CONCLUSION**

Follow-up pMRI is a reliable and effective alternative to standard head CT for monitoring TICH. It provides comparable diagnostic information while offering additional benefits such as portability and the absence of ionizing radiation, making it an excellent choice for routine clinical follow-up. These findings suggest that pMRI may enhance TICH follow-up and provide additional insights. Further research is necessary to confirm these results and evaluate the cost-effectiveness of incorporating pMRI into standard clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

pMRI is safer as it lacks ionizing radiation, enhancing patient outcomes and clinical treatment of TICH. Its superior soft tissue contrast and mobility improve follow-up care.

## T6-STCE2-3 EARLY EXPERIENCE SCANNING PATIENTS WITH CLINICAL CARDIOVASCULAR INDICATIONS ON A 0.55T MRI SCANNER

Adrienne Campbell (*Abstract Co-Author*) Nothing to Disclose
Rajiv Ramasawmy (*Abstract Co-Author*) Nothing to Disclose
Christine Mancini (*Abstract Co-Author*) Nothing to Disclose
Hui Xue, PhD (*Abstract Co-Author*) Nothing to Disclose
Haiyan Wang (*Abstract Co-Author*) Nothing to Disclose
W. Patricia Bandettini, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We present our early experience scanning patients with clinical cardiovascular (CV) diagnoses and indications on a 0.55T MRI scanner to demonstrate feasibility of using mid field strengths in cardiovascular magnetic resonance (CMR).

**METHODS AND MATERIALS**

Patients with known or suspected cardiovascular disease underwent an IRB-approved research CMR on a 0.55T MRI scanner (prototype MAGNETOM Free.Max, Siemens Healthineers, Erlangen, Germany). The commercial 0.55T MRI system is not FDA cleared for CMR, and our prototype system includes a custom gradient upgrade. All sequences were research sequences and triggered by an external monitor (Expression MR400 In Vivo, Philips, Amsterdam, the Netherlands). Sequences used were based upon the CV assessment needs with all patients undergoing localizers and cine assessment. Phase contrast, parametric mapping, perfusion imaging, contrast angiography, and late gadolinium enhancement were added as indicated. An AI-based denoising filter was applied to cine, perfusion, and late enhancement imaging. Standard doses of gadolinium contrast were used as indicated and as agreed upon by subjects. CV evaluations were categorized into the following categories: cardiomyopathy, valve/shunt, myocardial infarction (MI)/stress, myocarditis, complex congenital, mass, aorta.

**RESULTS**

Forty-five patients underwent CMR on the 0.55T system. 43 were resting studies; 21 studies used gadolinium contrast. 29 participants were male (16 female); mean age 53±15 yrs; 33 White, 9 Black or African American, 3 Asian; 4 Hispanic/Latino. Categories of scans were distributed as follows: 13 cardiomyopathy, 13 valve/shunt, 7 MI (included 2 stresses), 3 myocarditis, 6 complex congenital disease, 4 masses, one aorta. Some patients had more than one indication. 43 patients had a clinical CMR performed within two months of the 0.55T scan. All studies were evaluated qualitatively and were diagnostic for structural and cardiac chamber functional information. All contrast late gadolinium enhancement studies were diagnostic, but in some cases AI-based denoising caused blurring. Valvular and shunt information correlated well between field strengths.

**CONCLUSION**

In our early experience in a moderate size group of patients with suspected and known clinical CV disease, we have demonstrated that cardiovascular assessment of a broad selection of disease processes is feasible using our 0.55T MRI system. Validation in larger groups of patients with additional indications will strengthen the diagnostic confidence of imaging at lower field strengths.

**CLINICAL RELEVANCE/APPLICATION**

Imaging at low to mid-field field strengths may offer the potential to expand clinical CMR assessment globally in a sustainable fashion.

## T7-SSBR06-1 INTRATUMORAL HETEROGENEITY-BASED RADIOMICS FOR PREOPERATIVE DIFFERENTIATION OF HER2-POSTIVE, -LOW AND -ZERO BREAST CANCERS USING MULTIPARAMETRIC MRI:A MULTICENTER STUDY

Yulu Liu (*Abstract Co-Author*) Nothing to Disclose
Yi Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Haoquan Chen (*Presenter*) Nothing to Disclose

### PURPOSE

Targeted therapy employing anti-HER2 antibody-drug conjugates has demonstrated efficacy in treating patients with HER2-low breast cancers. However, intratumoral heterogeneity (ITH) presents a great challenge in the identification of HER2-low cancers via pathological evaluation. Hence, the purpose of this study is to develop an ITH-based radiomics model to differentiate HER2-postive, -low and -zero breast cancers using multiparametric MRI.

### METHODS AND MATERIALS

A total of 675 patients were enrolled in this retrospective study from two institutions between July 2017 and October 2021. To identify patients with HER2-low breast cancers, the study involved a two-step process. Initially, discrimination between HER2-positive and -negative status was conducted, followed by differentiation between HER2-low and -zero status in the second step. For each step, four models were developed, including the clinical model, radiomics model, ITH model, and combined model, respectively. Multivariable logistic regression analysis was used to identify significant clinicopathologic variables. ITH was reflected by radiomics features extracted from intratumoral subregions, with an ITH score derived from model output probabilities. Subregion radiomics features combing clinicopathologic variables were integrated into a combined model. The area under the receiver operating characteristic curve (AUC) was used to assess the predictive power of each model.

### RESULTS

The first step was comprised of 675 patients from two centers (training, n=371, validation, n=158, test, n=146). The second step was encompassed 503 patients (training, n=283, validation, n=123, test, n=97). Ki-67 emerged as the sole independent factor associated with the odds of HER2-low status (odds ratio = 0.92; 95%CI: 0.87, 0.97; $P < 0.05$). In both steps, the ITH model showed great performance in the test cohort, with AUCs of 0.80(95%CI: 0.73-0.87) in Step 1 and 0.80(95%CI: 0.73-0.87) in Step 2. Among HER2-positive, -low and -zero breast cancers, the combined models performed the optimal, achieving an AUC of 0.84 (95%CI: 0.77-0.90) in the test cohort for differentiating between Her2-positive and -negative cancers, and an AUC of 0.80(95%CI: 0.72-0.89) for differentiating between Her2-low and -zero cancers.

### CONCLUSION

A model combining subregion radiomics features, reflecting ITH, with clinicopathologic variables can differentiate patients with HER2-positive, -low and -zero breast cancers.

### CLINICAL RELEVANCE/APPLICATION

Our study revealed that an ITH-based radiomics model can effectively differentiate among HER2-postive, -low and -zero breast cancers. This might contribute to precise clinical selection of suitable populations that acquire benefit from anti-Her2 targeted therapies.

## T7-SSBR06-2 KINETIC ANALYSIS OF BACKGROUND PARENCHYMAL ENHANCEMENT FOR IMPROVED BREAST CANCER RISK STRATIFICATION IN BREAST MRI

Sven Nebelung, MD (*Abstract Co-Author*) Nothing to Disclose
Debora Jutz (*Abstract Co-Author*) Nothing to Disclose
Christiane K. Kuhl, MD, PhD (*Abstract Co-Author*) Advisory Board, Guerbet SA;Speaker, Bracco Group;Speaker, Bayer AG
Daniel Truhn, MD (*Abstract Co-Author*) Research Consultant, Aristra Medical
Gustav Mueller-Franzes, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Previous studies have shown that the degree of Background Parenchymal Enhancement (BPE) is associated with risk of subsequent breast cancer. This study aimed to evaluate whether a more refined analysis of BPE, i.e. analysis of BPE kinetics (BPEK) on dynamic contrast enhanced breast MRI, allows an improved risk stratification.

**METHODS AND MATERIALS**

The cohort consisted of 4,034 breast MRI scans from 2,017 women, including 585 women with breast cancer (186 pre-, 399 postmenopausal) and 1,432 cancer-free women (518 pre-, 914 postmenopausal). Breast MRI studies were acquired according to a fully standardized protocol, consisting of one pre- and four consecutive post-contrast T1-weighted images. A neuronal network was trained to segment the fibroglandular tissue automatically and to quantify degree of BPE as relative signal intensity increase between pre- and post-contrast. BPEK was defined as early to late BPE: (S1-S0)/(S4-S0), where S0, S1, and S4 refer to the mean signal intensity in the precontrast, first- and fourth post-contrast images. BPE and BPEK were compared for women with breast cancer in the contralateral healthy breast and women without breast cancer in the left or right breast.

**RESULTS**

Degree and kinetics of BPE differed significantly for the 1,313 postmenopausal women with vs. without breast cancer (5.51±3.70 vs. 4.55±2.73, P<.001 and 0.35±0.11 vs. 0.32±0.10, P=<.001). For the 704 premenopausal women with vs. without breast cancer, BPE did not differ significantly (11.27±7.21 vs. 10.78±7.86, P=0.53), while BPE kinetics did differ significantly (0.39±0.09 vs. 0.37±0.09, P=.05).

**CONCLUSION**

BPEK is significantly associated with breast cancer, independent of menopausal status, while BPE was not. BPEK may thus allow improved breast cancer risk stratification.

**CLINICAL RELEVANCE/APPLICATION**

Automatically derived quantitative measures of BPEK may help to stratify patients according to their risk of developing breast cancer.

## T7-SSBR06-3 A DEEP LEARNING-BASED APPROACH IN DISTINGUISHING BETWEEN BENIGN AND MALIGNANT BREAST LESIONS USING DIFFUSION-WEIGHTED MRI: A MULTICENTER STUDY

Yi Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Haoquan Chen (*Abstract Co-Author*) Nothing to Disclose
Yulu Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

Breast MRI has been recommended as a supplemental screening tool for breast cancer, but its long examination time and use of contrast material remains concerning. This study aims to develop a diagnostic model using deep learning approaches with an abbreviated, non-contrast-enhanced diffusion weighted (DW) MRI protocol.

**METHODS AND MATERIALS**

A total of 1888 patients were enrolled from 4 institutions, all with breast pathology diagnostic results. For model construction, 1290 patients from our institution were randomly divided at a 6:2:2 ratio (training n=774, validation n=258, test n=258). Data from 3 other institutions served as external test cohorts (external 1 n=102, external 2 n=144, external 3 n=352). Three diagnostic models, DWI model (b=800s/mm2 and b=0s/mm$^2$), non-enhanced model (DWI T2WI), and abbreviated enhanced model (DWI T2WI first contrast-enhanced T1WI), were developed using DenseNet121 convolutional neural network. DWI model's diagnostic AUCs was compared with non-enhanced and abbreviated enhanced models. Two radiologists reviewed external MR images using four protocols: i. DWI, ii. DWI T2WI, iii. DWI T2WI first contrast-enhanced T1WI and iv. standard breast MR protocol. Subgroups analysis based on tumor morphology, volume, glandular density, BPE, age, and malignant tumor types to evaluate model performance. Area under the curve (AUC) of receiver operating characteristic assessed the model performance.

**RESULTS**

Three models constructed based on DenseNet121 achieved good AUCs (training 0.849-0.907, validation 0.864-0.875, test 0.883-0.916, as well as external 1 0.726-0.758, external 2 0.783-0.823, external 3 0.738-0.791). Among these, DWI model showed no statistical difference in AUCs compared to the non-enhanced model and abbreviated enhanced model in validation, test and all external cohorts. The AUCs of DWI model showed no statistical difference compared to Reader 1 but were significantly lower than those of protocols iii and iv by Reader 2. Subgroup analysis revealed that BPE was a factor influencing DWI model's diagnostic performance ($p<0.05$), which demonstrated a sensitivity of 0.827 for invasive ductal carcinoma, significantly higher than for other malignant tumors ($p<0.05$).

**CONCLUSION**

The deep learning model utilizing abbreviated, non-contrast-enhanced DWI protocol displayed excellent diagnostic accuracy, comparable to non-enhanced model, abbreviated enhanced model and radiologists. These findings indicate that our model could potentially aid in breast cancer screening in the future.

**CLINICAL RELEVANCE/APPLICATION**

Our study showed that a deep learning model using DWI is effective in distinguishing breast lesions, which suggests its potentially assisst in screening breast cancers.

## T7-SSBR06-4 CANCER SCREENING IN BREAST MRI USING DEEP EXPLAINABLE ANOMALY DETECTION

Elyse S. Blum, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Anum S. Kazerouni, PhD (*Abstract Co-Author*) Nothing to Disclose
Habib Rahbar, MD (*Abstract Co-Author*) Research Grant, General Electric Company;Research Consultant, Guerbet SA
Savannah C. Partridge, PhD (*Abstract Co-Author*) Research Grant, General Electric Company;Research support, Koninklijke Philips NV;Consultant, Guerbet SA
Felipe Oviedo, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Deep learning has been proposed to improve efficiency and accuracy for breast cancer detection on breast MRI. However, these models have limitations. In screening of high risk patients, cancer cases are only a small fraction (< 5%) of patients, leading to reduced model performance. Furthermore, deep learning classification models have limited ability to highlight malignant regions in the MRI (explainability). Our purpose was to develop and evaluate an explainable AI model for cancer detection on breast MRI, effective in both high and low cancer prevalence populations.

**METHODS AND MATERIALS**

This IRB-approved study utilized 9,567 breast MRI examinations in 5,026 women, imaged at a single institution from 2005-2014. A Fully Convolutional Data Description (FCDD) deep anomaly detection model was developed to detect breast malignancies on contrast-enhanced MRI. FCDD estimates an overall anomaly score and provides a spatially resolved heatmap as model explanation. Performance was evaluated with grouped cross validation in both balanced (24.9% malignant) and imbalanced (1.85% malignant) detection tasks and compared to binary classification and non-explainable anomaly detection models. Explainability was assessed through comparison with ground-truth radiologist annotations for a subset of malignancies.

**RESULTS**

FCDD surpassed binary classification models with a mean AUROC=0.842 [95% CI: 0.838, 0.845] across folds in the balanced detection task, and AUROC=0.722 [0.711, 0.733], AUPR=0.111 [0.101, 0.123] in the imbalanced detection task. In the imbalanced task, FCDD positive predictive value (0.142 [0.102, 0.188]) was twice that of binary classification, reducing false positives by 24.9%. At an operating point with 97% sensitivity, FCDD had more than 50% higher specificity than binary classification models. Assessing model explainability, FCDD explanations had mean pixel-wise AUROC=0.920 [0.891, 0.946] compared with radiologists, surpassing the pixel-wise AUROC of saliency maps for binary classification 0.807 [0.773, 0.838].

**CONCLUSION**

The FCDD model performed well in breast MRI cancer detection with good spatial explainability of abnormal regions, which has the potential of accelerating breast MRI interpretation workflows.

**CLINICAL RELEVANCE/APPLICATION**

Our model has the potential to assist radiologists in breast MRI analysis, demonstrating both high detection performance and human explainability in low prevalence scenarios.

## T7-SSBR06-5 COULD BREAST MULTIPARAMETRIC MRI DISCRIMINATE BETWEEN PURE DUCTAL CARCINOMA IN SITU AND MICROINVASIVE CARCINOMA ?

**PURPOSE**

Ductal carcinoma in situ (DCIS) is often reclassified as invasive cancer in the final pathology report of the surgical specimen. It is of significant clinical relevance to acknowledge the possibility of underestimating invasive disease when utilizing preoperative biopsies for a DCIS diagnosis. In cases where such histologic upgrades occur, it is imperative to consider them in the preoperative planning process, including the potential inclusion of sentinel lymph node biopsy dueto the risk of axillary lymph node metastasis.To assess the capability of breast multiparametric magnetic resonance imaging (MP-MRI) in differentiating between pure DCIS and microinvasive carcinoma (MIC).

**METHODS AND MATERIALS**

Between January 2018 and November 2022, this retrospective study enrolled patients with biopsy-proven DCIS who had undergone preoperative breast MP-MRI. We assessed various MP-MRI features, including size, morphology, margins, internal enhancement pattern, extent of disease, presence of peritumoral edema, time-intensity curve value, diffusion restriction, and ADC value. Subsequently, a logistic regression analysis was conducted to explore the association of these features with the pathological outcome.

**RESULTS**

Of 129 patients with biopsy-proven DCIS, 36 had foci of micro-infiltration on surgical specimens and eight were diagnosed with invasive ductal carcinoma (IDC). The presence of micro-infiltration foci was significantly associated withseveral MP-MRI features, including tumor size (P <0.001), clustered ring enhancement (P <0.001), segmental distribution (P <0.001), diffusion restriction (P=0.005), and ADC values <1.3 × 10-3 mm2/s (P =0.004).

**CONCLUSION**

Breast MP-MRI has the potential to predict the presence of micro-infiltration foci in biopsy-proven DCIS and may serve as a valuable tool for guiding therapeutic planning.

**CLINICAL RELEVANCE/APPLICATION**

to predict the presence of micro-infiltration foci in biopsy-proven DCIS

## T7-SSBR06-6 PERFORMANCE OF BREAST MRI FOR HIGH-RISK SCREENING DURING LACTATION

Maxine S. Jochelson, MD (*Abstract Co-Author*) Speaker, General Electric Company
Jill Gluskin, MD (*Abstract Co-Author*) Nothing to Disclose
Rosa E. Ochoa Albiztegui, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hila Fruchtman (*Abstract Co-Author*) Nothing to Disclose
Janice S. Sung, MD (*Abstract Co-Author*) Research Grant, General Electric Company
Noam Nissan, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To summarize our institutional experience with high-risk screening breast MRIs performed during lactation.

**METHODS AND MATERIALS**

Consecutive screening breast MRIs performed between 4/2008 and 3/2024 were retrospectively reviewed. Background parenchymal enhancement (BPE) grade was compared between actively lactating patients and patients who stopped lactating prior to the scan using the Mann-Whitney U test. BI-RADS scores prevalence rate was compared with controls encompassing screening MRIs of young non-lactating patients, using the Chi-square test. Diagnostic performance was calculated for patients with adequate biopsy reference or at least one year of follow-up.

## RESULTS

Overall, 142/85,710 (0.17%) screening MRIs (median age, 36.0 ± 6.0 years) were performed during lactation, for mostly BRCA mutation (60/142, 42.2%). BPE was characterized as predominantly marked (116/142, 82%), and was lower in the post-weaning group, including patients who stopped nursing one month prior to MRI (P<0.001). BI-RADS scores were distributed as follows: 0 (1/142, 1%), 1/2 (88/142, 62%), 3 (40/142, 28%) and 4 (13/142, 9%), marking a higher rate of BI-RADS 3 score (P<0.001) and lower rate of BI-RADS 1/2 scores (P=0.002) for the lactating group compared with the controls (7.7%, n=8922). One pregnancy-associated breast cancer (PABC) was detected and one interval cancer occurred. All MRI-guided biopsies were negative (n=13). The following performance was yielded: 50% sensitivity (1/2), 60% specificity (72/120), 2.0% PPV (1/49) and 98.6% NPV (71/82).

## CONCLUSION

The efficacy of breast MRI for high-risk screening during lactation is limited by prominent BPE, leading to an increased rate of BI-RADS 3 categorization and diminished overall specificity.

## CLINICAL RELEVANCE/APPLICATION

Despite its noted lower performance, and amidst the significant risk of PABC, this screening approach remains relevant for patients with exceptionally high-risk profiles, such as BRCA carriers.

### PURPOSE

Radiologists interpreting screening mammography have performance benchmarks, as reported by the Breast Cancer Surveillance Consortium (BCSC) and others. There is growing evidence that AI devices can improve radiologist reading performance, but there are no benchmarks in the context of AI assistance. We sought to determine acceptable ranges for recall rates for different levels of AI suspicion scores using two different data-driven approaches.

### METHODS AND MATERIALS

Our study included 346,570 DBT screening mammograms from 03/2021 - 05/2022 performed at 1 large practice (73 radiologists) and exam-level data, including BI-RADS interpretations and biopsy outcomes with 12 months of follow-up. We retrospectively evaluated all mammograms with an FDA-cleared AI that sorts exams into 4 categories based on their suspicion for cancer (Minimal, Low, Intermediate, and High). The cancer detection rate (CDR) for the overall practice and for each suspicion level was calculated. We used two approaches to determine an acceptable range for recall rate (RR): a CDR-driven approach and an expert-driven approach. The CDR-driven approach set recommendations by calculating the ratio of the CDR for each suspicion level to the overall CDR, then multiplying by the range of BCSC accepted values for RR (5-12%). The expert-driven approach set recommendations based on the RR of 6 breast imaging specialists for each suspicion category. Selected experts had 1) a reading volume > 75% in breast imaging, 2) a RR below the BCSC 25th percentile, and 3) a CDR above the BCSC 25th percentile.

### RESULTS

CDR was 5.34 per 1,000 at the practice overall, 0.27 for Minimal (Min), 0.90 for Low, 6.22 for Intermediate (Int), and 83.42 for High suspicion exams. The CDR-driven approach indicates the recommended RR should be 0.3-0.6% for Min, 0.8-2.0% for Low, 5.8-14.0% for Int, and 78.0-100.0% for High suspicion exams. The expert-driven approach indicates that RR should be 2.5% for Min, 4.7% for Low, 10.3% for Int, and 26.9% for High suspicion exams. Radiologists on average had a RR of 7.8% for Min, 12.6% for Low, 22.6% for Int, and 37.0% for High suspicion exams.

### CONCLUSION

By combining AI performance with BCSC guidelines and the behavior of experts, we generated metrics for use in monitoring radiologist performance in the context of AI assistance. Most radiologists recall more exams than both CDR- and expert-driven recommendations for Minimal, Low, and Intermediate suspicion levels, indicating that further education on these AI outputs might improve overall performance.

### CLINICAL RELEVANCE/APPLICATION

Practice leaders could leverage this approach to monitor radiologist performance, identify radiologists who might need additional education, and provide targeted information on how they might improve.

## T7-SSBR07-2 AI SCORE ON SCREENING MAMMOGRAMS BY TIME

Christoph I. Lee, MD, MS (*Abstract Co-Author*) Royalites, The McGraw-Hill Companies;Royalties, Oxford University Press;Royalties, Wolters Kluwer nv;Research Consultant, GRAIL, LLC
Diana Miglioretti, PhD (*Abstract Co-Author*) Nothing to Disclose
Jonas Gjesvik (*Abstract Co-Author*) Nothing to Disclose
Solveig S. Hofvind (*Presenter*) Nothing to Disclose

**PURPOSE**

To analyze risk score for cancer detection given by a regulatory-approved tool using artificial intelligence (AI), on screening mammograms at consecutive screening rounds.

**METHODS AND MATERIALS**

In this this retrospective study we used data from 116,496 women aged 50-69 with no history of breast cancer who had at least three consecutive biennial screening mammograms in the Norwegian national screening program, 2004-2018. Mean breast-level AI scores (0-100, with 100 representing highest likelihood of cancer) were used to compare score of the two breasts for women who were screened negative in two consecutive screening rounds and developed screen-detected or interval cancer on or within two years after the third screening round, and for those who were screened negative during three consecutive screening rounds. Area under the receiver operating curve (AUC) for the AI score and the absolute difference in scores between the two breast among women developing screen-detected breast cancer was estimated nonparametrically.

**RESULTS**

Among the 1265 women diagnosed with screen-detected cancer in the third screening round, mean difference in AI score between the breast developing and not developing breast cancer was 9.7 (SD: 33.9), 22.6 (SD: 38.6), and 77.7 (SD: 32.3) in the first, second and third screening round, respectively. Mean difference in AI score between the breast developing and not developing interval cancer was 7.3 (SD: 32.7), 10.0 (SD: 33.3), and 24.6 (SD: 41.0) in the first, second and third screening round, respectively. For women not developing breast cancer mean difference for the two breasts were 0.0 (SD: 20.1), -0.1 (SD: 19.9), and -0.0 (SD: 19.6) in the first, second and third screening round. AUC for screen-detected cancer was 0.63 in the first, 0.73 in the second and 0.97 in the third screening round, and 0.64, 0.65, and 0.77 for interval cancer in the first, second and third screening round, respectively.

**CONCLUSION**

Among women undergoing biennial mammography screening, AI scores were elevated in the breast diagnosed with breast cancer 4 and 2 years prior to diagnosis.

**CLINICAL RELEVANCE/APPLICATION**

Commercial AI algorithms developed to help detect cancer at the time of mammography interpretation may identify women at high risk of a future breast cancer, opening for offering a pathway for earlier cancer diagnosis.

## T7-SSBR07-3 ARTIFICIAL INTELLIGENCE MAMMOGRAPHY INTERPRETATION SYSTEMS ARE MORE AFFECTED BY MAMMOGRAPHIC IMAGE QUALITY ISSUES THAN RADIOLOGISTS

Ioannis Sechopoulos, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation;Research Grant, Sectra AB;Research Grant, ScreenPoint Medical BV;Research Grant, Volpara Health Technologies Limited
Joana Boita (*Abstract Co-Author*) Nothing to Disclose
Mireille Broeders, PhD (*Abstract Co-Author*) Speaker, Siemens AG;Speaker, Hologic, Inc
Sarah D. Verboom, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine how common image quality variations in mammograms affect the performance of artificial intelligence (AI)-based mammography interpretation systems compared to expert breast radiologists.

**METHODS AND MATERIALS**

Common image quality issues were simulated on a dataset of 80 digital screening mammograms, which involved 60 cases with lesions (40 cancers, 20 benign findings) and 20 normal cases. Five image quality issues were simulated on 16 mammograms each: two acquisition-related issues (lower spatial resolution and increased random quantum noise to simulate lower dose), and three post-processing-related issues (increased or decreased contrast and increased pixel noise correlation). Each issue was simulated at two different levels: the most degradation that is still deemed acceptable by radiologists, and a realistic degradation that is no longer acceptable for radiologists. Thirteen expert breast radiologists from five countries assessed all mammograms at each degradation level and scored the mammograms with a probability of malignancy (PoM) score between 1 and 10 and a recall decision. All images were also scored by a commercial AI system with a PoM score and a recall decision with the specificity set at the specificity of the radiologists. At each degradation level the area under the receiver operating characteristics curve (AUC) is calculated for the radiologists and for the AI system. Lastly, the recall decisions of radiologists and AI for the two degradation levels were compared to the recall decisions at the standard quality images.

**RESULTS**

Radiologists achieved a mean AUC of 0.760 (95% CI 0.678 - 0.843) on the standard quality mammograms which was comparable to the AUCs at the two degradation levels 0.765 (95% CI 0.687 - 0.844), p=0.76, and 0.746 (95% CI 0.666 - 0.826), p=0.38. Although not significantly different, the AUC of the AI system decreased from an AUC of 0.717 (95% CI 0.603 - 0.830) to 0.676 (95% CI 0.554 - 0.798), p=0.47 and 0.612 (95% CI 0.486 - 0.738), p=0.06 for the two degradation levels. Radiologists were also more stable in their recall decisions, with the same recall decision in 83% (95% CI 71%-90%) and 82% (95% CI 67%- 91%) of the cases. In contrast, AI gave the same recall decision in 75% and 68% of the cases.

**CONCLUSION**

Image quality can affect AI predictions and performance, even when image quality is still acceptable for radiologists and radiologists performance is not affected.

**CLINICAL RELEVANCE/APPLICATION**

Performance of AI systems can be influenced by different image quality issues. Therefore, there is a need for a safety guard to recognize images with poor quality before AI can be safely deployed as a stand-alone application.

## T7-SSBR07-4 A COMPARATIVE STUDY OF AI AND EXPERT RADIOLOGIST PERFORMANCE FOR TECHNICAL RECALL ASSESSMENT IN SCREENING MAMMOGRAPHY

Thomas P. Matthews, PhD (*Abstract Co-Author*) Employee, Whiterabbit.ai;Stockholder, Whiterabbit.ai
Jason Su (*Abstract Co-Author*) Employee, whiterabbit.ai;Stockholder, whiterabbit.ai;Board Member, whiterabbit.ai;Pending Patent
Hugo Vergnes, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Safeguards are needed to protect autonomous artificial intelligence (AI) rule-out systems for breast cancer screening from exams with image quality (IQ) deficiencies that could impair the sensitivity of the models. This work introduces an AI system that assesses IQ in full-field digital mammography (FFDM)

exams and evaluates it against expert radiologists.

**METHODS AND MATERIALS**

An AI system was trained to identify screening FFDM exams that require a technical recall due to inadequate IQ. The system evaluates positioning and blur, with features based on MQSA criteria as well as learned features. This model was evaluated on 1,100 screening exams from 2 independent held-out U.S. datasets (Dataset 1: 835 exams, from 2012-2019; Dataset 2: 265 exams, from 2002-2009) that were labeled as requiring recall or not by 5 breast fellowship trained radiologists with at least 15 years of experience (used for testing only). The performance of the model was first evaluated based on a reference standard of the median assessment of the 5 readers. To compare the AI and individual readers, we employ an evaluation methodology similar to leave-one-out cross-validation. In this method, we left out one reader at a time to establish a consensus based on the assessments of the other readers. Then, we compared the excluded reader and the AI model to this consensus. We repeated this for each reader to ensure an unbiased comparison between the AI and readers.

**RESULTS**

The percentage of exams recalled (inadequate IQ) by the 5 readers ranged from 0.7% to 13.7% (Mean: 6.4% Standard Deviation: 4.8%). Pairwise agreement between the readers was low (Cohen's kappa: 0.06-0.36). Based on a reference standard established by all 5 readers, the AI model achieved a sensitivity of 66.7% [48.2%, 82.0%], a specificity of 96.3% [94.9%, 97.3%], and an area under the receiver operating characteristic curve (AUC) of 0.92 [0.88, 0.96]. The sensitivity of the model increased when more readers labeled a sample as inadequate (3/5 readers: 56.5%, 13/23; 4/5 readers: 83.3%, 5/6; 5/5 readers: 100.0%, 4/4). Based on the cross-validation approach, the system exhibited comparable performance to the mean of the readers in sensitivity (AI: 48.9% [45.5%, 52.3%]; Mean Rad.: 45.7% [18.3%, 73.1%]) and specificity (AI: 96.1% [95.6%, 96.5%]; Mean Rad.: 95.0% [89.5%, 100.0%]). The system achieved an average AUC of 0.86 [0.85, 0.87].

**CONCLUSION**

This study demonstrates that an AI model can achieve comparable performance to expert radiologists in assessing IQ for mammography, overcoming the inherent challenges in the task's subjectivity.

**CLINICAL RELEVANCE/APPLICATION**

AI systems that provide an automatic check on IQ can assist with improving image acquisition and also help safeguard cancer-detecting AI models from exams with poor IQ.

## T7-SSBR07-5 COMPARING DIFFERENT SCENARIOS FOR THE COMBINED USE OF TWO COMMERCIAL AI ALGORITHMS TO IMPROVE MAMMOGRAPHY INTERPRETATION AND DECREASE RADIOLOGIST WORKLOAD

Eun Young Chae, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Joo Hee Cha, MD (*Abstract Co-Author*) Nothing to Disclose
Hee Jung Shin, MD (*Abstract Co-Author*) Nothing to Disclose
Woo Jung Choi, MD (*Abstract Co-Author*) Nothing to Disclose
Hak Hee Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hee Jeong Kim, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare different scenarios for the combined use of two commercial AI algorithms in improving mammography interpretation and decreasing radiologist workload.

**METHODS AND MATERIALS**

In this retrospective analysis, 3012 mammograms, including 213 cancer cases, were assessed using two commercial AI algorithms (AI-1 and AI-2). Mammograms were categorized into "high-risk (highest 10%)," "minimal-risk (lowest 20%)," and "indeterminate" groups based on the likelihood of malignancy from each AI algorithm. In Scenario 1 (Sensitive mode), mammograms in the "high-risk" group in at least one AI algorithm were recalled without radiologist review, those in the "minimal-risk" group in both AI algorithms were deemed negative, and the rest were assessed by radiologists. In Scenario 2 (Intermediate mode), mammograms in the "high-risk" group in both algorithms were recalled, those in the "minimal-risk" group in both algorithms were deemed negative, and the rest were assessed by radiologists. In Scenario 3 (Specific mode), mammograms in the "high-risk" group in both algorithms were recalled, those in the "minimal-risk' group in at least one algorithm were deemed negative, and the rest were assessed by radiologists. Scenario 4 (Sequential mode A) used AI-1 to triage mammograms into recall or negative screening categories, followed by AI-2 for further triage. Scenario 5 (Sequential mode B) reversed the order of referencing AI-1 and AI-2. Changes in recall rate, sensitivity, specificity, and workload across Scenarios 1-5 were compared to using a single AI or no AI, using McNemar's test.

**RESULTS**

Scenario 1 showed an 18.3% reduction in workload, along with significantly higher sensitivity compared to using a single AI or no AI (84.0% vs. 81.7% [AI-1, $p = 0.025$]; 80.8% [AI-2, $p = 0.008$]; 81.2% [No AI, $p = 0.034$]). Scenario 2 resulted in a 9.8% reduction in workload and achieved higher specificity compared to single AI use (86.3% vs. 85.1% [AI-1, $p < 0.001$]; 83.9% [AI-2, $p < 0.001$]). Scenario 3 reduced workload by 45.7% without significant differences in sensitivity (78.4% vs. 81.2%, $p = 0.083$) or specificity (87.7% vs. 87.4%, $p = 0.371$) compared to no AI use. Both Scenario 4 and 5 reduced workload by 49.8% without significant changes in sensitivity compared to using a single AI or no AI (80.8% [Scenario 4] and 80.3% [Scenario 5] vs. 81.7% [AI-1], 80.8% [AI-2], and 81.2% [No AI], $p > 0.05$ for all).

**CONCLUSION**

The combined use of two AI algorithms can improve mammography interpretation while decreasing radiologist workload. Different scenarios can be considered based on specific clinical settings.

**CLINICAL RELEVANCE/APPLICATION**

Using two AI algorithms could enhance mammography interpretation over using a single AI or none. Tailoring the integration method may optimize screening efficacy.

## T7-SSBR07-6 PERFORMANCE OF AN ARTIFICIAL INTELLIGENCE SYSTEM ON SCREENING DIGITAL BREAST TOMOSYNTHESIS CASES IN DENSE AND NOT DENSE BREASTS

Murray D. Becker, MD, PhD (*Abstract Co-Author*) Stockholder, ScreenPoint Medical BV;Stockholder, Covera Health, Inc
Jennifer Levy, MD (*Abstract Co-Author*) Nothing to Disclose
Steve Higgins (*Abstract Co-Author*) Nothing to Disclose
Roger S. Yang, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Studies have shown that cancer detection among radiologists is lower for dense breasts than for not dense breasts. This provides an opportunity for artificial intelligence (AI) to aid radiologists in improving cancer detection in women with dense breasts. For this study, we evaluate the performance of an AI system on screening tomosyntheseis mammograms in patients with dense and not dense breasts.

## METHODS AND MATERIALS

This retrospective study included 28,278 DBT screening exams collected from February to July 2022 from multiple outpatient imaging centers within a private practice. The screening exams (Hologic) were evaluated by MQSA radiologists who scored the exams according to the Breast Imaging Reporting and Data Classification System (BIRADS) and assigned a breast density category [almost entirely fatty (A), scattered fibroglandular densities (B), heterogeneously dense (C), and extremely dense (D)]. Patients in categories A and B were considered "not dense," and those in categories C and D were considered "dense."BIRADS 0 cases were recalled for additional evaluation and potential biopsy. All exams were analyzed by an AI system (Transpara 1.7.1, ScreenPoint Medical), which assigned an exam score between 1-10 indicating an increasing likelihood of malignancy. The performance of the AI system was evaluated, overall and for dense and not dense breasts.

## RESULTS

Out of 28,278 screening exams, 4,170 exams were labeled as BIRADS 0, resulting in a recall rate of 14.8%. Of the 4,170 patients recalled, 3,531 returned to one of our facilities for diagnostic imaging. There were 581 diagnostic exams assigned BIRADS 4-5 and recommended for biopsy. Biopsy results were available for 331 cases at the time of analysis, revealing 70 biopsy-proven cancers. Including all densities, AI identified 59/70 cancers (84%) with an exam score of 10 and 65/70 cancers (93%) with an exam score 8-10. In women with not dense breasts, AI identified 29/34 cancers (85%) with exam score of 10 and 31/34 (91%) with exam score 8-10. In women with dense breasts, AI identified 30/36 (83%) with an exam score of 10 and 34/36 (94%) with an exam score 8-10.

## CONCLUSION

AI score 8-10 has a strong predictive value for cancer. The system performs similarly well in dense and not dense breasts.

## CLINICAL RELEVANCE/APPLICATION

The results of our study suggest that AI could serve as a helpful tool to aid radiologists in identifying cancers in women with dense and not dense breasts.

## T7-SSCA06-1 THE PREDICTIVE VALUE OF LEFT ATRIAL EPICARDIAL AND PERICORONARY FAT COMBINED WITH TRIGLYCERIDE GLUCOSE INDEX ON RECURRENCE AFTER RADIOFREQUENCY CATHETER ABLATION FOR ATRIAL FIBRILLATION

Zishuo Wang (*Abstract Co-Author*) Nothing to Disclose
Hu Chunfeng Sr, MD (*Abstract Co-Author*) Nothing to Disclose
Li-xiang Xie (*Abstract Co-Author*) Nothing to Disclose
Xiaole Li (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the correlation between left atrial epicardial adipose tissue (LA-EAT), pericoronary adipose tissue (PCAT), and the recurrence of atrial fibrillation (AF) in patients after radiofrequency catheter ablation (RFCA) and construct a predictive model combining the triglyceride glucose (TyG) index.

### METHODS AND MATERIALS

A retrospective cohort of 325 patients who underwent their initial successful RFCA surgery was enrolled. Follow-ups were conducted every three months after the initial treatment. Patients were categorized into a recurrence group (79 patients) and a non-recurrence group (256 patients) based on their recurrence status within three months to one year post-surgery. Imaging parameters of LA-EAT (volume and density, noted as LA-EATV and LA-EATD) and PCAT (fat attenuation index) were measured and compared with general clinical data. Multivariate logistic regression was applied to identify independent influencing factors. The receiver operating characteristic curve (ROC) was used to determine the optimal thresholds for AF recurrence risk factors. Post-hoc subgroup analysis was conducted to evaluate the predictive value of the TyG index for AF recurrence among different patient subgroups postoperatively.

### RESULTS

LA-EATV, LA-EATD, LCX-FAI, and the TyG index were independent risk factors for AF recurrence after RFCA, and the optimal thresholds for predicting post-ablation AF recurrence for LA-EATV, LA-EATD, LCX-FAI, and the TyG index were 21.7 cm3, -79.5 HU, -82.5 HU, and 8.625, respectively. A comprehensive model built on these factors achieved an AUC of 0.792, with a sensitivity of 0.671 and a specificity of 0.817. Post hoc subgroup analysis showed that the TyG index was significantly associated with an increased risk of AF recurrence after RFCA, independent of the type of AF and type 2 diabetes mellitus (T2DM).

### CONCLUSION

LA-EATV, LA-EATD, LCX-FAI, and the TyG index can effectively predict the recurrence of atrial fibrillation after radiofrequency catheter ablation. The combined predictive value of these factors is higher, and the TyG index's prediction of recurrence is unaffected by the state of T2DM and the type of atrial fibrillation.

### CLINICAL RELEVANCE/APPLICATION

This study identifies postoperative recurrence factors by preoperative measurement of LA-EAT and PCAT parameters combined with the TyG index, providing more reliable non-invasive predictive markers for clinical use, thus enabling the formulation of precise, individualized treatment plans to improve patient outcomes.

## T7-SSCA06-2 LEFT ATRIAL MECHANICAL DYSFUNCTION AND THE RISK FOR ISCHEMIC STROKE IN HCM PATIENTS WITHOUT PRIOR ATRIAL FIBRILLATION OR STROKE

Jiaxin Wang (*Abstract Co-Author*) Nothing to Disclose
Wei Zhuxin (*Presenter*) Nothing to Disclose

### PURPOSE

Patients with hypertrophic cardiomyopathy (HCM) are at high risk of atrial fibrillation (AF) and ischemic stroke. Left atrial enlargement and dysfunction that characterize atrial myopathy may precede and promote AF and cardiac thromboembolism. In HCM patients without prior AF or stroke, whether left atrial mechanical dysfunction can improve ischemic stroke prediction is unknown.

### METHODS AND MATERIALS

Patients with prior AF or stroke were excluded and 653 consecutive patients with HCM (mean age 47.3 ± 12.3 years, 71% male) who underwent cardiac magnetic resonance (CMR) at Hospital between January 2012 and December 2013 were finally enrolled. LA ejection fraction, strain and strain rate indices on reservoir, conduit and booster-pump phases that represent LA mechanical function were analyzed. The primary endpoint was ischemic stroke. The secondary endpoint was new-onset AF.

### RESULTS

At 7.6 ± 2.4 years of follow-up, 24 (3.7%) had ischemic stroke and 73 (11.2%) had new-onset AF. Patients with stroke had an older age ($p = 0.014$), higher incidence of hypertension ($p < 0.001$), more LGE presence ($p = 0.006$) and LGE extent ($p = 0.007$). For LA size and function, patients with stroke showed significantly higher LA volume index and lower LA ejection fraction and LA strain (all $p < 0.01$). Age, hypertension, LGE presence, LGE extent and all LA mechanical indices were univariably associated with stroke. On multivariate model, LA reservoir strain was associated with stroke (Hazard Ratio = 0.91. 95%CI 0.85-0.97, $p = 0.005$) independent of Age ($p = 0.292$), hypertension ($p = 0.002$), LGE extent ($p = 0.003$) and LA volume ($p = 0.737$). In addition, LA reservoir strain was also associated with new-onset AF (Hazard Ratio = 0.93. 95%CI 0.89-0.96, $p < 0.001$) independent of Age ($p < 0.001$), hypertension ($p = 0.607$), LGE extent ($p = 0.882$) and LA volume ($p = 0.002$).

### CONCLUSION

In HCM patients without prior AF or stroke, LA mechanical dysfunction was a strong predictor for stroke and new-onset AF independent of LA enlargement, age, hypertension and LGE extent.

### CLINICAL RELEVANCE/APPLICATION

This study provides a predictor for stroke and new-onset AF in HCM patients without prior AF or stroke,

## T7-SSCA06-5 RECURRENCE AND NON-IMPROVEMENT OF EUROPEAN HEART RHYTHM ASSOCIATION SYMPTOM SCORES AFTER ATRIAL FIBRILLATION ABLATION: THE ROLE OF LEFT ATRIAL FRACTAL DIMENSION

Mengyuan Jing (*Presenter*) Nothing to Disclose

### PURPOSE

Left atrial (LA) morphology can characterize LA remodeling and is correlated with the outcomes of ablation for atrial fibrillation (AF) . We aimed to explore the relationship between LA morphologic heterogeneity quantified by fractal dimension (FD) and AF recurrence, and whether European Heart Rhythm Association (EHRA) symptom scores improved after recurrence following radiofrequency ablation.

### METHODS AND MATERIALS

This study retrospectively collected the data of patients with AF who underwent their first radiofrequency ablation procedure between October 2019 and September 2022 and underwent cardiac computed tomography angiography (CTA) within 3 days before the procedure. On the cardiac CTA images, we calculated the FD of each patient's LA using fractal analysis. Cox proportional risk models were used to calculate the risk ratios for the predictors of AF recurrence and no improvement in the EHRA symptom scores.

### RESULTS

A total of 512 patients with AF were included with a mean follow-up of 29 (18, 37) months, of which 146 had recurrence of AF and 366 did not have recurrence, and 48 had improvement of EHRA symptoms and 98 did not have improvement. COX regression analysis showed that LA-FD (HR=16.056 [7.493, 34.406], P<0.001; 10.500 [3.086, 35.728], P<0.001) was an independent predictor of recurrence and non-improvement in EHRA symptom score after AF ablation. Furthermore, patients with a larger LA-FD (>1.208) had a higher incidence of AF recurrence and EHRA symptom score non-improvement than those with a smaller LA-FD (<1.208).

### CONCLUSION

A larger LA-FD on cardiac CTA could be a predictor for adverse LA remodeling and was independently associated with recurrence and non-improvement of the EHRA symptom score after AF ablation.

### CLINICAL RELEVANCE/APPLICATION

The FD can be used as a quantitative marker to characterize LA morphology and has been used to assess several cardiovascular diseases. A larger LA-FD on cardiac CTA images is an indication of adverse LA remodeling and an independent predictor of recurrence and non-improvement in the EHRA symptom score after ablation for AF.

## T7-SSCA06-6 CORRELATION BETWEEN LEFT ATRIAL APPENDAGE MORPHOLOGY BASED ON FRACTAL DIMENSION QUANTIFICATION AND ITS HEMODYNAMIC PARAMETERS IN PATIENTS WITH ATRIAL FIBRILLATION

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Mengyuan Jing (*Presenter*) Nothing to Disclose

### PURPOSE

In patients with atrial fibrillation (AF), although left atrial appendage (LAA) morphology and hemodynamic parameters are closely associated with the development of LAA thrombosis, the relationship between LAA morphology and its hemodynamic parameters remains unclear. Therefore, this study aimed to investigate the relationship between LAA morphology, quantified based on fractal dimension (FD), and LAA hemodynamic parameters in patients with AF, in an effort to reveal the effect of LAA shape on blood flow.

### METHODS AND MATERIALS

A total of 225 patients with AF who underwent cardiac computed tomography angiography (CTA) and transesophageal echocardiography (TEE) on the same day between March 2020 and December 2022 at our institution were enrolled. LAA morphology was quantified based on FD on cardiac CTA images, and LAA hemodynamic parameters, including injection fraction (EF), filling peak flow velocity (FV), maximum speed of emptying (PEV), and wall motion velocity (WMV), were assessed using TEE.

## RESULTS

Among the enrolled participants, 134 (59.60%) were men and 91 (40.40%) were women. The average age of all participants was 61.71±0.72 years. We divided the patients with AF into two groups based on a mean LAA FD of 1.32: the low FD group (n = 124) and the high FD group (n = 101). Compared to the low FD group, there were more patients with LAA circulatory stasis/thrombus (P = 0.008) in the high FD group, as well as lower LAA FV (P = 0.004), LAA PEV (P = 0.007), and LAA WMV (P = 0.007). Correlation analysis showed that LAA FD was negatively associated with LAA EF (r = -0.211, P = 0.001), LAA FV (r = -0.209, P=0.002), LAA PEV (r = -0.189, P = 0.004), and LAA WMV (r = -0.244, P <0.001). Furthermore, LAA FD was an independent and significant determinant of LAA EF (ß = -11.755, P = 0.001), LAA FV (ß = -17.364, P = 0.004), LAA PEV (ß = -18.743, P <0.001), and LAA WMV (ß = -7.740, P = 0.001) in multiple linear regression analysis.

## CONCLUSION

LAA FD is an essential determinant of LAA hemodynamic parameters, suggesting that the relatively complex morphology of the LAA may influence its hemodynamics, which can correlate with embolic events.

## CLINICAL RELEVANCE/APPLICATION

Left atrial appendage fractal dimension is an essential determinant of its injection fraction, filling peak flow velocity, maximum speed of emptying, and wall motion velocity. These findings indicate relatively complex morphology of the left atrial appendage may influence its hemodynamics, which can correlate with embolic events.

Takashi Ota, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The severity of abdominal atherosclerosis (AA) remains uncertain despite clarified cardiac severity. Agatston score (AS) assesses calcified coronary artery plaques, predicting major adverse cardiovascular events (MACE). An increased risk of MACE was reported when AS exceeded 100. This study investigated the relationship between AS and abdominal aortic calcification (AAC) and determined the severity of AA using a virtual calcium removal algorithm (PureLumen) on photon-counting detector CT (PCD-CT), with the risk of MACE as the outcome.

### METHODS AND MATERIALS

This retrospective study included 132 patients with AAC who underwent abdominal CT angiography (CTA) and non-contrast-enhanced chest CT (nCE-CCT) with PCD-CT. We randomly divided the 132 patients into a training group (n = 106) and a validation group (n = 26) in an 80:20 ratio to build prediction models for the high-risk group for MACE. AAC maps were generated by subtracting the PureLumen from the corresponding CTA images. Abdominal calcification volume (ACV [mL]), CT value [HU], and histogram indices were calculated. Abdominal aortic 3D images without calcification were generated from the PureLumen. The aortic wall volume (AWV [mL]) was computed, and the percentage calcification volume (PCV [%]) was calculated by dividing ACV by AWV. AS was automatically calculated from the nCE-CCT images using dedicated software. To reduce bias from the imbalanced dataset, the AS>100 group was oversampled using the synthetic minority oversampling technique (SMOTE). Receiver operating characteristic curve analysis was used to calculate the area under the curve (AUC).

### RESULTS

In the training group, 29 patients had AS>100 and were oversampled to 58. Univariate analysis identified ACV, PCV, CT_mean, CT_SD, CT_Max, CT_min, CT_dif, skewness, kurtosis, and entropy as significant variables ($p < .05$). In the training group, PCV had the highest AUC (0.94). A PCV cutoff of 9.74% differentiated AS=100 from AS>100 with 74.4% sensitivity and 96.1% specificity. In a multivariate logistic regression (MLR) model incorporating five variables, PCV was the only significant variable, with an AUC of 0.94. In the support vector machine (SVM) model with 10 variables, the AUC was 0.97. In the validation group, the AUC of the PCV, MLR, and SVM models were 0.98, 0.98, and 0.98, respectively. PCV alone showed a discriminative ability comparable to that of the MLR and SVM models.

### CONCLUSION

PCV effectively discriminated between the high and low MACE risk groups. Measuring PCV is crucial for assessing the severity of AA, with =9.74% indicating a high severity.

### CLINICAL RELEVANCE/APPLICATION

As the demand for abdominal CT increases, prediction of cardiovascular risk from abdominal CT can guide additional surveillance recommendations.

## T7-SSGI10-3 EFFICIENCY EVALUATION OF DUAL-ENERGY CT TO PREDICT THE POSTOPERATIVE EARLY RECURRENCE OF PANCREATIC DUCTAL ADENOCARCINOMA

Qing Xu, MD (*Abstract Co-Author*) Nothing to Disclose
Siyao Yu, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the predictive value of dual-energy CT (DECT) quantitative parameters and basic CT features for the postoperative early recurrence (ER) of pancreatic ductal adenocarcinoma (PDAC).

**METHODS AND MATERIALS**

This study included patients with PDAC who underwent radical resection and DECT from January 2018 to December 2022. Patients were divided into ER and non-ER groups. The clinical data, basic CT features and DECT parameters of all patients were analysed. Univariate and multivariable logistic regression analyses were performed to identify independent predictors of ER. Three models (model A: basic CT features; model B: DECT parameters; model C: basic CT features + DECT parameters) were established. Receiver operating characteristic curve analysis was performed to evaluate prediction efficiency.

**RESULTS**

In total, 150 patients were enrolled (ER group: n = 63; non-ER group: n = 87). Rim enhancement (odds ratio [OR], 3.32; 95% confidence interval [CI], 1.221-9.026; p = 0.019), peripancreatic strands appearance (OR, 2.68; 95% CI, 1.021-7.079; p = 0.045), electron density in the pancreatic parenchymal phase (P-Rho; OR, 0.90; 95% CI, 0.820-0.992; p = 0.033), arterial enhancement fraction (AEF; OR, 0.05; 95% CI, 0.008-0.409; p = 0.004) and pancreatic parenchyma fat fraction in the delayed phase (OR, 1.25; 95% CI, 1.142-1.374; p < 0.001) were identified as independent predictors of ER. The areas under the curves (AUCs) of the three models were 0.739, 0,859, and 0.898, respectively. Model C showed the highest AUC.

**CONCLUSION**

Quantitative parameters derived from DECT can be used to noninvasively predict postoperative ER in patients with PDAC, and the combination of DECT parameters and basic CT features shows a high prediction efficiency.

**CLINICAL RELEVANCE/APPLICATION**

Preoperative DECT parameters and basic CT features were identified as independent predictors of postoperative ER in patients with PDAC and can guide clinicians in developing more effective treatments.

## T7-SSGI10-4 DEEP-DIABETES: FUSION DEEP LEARNING MODEL FEATURES PREDICT DIABETES OCCURRENCE, SEVERITY, AND MEDICATION RESPONSIVENESS ON CT IMAGING

Ronald M. Summers, MD, PhD (*Abstract Co-Author*) Royalties,iCAD, Inc;Royalties, Koninklijke Philips NV;Royalties, ScanMed, LLC;Royalties, Ping An Insurance (Group) Company of China, Ltd;Royalties, Translation Holdings;Research support, Ping An Insurance (Group) Company of China, Ltd
Perry J. Pickhardt, MD (*Abstract Co-Author*) Advisor, Bracco Group;Advisor, Zebra Medical Vision Ltd;Advisor, Nano X Imaging;
Pritam Mukherjee, PhD (*Abstract Co-Author*) Nothing to Disclose
Abhinav Suri, BA, MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

Diabetes is one of the leading causes of morbidity and mortality in the United States. However, 17.8% of adults who have diabetes are undiagnosed. Prior work has examined the use of CT scans for opportunistic screening of diabetes on non-contrast CT scans. However, no observation of its efficacy has been undertaken in a multi-institutional cohort with contrast scans. Furthermore, no work has attempted to assess severity of diabetes and pharmacologic resistance on CT scans. Here we aim to create a deep learning network architecture that achieves all of these goals.

**METHODS AND MATERIALS**

This retrospective study included patients from two institutions (9747 patients) who had contrast or non-contrast abdominal CT scans performed from 2004-2023 (Fig1A). Each patient's first scan (repeat scans excluded) was labeled as either being "Diabetes" (patient had diabetes at time of scan, n=416), "Incident" (patient will develop diabetes w/in 4 years of scan, n=183), or "Non-Diabetic" (patient will not develop diabetes w/in 4 years of scan, n=9148). For diabetic patients at institution 1, we determined diabetes severity (HbA1c w/in 3 months of scan <9, n=171 vs HbA1c=9, n=45) and drug resistance (on =3 unique medications, n=34, or not, n=156) since HbA1c and medication information was available for these patients.A fusion deep learning model that combines convolutional neural network embeddings with 29 imaging biomarkers was trained (Fig1B). A 3D DenseNet was originally trained to predict diabetes status using pancreas and liver segmentations (predicted using TotalSegmentator v1.5.0). Its embeddings (added to the 29 biomarkers) were used to train separate models (via PyCaret v3.3.2) to predict all tasks (diabetes prediction, severity, drug resistance).

**RESULTS**

The model achieved an overall AUC of 0.83 (95%CI: 0.81,0.86) when tasked with predicting diabetes status (Fig1C). This performance exceeded that of a baseline logistic regression that used only 29 imaging biomarkers [AUC: 0.69 (0.65, 0.73)]. AUCs were similar for obese [macro-AUC: 0.80] vs non-obese [0.83] and older (=60yo [0.79]) vs younger patients [0.85]; however, performance degraded on contrast scans [0.63] in comparison to non-contrast scans ([0.78], Fig1c). For diabetes severity prediction and drug resistance, the classifier achieved an AUC of 0.76 (0.64-0.87) and 0.82 (0.73-0.90), respectively (Fig1D,E).

**CONCLUSION**

We created a fusion deep learning model that can generalize to multiple tasks: diabetes prediction, diabetes severity assessment, and diabetes drug resistance prediction.

**CLINICAL RELEVANCE/APPLICATION**

This network can be used for opportunistic screening of diabetes in a general population and additional prediction of uncontrolled diabetes and medication resistance.

## T7-SSGI10-5 COMPARISON OF LESION DETECTABILITY OF HYPOVASCULAR LIVER METASTASES BETWEEN 70- AND 40-KEV IMAGES RECONSTRUCTED FROM DUAL-ENERGY CT

**PURPOSE**

This study compares the lesion detectability of hypovascular liver metastases between 70 and 40-keV images from dual-energy computed tomography (DE-CT) reconstructed with deep-learning image reconstruction (DLIR).

**METHODS AND MATERIALS**

This multi-institutional, retrospective study was conducted between January 2019 and December 2022. This study included adult patients pre- and post-treatment for gastrointestinal adenocarcinoma. All patients underwent contrast-enhanced CT and reconstruction of virtual monoenergetic images at 40- and 70-keV. The presence or absence of liver metastases was confirmed using gadoxetic acid-enhanced magnetic resonance imaging performed within 1 month pre- or post-DE-CT. Four radiologists (two experts and two residents) independently scored the lesion conspicuity (per patient and lesion) of the 70- and 40-keV images using a 5-point scale. The five largest lesions were selected for evaluation among patients with multiple lesions. Interobserver agreement regarding lesion conspicuity was also evaluated. The image noise, tumor-to-liver contrast, and contrast-to-noise ratio (CNR) of the hepatic parenchyma and metastatic lesions were measured by a radiologic technologist.

**RESULTS**

The final cohort comprised 208 liver metastases in 138 patients (mean age, 68.9 ± 11.7 years; 80 men) from four institutions. Seventy-one patients had liver metastases while 67 did not. The breakdown of the primary sites was as follows: 68 pancreatic, 50 colorectal, 12 stomach, and eight gallbladder or bile duct sites. No statistical difference was observed in per-patient lesion detectability for liver metastases between 70-keV images (sensitivity, 71.8-90.1%; specificity, 61.2-85.1%; accuracy, 73.9-79.7%) compared with the 40-keV protocol (sensitivity, 76.1-90.1%; specificity, 53.7-82.1%; accuracy, 71.7-79.0%) by all four radiologists (P = 0.18-1.00). No statistical difference was observed by the four radiologists in per-lesion lesion detectability for liver metastases between the 70-keV images (sensitivity, 67.3-82.2%) compared to the 40-keV images (sensitivity, 68.8-81.7%) (P = 0.20-1.00). The interobserver agreement for each image was moderate (kappa = 0.58 on 70-keV and 0.53 on 40-keV for per-patient, kappa = 0.56 on 70-keV and 0.59 on 40-keV for per-lesion). The image noise, tumor-to-liver contrast, and CNR of the 40-keV images were significantly higher than those of the 70-keV images (P lt;0.01).

**CONCLUSION**

No significant difference was found in detecting hypovascular liver metastases between 70- and 40-keV images using the latest DLIR.

**CLINICAL RELEVANCE/APPLICATION**

With the latest DLIR, using 40-keV images to improve hypovascular liver metastasis, detection may be less significant.

## T7-SSGI10-6 ASSESSMENT OF CT IMAGING FEATURES AND ENERGY SPECTRUM CT QUANTITATIVE PARAMETERS FOR THE PREDICTION OF C-KIT EXON 11 MUTATION STATUS IN GASTROINTESTINAL STROMAL TUMORS

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Jiachen Sun, PhD, MA (*Presenter*) Nothing to Disclose

**PURPOSE**

Mutation type in patients with gastrointestinal stromal tumors (GISTs) is strongly associated with targeted drug selection and therapeutic efficacy. Therefore, this study aims to evaluate the value of CT imaging features and energy spectrum CT quantitative parameters in predicting the mutation status of c-KIT exon 11 in GISTs and to construct a predictive model to assist in clinical treatment decision-making.

**METHODS AND MATERIALS**

We retrospectively reviewed 69 pathologically confirmed patients with GISTs who underwent preoperative energy spectrum CT (Discovery CT 750 HD, General Electric) and c-KIT gene testing. chi-square test, Mann-Whitney U test and independent samples t test were used to compare and analyze the CT imaging features and energy spectrum CT quantitative parameters of patients. The statistically significant parameters in the above univariate analysis were entered into logistic regression to screen independent predictors for prediction of c-KIT exon 11 mutation status. Establishing a model for predicting c-KIT exon 11 mutation status and evaluating the clinical applicability of the model by receiver operating characteristic (ROC).

**RESULTS**

There were 34 men and 35 women in our study. The average age of all participants was 57.55±12.78 years. There was a significant statistical difference in the age of the c-KIT exon 11 mutation status (P=0.028). In terms of CT imaging features, there were significant statistical differences between the two groups for tumor size, shape, margin, necrosis/cystic change, enhancement pattern, and enhancement grade (all P<0.05). In the energy spectrum CT quantitative parameters, CT-AP40keV, energy spectrum curve slope (K), and iodine concentration (IC) in the arterial phase, CT-VP40keV, CT-VP70keV, CT-VP100keV, K, IC, and normalized iodine concentration (NIC) in the venous phase, and CT-DP40keV, CT-DP70keV, K, IC, and NIC in the delay phase of c-KIT exon 11 mutant type is lower than c-KIT exon 11 wild type (all, P<0.05). The AUC of the model was 0.851 (95% CI: 0.760-0.941), the sensitivity and specificity were 78.4% and 88.7%, respectively.

**CONCLUSION**

Age, CT imaging features and energy spectrum CT quantitative parameters can be used as preliminary evaluation indicators for the mutation status of GISTs c-KIT exon 11. The clinical indicators, CT imaging features combined energy spectrum CT quantitative parameter model has high efficiency in predicting the mutation status of GISTs c-KIT exon 11.

**CLINICAL RELEVANCE/APPLICATION**

The energy spectrum CT serves as a useful, non-invasive imaging tool that can be used to predict the mutation status of c-KIT exon 11 in GISTs before surgery and can assist in clinical risk stratification and determining the treatment plan for patients.

### PURPOSE

Breathing artifacts in liver MRI lead to impaired image quality, decreased diagnostic confidence, and, as a result, longer acquisition times. This study aimed to evaluate the image quality and scan efficiency of newly developed in-bore breathing guidance application for diffusion-weighted imaging (DWIBG) and T2-weighted sequences with propeller acquisition (MultiVaneXD) (T2BG).

### METHODS AND MATERIALS

Patients with clinical indications to liver MRI, who underwent examination at 3T MRI were consecutively included in this study. MRI protocol included DWIconv and T2 conv followed by DWIBG with T2BG. For the active breathing guidance, a pre-clinical software was installed on the scanner. Prior to the scan session, each patient received short video instruction about the MRI with breathing guidance. Suitable parameters for desired breathing pattern for DWIBG and T2BG were set individually for each patient based on the patient`s physical respiratory ability and adaptivity. Artifacts, sharpness, lesion conspicuity, and overall image quality were assessed using a Likert grading scale from 1 (non-diagnostic) to 5 (excellent). Additionally, scanning time, time of repetition (TR), contrast-to-noise (CNR: SIliver-SInoise/SDnoise), and signal-to-noise ratio (SNR: SIliver/SInoise) were analyzed. Measurements were performed in consensus by two experienced board-certified radiologists. Paired t-test and Wilcoxon test were used for statistical analysis.

### RESULTS

27 patients (46±16 years; 11 female) were included. T2BG showed significantly less artefacts (4.5±0.7 vs.4.0±0.9, P<0.001) and better sharpness (4.7±0.6, P=0.003) compared to T2conv. Overall image quality (4.5±0.8 vs. 4.3±0.9, P=0.062) and lesion conspicuity (4.7±0.6 vs. 4.6±0.6, P=0.5) were similar for both T2BG and T2conv. T2BG had significantly longer TR (3608±667ms vs. 2244±384ms; P<0001). DWIBG provided similar overall image quality compared to DWIconv (P>0.4). Sequence scan time was shorter with T2BG (4.8±0.2min vs. 5.4±1.4min; P=0.041), with a reduction of scan time by 11%. Scanning time of DWIBG was also shorter compared to DWIconv (4.3±1,2 min vs. 2,6±0.06 min, P<0.001). DWIBG and T2BG provided not only reduced, but more constant and predictable total scan times.

### CONCLUSION

Our study results indicate that active breathing guidance for T2w and DWI liver MRI sequences lead to the significant reduction of breathing artifacts by significantly shorter and predictable total scan times while maintaining high image quality.

### CLINICAL RELEVANCE/APPLICATION

The application of an active visualized breathing guidance for breathing sensitive MRI sequences could improve scan efficiency, image quality, diagnostic confidence, and possibly patient experience.

## T7-SSGI11-2 INTRAINDIVIDUAL COMPARISON OF HALF-DOSE GADOPICLENOL AND STANDARD DOSE OF GADOBENATE DIMEGLUMINE FOR ABDOMINAL MRI

**PURPOSE**

To intraindividually compare image quality and lesion conspicuity of abdominal MRI using gadopiclenol at 0.05 mmol/kg and gadobenate dimeglumine (Gd-BOPTA) at 0.1 mmol/kg.

**METHODS AND MATERIALS**

From September 2023 to March 2024, consecutive patients who had undergone two clinically-indicated contrast-enhanced abdominal MRIs within 12 months using gadopiclenol and Gd-BOPTA on the same scanner were retrospectively enrolled. One independent radiologist manually measured the signal intensity of abdominal organs, arterial and venous vessels, and abdominal lesions (liver, pancreas, and kidneys) on unenhanced, late arterial, venous, and equilibrium phases. Signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and magnitude of contrast enhancement (?E) were calculated for all organs and vessels on each contrast-enhanced phase. Percentage enhancement (%E) was calculated for all lesions on contrast-enhanced each phase. Subjective image quality was assessed for each phase using a 5-point Likert scale, including: enhancement of abdominal organs and vessels, liver-to-vessels contrast, and overall image quality. Lesion characteristics were also evaluated, including borders delineation, internal enhancement pattern, and lesion-to-liver visual contrast. Statistical analysis employed paired t- and Wilcoxon tests.

**RESULTS**

One hundred subjects (mean age, 63.7 years ± 14.1 [SD]; 55 men) were selected and a total of 21 abdominal lesions were included. Compared to Gd-BOPTA, gadopiclenol yielded significantly higher ?E value for all abdominal organs and vessels in each contrast-enhanced phase (all p = .024) Figure 1. Gadopiclenol yielded significantly higher SNR and CNR for the pancreas, kidneys, and spleen in the late hepatic arterial phase (p = .04). No significant differences in CNR were observed between gadopiclenol and Gd-BOPTA for all organs in the portal venous and equilibrium phases. The %E of abdominal lesions was significantly higher with gadopiclenol compared to Gd-BOPTA for all contrast-enhanced phases (p <.001).No significant differences were observed between gadopiclenol and Gd-BOPTA in readers' perception of image quality and lesions' characteristics.

**CONCLUSION**

Gadopiclenol at 0.05 mmol/kg yields comparable image quality compared to Gd-BOPTA at 0.1 mmol/kg, along with improved measurements of enhancement for abdominal organs and lesions.

**CLINICAL RELEVANCE/APPLICATION**

By providing comparable image quality at half the dosage, gadopiclenol may improve patient's safety and reduce costs compared to Gd-BOPTA for abdominal MRI.

Omar Darwish (*Abstract Co-Author*) Nothing to Disclose
Vitali Koch, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Magnetic resonance elastography (MRE) is able to quantify tissue biomechanics noninvasively, including pathological hepatic states like metabolic dysfunction-associated steatohepatitis. This prospective single-center study aimed to compare the diagnostic performance of 2D/3D-MRE using the gravitational transducer concept (GT) with the current commercial acoustic (AC) solution utilizing a 2D-MRE approach. Additionally, quality index markers (QIs) were proposed based on quantitative measures to identify image pixels that yield sufficient quality for reliably estimating tissue biomechanics.

**METHODS AND MATERIALS**

193 participants were recruited with suspected or confirmed liver disease (median age 57 years [IQR, 47-65]; 78 females). Participants were scanned twice at 60Hz vibration frequency on a 1.5T scanner: firstly, using the commercial MRE system (AC, 2D-MRE, spin-echo EPI sequence, 11s breath-hold [BH]), and, secondly, using the GT transducer (2D- and 3D-MRE, gradient-echo sequence, 14s BH). Image analysis was performed blinded by two independent readers. Additionally, analytic plane shear waves were used to propose pertinent QIs.

**RESULTS**

Liver stiffness values quantified via GT-2D/3D correlated well with AC-2D (r=0.89 [95% CI: 0.85-0.92]; P<0.001) and histopathological grading (r=0.84 [95% CI: 0.72-0.91]; P<0.001), demonstrating excellent agreement in Bland-Altman plots and between readers (?=0.86 [95% CI: 0.81-0.91]). However, 2D-MRE showed a bias in overestimating stiffness compared to 3D-MRE. Proposed QIs enabled the identification of pixels deviating beyond 10% from true stiffness, based on a combination of total wave amplitude, temporal sinusoidal nonlinearity, and additionally wave signal-to-noise ratio in the case of 3D-MRE.

**CONCLUSION**

GT-MRE represents a precise alternative to AC-MRE for noninvasive liver tissue characterization. Both 2D and 3D approaches showed a strong correlation to the established commercial approach, providing a new biomechanical ground truth for advanced capabilities in abdominal imaging.

### CLINICAL RELEVANCE/APPLICATION

GT-MRE promises to become a precise alternative to the current commercial solution for liver fibrosis characterization based on a new biomechanical ground truth with advanced capabilities in abdominal imaging.

## T7-SSGI11-6 ACCELERATED MRI LIVER AT 3T USING FIVE SEQUENCES WITH DEEP LEARNING BASED IMAGE RECONSTRUCTION: IMPACT ON IMAGE QUALITY

Hersh Chandarana, MD, MBA (*Abstract Co-Author*) Institutional research agreement, Siemens AG;Equipment support, Siemens AG;Software support, Siemens AG
Krishna Prasad Shanbhogue, MD (*Abstract Co-Author*) Nothing to Disclose
Mary Bruno, RT (*Abstract Co-Author*) Nothing to Disclose
Hanisha Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Mahesh Bharath Keerthivasan, MS (*Abstract Co-Author*) Nothing to Disclose
Luke A. Ginocchio, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the image quality of five MRI prototype sequences with deep learning-based image reconstruction to the corresponding five conventional sequences for 3T liver MRI.

### METHODS AND MATERIALS

59 consecutive patients who prospectively underwent clinical liver MRI at 3T between 5/1/2023 and 12/26/2023, including the five prototype sequences, were included. Images were anonymized and subsequently reviewed by two fellowship trained radiologists using a 5-point Likert scale for image quality metrics. Acquisition time for each sequence was collected.

### RESULTS

Acquisition times for four of the five DL sequences were significantly shorter than for the corresponding conventional sequences: Coronal HASTE (DL 63.8±12.0 vs Conv 72.0±12.2 seconds, p<.001), Axial T2 FS (DL 62.8±13.5 vs Conv 150.5±25.6 seconds, p<.001), Axial T1 precontrast (DL 18.8±4.8 vs Conv 20.3±11.4 seconds, p=.296), Axial T1 postcontrast (DL 24.2±9.6 vs Conv 45.8±9.6 seconds, p<.001), and Axial DWI (DL 91.5±9.8 vs Conv 156.1±19.9 seconds, p<.001). On average, the combined savings in acquisition time from replacing the five conventional sequences with the respective DL sequences is 183.5 seconds. All five DL sequences received significantly higher scores than the corresponding conventional sequences for overall image quality (DL vs Conv: Coronal HASTE 4.5 vs 4.0, Axial T2 FS 4.0 vs 3.4, Axial T1 precontrast 4.2 vs 3.9, Axial T1 postcontrast 4.3 vs 4.0, and Axial DWI 4.2 vs 3.8, all p<.001), in addition to artifact and sharpness of liver margin scores. For studies with liver lesions, all five DL sequences received significantly (p<.001) higher scores for sharpness of lesion margin. All lesions detected on conventional sequences were detected on DL sequences.

### CONCLUSION

All five MRI prototype sequences with deep learning-based image reconstruction demonstrated decreased acquisition times compared with conventional liver sequences, while improving image quality for liver MRI. On average, replacing the five conventional liver MRI sequences with the respective DL sequences would save over 3 minutes in acquisition time, offering potential alternatives to the corresponding conventional sequences in routine clinical liver MRI.

### CLINICAL RELEVANCE/APPLICATION

Five MRI prototype sequences for liver MRI demonstrated decreased acquisition times while improving image quality, saving over 3 minutes of acquisition time in total, resulting in decreased cost and increased patient throughput and patient satisfaction.

## T7-SSIN03-1 AI-POWERED ASSISTANT FOR PROCEDURE REQUEST ROUTING IN A LARGE HOSPITAL SYSTEM

Nicholas T. Befera, MD (*Abstract Co-Author*) Founder and CEO, Scanslated, Inc
Christopher J. Roth, MD (*Abstract Co-Author*) Nothing to Disclose
Brendan C. Cline, MD (*Abstract Co-Author*) Nothing to Disclose
Walter F. Wiggins, MD,PhD (*Abstract Co-Author*) Advisor, Qure.ai;
Brian Triana, MD, MBA (*Presenter*) Nothing to Disclose

### PURPOSE

Within large hospital systems, difficulty with routing procedure requests to the appropriate team and covering provider can delay patient care and cause frustration for both radiologists and ordering clinicians. Furthermore, the heterogeneity of interventional radiology practices further increases complexity for procedure requests between non-vascular interventional teams or procedure teams from other specialties. Artificial intelligence (AI) large language models (LLMs) enable a wide range of capabilities across industries. This work demonstrates a proof-of-concept, LLM-based tool to route procedure requests to the appropriate teams.

### METHODS AND MATERIALS

At a large academic hospital, existing teams, pager/phone numbers, and schedules were used to create text-based rules for procedure requests. An LLM-based assistant was created to route procedure requests at specific days and times to the appropriate teams. The assistant was tested on 270 requests within the scope of the provided rules, and 23 requests out of sample requests using GPT-3.5-turbo and GPT-4 models from OpenAI and four open-weight models.

### RESULTS

The assistant correctly routed 96.3% of procedure requests using GPT-4 and 81.1% using GPT-3.5-turbo. Llama 3 70B outperformed GPT-3.5-turbo with an accuracy of 84.3%, although the remaining open-weight models demonstrated inferior performance. Open AI API costs were approximately $0.03 per request for GPT-4 and $0.0006 per request for GPT-3.5-turbo. The most common errors were in early morning requests, times at which multiple subspecialty division procedure services are covered by overnight resident phones. Secondary analysis on procedure requests outside the scope of provided rules, such as epidural blood patch, demonstrated decreased accuracy measuring up to 73.9% for GPT-4.

### CONCLUSION

This work demonstrates the feasibility of an accurate, low-cost AI-powered assistant to appropriately route procedure requests in a large academic hospital system. Given the free-text input, the rules and teams can easily be adapted to different coverages or hospital systems. A similar approach may be used to help clinicians navigate a radiology phone tree, or as a tool to help reading room coordinators route requests effectively with decreased training.

### CLINICAL RELEVANCE/APPLICATION

While many implementations of artificial intelligence in healthcare focus on aiding clinical decision making, this tool augments existing workflows and would coexist in parallel to the current call-routing or paging infrastructure. Compared to clinical decision-making tools, this type of implementation has a much lower risk profile and thus has fewer barriers to implementation within a hospital system.

## T7-SSIN03-2 EXTRACTING INFORMATION FROM UNSTRUCTURED DIAGNOSTIC REPORTS USING LARGE LANGUAGE MODELS FOR LOCAL VALIDATION OF INTERPRETIVE AI ALGORITHMS - INTRACRANIAL ANEURYSM USE CASE

Po-Hao Chen, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Scott Robertson (*Abstract Co-Author*) Nothing to Disclose
Samer Albahra (*Abstract Co-Author*) Nothing to Disclose
Todd M. Emch, MD (*Abstract Co-Author*) Nothing to Disclose
Chintan Shah, MD, MS (*Presenter*) Spouse, Employee, Merck & Co, Inc

**PURPOSE**

Pre-deployment local validation of artificial intelligence (AI) models is an important but commonly overlooked step, as it is labor-intensive. Large language models (LLMs) have been shown to be effective for medical text analysis. Local hosting reduces data privacy risks versus cloud hosted LLM solutions. We compared multiple LLMs to extract information from unstructured radiology reports, then applied the best model towards the local validation of a commercial AI product for intracranial aneurysm triage.

**METHODS AND MATERIALS**

LLMs were locally hosted using Ollama (ollama.com). Open-source LLMs tested included llama2 (7b, q4, Meta Platforms), wizardlm (70b, q8, Microsoft), mixtral (8x7b, fp16, Mistral AI). These were compared with GPT-4 (Open AI). LLMs were employed to extract the presence, location, and size of an aneurysm from the report for head/neck CTAs. Prompt engineering techniques utilized included role definition, explicit instructions, and multi-shot example prompting. The commercial Computer Aided Triage (CADt) device for local validation was for intracranial aneurysms = 4 mm on head CTA (Viz Aneurysm, Viz.ai). It was tested on 1470 head/neck CTAs from 4 sites over 105 days. LLMs were compared on reports of the first 37 CADt positive CTAs. The chosen LLM was then applied to all CTA reports to assess CADt device performance. All CADt positive and discordant CADt negative reports were manually reviewed for LLM accuracy. CADt positive cases with no aneurysm reported were adjudicated via image review. Summary performance statistics were calculated utilizing size thresholds of 4 mm or any size.

**RESULTS**

Aneurysm presence was correctly categorized in all 37 reports (15 present, 22 absent) by all LLMs except llama2. Size threshold = 4 mm was correctly categorized in all 37 reports only by mixtral. All CTAs were processed with wizardlm. Of 114 manually reviewed reports, 104 were correctly categorized for aneurysm presence; 6 false positives were due to extracranial aneurysms, and 4 false negatives were due to mention only in the body of the report. The sensitivity, specificity, PPV, and NPV of the aneurysm CADt device were: 88.9, 96.6, 32.9, and 99.8%, respectively (aneurysms = 4 mm); and 62.7, 97.8, 57.5, and 98.2%, respectively (any size).

**CONCLUSION**

Open source locally deployed LLMs can achieve similar performance to commercial LLMs for information extraction from radiology reports, but allow processing of protected data. This can enable local validation and performance monitoring, important aspects of commercial imaging AI deployments.

**CLINICAL RELEVANCE/APPLICATION**

Assessing local performance of commercial imaging AI products is imperative prior incorporating these into clinical workflows, and locally deployed LLMs can enable this process.

## T7-SSIN03-3 THE EFFECTS OF DIFFERENT AI SCENARIOS ON RADIOLOGISTS AND RESIDENTS PERFORMANCE

Ali Adibi (*Abstract Co-Author*) Nothing to Disclose
Carlo N. De Cecco, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Covanos, Inc
Elizabeth A. Krupinski, PhD (*Abstract Co-Author*) Nothing to Disclose
Mohammadreza Zandehshahvar (*Abstract Co-Author*) Nothing to Disclose
Marly Van Assen, MSc, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Understand decision-making process of human readers with and without assistance of different AI prompts.

**METHODS AND MATERIALS**

Five radiologists and 3 residents served as readers in 5 sessions, each with 2 parts. There were 80 COVID chest xray cases per scenario (40 per part). AI scenarios were image only, heatmaps, class prediction, probability+uncertainty, combined AI. A Bayesian neural network predicted pneumonia severity, trained on the RSNA pneumonia dataset (13k CXRs) and 348 COVID Emory patients - accuracy was 0.94. Monte Carlo Dropout and Grad-CAM created the AI scenarios. Readers rated severity (normal, mild, moderate, severe) and confidence (possible, probably, definite). Search was recorded with a Tobii eyetracker. Gold standard was consensus reading by 6 radiologists. Decisions are defined as AI does not impact original decision (no change), impacts positively (positive change), impacts negatively (negative change).

**RESULTS**

86.99% of severity ratings were unchanged between image only and AI read, with no significant differences by AI scenario ($X2 = 6.59$, $p = 0.6792$). Of those, 83.66% overall were correct (TP, TN) with no significant differences ($X2 = 6.27$, $p = 0.7126$) by AI scenario. There was no significant difference in the no change group by AI scenario ($X2 = 0.80$, $p = 0.8489$). There was a difference in the positive change group ($X2 = 21.78$, $p < 0.0001$) with combined AI having the most changes; and in the negative change group ($X2 = 25.06$, $p < 0.0001$) with heatmaps having the most changes. There were no significant differences between radiologists and residents for no change ($X2 = 0.27$, $p = 0.9655$) or positive ($X2 = 3.93$, $p = 0.2690$), but was for negative ($X2 = 12.52$, $p = 0.0058$) with radiologists having the most with heatmaps (10 vs 1.67%) but more similar with class prediction (3 vs 3.75%) compared to residents. For confidence, the was no significant difference between scenarios for no change ($X2 = 1.03$, $p = 0.7928$) or positive change ($X2 = 0.20$, $p = 0.9777$); although for positive there was for possible to definite ($X2 = 10.86$, $p = 0.0136$) with more changes with probability+uncertainty There was a significant difference ($X2 = 8.19$, $p = 0.0423$) for negative, with combined AI having the most. There were no differences between radiologists and residents for no change ($X2 = 2.33$, $p = 0.5073$) or negative change ($X2 = 0.83$, $p = 0.8413$) but was for positive ($X2 = 14.78$, $p = 0.0020$) with radiologists having more than residents with probability+uncertainty having the most (31.5 vs 9.58%)

**CONCLUSION**

Different AI scenarios can impact clinical performance and confidence, impacting radiologist and residents differently.

**CLINICAL RELEVANCE/APPLICATION**

Choosing an AI tool for clinical use should not only take accuracy into account but also how the output is shown to radiologist users.

## T7-SSIN03-4 A CUSTOM GPT CAN EFFECTIVELY ANSWER BOTH SIMPLE AND COMPLEX QUESTIONS ASKED OF RADIOLOGISTS

Amish H. Doshi, MD (*Abstract Co-Author*) Speaker, Becton, Dickinson and Company;Consultant, Siemens AG
Chloe G. Cross, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Phone calls and interruptions significantly compromise radiologists clinical efficiency. The purpose of this research was to assess whether a custom Chat-GPT4 can be successful in answering common questions asked of radiologists.

**METHODS AND MATERIALS**

A custom Chat-GPT 4 model, called Radiology GPT, was developed by the co-authors using informational material readily available to radiologists at the author's institution. 45 questions commonly asked of radiologists were developed by the co-authors. Each question was assigned a complexity grade of a simple technical question (level 1), a multistep technical question (level 2), or a multistep technical question with incomplete information (level 3). Each output was graded using a 6-point Likert scale for accuracy (1 = completely incorrect, 2 = more incorrect than correct, 3 = approximately equal parts correct and incorrect, 4 = more correct than incorrect, 5 = nearly all correct, 6 = correct), 3-point scale for completeness (1 = incomplete, 2 = adequate, 3 = comprehensive), and 5-point Likert scale for clarity (1 = strongly unclear, 2 = unclear, 3 = neutral, 4 = clear, 5 = strongly clear). All outputs were graded by 3 blinded MDs (2 resident radiologists, 1 attending radiologist), and clarity metric-only was graded by 2 blinded MD vascular surgery residents.

**RESULTS**

45 total questions were prompted to the Radiology GPT (level 1: n=26, level 2: n=11, level 3: n=7). Mean accuracy for all questions was 5.5 (SD±0.90), mean completeness was 2.3 (SD±0.50), and mean clarity was 4.7 (SD±0.67). Of the 135 scores for accuracy (45 questions, 3 radiology reviewers), only 7 received a score of 3 or less (approximately equal parts correct and incorrect). For completeness, 5/135 scores received a score of 1 (addresses some aspects of the question, but significant parts are missing or incomplete). Of the 225 scores for clarity (45 questions, 3 radiology reviewers, 2 clinician reviewers), 5 received a score of 2 or less.

**CONCLUSION**

A custom Chat GPT 4 can accurately and completely answer questions commonly posed to radiologists. Enabling this feature would enable radiologists to dedicate more time on clinical work and enhance wellness.

**CLINICAL RELEVANCE/APPLICATION**

A custom Chat GPT 4 targeted to radiology may be able to alleviate phone calls and interruptions for common questions posed to radiologists.

## T7-SSIN03-5 A NOVEL APPROACH TO ACCELERATE DEVELOPMENT OF IMAGING COMMON DATA ELEMENTS BY CAPTURING RADIOLOGISTS' OBSERVATIONS WITH A LARGE LANGUAGE MODEL

Tarik K. Alkasab, MD, PhD (*Abstract Co-Author*) Consultant, Nuance Communications, Inc;Medical Advisory Board, Nuance Communications, Inc
Roshan Fahimi, MD (*Abstract Co-Author*) Nothing to Disclose
Heather Chase, BS (*Abstract Co-Author*) Nothing to Disclose
Michael Hood, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Common Data Elements (CDEs) are data structures that comprehensively encode the information about a particular imaging finding from the unstructured text of a diagnostic radiology report. To date, CDE creation has been labor-intensive. We introduce a novel methodology that uses a large language model (LLM) to reliably generate preliminary CDEs for specified findings by automatically capturing the terms and associations used by radiologists to describe them.

**METHODS AND MATERIALS**

We assembled a corpus of anonymized chest CT reports from a single institution using a large language model (LLM). Each report was broken into overlapping chunks and semantic vectors were generated for each chunk using an embedding model (BAAI's bge-base-en-v1.5). The chunks were maintained in a vector-search-enabled database (Microsoft Azure). The created tool takes the name of a CT finding as input. Relevant report chunks were retrieved from the database using a cosine-similarity search to the semantic vector of the finding name, reranked using a reranking cross-encoder (BAAI's bge-reranker). These chunks were then included as context for a prompt to a GPT model (Microsoft Azure) to generate a structured data model describing the attributes radiologists used in the reports to describe the finding. The output data models included attributes such as Identification (presence and status changes), Characteristics (severity, distribution, location, etc.), and Associated Findings. Multiple iterations were generated, then integrated and reconciled to address redundancies. A fellowship-trained emergency radiologist reviewed each CDE definition to ensure its clinical accuracy.

**RESULTS**

An initial pilot of this methodology tested 20 selected findings that appear commonly in chest CT reports. Iteration of this process led to a refined definition of CDE sets and their standard element properties for 180 chest CT findings, which were then sent to a centralized repository (GitHub) for further review.

**CONCLUSION**

We show that an LLM can harness a corpus of diagnostic chest CT reports to rapidly and dependably produce a preliminary CDE for any specified imaging finding. This greatly broadens the basis for modeling chest CT reports. Future iterations of this methodology will aim to capture a broader range of observations by incorporating diagnostic reports from multiple institutions.

**CLINICAL RELEVANCE/APPLICATION**

CDEs are central to the Open Imaging Data Model initiative, which provides a standardized framework for representing the vast data within imaging exams to power downstream applications in the imaging informatics ecosystem. This method accelerates the development of the many CDEs needed to capture the detailed observations in a radiology report.

## T7-SSIN03-6 AI-AIDED DIAGNOSTIC SYSTEM PROVIDING EXPLANATIONS IN LI-RADS LANGUAGE IN LIVER CANCER DIAGNOSIS USING MRI

Kenji Suzuki, PhD (*Abstract Co-Author*) Nothing to Disclose
CHEN ZHANG (*Abstract Co-Author*) Nothing to Disclose
Takamichi Murakami, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Masatoshi Hori, MD, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Keitaro Sofue, MD (*Abstract Co-Author*) Nothing to Disclose
Ze Jin, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

AI for diagnosis has been developed to aid radiologists. Because of the "black-box" nature, AI does not provide reasons for its decisions, which prevents diagnostic AI from utilizing in clinical practice. This study aims to develop an innovative, interpretable AI model that mimics the decision-making process of radiologists by using the Liver Imaging Reporting and Data System (LI-RADS). The model is designed to provide transparent liver cancer diagnostic predictions with explanations in LI-RADS language.

## METHODS AND MATERIALS

Our study utilized an image database containing 221 dynamic contrast-enhanced (DCE) liver MRI studies from 94 patients with 89 malignant and 132 benign tumors, with radiologists-assessed LI-RADS reports. Our proposed interpretable AI scheme comprised three sections: AI model for LI-RADS feature prediction and selection based on segmented tumors, liver tumor classification with a support-vector AI with the predicted LI-RADS features, and AI for generating conversational explanations with LI-RADS and natural language expressions. The process started with identifying the most impactful LI-RADS features with our original maximal area-under-the-curve feature selection method. The support-vector AI model was then trained to differentiate between malignant and benign tumors to leverage the LI-RADS features to boost its classification performance. The predicted LI-RADS features from our model were transformed into clinically meaningful explanations with natural language expressions.

## RESULTS

In the feature prediction and selection section in our scheme, seven LI-RADS features were selected, including APHE (arterial phase hyperenhancement), marked T2 hyperintensity, mild-moderate T2 hyperintensity, restricted diffusion, capsule appearance, and washout. Our scheme predicted LI-RADS features very accurately: APHE (AUC of 0.88), marked T2 hyperintensity (0.86), mild-moderate T2 hyperintensity (0.89), restricted diffusion (0.88), capsule (0.92), washout (0.9), and the size feature achieved an MSE of 26.30 pixels2. With the predicted LI-RADS features, the liver tumor classification model achieved an AUC of 0.85, higher than the state-of-the-art deep leaning models such as VGGNet (0.39), DenseNet (0.36), and ResNet (0.54).

## CONCLUSION

We developed an interpretable AI model for liver cancer diagnosis that provided the reasons for the AI decisions in LI-RADS language.

## CLINICAL RELEVANCE/APPLICATION

Our scheme is not only theoretically sound for AI developers but also has great potentials for increasing the acceptance and trust of radiologists in its practical use.

## T7-SSIN04-1 THE IMPACT OF LARGE LANGUAGE MODEL-GENERATED RADIOLOGY REPORT SUMMARIES ON PATIENT COMPREHENSION: A RANDOMIZED CONTROLLED TRIAL

Nicholas T. Befera, MD (*Abstract Co-Author*) Founder and CEO, Scanslated, Inc
Naiim S. Ali, MD,FRCPC (*Abstract Co-Author*) Nothing to Disclose
Kayla Berigan, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Assess the impact of Large Language Model (LLM)-generated radiology report summaries, alone and combined with lay language reports, on patient comprehension and need to search report content online.

### METHODS AND MATERIALS

In this prospective, randomized controlled study, adult patients with imaging ordered by a primary care provider were randomized to receive the standard radiology report only (Group 1) or the standard report and: LLM-generated report summary (Group 2), commercially available lay language report with explanations and diagrams of clickable terms (Group 3), LLM-generated summary + commercially available lay language report (Group 4). Participants were asked two survey questions: 1) How would you rank your understanding of your radiology report? 2) Do you plan to look anything up online that is in this report? Summaries were generated by a publicly available LLM using the prompt: “Explain this radiology report to a patient in layman's terms in second person: (manually deidentified report text).” Output was edited for accuracy and scope by a board-certified radiologist before delivery to patients.

### RESULTS

Patients who received LLM-generated summaries, alone or combined with lay language reports, were most likely to report high understanding and least likely to report needing to search content online. Of 51 LLM-generated summaries made available to patients, most (80.4%, 41/51) were edited before release, usually to remove suggestions of prognosis, treatment, or causality.

### CONCLUSION

LLM-generated radiology report summaries can improve patient understanding and decrease the need to search the internet but require human editing in most cases.

### CLINICAL RELEVANCE/APPLICATION

Reports of increased patient anxiety and clinician burden due to immediate patient access to radiology reports have sparked investigation into patient-friendly reports. Single arm studies have shown that patient-friendly reports increase comprehension and decrease anxiety, but these have not utilized LLMs or randomized controlled designs. LLM-generated lay language reports have been retrospectively evaluated for readability and accuracy according to established scales or review by radiologists, clinicians, or lay volunteers, but this study is the first in which patients were given access to LLM-generated lay language summaries of their own reports and impact was evaluated in a prospective randomized controlled trial. This novel study demonstrates that LLM-generated report summaries, alone and combined with commercially available lay language reports, can improve patient understanding and decrease their need to search report content online.

## T7-SSIN04-2 HARNESSING GPT-4 FOR CLINICAL DECISION SUPPORT: USING A LARGE LANGUAGE MODEL FOR TRIAGING PATIENTS AT RISK OF INTRAVENOUS CONTRAST REACTIONS

Evis Sala, MD, PhD (*Abstract Co-Author*) Co-founder, Lucida Medical Ltd
Matteo Bonatti, MD (*Abstract Co-Author*) Nothing to Disclose
Benedetta Gui, MD (*Abstract Co-Author*) Nothing to Disclose
Luca D'Erme, MD (*Abstract Co-Author*) Nothing to Disclose
Roberta Chianura (*Abstract Co-Author*) Nothing to Disclose
Matteo Marin (*Abstract Co-Author*) Nothing to Disclose
Miriam Dolciami, MD (*Abstract Co-Author*) Nothing to Disclose
Giacomo Avesani, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine whether a Large Language Model (GPT 4) can provide accurate and valuable guidance on management for at risk for reaction during intravenous contrast administration.

**METHODS AND MATERIALS**

Six guidelines from various scientific societies were collected, both in English and the local language. These documents were embedded using OpenAI embeddings within the LangChain framework, creating a database to provide information to a GPT-4 turbo model. We formulated 200 clinical scenarios describing different situations, combining allergic and renal problems (e.g., moderate to severe allergic reaction and different renal functions) and different types of contrast media (iodine and gadolinium). We asked the model to give a textual answer for each clinical scenario indicating the correct patient management following the previously given guidelines. The responses generated by the model were evaluated by a human expert in the field, considering formal correctness and clinical usefulness. A Likert 5-point scale for each task (correctness and usefulness) was used to judge the answers (from 5=correct/safe or very useful to 1=completely wrong or completely useless for clinical purposes). We dichotomised the responses with a cut-off of =4 to consider the answers acceptable.

**RESULTS**

The model's answers were judged formally correct and safe for patients in 94% of scenarios and valuable in 82% of cases. Predominantly, answers deemed not valid were considered too vague to be used.

**CONCLUSION**

LLMs have the potential to aid in the clinical management of critical patients. Such models can be very useful for novice personnel or initial screenings. Better performance might be achieved with fine-tuning and the "tree of thought" techniques.

**CLINICAL RELEVANCE/APPLICATION**

Large Language Models can effectively assist in clinical decision-making, such as identifying patients at risk of reactions during intravenous contrast procedures, but require supervision.

## T7-SSIN04-3 FINE-TUNED LARGE LANGUAGE MODELS FOR ACCURATE BREAST PATHOLOGY INFORMATION EXTRACTION

**PURPOSE**

The objective is to evaluate the performance of general and fine-tuned large language model (LLM)-based tools for automated extraction of pathology outcomes from breast pathology reports.

**METHODS AND MATERIALS**

We conducted a single-institution, retrospective review of breast pathology reports from FNAs, core biopsies, surgical excisions, and mastectomies from 1/2019-8/2023. We selected 978 pathology reports consisting of 609 reports containing =1 malignant diagnoses and 369 with only benign and/or high-risk pathologies for a cancer-enriched dataset. For each report, we annotated the source of the sample (left/right breast, left/right lymph node) and diagnosis category (benign, high-risk, or cancer). For cancers, the subtype (DCIS, invasive ductal carcinoma, invasive lobular carcinoma, adenocarcinoma not otherwise specified, or other malignant pathology) was collected. This dataset was split into 489/244/245 for training, validation, and testing. We selected 5 pre-trained LLMs (Mistral 7B Instruct, Mixtral-8x7b-instruct, GPT-4, Llama 2 7B Chat, and Llama3-8B-Instruct). We created prompts to extract the following information from the pathology reports: 1) Tissue source, including lateralities and tissue types; 2) Presence of cancer or high-risk lesion; 3) Cancer subtype and the laterality. We compared the performance of the general LLMs to a version of Mistral 7B Instruct that was fine-tuned on our training set. Question exact match accuracies (e.g., all cancer types across all sites extracted correctly) and category accuracies (e.g. left breast DCIS extracted correctly) were calculated as test metrics.

**RESULTS**

Our fine-tuned Mistral-7B obtained high accuracy across all tasks, obtaining exact match accuracies of 98.8%, 95.9%, and 96.3% for tissue source, cancer presence, and cancer subtype, respectively. Per category accuracies (e.g., correctly identified left breast DCIS) ranged from 97.1% to 100%. Exact match accuracy across 3 tasks was 91.4%. This vastly outperformed the best general LLM, GPT-4, which obtained an exact match accuracy of 76.7% across the tasks. GPT-4 obtained exact match accuracies of 98.4%, 98.0%, and 78.8% across the three questions, and per category accuracies ranged from 90.2% to 100%.

**CONCLUSION**

Mistral-7B fine-tuned on 489 breast reports achieved high accuracy in extracting tissue source, cancer presence, and cancer subtyping from pathology reports.

**CLINICAL RELEVANCE/APPLICATION**

Fine-tuned LLMs can accurately extract information from breast pathology reports, providing an efficient avenue for creating large-scale databases. Prompts and an open-source development platform from this study will be shared on a user-friendly platform to facilitate greater utilization of LLMs in cancer research.

## T7-SSIN04-4 LARGE LANGUAGE MODELS, THE FUTURE REPLACEMENT OF RADIOLOGY RETROSPECTIVE RESEARCH?

Tessa S. Cook, MD, PhD (*Abstract Co-Author*) Grant, Independence Blue Cross;Speaker, Sectra AB;
William W. Boonn, MD (*Abstract Co-Author*) CEO, Equium Intelligence Inc;Shareholder, Equium Intelligence, Inc
Michael Corbin, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

GPT-4 leverages large language models (LLMs) and natural language processing (NLP), opening the door to improve healthcare efficiency, quality, and research. After a manual internal institutional retrospective review, we found that, similar to Yousef et al., our radiologists use multiple descriptors when characterizing ascending thoracic aortic aneurysms (TAA). Our studies aim is to evaluate the accuracy, sensitivity (Sen), and specificity (Spe) of GPT-4 in data extraction and internal validation from radiology reports compared to manual data collection in the diagnosis of TAA.

**METHODS AND MATERIALS**

464 patients with TAA were initially reviewed in this IRB-approved study. Radiologic and clinical data were obtained retrospectively from the medical record. Patients with congenital malformations, bicuspid valves, ascending graft repairs, traumatic aortic injury, or Stanford type A and B dissections were excluded. TAA descriptors and sizes documented for the "ascending aorta" in the report were manually extracted. GPT-4 (in a HIPAA-compliant environment in Microsoft Azure) was used to parse the reports for the same data. GPT-4 was optimized to perform batched data extraction of descriptors and diameters of the aortic root, ascending, and descending aorta from radiology reports and perform internal validations. Manual and GPT-4 extracted data were compared. TAA descriptors were matched to "normal", "dilated", or "aneurysmal".

**RESULTS**

Reports from 363 patients were analyzed (75% male; average age 67 years). 39/363 patients had no aortic descriptor. Across 324 patients, radiologists (RAD) descriptors mapped to "normal" (16), "dilated" (38), and "aneurysmal" (270), while GPT-4's mapped to "normal" (15), "dilated" (31), and "aneurysmal" (327). RAD diagnosed 74% patients with TAA, while GPT-4 identified 90%. Average TAA size was 4.64 cm (RAD) vs. 4.62 cm (GPT-4). 261/270 patients were found to be "aneurysmal" by GPT-4 (Sen 97%). GPT-4 self-validation tracked number of diagnoses it extracted per report. GPT-4 found 6/48 cases with >1 diagnosis (Sen 13%, Spe 97%). GPT-4 correctly flagged 16/31 cases in its summary report for further review when identifying discrepancies. GPT-4 was congruent between the extracted data and its self-generated validation summary (87%).

**CONCLUSION**

GPT-4 efficiently extracts data from radiology reports and can be optimized to be sensitive and specific for medical diagnoses. Further work should be done to improve its accuracy and reliability. GPT-4, when optimized correctly, offers a promising platform for future radiology retrospective research and quality management.

**CLINICAL RELEVANCE/APPLICATION**

Leveraging LLMs and artificial intelligence for excellent patient care will shape the future of healthcare.

## T7-SSIN04-5 LEVERAGING FINE-TUNED LARGE LANGUAGE MODELS FOR AUTOMATED PROTOCOLING OF CT EXAMINATIONS

Joshy Cyriac (*Abstract Co-Author*) Nothing to Disclose
Shan Yang, MSc (*Abstract Co-Author*) Nothing to Disclose
Jakob Wasserthal (*Abstract Co-Author*) Nothing to Disclose
Maurice Pradella, MD (*Abstract Co-Author*) Nothing to Disclose
Tobias Heye, MD (*Abstract Co-Author*) Nothing to Disclose
Jan Vosshenrich, MD (*Abstract Co-Author*) Nothing to Disclose
Martin Segeroth, MD, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To leverage large language models (LLMs) for automated protocoling of requested cardiothoracic and abdominal CT examinations and investigate their protocol assignment accuracies.

**METHODS AND MATERIALS**

Consecutive CT examinations from our cardiothoracic (n = 66,173) and abdominal imaging (n = 54,944) divisions performed between 01/2010-10/2021 were retrospectively included. Protocoling had been performed by radiology residents during clinical routine, assigning one of 25 institutional cardiothoracic or one of 33 abdominal standardized imaging protocols, respectively serving as ground-truth.Using LoRA and the transformer library for Python, we fine-tuned two LLMs (Mistral-7B-v0.1 and BioMistral-7B). The clinical question (e.g. "r/o pulmonary embolism") and the referrer (e.g. "emergency department") served as input for the classification task. The dedicated imaging protocols represented the output. Fine tuning was trained for 10 epochs.For comparison, we trained a simple deep neuronal network consisting of three dense layers with 64 neurons each and one dense layer with 25 respectively 33 neurons as output layer. The network was trained for 100 epochs on the most frequently used terms. Data was split 90%/10% for model training/validation.

**RESULTS**

The fine-tuned Mistral-7B model achieved overall accuracies of 77% for the cardiothoracic and 73% for the abdominal data set. In contrast, the overall accuracies for the simple deep neuronal network were 65% and 54%, respectively. Fine-tuning of already specialized models like BioMistral-7B increased the overall accuracy by only 1% to 78% for the cardiothoracic data set.On a protocol level, assignment accuracies of the Mistral-7B model for the most frequently performed cardiothoracic CT protocols in the validation dataset were 94% for CT pulmonary angiograms (n = 1,761), 91% for unenhanced chest CTs (n = 2,096), 80% for arterial phase chest CTs (n = 610) and 85% for ECG-gated aortic CT angiograms (n = 253).For abdominal imaging division protocols, Mistral-7B assignment accuracies in the validation dataset were 89% for portal venous phase CT abdomen (n = 993), 87% for portal venous phase CT chest/abdomen (n = 1,161), 96% for unenhanced kidney stone CT (n = 397), and 92% for multi-phase abdominal CT (n = 190).

**CONCLUSION**

Fine-tuned LLMs achieve good to excellent protocoling accuracies for the most frequently performed cardiothoracic and abdominal CT examinations and outperform a simple deep neuronal network trained solely on frequently used terms.

**CLINICAL RELEVANCE/APPLICATION**

LLMs may help streamlining the CT protocoling workflow, potentially reducing noninterpretative tasks for radiologists given accurate protocol assignment for the most frequently performed CT examinations.

### PURPOSE

To fill the unmet need for an updated systematic review and meta-analysis on the diagnostic performance of MRI for meniscus tears compared to arthroscopy with subgroup analyses to identify factors that impact accuracy.

### METHODS AND MATERIALS

Literature search using PubMed®, Scopus®, and Embase® databases identified peer-reviewed publications on preoperative MRI of native menisci compared with subsequent arthroscopy using a combination of root words: "arthroscop*", "knee", "menisc*", and "MRI". Publications were excluded if true and false positives and negatives for each meniscus were not reported. Methodologic quality was determined using the QUADAS-2 tool. Publication bias was assessed with a funnel plot. Diagnostic performance with receiver operating characteristics (ROC) was calculated using random effects models with subgroup analyses for change over time, patient age, imaging parameters, and tear criteria. Student's t-test, ANOVA, and variate tests were used.

### RESULTS

75 studies (36 retrospective, 39 prospective) from 28 countries published from 1986 to 2023 yielded 10,694 patients (mean age: 35.8±8.5 years, range: 13.3-52.0) with 42.2±31.2 days (range: 2-180) between MRI and arthroscopy. QUADAS-2 assessment found overall low risk for methodologic bias and the funnel plot showed low risk of publication bias. Pooled weighted sensitivity was higher for medial than lateral meniscus tears (91.9%, 95%CI: 90.3-93.2 vs. 81.1%, 95%CI: 77.9-84.0), but specificity was higher laterally than medially (94.1%, 95%CI: 92.8-95.1 vs. 88.2%, 95%CI: 85.9-90.1, p<0.001). Except for increased specificity for lateral meniscus tears for each decade after 2000 (p range <0.001-0.040), diagnostic performance did not significantly change over time. Subgroup analyses found no significant differences in diagnostic performance based on patient age, study size, magnetic field strength, or use of 3D isotropic imaging. Bivariant ROC models found that for the lateral meniscus, the use of two tear criteria (linear signal extending to the articular surface and meniscus distortion) outperformed the use of only one of these criteria (p=0.020); this remained significant on multivariable analysis (p=0.005).

### CONCLUSION

MRI diagnostic performance for tears differs between menisci, with higher sensitivity for the medial meniscus and higher specificity for the lateral meniscus. For the lateral meniscus, specificity improved over time and with the combined use of two tear criteria.

### CLINICAL RELEVANCE/APPLICATION

This systematic review and meta-analysis on the diagnostic performance of MRI for meniscus tears provides updated benchmarking for clinical reporting (e.g., quality improvement) and helps direct health care resources (e.g., for clinical trials).

**PURPOSE**

To identify interdisciplinary consensus guidelines for reporting meniscus findings on MRI using a systematic, interactive approach.

**METHODS AND MATERIALS**

33 panelists (22 radiologists and 11 orthopaedists) with subspecialty expertise in menisci from 23 North American institutions were convened to assess for areas of agreement and disagreement related to MRI reporting of menisci. A 3-round Delphi method with anonymized feedback at each round was employed to encourage independent opinions while facilitating iterations toward agreement. In Round 1, each panelist responded to open-ended questions to identify potentially problematic terms and diagnostic criteria. With these data, 11 teams (each with 2 radiologists and 1 orthopaedist) created a total of 32 consensus statements on 11 topics with explanatory text supported by approximately 125 peer-reviewed references, prioritizing the highest levels of evidence by Oxford CEBM criteria. In Round 2, each statement was scored by panelists using a 9-point Likert scale, again with anonymized open-ended text feedback. Round 2 data were reviewed by each team to revise statements for a third, final round of voting. Consensus was defined as a score of =7 by =80% panelists and median of =7 (IQR: =3). Chi-square and Mann-Whitney U tests were used.

**RESULTS**

All panelists completed all Delphi rounds. In Round 1, the three most frequently identified problematic issues were MRI reporting of 1) the postoperative meniscus, 2) tear pattern terminology, and 3) criteria for diagnosing root tears. In Round 2, 24/32 (75%) statements achieved consensus, which included all statements covering 6 topics (MRI criteria for tear, meniscocapsular junction, extrusion, tear descriptors, recurrent tear descriptors, ancillary findings). The remaining 8/32 (25%) statements on 5 topics (MRI criteria for possible tears, postoperative menisci, meniscus roots, tear patterns, non-tear descriptors) did not reach consensus in Round 2. Between Rounds 2 and 3, agreement increased significantly ($p<.05$) among all panelists for MRI criteria for possible tears, among orthopaedists for the postoperative menisci, and among radiologists for meniscus roots, tear patterns, and non-tear descriptors. In Round 3, all statements achieved consensus.

**CONCLUSION**

Consensus among radiologists and orthopaedists was achieved for 32 evidence-based statements on MRI reporting of menisci, with iterative Delphi rounds improving agreement on reporting criteria for possible tears, postoperative menisci, meniscus roots, tear patterns, and non-tear descriptors.

**CLINICAL RELEVANCE/APPLICATION**

Interdisciplinary, multi-institutional consensus on MRI reporting of menisci facilitates consistent communication and minimizes misunderstanding.

## T7-SSMK06-3 MENISCAL RAMP LESION: OVER-REPORTED ON MRI? OR UNDER-REPORTED AT ARTHROSCOPY?

Richard E. Walker, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Peter Salat, MD (*Abstract Co-Author*) Nothing to Disclose
Callie Stirling (*Abstract Co-Author*) Nothing to Disclose
Steven K. Boyd, PhD (*Abstract Co-Author*) Nothing to Disclose
Sarah Manske (*Abstract Co-Author*) Nothing to Disclose
Nina Pavlovic (*Abstract Co-Author*) Nothing to Disclose
Victoria Peterson, MD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

We aim to correlate the incidence of meniscal ramp lesions (RLs) on MRI versus surgery and the distribution of ramp lesion type in a large cohort of ACL-injured subjects.

**METHODS AND MATERIALS**

MRI results and arthroscopy reports from a large, prospective multimodal imaging study evaluating bone injury associated with ACL tear were evaluated. Prospective MRI reports were compared to a blind consensus read by a single experienced MSK subspecialist radiologist and senior trainee, both with comparison to knee arthroscopy.

**RESULTS**

101 subjects completed baseline MRIs, 78 of which went on to surgery, including 55 females (71%), and an average age of 32.0 years (15-55 years). Average time between injury and MRI was 29.5 days (± 9.9) and 144.9 days between MRI and surgery (± 108.8). RLs were prospectively reported on MRI in 53% of participants (41/78). Consensus read identified 53 RLs (68.5%), with 4B the most common type (23/53 cases, 43%). 77% (41/53) were classified as unstable at consensus read. Surgical reports utilizing standard anteromedial and anterolateral portals identified 21 ramp lesions (27%). There was a statistically significant difference between the reporting of a RL on MRI (prospective read ($p<0.001$) and consensus read ($p<0.001$)) when compared to surgery. No surgical reports indicated the use of a posteromedial portal, which could result in under-reporting. The delay between MRI and surgery could result in interval RL healing.

**CONCLUSION**

There was a significant discrepancy in reporting of RLs on MRI compared to surgery. Potential explanations include MRI over-reporting, surgical under-reporting, or both.

**CLINICAL RELEVANCE/APPLICATION**

Accurate identification of ramp lesions on MRI and repair at the time of ACL reconstruction is important for restoration of knee stability.

## T7-SSMK06-4 DEEP LEARNING SUPER-RESOLUTION FOR SIMULTANEOUS MULTISLICE-PARALLEL IMAGING-ACCELERATED KNEE MRI: ARTHROSCOPY VALIDATION OF DIAGNOSTIC PERFORMANCE

**PURPOSE**

Deep learning methods can improve accelerated MRI but require validation against an independent reference standard to ensure robustness and accuracy. Thus, the purpose was to validate the efficacy of fourfold simultaneous multislice-(SMSx2)-parallel imaging (PIx2)-accelerated deep learning super-resolution (DLSR) MRI against conventional SMSx2-PIx2-accelerated MRI and arthroscopic surgery.

**METHODS AND MATERIALS**

Adults with painful knee conditions were prospectively enrolled from December 2021 to October 2022. Participants underwent fourfold SMSx2-PIx2-accelerated standard-of-care and investigational DLSR MRI at 3.0T. Seven radiologists independently evaluated the MRI studies for overall image quality (Likert scale, 1=very bad, 5=very good), meniscus and ligament tears, and articular cartilage defects. Statistical analyses included ?-based interreader agreements and diagnostic performance testing. $P < .05$ was considered significantly different.

**RESULTS**

A total of 116 adults (mean age ± standard deviation: 45 years ± 15; 74 men) who underwent arthroscopic surgery within 38 ± 22 days were evaluated. Overall image quality was significantly better ($p <.001$) for DLSR MRI (5 [range, 3-5]) than conventional MRI (4 [3-5]) with good interreader agreements (? =0.81 [95%-CI: 0.79, 0.84]). Diagnostic performances of conventional versus DLSR MRI were similar for medial meniscus tears (AUC, 0.94 [95%-CI: 0.89, 0.97] vs. 0.94 [0.90, 0.98]; p >.99), lateral meniscus tears (0.85 [0.78, 0.91] vs. 0.87 [0.81, 0.94]; p >.96), and anterior cruciate ligament tears (0.98 [0.93, >0.99] vs. 0.98 [0.93, >0.99]; p >.99). Diagnoses of articular cartilage defects were significantly more accurate (p=.002) with DLSR MRI (0.78 [0.75, 0.81]) than conventional MRI (0.71 [0.67, 0.74]). Structural abnormalities were detected with good interreader agreements (? =0.64 [95%-CI: 0.57, 0.71]). DLSR MRI did not introduce hallucinations or erroneously omit abnormalities.

**CONCLUSION**

Fourfold SMSx2-PIx2 accelerated DLSR MRI of the knee is robust, provides better image quality, similar accuracy for meniscus and ligament tears, and improved accuracy for articular cartilage defects compared to conventional SMSx2-PIx2 accelerated MRI.

**CLINICAL RELEVANCE/APPLICATION**

Fourfold accelerated knee MRI augmented with deep learning super-resolution adds value to musculoskeletal radiology practice by optimizing scan efficiency while improving image quality and maintaining diagnostic accuracy.

## T7-SSMK06-5 PROGRESSION OF BONE MARROW LESION VOLUME AND RISK OF KNEE OSTEOARTHRITIS INCIDENCE: A LONGITUDINAL DEEP-LEARNING ANALYSIS OF MRI FROM OSTEOARTHRITIS INITIATIVE COHORT

Soheil Mohammadi, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Sara Momtazmanesh (*Abstract Co-Author*) Nothing to Disclose
Kamyar Moradi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Bone marrow lesions (BMLs) are a risk factor for incident knee osteoarthritis (OA) and deep-learning (DL) methods can help in automated segmentation and risk prediction. We aimed to develop and validate a DL model for quantifying tibiofemoral BML volume from MRIs in knees without radiographic OA and assess the association between longitudinal changes in these volumes and knee OA incidence.

**METHODS AND MATERIALS**

The DL model segmented tibiofemoral joint into 10 subregions (akin to MRI Osteoarthritis Knee Score (MOAKS) system) and measured BML volume in each subregion. Baseline and 4th-year follow-up MRIs from 4700 participants (9400 knees) of the Osteoarthritis Initiative cohort were analyzed. Knees without OA at baseline were categorized into three groups based on 4-year BML volume changes: BML-free, regressing BML, and progressive BML. Over a 9-year period, the risk of radiographic and symptomatic knee OA incidence was compared among these groups.

**RESULTS**

We included 3869 non-OA knees from 2430 participants (age mean±SD: 59.5±9.0, female/male: 1.3). At the 4th-year follow-up, 2216 remained BML-free, 1106 showed an increase, and 547 showed a decrease in BML volume. Knees with progressive BML had a higher risk of radiographic knee OA incidence compared to BML-free (hazard ratio (HR), 95% confidence interval (CI): 3.01, 2.53 to 3.57, P<0.001) and regressing BML (HR, 95% CI: 2.00,1.56 to 2.56, P<0.001) knees. They also had a higher risk for symptomatic OA incidence compared to BML-free knees (HR, 95% CI: 1.25, 1.11 to 1.41, P:0.001). Larger volume changes in BML progression were associated with a higher risk of knee OA incidence (radiographic HR: 1.95, symptomatic HR: 1.70, P-values<0.001). In all subchondral plates, especially the medial femur and tibia, BML progression was associated with a higher risk of developing both radiographic and symptomatic knee OA compared to BML-free plates.

**CONCLUSION**

Progressive BMLs, according to the subregion and volume changes extent, are associated with an increased risk of OA incidence compared to BML-free or regressing BML knees, emphasizing the importance of monitoring BML volume changes in evaluating early interventions to prevent OA incidence.

**CLINICAL RELEVANCE/APPLICATION**

Changes in BML volume over time play a crucial role in predicting OA incidence. Monitoring BML changes may help assess the efficacy of early strategies aimed at preventing OA incidence in at-risk individuals.

## T7-SSMK06-6 EVALUATION OF THE ASSOCIATION BETWEEN CENTRAL OBESITY AND MRI-BASED BIOMARKERS OF KNEE OSTEOARTHRITIS INDEPENDENT OF BMI: A CROSS- SECTIONAL STUDY FROM OSTEOARTHRITIS INITIATIVE DATABASE

John A. Lynch, PhD (*Abstract Co-Author*) Nothing to Disclose
Ayush Arora (*Abstract Co-Author*) Nothing to Disclose
Thomas M. Link, MD, PhD (*Abstract Co-Author*) Research Consultant, General Electric Company
Gabby B. Joseph (*Abstract Co-Author*) Nothing to Disclose
Zehra Akkaya (*Abstract Co-Author*) Nothing to Disclose
Fatemeh Dehghani Firouzabadi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the association between central obesity (using waist circumference (WC)) and MRI-based biomarkers of knee osteoarthritis (KOA), and to assess the association between WC with knee synovial inflammation using non-contrast-enhanced MRI, independent of BMI.

**METHODS AND MATERIALS**

3167 individuals with radiographic Kellgren-Lawrence grades 0-3 in the right knee at baseline from the Osteoarthritis Initiative (OAI) were included and WC was measured at baseline. Cartilage composition and joint structural abnormalities were assessed using MRI T2 cartilage and whole-organ magnetic resonance imaging score (WORMS), respectively. MRI-based synovial inflammation was semi-quantitatively assessed for effusion-synovitis. Linear regression analysis was used to investigate the associations between various measures of adiposity and MRI-based biomarkers of KOA (i.e. WORMS and T2-values), both with and without adjustment for BMI.

**RESULTS**

The participants in the study had a mean age of 60.82±9.12 years and average BMI of 29.27 ±4.47 kg/m². Central obesity showed positive associations with severity of knee structural abnormalities, particularly of meniscus(WC coeff.=0.042, 95%CI=[-0.002-0,085], p=0.05 and cartilage (WC coeff.=0.263, 95%CI=[-0.203-0.323], p<0.001), even after adjusting for BMI (WC coeff.=0.075[0.002-0.148], p=0.04, and WC coeff.=0.163, 95%CI= [0.062-0.264], p=0.002, respectively). Central obesity demonstrated positive associations with T2-values including average T2 values (WC coeff.=0.221, 95%CI= [0.157-0.285], p<0.001, lateral tibia(WC coeff.=0.145, 95%CI= (0.065-0.226), p<0.001), and lateral femur (WC coeff.=0.413, 95%CI= [0.322-0.504], p<0.001), even after adjusting for BMI(WC coeff.=0.110, 95%CI= [0.002-0.218], p=0.04, WC coeff.=0.188, 95%CI= [0.053-0.324], p=0.006, and WC coeff.=0.373, 95%CI= [0.219-0.527], p<0.001, respectively) Central obesity (via WC) and obesity (via BMI) were positively associated with effusion-synovitis. However, after adjusting for BMI, significant association between WC and effusion-synovitis score no longer persisted.

**CONCLUSION**

Central adiposity was significantly associated with T2-based cartilage composition and structural abnormalities of the meniscus and cartilage (WORMS), even after adjustment for BMI, indicating that central adiposity may provide information independent of BMI in knee OA.

**CLINICAL RELEVANCE/APPLICATION**

Waist circumference may be an independent risk factor for T2-based cartilage composition and structural abnormalities of the meniscus and cartilage (WORMS) outcomes, apart from general obesity as measured by BMI. This indicates that abdominal fat specifically, rather than overall body weight, may play a crucial role in KOA.

## T7-SSMK07-1 DEEP LEARNING APPROACH FOR CLASSIFICATION OF OSTEOPOROSIS AND OSTEOPENIA ON CHEST X-RAY WITH A MULTINATIONAL STUDY

Namkug Kim, PhD (*Abstract Co-Author*) Stockholder, Anymedi, Inc
Junhyeok Park (*Abstract Co-Author*) Nothing to Disclose
Saerom Park (*Abstract Co-Author*) Nothing to Disclose
Jinhoon Jeong (*Abstract Co-Author*) Nothing to Disclose
Miso Jang (*Abstract Co-Author*) Nothing to Disclose
Minje Kim (*Presenter*) Nothing to Disclose

### PURPOSE

We aimed to determine the feasibility and performance of deep learning (DL) models based on CXR with screening osteoporosis and osteopenia with diverse external validation.

### METHODS AND MATERIALS

Our DL model assesses the bone status of patients on CXR to predict whether it is normal, osteopenia, or osteoporosis. We initially constructed the fundamental training set using the radiographs of 55,600 patients (54.3% men; mean age, 55.38 ± 7.28 years) from the tertiary university hospital A. Besides, to obtain bone information from other multi-ethnic, we collected 17,577 unlabeled radiographs (57.1% men; mean age, 62.08 ± 8.74 years) from several public datasets. The unlabeled radiographs were appended pseudo labels via semi-supervised learning to achieve global robustness and generalizability. Total radiographs of 73,177 patients were utilized to train the model, with 1,989 (83.9% men; mean age, 58.7 ± 6.76) radiographs employed for internal validation. For external validation, we collected radiographs from 3 institutions, which consist of multi-ethnic/regions. Hospital B (55.5% men; mean age, 59.38 ± 7.31) is a secondary healthcare facility, the dataset of Hospital C (56.2% men; mean age, 73.64 ± 6.74) represents diverse settings within the healthcare delivery system, and the dataset of D (2.4% men; mean age, 66.37 ± 7.27) denotes global medical platform.

### RESULTS

Our results of hospital A internal validation AUC scores of normal, osteopenia, and osteoporosis were 0.936, 0.891, and 0.965, respectively. In external validation, hospital B, hospital C, and platform D, AUC scores of normal were 0.911, 0.885, and 0.812, AUC scores of osteopenia were 0.845, 0.728, and 0.630, and AUC scores of osteoporosis were 0.921, 0.880, and 0.703, respectively.

### CONCLUSION

This study presents a DL model for CXR-based classification of Osteopenia and Osteoporosis via semi-supervised learning. Evaluating external multinational validation demonstrated that the proposed DL model is feasible for classification of Osteopenia and osteoporosis with CXR contrary to DXA with limited accessibility.

### CLINICAL RELEVANCE/APPLICATION

This study has the potential to demonstrate its value by facilitating opportunistic screening for osteoporosis and osteopenia patients using CXRs, which are among the most prevalent and cost-effective medical imaging techniques. Furthermore, compared to previous studies, the proposed DL model via semi-supervised learning improved global robustness and generalizability across multinational areas. In clinical practice, timely identification of osteoporosis patients is crucial for initiating appropriate medical treatment, while recognizing osteopenia allows for appropriate preventive interventions.

## T7-SSMK07-2 MUSCULAR FAT FRACTION QUANTIFIED WITH DUAL-LAYER DETECTOR SPECTRAL-CT AS A NEW IMAGING BIOMARKER OF FRAILTY

Jin Yamamura, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Alina Busch (*Abstract Co-Author*) Nothing to Disclose
Gerhard B. Adam, MD (*Abstract Co-Author*) Nothing to Disclose
Roland Fischer Sr, DiplPhys (*Abstract Co-Author*) Nothing to Disclose
Graeme M. Campbell, PhD (*Abstract Co-Author*) Scientist, Koninklijke Philips NV
Niklas Schubert (*Abstract Co-Author*) Nothing to Disclose
Isabel Molwitz, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the accuracy of dual-layer detector spectral-CT (dlCT) fat quantification in the skeletal muscle and assess the potential of dlCT to identify patients with clinically impaired muscle strength.

**METHODS AND MATERIALS**

In this prospective study, patients are included with a) gastrointestinal adenocarcinoma under palliative chemotherapy and b) a need for CT staging. All patients receive contrast-enhanced dlCT scans (CT7500) at 120 kV and MRI scans (both: Philips, the Netherlands), including mDIXONquant sequences for MRI fat quantification. In dlCT, fat was quantified using three-material decomposition for muscle tissue, iodine, and fat. Regions of interest for dlCT and MRI fat quantification were placed in the paraspinal muscle at the height of the third lumbar vertebra (L3). Clinically impaired muscle strength was defined by the chair-rise test (cut-off male/female: time to rise five times >15 s). Bland-Altman analysis, receiver operating characteristic (ROC) analysis, and univariate linear regression models were employed for statistics.

**RESULTS**

To date, 49 patients (20, 21.7% female) with a mean age of 63 ±12 years and a mean body mass index of 25±3 kg/m2 were included. The mean dlCT muscle fat content was 9.9 ±6.7%. The mean difference between dlCT and MRI was 2.7 % [95%-limits of agreement -3.4; 8.8%). The area under the ROC curve to identify patients below the chair-rise cut-off using the dlCT fat fraction was good (0.76 [95%-CI 0.603-0.910]). The number of times (one to a maximum of five times) a patient was able to rise from a chair was predicted well by the dlCT fat fraction (P=0.006).

**CONCLUSION**

The muscle fat fraction can be validly determined in dlCT scans. The dlCT muscle fat fraction appears to be suitable for identifying patients with clinically impaired muscle strength.

**CLINICAL RELEVANCE/APPLICATION**

Sarcopenia as indicated by low muscle strength has a negative impact on outcome in many diseases, e.g., in cancer patients. CT parameters that reliably predict the clinical muscle status in routine scans are important to enable risk stratification without the need for further clinical testing. In contrast to the CT muscle density or muscle mass, the dlCT fat fraction is not biased by contrast agent or water retention. The spectral muscle fat fraction therefore has the potential to replace these body composition parameters in research and clinical routine.

## T7-SSMK07-3 AGE-DEPENDENT CHANGE OF VERTEBRAL ATTENUATION VALUES IN OPPORTUNISTIC SCREENING OF OSTEOPOROSIS: A NATIONWIDE MULTI-CENTER STUDY

Hae Young Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Joon Woo Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Youngjune Kim, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To examine how vertebral attenuation value changes with aging, and establish age-adjusted attenuation value cutoffs for diagnosing osteoporosis.

**METHODS AND MATERIALS**

This multi-center retrospective study included 11246 patients (mean age ± standard deviation, 50 ± 13 years; 4107 women) who underwent CT and DXA on same day in six health-screening centers in Korea from January 2022 to January 2023. A deep learning-based software was used to measure the L1 attenuation values. Segmented linear regression in women and simple linear regression in men was used to assess how attenuation value changes with aging. Multivariable linear regression analysis with DXA T-score as a covariate was also performed to determine whether age is associated with the attenuation value independently of BMD. Quantile regressions were used to derive age-adjusted cutoffs targeting either 90% sensitivity or 90% specificity, and were then compared to age-unadjusted cutoffs. Target sensitivity or specificity was deemed achieved, if their 95% confidence interval encompassed 90%.

**RESULTS**

The attenuation values showed a constant decline over all ages in men, but an abrupt decline in women after the age 42 years. Such decline was independent of DXA T-score ($P < 0.001$). The effect of age adjustment seemed to be critical for patients aged = 65 years, in whom the age-adjusted cutoffs achieved either the target sensitivity (91.5% [86.3-95.2%]) or specificity (90.0% [88.3-91.6%]), unlike the age-unadjusted cutoffs with compromised performance of either sensitivity of 95.5% (91.2-98.0%) or specificity of 73.8% (71.4-76.1%).

**CONCLUSION**

The vertebral attenuation values declined with aging, independently of DXA T-score. Our age-adjusted attenuation value cutoffs performed better than age-unadjusted cutoffs for diagnosing osteoporosis especially in the elderly.

**CLINICAL RELEVANCE/APPLICATION**

Owing to the decline in vertebral attenuation value with aging that occurs independently of DXA T-score, age adjustment in opportunistic screening of osteoporosis is needed especially in the elderly. Our age-adjusted cutoffs may contribute to reducing the treatment gap caused by under-utilization of DXA.

## T7-SSMK07-4 OPPORTUNISTIC BONE MINERAL DENSITY MEASUREMENT USING PHOTON-COUNTING DETECTOR CT LOCALIZER RADIOGRAPHS

Elisabeth Shanblatt, PhD (*Abstract Co-Author*) Employee, Siemens AG
Gina Mazza (*Abstract Co-Author*) Nothing to Disclose
Ahmed O. El Sadaney, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Localizer radiographs are used in CT scan to prescribe the scan volume. In photon-counting-detector (PCD) CT, localizer data sets having different x-ray spectra are automatically acquired and may be used opportunistically to determine areal bone mineral density (aBMD). Our purpose was to determine in a patient cohort the accuracy of spine aBMD values and T-scores derived from PCD-CT localizer radiographs.

### METHODS AND MATERIALS

Between October 2023 and March 2024, adult patients (>18 years) having a dual-energy x-ray absorptiometry (DEXA) scan (GE iLunar DEXA, USA) within 1 year were recruited to undergo a PCD-CT exam (NAEOTOM Alpha, Siemens Healthineers). Anteroposterior PCD localizers were acquired using 140 kV and 40 mA. Hydroxyapatite maps were derived using a prototype software from the vendor and used to calculate vertebral body aBMD and T-scores. For both DEXA and PCD-CT, a T-score =-1.0 was considered normal and a T-score <-1.0 was considered abnormal (i.e., osteopenia/osteoporosis). The relationship between PCD-CT and DEXA T-scores was examined with a Bland-Altman plot and agreement estimated with Pearson's correlation and Lin's concordance correlation.

### RESULTS

51 participants were included (20 male (39.2%); 31 female (60.8%); mean age = 62 years [SD = 12]; mean body mass index = 30.1 [SD = 6]). Mean duration between PCD-CT and DEXA was 63.6 days. 46/51 (90%) patients were classified as normal/abnormal by both DEXA and PCD CT (36 normal by both; 10 abnormal by both; accuracy: 0.90; 95% CI 0.79, 0.97). Only one patient was classified as abnormal by DEXA but not PCD-CT (T-scores: DEXA: -1.1; PCD-CT: -1.0). PCD-CT T-scores (mean=0.39, SD=1.64) were not significantly different than DEXA T-scores (mean=0.20, SD=1.73), p=0.09. Pearson's correlation (0.89 (95% CI [0.82, 0.94]) and Lin's concordance correlation (0.89 (95% CI [0.81, 0.93]) between PCD-CT and DEXA T-scores demonstrate a strong linear relationship between the two values. Differences between PCD-CT and DEXA T-scores were not correlated with age (r=-0.08, p=0.58), sex (r=0.09, p=0.54), or duration between PCD-CT scans and DEXA (r=0.07, p=0.61); however, differences were weakly positively correlated with BMI (r=0.28, p=0.05).

### CONCLUSION

BMD and T-scores can be derived opportunistically from PCD-CT localizer radiographs. PCD-CT derived T-scores identify patients with abnormal BMD but do not always yield identical values compared to DEXA, with differences potentially related to higher BMI. Furthermore, lack of population reference for PCD-CT data may be responsible for some of the discrepancies observed in the T-scores.

### CLINICAL RELEVANCE/APPLICATION

Accurate BMD values from PCD-CT localizer radiographs may expand the utility of PCD-CT for opportunistic osteoporosis screening.

## T7-SSMK07-5 ACCELERATED UTE MAGNETIZATION TRANSFER IMAGING OF BONE MATRIX BASED ON U-NET CNN

Kevin Du (*Abstract Co-Author*) Nothing to Disclose
Harry Tang (*Abstract Co-Author*) Nothing to Disclose
Eric Y. Chang, MD (*Abstract Co-Author*) Nothing to Disclose

Jiyo Athertya (*Abstract Co-Author*) Nothing to Disclose
Yidan Wang (*Abstract Co-Author*) Nothing to Disclose
Megan Hu (*Abstract Co-Author*) Nothing to Disclose
James Lo, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Collagen has a profound effect on bone fragility. However, current medical imaging modalities cannot assess unmineralized bone matrix. Ultrashort echo time (UTE) MRI can directly image bone. UTE with quantitative magnetization transfer (UTE-qMT) can model macromolecular fraction (MMF) in bone. The major drawback is the long scan time due to the requirement of repeated UTE acquisitions with different MT powers and frequency offsets required for modeling. Recently, deep learning (DL) has been used for image analysis in medicine. We propose a U-Net convolutional neural network (CNN) for accelerated UTE-qMT imaging of bone matrix.

### METHODS AND MATERIALS

83 female participants were recruited following local IRB approval, with 3T MRI centered in the tibial midshaft. The UTE-qMT sequence employed 14 cm field of view, 5 mm slice thickness, 7° flip angle, 160×160×24 acquisition matrix, three saturation power levels (500°, 1000°, 1500°), and five frequency offsets (2, 5, 10, 20, 50 kHz) for each power (a total of 15 datasets under 13 minutes scan time). MMF was defined as the ratio of collagen proton pool over the water pool and was estimated using a previously reported two-pool UTE-qMT model. Pixel maps of the MMF were generated for each subject. To accelerate data acquisition, we proposed to derive MMF maps from a reduced number of input image datasets (e.g., three MT powers and two frequency offsets). Therefore, 6 out of 15 UTE-qMT image datasets were used to predict bone MMF. The method is illustrated in Figure 1A,B, where all UTE-qMT data were used for training and testing with the application of 8-fold cross-validation. The predicted MMF of bone was compared with the ground truth derived from UTE-qMT modeling using all 15 input image datasets.

### RESULTS

With established U-Net models, accurate MMF mapping was obtained using only 6 out of the total 15 UTE-qMT datasets, corresponding to an acceleration factor of 2.5, as shown in Figure 1C-F. The overall error between the ground truth and predicted mean MMFs within the ROI of the bone is 2.36%. These results suggest that the proposed deep learning method allows accelerated UTE-qMT MMF mapping of collagen backbone protons, providing non-invasive assessment of bone matrix with approximately 5 minutes of scan time.

### CONCLUSION

The U-Net CNN can significantly accelerate UTE-MT modeling of MMF by exploiting data redundancy in the parameter direction with high accuracy. The clinical significance of this technique remains to be demonstrated in a future large scale study of patients with osteoporosis.

### CLINICAL RELEVANCE/APPLICATION

DL-based UTE-qMT allows accurate mapping of bone matrix in clinically compatible times, and may significantly increase the accuracy of fracture risk assessment and treatment monitoring.

## T7-SSMK07-6 HORMONE REPLACEMENT THERAPY AND MUSCLE LOSS IN POST-MENOPAUSAL WOMEN: LONGITUDINAL ANALYSIS FROM THE BALTIMORE LONGITUDINAL STUDY OF AGING USING REPEATED DUAL-ENERGY X-RAY ABSORPTIOMETRY

Elena Ghotbi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

In 2050, older adults are expected to comprise 22% of the global population. Older women commonly experience a decline physical function and an increase in age-related muscle loss. It has been theorized that post-menopausal hormonal changes could be a cause of muscle loss and body composition alterations. Current literature is controversial, with some studies reporting a favorable impact of estrogen with/without progesterone-based hormone replacement therapy (HRT) on body composition, while others fail to observe such effects. We aimed to determine the relationship between post-menopausal HRT and longitudinal body composition changes (i.e. muscle and fat-mass) in the Baltimore Longitudinal Study of Aging (BLSA), a large, community-based cohort of aging adults.

**METHODS AND MATERIALS**

We applied propensity score matching (ratio 1:3) to pair women who received HRT with those who did not, based on baseline characteristics : age, race, history of smoking, baseline height, and weight. Linear mixed-effects models (LMEM) accounting for between-participant variability were used to estimate cross-sectional and longitudinal relationships between HRT and repeated measurements of muscle (grams) and fat-mass (grams) using Dual-Energy-X-ray Absorptiometry.

**RESULTS**

We identified 192 menopausal women, comprising 48 HRT-treated and 144 non-treated participants, with a total of 873 eligible study visits from 2003 to 2020 (mean of 2 visits per HRT-treated and 5 visits per non-treated participant). The cohort was 70% White, with a median age of 68 and a median of BMI 25.7 at the index visit. In cross-sectional analysis, HRT displayed a positive association with total-body lean-mass (beta: 969.9;95% CI: 518.9;1420.05;p<0.001) and a negative association with total-body fat-mass (beta: -1397.7;95% CI:-2248.22, -547.61;p: 0.001). Upon introducing time-interaction into the models, the association between HRT and total-body lean-mass became non-significant (beta: 212.5; 95% CI: -268.78, 693.84,p:0.38), while the negative association with fat-mass remained significant (beta: -1722.67; 95% CI: -2682.69, -762.39; p< 0.001).

**CONCLUSION**

Among post-menopausal women in the BLSA, HRT was not associated with the longitudinal preservation of muscle-mass.

**CLINICAL RELEVANCE/APPLICATION**

Our longitudinal observational analysis does not support the hypothesis that HRT could have beneficial effect on sarcopenia progression among older adults.

## T7-SSNPM02-1 THE WORKFORCE SHORTAGE AND STRATEGIES FOR MITIGATION: RESULTS FROM THE 2023 ACR/RBMA WORKFORCE SURVEY

Eric M. Rubin, MD (*Abstract Co-Author*) Nothing to Disclose
Jay R. Parikh, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Elizabeth H. Dibble, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the radiology workforce shortage in the United States and various strategies for mitigation

### METHODS AND MATERIALS

The ACR Commission on Human Resources fielded the 2023 ACR/RBMA Workforce Survey from 1/5/24-2/4/24. The sample drew from the ACR members (31,085) and non-members (11,565) and RBMA members (1,739). The survey used structured closed-end questions, consistent with earlier surveys. Responses were group practice deduplicated, weighted, and compared to 2022 and 2021. Statistical significance was defined as $p<0.05$.

### RESULTS

1642 respondents completed the survey. 69% indicate working in an understaffed practice in 2023, stable from 2022 (67%). There is steady growth in anticipated hiring by practices with 83% of practices reporting plans to hire in the upcoming year compared to 80% in 2022 and 79% in 2021. Subspecialty hiring importance has been largely consistent over the past three years with body, breast, and neuroradiology representing the largest proportion of planned and actual subspecialty hiring in 2023, 2022, and 2021. The likelihood of respondents to seek new employment is stable in 2023 vs 2022 (11% extremely or very likely to seek new employment). Among respondents who had greater rates were those who work overnight call (18%), feel their life is balances more toward work than life (17%), are in the first 5 years of their career (15%), or when they report that they intend to reduce their hours in the upcoming year. (15%). Respondents' likelihood to retire was stable in 2023 vs 2022 at 6%. 52% of respondents reported working remotely in some capacity in 2023, a significant increase compared to 2022 (48%), $p<0.01$. The proportion of practices that allow some telework increased significantly in 2023 compared to 2022, $p<0.01$ (Figure). A stable proportion of respondents report that they would like to work remotely in the future (46% in 2023 vs 48% in 2022). Practices report employing significantly more physician assistants ($p=0.03$) and nurse practitioners ($p=0.04$) in 2023 when compared to 2021, while the presence of radiologist assistants has been stable or dropped (Figure).

### CONCLUSION

Practices are experiencing a worsening radiologist workforce shortage. Based on survey responses, effective strategies to mitigate the shortage at the practice level appear to include increasing remote work opportunities, reducing overnight call, and hiring NPRPs.

### CLINICAL RELEVANCE/APPLICATION

Awareness of mitigation strategies for the ongoing radiologist workforce shortage can help practices recruit and retain adequate staff to optimize patient care and minimize radiologist burnout.

## T7-SSNPM02-2 PROJECTED RADIOLOGIST WORKFORCE SUPPLY, 2025-2055

Eric M. Rubin, MD (*Abstract Co-Author*) Nothing to Disclose
Jay R. Parikh, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Elizabeth Y. Rula, PhD (*Abstract Co-Author*) Nothing to Disclose
Eric Christensen, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To project the future radiologist workforce through 2055 based on historical numbers of radiologists completing residencies and historical rates of radiologist attrition.

### METHODS AND MATERIALS

We used the 2014-2023 CMS National Downloadable Files, which includes all clinicians enrolled to provide care to Medicare patients, to assess both the current supply of radiologists and model the attrition (i.e., retirement) based on years of practice. Using a non-linear regression model, differences in attrition patterns were assessed by sex as well as pre- and post-COVID. New entrants to the workforce were modeled via linear regression based on

2005-2024 National Residency Matching Program data on new radiologist residents. Finally, we integrated estimates of radiologists' attrition and new entrants to generate estimates of radiologist supply through 2055.

**RESULTS**

In 2023, 37,482 radiologists were enrolled to provide care to Medicare patients of whom 24.4% were female. Given attrition patterns, the projected number of years these radiologists will practice is 35.7 for males and 34.2 for females. Attrition increased post- compared to pre-COVID. For example, the projected mean years of practice for females is 35.0 and 32.3 years using pre- and post-COVID attrition patterns, respectively. We project that the radiologist workforce will be 46,152 in 2055 (23.1% above the 2023 level). This projection assumes no growth in radiology residencies after 2024. Assuming radiologist residency numbers will follow the historical trend (2005-2024) through 2055, the radiology workforce will be 51,498 in 2055 (37.4% above the 2023 level). These projections are based on an average of the pre- and post-COVID attrition patterns. If the projections (assuming no growth in residency positions after 2024) were based only on pre-COVID attrition patterns, the 2055 workforce would be 47,357 radiologists (26.3% above the 2023 level). Using the post-COVID attrition patterns, the 2055 workforce would be 44,448 radiologists (18.6% above the 2023 level).

**CONCLUSION**

The radiologist workforce is projected to grow at least 23.1% between 2023 and 2055. If residency positions continue to increase each year, we project the workforce will be 37.4% higher in 2055. Attrition is higher among female compared with male radiologists. Likewise, the post-COVID attrition patterns are significantly higher than pre-COVID levels.

**CLINICAL RELEVANCE/APPLICATION**

Modelling future radiologist supply in the U.S. will assist decision making regarding the funding for radiologist residencies. While a separate study should assess demand, we note for comparison that the U.S. Census population projections for 2055 show that the 65+ and 85+ populations will be 43% and 164% above the 2023 level, respectively.

## T7-SSNPM02-3 HOUR-BY-HOUR CHARACTERIZATION OF THE INCREASING PRESSURE ON RADIOLOGISTS - LOAD IS IN THE DETAILS

Eyal Bercovich, MD (*Abstract Co-Author*) Nothing to Disclose
Nitai Bar, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The escalating radiologic workloads in recent years have been well documented. Nevertheless, the effects on performance metrics such as reading speed and accuracy have not been quantified, limiting the ability to define safety and good-practice guidelines. We aim to characterize the distribution of workload pressures and delineate critical workload levels beyond which radiologist efficiency may be compromised.

**METHODS AND MATERIALS**

An analysis of CT scan data from 2016 to 2023 a tertiary trauma center was conducted. The dataset included timestamps of various stages of imaging workflow, patient demographics, and scan specifics. Statistical analyses were performed using R, focusing on workloads during off-hours, when staffing is minimal. We investigated performance metrics during peaks in workload based on an hour-by-hour analysis. We compared means of continuous variables with the independent t-test.

**RESULTS**

Data from 38,749 scans performed during 521 off-hour shifts (excluding weekends) were analyzed. The average daily workload increased by 36.4% from 62.9 in 2016 to 85.8 in 2023 (CI 25.5-20.2, $p<0.001$). Hour-by-hour analysis revealed that the average peak in workload occurred most commonly during 19:00-21:00 in 2016 and was shifted towards later hours in 2023, occurring between 21:00-00:00. The rise in workload was more pronounced during peak activity periods. The growing workload correlated with longer patient waiting times and increased pressure on radiologists.

**CONCLUSION**

The study identifies critical periods of workload surges, correlating these with potential declines in radiologist performance. It suggests that traditional metrics of average workload fail to capture the nuances of workload distribution and its effects on radiology departments.

**CLINICAL RELEVANCE/APPLICATION**

The findings underscore the need for revisiting radiology department protocols, particularly during off-hours. Adjustments in staffing and workflow during these peak times could mitigate the risks associated with high workload periods, ultimately enhancing patient care and radiologist well-being.

## T7-SSNPM02-4 WHICH DIAGNOSTIC IMAGING EXAMS ARE CONTRIBUTING THE MOST TO INCREASED RADIOLOGIST PRODUCTIVITY?

Richard E. Sharpe JR, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Alan Zhu, BS (*Abstract Co-Author*) Nothing to Disclose
Aditya Khurana, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine which imaging exams are contributing most to the productivity increases of radiologists.

**METHODS AND MATERIALS**

All fee-for-service outpatient imaging claims billed to Original Medicare Part B by radiologists for diagnostic imaging services from 2013 through 2021 were extracted from the CMS POSPUF database. Claims data was merged with year specific national work relative value unit (wRVU) files. For each diagnostic radiologist, the total wRVUs produced per year was calculated by multiplying the wRVU value of each CPT code by the total number of services by CPT code. Each code was also given a modality and body region classification. The absolute difference in wRVUs as well as the compound annual growth rate (CAGR) were calculated for each subanalysis.

**RESULTS**

After stratifying wRVU volumes by imaging modality and body region, the top five modality-body combinations with the highest number of wRVUs in 2013 were: CT-Abdomen/Pelvis (9189020.9), Radiography-Chest (5471996.1), Radiography-Breast [Mammography] (5091364.0), CT-Chest (4948370.4), and CT-Brain (4812475.2).The top five modality-body combinations with the highest number of wRVUs in 2021 were: CT-Abdomen/Pelvis (10928245.6), Radiography-Breast [Mammography] (8798231.4), CT-Chest (6745049.2), CT-Brain (5169016.3), and Radiography-Chest (3748685.0).The top five modality-body combinations with the largest increase in wRVUs from 2013-2021 were: Radiography-Breast [Mammography] (+3706867.3), CT-Chest (+1796678.8), CT-Abdomen/Pelvis (+1739224.7), MRI-Abdomen/Pelvis (+759537.4), and CT-Head/Neck (+680363.0).The top five modality-body

combinations with the largest decrease in wRVUs from 2013-2021 were: Radiography-Chest (-1723311.1), Radiography-Abdomen/Pelvis (-477542.6), US-Abdomen/Pelvis (-391467.2), Nuclear Medicine-Cardiac (-247762.5), and Radiography-Spine (-190695.5).The modality-body combinations with the highest number of unique radiologists that billed for that service were: Radiography-Chest (25442/32339 in 2021; 78.7%), CT-Abdomen/Pelvis (22746/32339 in 2021; 69.5%), Radiography-Abdomen/Pelvis (22180/32339 in 2021; 68.6%), CT-Chest (21711/32339 in 2021; 67.1%), and CT-Brain (20115/32339 in 2021; 62.2%).

**CONCLUSION**

Over the past decade, the imaging modality and body part combinations resulting in the largest growth in wRVUs were from radiography breast(mammography), CT chest, CT Abdomen/Pelvis, MR abdomen/pelvis, and CT head/neck.

**CLINICAL RELEVANCE/APPLICATION**

Practices may be well served to concentrate strategic growth efforts on complex imaging modality body part combinations that are growing faster than others.

## T7-SSNPM02-5 THE 52 MODIFIER: AN OFTEN-OVERLOOKED REASON FOR REDUCED PHYSICIAN PAYMENTS

Richard Duszak JR, MD (*Abstract Co-Author*) Advisor, Ethos Medical, Inc;Shareholder, Ethos Medical, Inc
Brandon Huddleston (*Abstract Co-Author*) Nothing to Disclose
Bryson Brister (*Abstract Co-Author*) Nothing to Disclose
Areejah Umar (*Abstract Co-Author*) Nothing to Disclose
Quinn Cottone (*Abstract Co-Author*) Nothing to Disclose
Stephen Atkins (*Abstract Co-Author*) Nothing to Disclose
Clinton Case (*Abstract Co-Author*) Nothing to Disclose
Robert W. Morris, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

CPT code modifier 52 is used to bill services performed at a level substantially reduced from a typical service, with an accompanying decrease in reimbursement. Its appropriate use in diagnostic radiology would be in the rare setting of an intentionally limited or incomplete examination (e.g., a few CT images to evaluate for questionable pneumothorax on a CXR), but not in situations in which a complete examination was performed but not ideally interpretable (e.g., motion degradation). At our institution, we identified numerous CT and MRI examinations billed with a 52 modifier resulting in reduced revenue. We aimed to identify factors in radiology reports leading coders to apply this modifier.

**METHODS AND MATERIALS**

Searching our billing database, we identified 389 MRIs and 134 CTs performed between 3/1/2022 and 2/28/2023 billed with the reduced services 52 modifier. Each radiology report was manually evaluated for words suggesting that the exam was limited, as well as the reasons for limitation, severity, and additional recommendations. Descriptive statistical analysis was performed.

**RESULTS**

Of MRIs and CTs billed with a 52 modifier, 65% and 57% respectively included the word “limited.” The next most used words were “degraded” and “incomplete” for MRI and “suboptimal” and “degraded” for CT. In 70% of MRIs and 40% of CTs, the degree of limitation was not specified, but for those with a characterized degree, “severely” and “significantly” were most common. For both MRI and CT, “motion” was the most common reason given for limitations. Recommendations for repeat or additional examinations were made in 19% of MRI and 30% of CT reports.

**CONCLUSION**

All identified exams billed with a 52 modifier had wording in the report to suggest that the exam was limited, and the largest number of limitations were study quality rather than for a true reduced service. Radiology coder education is warranted to ensure appropriate use of this modifier and to avoid inappropriate reduction in payments.

**CLINICAL RELEVANCE/APPLICATION**

In order to improve compliance and collections, radiology practices should ensure that the 52 reduced services modifier is being appropriately used by their coders.

## T7-SSNPM02-6 COST-EFFECTIVENESS OF ENDOVASCULAR THROMBECTOMY FOR BASILAR ARTERY OCCLUSION STROKE

Wolfgang G. Kunz, MD, MBA (*Presenter*) Nothing to Disclose

**PURPOSE**

Two recent studies showed clinical benefit for endovascular treatment (EVT) in basilar artery occlusion (BAO) stroke up to 12 h (ATTENTION) and between 6 and 24 h from onset (BAOCHE). Our aim was to investigate the cost-effectiveness of EVT from a U.S. healthcare perspective.

**METHODS AND MATERIALS**

Clinical input data were available for both trials, which were analyzed separately. A decision model was built consisting of a short-run model to analyze costs and functional outcomes within 90 days after the index stroke and a long-run Markov state transition model (cycle length of 12 months) to estimate expected lifetime costs and outcomes from a healthcare and a societal perspective (Figure 1). Incremental cost-effectiveness ratios (ICER) were calculated, deterministic (DSA) and probabilistic (PSA) sensitivity analyses were performed.

**RESULTS**

EVT in addition to best medical management (BMM) resulted in additional lifetime costs of $32,063 in the ATTENTION trial and lifetime cost savings of $7690 in the BAOCHE trial (societal perspective, Figure 2). From a healthcare perspective, EVT led to incremental costs and effectiveness of $37,389 and 2.0 QALYs (ATTENTION) as well as $3516 and 1.9 QALYs (BAOCHE), compared to BMM alone. The ICER values were $-4052/QALY (BAOCHE) and $15,867/QALY (ATTENTION) from a societal perspective. In each trial, PSA showed EVT to be cost-effective in most calculations (99.9%) for a willingness-to-pay threshold of $100,000/QALY. Cost of EVT and age at stroke represented the greatest impact on the ICER (Figure 3).

**CONCLUSION**

From an economic standpoint with a lifetime horizon, EVT in addition to BMM is estimated to be highly effective and cost-effective in BAO stroke.

## CLINICAL RELEVANCE/APPLICATION

The expanded EVT indication beyond the anterior circulation increases the need for EVT. Based on the projected health and cost benefits, healthcare investments are justified to cover this demand.

## T7-SSNR09-1 ASSOCIATION OF LONG-TERM BLOOD PRESSURE EXPOSURE WITH GLYMPHATIC FUNCTION: A POPULATION-BASED COHORT STUDY

Zhenchang Wang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Han Lv, MD (*Abstract Co-Author*) Nothing to Disclose
Jing Sun, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaoshuai Li (*Abstract Co-Author*) Nothing to Disclose
Yufan Zhang (*Abstract Co-Author*) Nothing to Disclose
Sihui Guo (*Presenter*) Nothing to Disclose

### PURPOSE

The relationship between long-term blood pressure exposure and glymphatic system function of the brain in the general population remains unknown. This study aimed to investigate the associations between cumulative exposure of blood pressure and neuroimaging metrics of glymphatic system function.

### METHODS AND MATERIALS

A multicenter, community-based cohort study involving 981 participants was conducted. The glymphatic system function was evaluated using diffusion tensor image analysis along the perivascular space (DTI-ALPS) based on brain MRI data acquired between 2020 and 2022. Cumulative systolic and diastolic blood pressure (cSBP, cDBP) during follow-up periods of 4, 8, and 12 years prior to neuroimaging data acquisition were calculated. Generalized linear models were employed to assess the association between cSBP and cDBP exposure across different time periods and the DTI-ALPS index.

### RESULTS

The mean age of participants was 55.9 years, with females accounting for 45.9 %. Participants with higher cDBP over 90 mmHg during a follow-up period of 12 years exhibited a lower average DTI-ALPS index compared to normotensive individuals (beta=-0.036, 95% confidence interval [CI] -0.065 to -0.006). This association remained significant among middle-aged individuals (beta=-0.052, 95% CI -0.098 to -0.006). No statistical difference was observed regarding high cSBP exposure or for groups with shorter follow-up periods.

### CONCLUSION

Prolonged exposure to high cDBP is associated with impaired glymphatic function, suggesting that controlling DBP may benefit brain health more than systolic blood pressure does, especially in midlife.

### CLINICAL RELEVANCE/APPLICATION

Our results provide new insights into understanding the impact of hypertension on negative brain health. Our results shed light on the potential detrimental impact of sustained high diastolic blood pressure over an extended period. It is worth noting that the association between a higher cDBP over a 12-year period and lower DTI-ALPS index, raises intriguing questions about the long-term effects of high DBP on brain health. A comprehensive understanding of the relationship between blood pressure exposure and glymphatic dysfunction will facilitate proactive preventive measures for public brain health.

## T7-SSNR09-2 QUANTITATIVE ASSESSMENT OF GADOLINIUM DEPOSITION IN DENTATE NUCLEI WITH MR FINGERPRINTING

Yuta Urushibata (*Abstract Co-Author*) Employee, Siemens AG
Yang Wang, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

Gadolinium deposition in dentate nuclei (DN) has been evaluated by T1WI, T1 (R1) mapping, but not MR fingerprinting (MRF). This study aimed to investigate associations between T1 and T2 values of DN and gadolinium-based contrast agents (GBCAs) using 2-dimensional MRF.

**METHODS AND MATERIALS**

This study included 101 patients. All patients underwent a 2D section-selective fast imaging with steady precession (FISP) MRF sequence for the axial slice of DN. ROI analysis was performed for T1 and T2 values of DN on MRF (T1-MRF, T2-MRF) and T1-weighted images (T1WI ratio). T1 and T2 ratios compared to normal cerebellar white matter (T1-MRF ratio, T2-MRF ratio) were calculated. Correlation analyses were performed for all 101 patients using Spearman rank correlation coefficient and Pearson correlation coefficient. The type of previous GBCA was confirmed in 79 patients, and linear regression (univariate and multivariate analyses respectively) were performed between T1, T2 values and the number of GBCAs.

**RESULTS**

Good correlation was observed between T1-MRF and T1WI ratio (?= -0.69, P < 0.001), and between T1-MRF ratio and T1WI ratio (? = -0.76, P < 0.001) in all patients (n = 101). Mild correlation was observed between T2-MRF and T1WI ratio (? = -0.32, P < 0.001) and between T2-MRF ratio and T1WI ratio (? = -0.44, P < 0.001). Associations of the number of GBCA administrations with MRF or T1WI were analyzed in subgroup (n = 79). The number of linear-type GBCAs was associated with T1-MRF (ß = -0.62, P < 0.001) and T1-MRF ratio (ß = -0.54, P < 0.001) in univariate linear regression analyses, and with T1-MRF (ß = -0.61, P < 0.001) and T1-MRF ratio (ß = -0.53, P < 0.001) in multivariate analysis. The number of linear-type GBCAs was associated with T2-MRF (ß = -0.30, P < 0.001) and T2-MRF ratio (ß = -0.29, P < 0.001) in univariate analyses, and with T2-MRF (ß=-0.31, P<0.001) and T2-MRF ratio (ß = -0.32, P < 0.001) in multivariate analyses. The number of linear-type GBCAs was associated with T1WI ratio (ß = 0.65, P < 0.001) in univariate analyses, and with T1WI ratio (ß = 0.65, P < 0.001) in multivariate analyses. No associations were observed between number of macrocyclic GBCAs and T1-MRF (ratio) or T2-MRF (ratio) or T1WI ratio.

**CONCLUSION**

T1 and T2 values obtained from MRF can be used to detect DN changes related to previous GBCA administrations. The number of linear-type GBCA administrations was associated with lower T1 and T2 values (ratios) in DN, but not with the number of macrocyclic GBCA administrations.

**CLINICAL RELEVANCE/APPLICATION**

MRF is easily used to follow up gadolinium deposition in DN over time by providing T1 and T2 values, which may help to understand the potential clinical implications of gadolinium deposition.

## T7-SSNR09-3 WHOLE-CEREBRUM GUANIDINO CHEMICAL EXCHANGE SATURATION TRANSFER (CEST)MRI MAPPINGS AT 3T - A FEASIBILITY STUDY WITH A 3D STACK-OF-SPIRALS GRADIENT ECHO ACQUISITION

**PURPOSE**

Creatine serves as a rapid energy source in the brain, linked with brain metabolism. Recent study on creatine exchange rate verifies the possibility of its indirect measurement via chemical exchange saturation transfer (CEST) MRI. This non-contrast, non-invasive method utilizes the guanidino group of creatine, a feature it shares with arginine from proteins. The resulting signal is known as guanidino CEST (GuanCEST), and we could achieve amideCEST from protein at the same time. However, GuanCEST observed in previous study only achieved less than 2% signal and partial coverage in 7 minutes or so. To better understand the creatine metabolism of the brain and differentiate small changes in the disease status, an optimized protocol should be established for an enhanced GuanCEST signal. Also, for clinical translation, a robust, whole-cerebrum, high-sensitivity 3D technique optimized for GuanCEST at 3T within a clinically acceptable timeframe is in great desire.

**METHODS AND MATERIALS**

In a pilot study, 22 healthy volunteers (age: 40.1±15.6 years; 10 females, 12 males) and a low-grade glioma patient (28 years, male) underwent scans at 3T (Philips Elition Achieva). We first optimized the saturation duration (1/2/3/4 s) and recovery delay (1.4/3 s) for the most time-efficient signal acquisition, then evaluated the 3D stack-of-spirals gradient echo readout (3DSOS) against 3D echo-planar imaging (3DEPI), and other spin echo techniques, comparing signal intensity in gray matter and white matter, test-retest reliability, and motion robustness. CEST contrasts were extracted by PLOF method. Then the optimized protocol was applied on the patient.

**RESULTS**

The optimal recovery delay/saturation were determined as 1.4/2 s. Only 3DSOS and 3DEPI achieved whole-cerebrum CEST imaging within a clinically acceptable timeframe (around 4 minutes). Both methods provided similar GuanCEST contrast, enhanced by more than 30% than previous studies, while 3DSOS outperforms with significantly larger amideCEST, higher test-retest reliability, and motion robustness. For the glioma (see the figure), GuanCEST from 3DSOS showed markedly enhanced contrast compared to 3DEPI, while M0 and amideCEST images exhibited no significant differences in both techniques. This suggests that GuanCEST mapping may be valuable for assessing tumor metabolism.

**CONCLUSION**

Whole-cerebrum GuanCEST mappings have been achieved by 3DSOS with consistent contrast and robustness to motion in around 4 minutes at 3T.

### CLINICAL RELEVANCE/APPLICATION

3DSOS enables rapid GuanCEST imaging that comprehensively covers the brain at 3T, featuring high motion robustness due to its spiral sampling scheme. It provides a promising mapping tool for creatine metabolism in the brain and studying tumor metabolism.

## T7-SSNR09-4 DIAGNOSTIC PERFORMANCE EVALUATION OF NATIVE 3D-FLAIR* IN THE ASSESSMENT OF CENTRAL VEIN SIGN IN MULTIPLE SCLEROSIS AT 1.5T VS. 3T; A PILOT STUDY

Ayse Altintas (*Abstract Co-Author*) Nothing to Disclose
Hande Ozen Atalay, MD (*Abstract Co-Author*) Nothing to Disclose
Ali Yusuf Oner, MD (*Abstract Co-Author*) Nothing to Disclose
Ahmet Peker (*Abstract Co-Author*) Nothing to Disclose
Yunus Emre Senturk, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Central vein sign (CVS) is a useful imaging biomarker in the identification of the demyelinating lesion, particularly in the context of radiological isolating syndrome (RIS). Recent literature has utilized segmented 3D-FLAIR* imaging at 3T settings to evaluate the CVS status of white matter lesions. Our objective is to evaluate the performance of unenhanced, segmented 3D-FLAIR* at 1.5T magnetic field strength by comparing it with 3T outcomes in participants with multiple sclerosis (MS).

### METHODS AND MATERIALS

Sixteen clinically established MS patients were recruited for this single-center prospective study. Patients were initially scanned with a 3D-FLAIR* protocol at an isotropic resolution of 0.8 mm at 3T (Skyra, Siemens, Germany). Subsequently, patients were transferred to a 1.5T scanner (Aera, Siemens, Germany) to perform the identical 3D-FLAIR* protocol with the same voxel size. Scans were accomplished without any contrast. The CVS status of each lesion was evaluated by two raters, using the NAIMS criteria for lesion eligibility. CVS assessment was performed using two different methods, Select-6* and the percentage-based method, on both scanners. Lesion distribution was also noted for both scans.

### RESULTS

Two hundred three (67%) of 304 lesions were eligible for CVS assessment in both magnetic strengths. Out of 203 eligible lesions, 149 (73.3%) in 3T, and 128 (60.6%) in 1.5T systems were CVS+ (p=0.031). The interrater reliability of CVS+ was almost perfect for both magnetic field strengths (Cohen's kappa coefficient: 0.87 in 3T and 0.83 in 1.5T system). Fifteen of 16 cases met the Select-6* prerequisites in both scanners. One case was Select-6* incompliant in both magnetic field strengths. For the percentage-based method of 3D-FLAIR*, the mean CVS+ ratio per participant was 75.2% ± 13.8 in the 3T scanner, and 64.6% ± 14.7 in the 1.5T scanner ($p<0.01$). Moreover, no differences were noted in the location-based distribution of CVS+ lesions in both scanners, (Table).

### CONCLUSION

Native segmented 3D-FLAIR* at 1.5T demonstrates remarkable and reproducible CVS assessment. Although outperformed by 3T based on a percentage-based method, the 1.5T scan demonstrated to be as effective as its counterpart when the widely established Select-6* is used. Therefore, when a 3T scanner is unavailable, CVS assessment in MS with native 3D-FLAIR* can also be done at a 1.5T magnetic field strength.

### CLINICAL RELEVANCE/APPLICATION

3D-FLAIR* at 1.5T proves to be effective in assessing CVS, especially using the Select-6* method, compared to its counterpart at 3T. This initial finding holds significance, considering the widespread use of 1.5T magnetic field systems globally.

## T7-SSNR09-5 STRUCTURAL AND FUNCTIONAL CHANGES IN THE SUBCORTICAL NUCLEUS AND ASSOCIATED NEGATIVE EMOTIONAL STATES IN PATIENTS WITH POST-COVID HEADACHE

Wenrui Bao (*Abstract Co-Author*) Nothing to Disclose
Xuan Niu (*Abstract Co-Author*) Nothing to Disclose
Qiange Zhu (*Abstract Co-Author*) Nothing to Disclose
Ming Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Xingpu Quan (*Presenter*) Nothing to Disclose

### PURPOSE

Mechanisms of chronic pain remain poorly understood and impose a significant health burden. Headache is a frequent symptom of coronavirus disease 2019 (COVID-19). Transitioning from acute to chronic pain and its associated negative emotional valence may be determined by the physiology of the limbic brain. The aim of this study was to investigate the structural and functional changes in subcortical nucleus in patients with post-COVID headache, and to further evaluate the relationship between the alterations and negative emotion.

### METHODS AND MATERIALS

This multi-center, prospective case-control study involved 195 COVID-infected participants, categorized into post-COVID headache (COVID H+) and non-headache (COVID H-) groups. Subcortical nucleus volumes were measured using Freesurfer, with ANCOVA and Bonferroni adjustments for inter-group comparisons. The Conn toolkit facilitated seed-to-voxel functional connectivity (FC) analysis, while structural equation modeling (SEM) explored the interplay among brain markers, negative emotions, and headache persistence.

### RESULTS

Patients with post-COVID headache had a longer temperature recovery time and a higher proportion of female ($P < 0.05$). The COVID H+ group had reduced volumes in the nucleus accumbens and amygdala, and lower psychosomatic scores ($P < 0.05$). FC analysis showed increased connectivity of the right amygdala with the putamen/pallidum and decreased with the middle temporal gyrus ($P < 0.05$, FDR corrected). The left nucleus accumbens had enhanced connectivity with the lingual gyrus/occipital fusiform gyrus, and the right with the cerebelum crus1/lingual gyrus ($P < 0.05$, FDR corrected). SEM indicated that lower amygdala volume and FC with the putamen/pallidum were linked to chronic pain through BAI and BDI scores ($P < 0.05$), while nucleus accumbens volume and FC directly influence post-COVID headache ($P < 0.05$).

### CONCLUSION

Limbic system alterations, notably in the nucleus accumbens and amygdala, predispose to post-COVID headache. The amygdala potentially drives chronic pain via negative emotions like anxiety and depression, whereas the nucleus accumbens has a direct role in pain chronicity, possibly linked to heightened negative visual memory recall and altered pain perception.

### CLINICAL RELEVANCE/APPLICATION

Our study affirms the limbic system's role in the negative emotion-pain model and uncovers distinct pathways through which the amygdala and nucleus ambiguus intensify chronic pain. Crucial for therapeutic research, neuroimaging-based structural biomarker analysis deepens our understanding of post-COVID-19 headache pathophysiology, enabling predictive modeling and personalized treatment development.

## T7-SSNR09-6 MULTIPLE SCLEROSIS LESION DETECTION WITH 3D DOUBLE INVERSION RECOVERY AS COMPARED TO 3D FLUID LOW ATTENUATION INVERSION RECOVERY (T2-FLAIR): A SYSTEMATIC REVIEW AND META-ANALYSIS

Bruno Murad (*Abstract Co-Author*) Nothing to Disclose
Fabricio S. Feltrin, MD (*Abstract Co-Author*) Nothing to Disclose
Giovanni B. Torri, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza G. Schmitt, MD (*Abstract Co-Author*) Nothing to Disclose
Yin Xi, PhD (*Abstract Co-Author*) Nothing to Disclose
Fillipe T. Xavier de Campos, MD (*Abstract Co-Author*) Nothing to Disclose
Thomaz R. Mostardeiro, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Several sequences have been developed to increase lesion detection in Multiple Sclerosis, including Double Inversion Recovery (DIR). The superiority of these pulse sequences is not well established compared to traditional T2-FLAIR images. This meta-analysis aims to describe if lesion detection rates are higher in DIR compared to conventional T2-FLAIR images in a 3D acquisition comparison.

### METHODS AND MATERIALS

Search was performed of the PubMed/MEDLINE, EMBASE and Cochrane databases between January 1995 and December 2023. Studies identified were assessed independently by two physicians following PRISMA guidelines. Articles were screened to exclude articles not reporting original data, not performing direct 3D DIR and 3D T2-FLAIR comparisons or abstracts excluded. Remaining articles were reviewed in a full-text review by two physicians independently, compelling a total of 5 articles.

### RESULTS

Cortical lesion count ranged from to 12.4 to 40.0 for DIR; 5.25 to 27.9 for T2-FLAIR, with juxtacortical lesions ranging from 4.9 to 19.7 and 4.72 to 22.0 on DIR and T2-FLAIR respectively. Intracortical lesions varied from 1.2 to 8.0 for DIR and 1.1 to 3.1 for T2-FLAIR. Infratentorial lesions mean lesions count varied from 2.0 to 12.0 for DIR, as compared to 1.45 to 8.4 for T2-FLAIR. In the periventricular WM, results varied from 11.84 to 73 and 11.31 to 69 for DIR and T2-FLAIR respectively.Pooled estimates showed relative significant differences in lesion detection for intracortical (175.41 [95% Confidence Interval (95%-CI): 48.68; 410.16]) and infratentorial (30.56 [95%-CI: 9.34; 55.91]) regions with the entire 95% confidence intervals >0. Confidence intervals were <0 when counting differences for total cortical lesions (37.35 [95%-CI: -12.47; 115.54]), including juxtacortical (25.44 [95%-CI: -32.12; 131.81]) and for supratentorial WM lesions (1.93 [95%-CI: -14.41; 21.39]), including the periventricular WM (11.22 [95%-CI: -4.02; 28.90]).

### CONCLUSION

3D-DIR acquisition allows higher detection in intracortical and infratentorial lesions compared to 3D T2-FLAIR.

### CLINICAL RELEVANCE/APPLICATION

DIR provides powerful information in Multiple Sclerosis detection lesion compared to the more traditional 2T-FLAIR acquisition. The sequence may further help diagnosing Multiple Sclerosis and during its imaging surveillance.

## T7-SSPH09-1 EVALUATING THE INFLUENCE OF SCAN AND PATIENT VARIABLES ON DEEP LEARNING-BASED ESTIMATION OF VIRTUAL MONOENERGETIC IMAGES FROM SINGLE-ENERGY CT

Brian F. Mullan, MD, MMed (*Abstract Co-Author*) Nothing to Disclose
Guang-Hong Chen, PhD (*Abstract Co-Author*) Nothing to Disclose
Prashant Nagpal, MD (*Abstract Co-Author*) Nothing to Disclose
Ran Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Thomas M. Grist, MD (*Abstract Co-Author*) Nothing to Disclose
Yijing Wu, PhD (*Abstract Co-Author*) Nothing to Disclose
John W. Garrett, PhD (*Abstract Co-Author*) Nothing to Disclose
Ke Li, PhD (*Presenter*) Research Consultant, Pulmera Inc.

### PURPOSE

Recent advancements in deep learning (DL) have opened avenues for estimating virtual monoenergetic (VME) images from single-energy CT (SECT) data. Despite multiple DL networks being validated using SECT data from dual-energy CT exams—which feature similar acquisition hardware conditions to the training data—it remains an open question whether such DL methods can be applied to real-world SECT data from various SECT scanners. In this study, we report the results of the first radiologist reader study to investigate the potential impacts of scanner model, SECT acquisition protocol, and patient demographics on the image quality and diagnostic accuracy of DL-based VME images.

### METHODS AND MATERIALS

A cohort of 52 patients who underwent SECT pulmonary angiography was retrospectively assembled. The images were acquired from a hospital independent of the institution where the DL training data was collected. The SECT dataset encompasses four scanner models, four tube potential levels ranging from 80 to 140 kV, and varying radiation dose levels from 1.8 to 20.2 mGy. A novel DL network was employed to generate 40 keV VME images from the SECT data. After randomizing the type of images and subject order, two experienced thoracic radiologists performed PE diagnosis and evaluated pulmonary vessel opacification and overall image quality using 5-point Likert scales. Additionally, the CNR of pulmonary vessels was measured. Statistical data analysis was performed for different sub-groups based on the scanner model, kV, dose, sex, and BMI.

### RESULTS

Among all cases, the mean vessel enhancement score for clinical SECT is 4.2 [95% CI: 4.0, 4.4], while for DL-VME, it is 4.7 [95% CI: 4.5, 4.8] (p=.001). The mean image quality score for SECT is 3.3 [95% CI: 3.1, 3.5], whereas for VME, it is 4.3 [95% CI: 4.0, 4.6] (p<.001). The CNR of pulmonary vessels is consistently improved by VME, with a mean improvement factor of 2.4 [95% CI: 2.1, 2.8]. The area under ROC is 0.874 for SECT and 0.875 for VME (p=.50). Results of the subgroup analysis indicate no significant variation (p=.67) in VME performance across patient sex, scanner, dose, and kV. However, both VME and SECT demonstrate dependence on patient BMI, with VME providing better image quality for both small and larger patient groups.

### CONCLUSION

DL-VME consistently outperforms SECT in pulmonary angiography in terms of vessel conspicuity and overall image quality. The advantage of DL-VME over SECT remains robust across variations in data acquisition and patient variables. Notably, the image quality of DL-VME shows a reduced dependence on X-ray tube potential and radiation dose levels.

### CLINICAL RELEVANCE/APPLICATION

This study offers the first expert analysis of the clinical advantages and robustness of DL-based dual-energy CT image estimation.

## T7-SSPH09-2 ENHANCING LESION DETECTABILITY FOR DEEP-LEARNING-BASED CT DENOISING AT LOWER RADIATION DOSE THROUGH INCORPORATING UNCERTAINTY AND PREDICTIVE MEAN

Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Joel G. Fletcher, MD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Pfizer Inc;Research Grant, Takeda Pharmaceutical Company Limited;Consultant, Takeda Pharmaceutical Company Limited;Research Grant, Nextrast, Inc;Consultant, Medtronic plc
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Lifeng Yu, PhD (*Abstract Co-Author*) Nothing to Disclose
Scott S. Hsieh, PhD (*Abstract Co-Author*) Nothing to Disclose
Hao Gong, PhD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Deep-Learning-based Denoising (DLD) has the potential to improve image quality and reduce radiation dose in x-ray CT. However, the uncertainties of DLD outputs are detrimental to robust lesion detection in clinical deployment. We aim to enhance lesion detectability using the predictive mean and uncertainty of DLD outputs

**METHODS AND MATERIALS**

Data uncertainty (from noise in inputs) and model uncertainty (from randomness of network parameters) in DLD outputs were quantified in inference, using validated methods: the former via injecting augmented noise realizations to inputs; the latter through inserting Monte Carlo Dropout to approximate the posterior distribution of network parameters. The predictive mean was derived as the ensemble average after marginalizing over sampled noise and network parameters. Local mean to uncertainty ratio (MUR) served as a test statistic: if MUR < 1, local DLD outputs were deemed as over-dispersed and unreliable; otherwise, local predictive mean images were used for lesion searching. For validation, we used a pre-trained DLD and reader interpretations (3 radiologists) from a virtual lung nodule localization trial [10 experimental conditions with 4 dose levels (full and simulated 10%, 25%, 50% dose), 2 nodule types (ground glass (GGN) and partial solid (PSN)), and 3 nodule sizes (3.4, 5.4, and 7.4 mm)]. A recently validated deep-learning model observer (DLMO) method was used to quantify theoretical lesion detectability. To establish the baseline performance, DLMO was trained using independent data and well calibrated to mean radiologist performance on original DLD outputs. To assess performance gain, MUR calculation and the calibrated DLMO were integrated in lesion searching process in all experimental conditions. The area under localization receiver operating characteristic curve (AL) was the figure of merit

**RESULTS**

Predictive mean improved lesion visualization across different noise realizations and patients. MUR degraded as dose decreased (median MUR at lesions from 100% to 10% dose levels: GGN 5.53, 4.53, 3.54, 2.44, and PSN 5.5, 4.55, 3.55, 2.37). This indicated worse reliability of original DLD outputs at lower dose. Using MUR and predictive mean, lesion detectability was improved (Signed Rank test $p<0.01$) : median performance gain 5.5%, and range of performance gain 1% to 13%. More performance gain was achieved at the challenging conditions with lower dose and smaller lesions

**CONCLUSION**

Theoretical lesion detectability was enhanced using predictive mean and uncertainty of DLD outputs

**CLINICAL RELEVANCE/APPLICATION**

The proposed method can detect unreliable regions in DLD-denoised images and provide robust predictive mean images to systematically improve lesion detectability in clinical deployment

## T7-SSPH09-3 ULTRA-HIGH-RESOLUTION METAL ARTIFACT REDUCTION FOR PHOTON COUNTING DETECTOR CT IMAGES USING DEEP-LEARNING-BASED SUPER RESOLUTION

Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Nikkole Weber, ARRT, RT (*Abstract Co-Author*) Nothing to Disclose
Hao Gong, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Emily Koons (*Presenter*) Nothing to Disclose

**PURPOSE**

The maximum spatial resolution (i.e., kernel sharpness) available with some iterative metal artifact reduction (iMAR) software is limited although the intrinsic CT data contains higher spatial resolution. The purpose of this work was to develop and evaluate the performance of a Super-resolution convolutional neural network for ultra-high-resolution (UHR) imaging with Metal ARtifact reducTion (SMART).

**METHODS AND MATERIALS**

With IRB approval and written informed consent, 6 patients were scanned on a commercial photon-counting-detector (PCD) CT system (NAEOTOM Alpha, Siemens Healthineers) for clinically indicated imaging of the wrist. Scans were performed using a UHR (120 x 0.2 mm) protocol with 120kV/140kV tube potential in patients without/with metal, respectively. The four patients without metal served as the training dataset and were reconstructed with sharp (Qr56) and ultra-sharp (Qr89) kernels, 0.2/0.1-mm slice thickness/increment, 1024 matrix size, 100 mm FOV, and iterative reconstruction (QIR) strength 3. SMART is based on a U-Net architecture with 2 max pooling and 2 up convolutional layers, ReLU activation function, Adam optimizer, and mean squared error loss. The lower resolution Qr56 images and UHR Qr89 images served as training inputs and labels, respectively. A total of 55,820 patches of 128x128 pixels were extracted from corresponding locations on input and label images. For testing, data from the two patients with metal implants were reconstructed with the same parameters (Qr56 kernel, sharpest available with iMAR) in training but with iMAR software. Trained SMART was applied to the testing images. Resultant images were evaluated qualitatively and quantitatively by visual inspection of sharpness and metal artifacts and line profiles drawn through trabecular bone. Results were compared among Qr56 without iMAR, Qr56 with iMAR, and SMART output images.

**RESULTS**

iMAR substantially reduced metal artifacts in the testing cases but with low spatial resolution and poor trabecular bone visualization. SMART improved image quality in testing cases, with images showing spatial resolution similar to that of Qr89 kernel and reduced metal artifact similar to iMAR images at Qr56 kernel. Line profiles showed the improved resolution with SMART allowing for enhanced trabecular bone feature visualization and delineation, including bones neighboring metal devices.

**CONCLUSION**

SMART improved the resolution of iMAR images to take full advantage of the UHR capabilities of PCD-CT and allow for improved visualization of fine structures in the CT images.

**CLINICAL RELEVANCE/APPLICATION**

SMART allows iMAR images to be transformed to UHR iMAR images, enhancing the value of iMAR and PCD-CT in extremity imaging.

## T7-SSPH09-4 DIFFERENTIABLE SPECTRAL CT IMAGING: PHYSICS-INFORMED CROSS-DOMAIN LEARNING AND OPTIMIZATION

Adam S. Wang, PhD (*Abstract Co-Author*) Research support, General Electric Company;Research support, Siemens AG;Research collaboration, Varex Imaging Corporation;
Yirong Yang, MEng (*Abstract Co-Author*) Research support, General Electric Company
Grant M. Stevens, PhD (*Abstract Co-Author*) Employee, General Electric Company
Sen Wang, PhD (*Presenter*) Research support, General Electric Company

**PURPOSE**

We aim to leverage the quantitative information offered by photon counting CT (PCCT) systems to perform physics-informed cross-domain learning and optimization by constructing an imaging chain that is fully differentiable. This approach enables optimization of the PCCT imaging chain automatically and adaptively by minimizing loss in the image domain and propagating updates upstream through reconstruction and material decomposition to the detector model and corrections.

**METHODS AND MATERIALS**

Quantitative PCCT generally consists of preprocessing, photon counting detector (PCD) modeling, material decomposition (MD), and image reconstruction. While some operations have explicit formulas and can readily be made differentiable, sinogram-domain MD is non-linear and often solved iteratively. In this work, we focus on enabling differentiable MD, i.e., finding its gradients. We show that its gradients can be given analytically by the implicit differentiation theorem. This enhances its robustness and GPU efficiency compared to the unrolled method, making it more suitable for detector pixel-specific modeling. We validated its performance with two tests: 1) a perturbation test of MD around a selected data point (10 cm water and 1 cm calcium) to visualize the gradients; 2) a cross-domain optimization task where we performed bin drift correction by minimizing loss in material images of a scanned phantom. A detector of 256 pixels with 4 energy bins was simulated, with three pixels having a bin drift of +/-1.5 keV in one of their bins. A water and calcium elliptical phantom was used for calibration, and a patient case was used for testing.

**RESULTS**

The perturbation test confirms the alignment between the tangent space from gradients and the MD results from the solver when a perturbation is applied on detector thresholds. In the detector bin drift correction test, the loss in material images is backpropagated through the differentiable reconstruction and the differentiable MD to correct the bin drift in the three pixels simultaneously. The bin error is reduced to less than 0.03 keV after the correction, effectively eliminating the ring artifacts.

**CONCLUSION**

We conducted theoretical analysis for the proposed differentiable PCCT imaging regarding its cross-domain capability and showed its application in PCD model correction. It holds additional potential applications for various learning and optimization tasks including correction for detector crosstalk, pulse pileup, energy response, and object scatter.

**CLINICAL RELEVANCE/APPLICATION**

The proposed differentiable PCCT imaging bridges the image domain and the upstream imaging chain, enabling distillation of knowledge from images to the entire imaging pipeline to improve clinical image quality.

## T7-SSPH09-5 AI-BASED METAL ARTIFACT REDUCTION ALGORITHM FOR SPECTRAL BASIS CT IMAGES IN INTERVENTIONAL ONCOLOGY (SPECTRAL MARIO): PHANTOM-BASED ASSESSMENT OF MODEL PERFORMANCE ACROSS QUANTITATIVE SPECTRAL RESULTS

Andrea Ferrero, PhD (*Abstract Co-Author*) Nothing to Disclose
Christopher P. Favazza, PhD (*Abstract Co-Author*) Nothing to Disclose
Andrew Missert, PhD (*Abstract Co-Author*) Nothing to Disclose
Wenchao Cao, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the performance of a deep convolution neural network (CNN) framework, spectral MARIO, to reduce metal artifact from interventional oncology probes directly on the multi-energy CT basis images used for generating all spectral results, including quantitative image sets.

**METHODS AND MATERIALS**

An image domain data synthesis framework was implemented to virtually insert 20 different probe configurations into 21 different patients' pre-ablation planning images. Thus, a library was created consisting of co-registered Photelectric (PE) and Compton Scattering (CS) basis images (Spectral CT7500, Philips Healthcare) with and without metal artifact for training. A 2-channel U-Net style CNN was developed and trained using 100,000 128x128 pixel image patches. Performance was tested on images of a 30 cm (lateral dimension) water-filled anthropomorphic phantom containing either a single iodine (5 mgI/ml) or calcium (100 mg/cc) target rod. Each rod was scanned in 3 conditions: a) without cryoablation probes (reference), b) with 1 in-plane cryoablation probe above the rod (streak artifact) and c) with the rod sandwiched between 2 cryoablation probes (blooming artifact). Spectral MARIO was applied to the basis images from the scans with probes. Various spectral results were generated with and without spectral MARIO. Quantitative assessment compared mean attenuation values and iodine concentrations with and without spectral MARIO against reference values without probes.

**RESULTS**

Metal artifact severity was higher for spectral results more heavily weighted by the PE image relative to the CS image. Across all spectral results, spectral MARIO reduced both blooming and streaking metal artifacts in the phantom images, with improvements ranging from 66% to 96% compared to the original data. Specifically, iodine quantification within 1 and 6.9 mgI/ml could be obtained with and without spectral MARIO, respectively. Calcium suppression image values within 14 and 280 HU* could be obtained with and without spectral MARIO, respectively Finally, CT number accuracy within 41 and 345 HU could be obtained on low (50) keV data with and without spectral MARIO, respectively.

**CONCLUSION**

The study highlights the potential of spectral MARIO to improve image quality and quantitative accuracy in detector-based spectral CT by reducing metal artifacts in basis and thus obtaining more precise quantitative accuracy across all spectral results.

**CLINICAL RELEVANCE/APPLICATION**

The demonstrated performance of spectral MARIO opens the opportunity to leverage intraprocedural spectral CT data to extract quantitative biomarkers to increase radiologist confidence in probe placement, treatment monitoring and margin assessment during percutaneous, CT-guided ablations.

## T7-SSPH09-6 CONTINUAL SEGMENTATION OF WHOLE-BODY ORGANS IN 3D CT SCANS USING PYRAMID VISION TRANSFORMER AND LIGHT-WEIGHTED LOW-RANK ADAPTATION

Puyang Wang, PhD (*Abstract Co-Author*) Nothing to Disclose
Le Lu (*Abstract Co-Author*) Nothing to Disclose
Xianghua Ye (*Abstract Co-Author*) Nothing to Disclose

Vince Zhu (*Abstract Co-Author*) Nothing to Disclose
Dazhou Guo (*Abstract Co-Author*) Nothing to Disclose
Zhanghexuan Ji, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Deep segmentation networks achieve high performance when trained on specific datasets. However, in clinical practice, patient privacy and data storage constraints often require that pretrained models are capable of adapting dynamically, allowing for the segmentation of new organs without access to the previous training datasets. This clinically preferred process can be viewed as a continual semantic segmentation (CSS) problem, which is a non-trivial task and understudied in medical imaging. Previous CSS works would either experience catastrophic forgetting or lead to unaffordable memory costs as models expand. In this study, we introduce a novel continual whole-body organ segmentation model using a lightweight low-rank adaptation mechanism (LoRA), which effectively segments 121 organs without catastrophic forgetting and meanwhile maintaining a low parameter increasing rate (PIR).

## METHODS AND MATERIALS

For the model development and validation, we train a 3D Pyramid Vision Transformer (PVT) based segmentation model on the public TotalSegmentator dataset (1204 CTs with 103 labeled organs). Subsequently, for each new learning task, we freeze the already trained network parameters and introduce additional lightweight trainable LoRA parameters to continually segment new chest organs (9 organs, 153 CTs), new head-neck organs (9 organs, 244 CTs), and tumorous esophageal (567 CTs) over three in-house datasets. In each continual step, trainable LoRA parameters are incorporated into the patch-embedding, multi-head attention, and feed-forward layers. For validation, 20% of each dataset is reserved as test set. We report the Dice score (DSC) and 95% Hausdorff Distance (HD95) as evaluation metrics.

## RESULTS

Our proposed model exhibits segmentation performance comparable to the PVT model separately developed on each dataset (achieving an average DSC of 89.3% and HD95 of 4.2mm), while only requiring about 29% of the parameters. Other CSS models either experience catastrophic forgetting (yielding very low performance, e.g., (25% DSC for [PLOP, MiB] and 40% for [LISMO]) or have exploding PIR (32% for [SUN]). In comparison, our model avoids the knowledge forgetting (segmentation performance very similar to the upper bound) and meanwhile has the PIR of only 5.6%.

## CONCLUSION

We develop a lightweight LoRA-based continual whole-body organ segmentation model that accurately and efficiently segments 121 organs across different body parts. This method prevents catastrophic forgetting while maintaining high segmentation performance with minimal parameter growth.

## CLINICAL RELEVANCE/APPLICATION

Our model may reduce the time cost and inter-user variation in clinician's daily practice, where delineation or measurement of organs and lesions are required.

### PURPOSE

The optimal treatment for locally advanced rectal cancer (LARC) involves neoadjuvant chemoradiotherapy (nCRT) and total mesorectal excision (TME). Fully automated image segmentation models help to reduce the workload of radiologists, and the extraction of radiomics features helps to understand and quantify the image feature information. In this study, we first utilized a large segmentation model to segment pre- and post-nCRT bimodal images and validated the radiomics extraction efficacy of the model.

### METHODS AND MATERIALS

Totally 378 patients diagnosed with LARC who underwent pelvic MRI examinations consisting of pre- and post-nCRT T2-weighted imaging (T2WI) and the logarithmic form of diffusion-weighted signal at a b value of 1000 sec/mm2 [DWI (logb1000)]. Four types of MRI images were input into MedSAM for segmentation. Specifically, the network architecture primarily consisted of an image encoder, followed by an image embedding module, a prompt encoder, and a mask decoder. Radiomics features (First order and Shape) were extracted from the segmented resultant images.

### RESULTS

The mean Dice coefficient and correlation coefficient R for pre-nCRT T2WI were 0.74, 0.808 (First order) and 0.876 (Shape). For post-nCRT T2WI, these values were 0.66, 0.768 (First order), and 0.866 (Shape). For pre-nCRT DWI (logb1000), these values were 0.67, 0.525 (First order), and 0.864 (Shape). For post-nCRT DWI (logb1000), these values were 0.46, 0.606 (First order), and 0.545 (Shape).

### CONCLUSION

This approach shows that the large model has a stabilizing effect on segmenting the four types of images. The first-order and shape radiomics features extracted from the model-based tumor segmentation exhibit robustness and reproducibility.

### CLINICAL RELEVANCE/APPLICATION

The model shows promise as a tool for accurately assessing tumor downstaging and achieving pathological complete remission (pCR). Additionally, it can form the basis for reducing the need for manual delineation.

## T7-SSRO03-3 BASED ON SPECTRAL CT DERIVED EXTRACELLULAR VOLUME FOR THE PREDICTION OF POST-RESECTION HEPATIC METASTASIS IN PATIENTS WITH GASTRIC ADENOCARCINOMA

Yang Haiting, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to develop a model based on extracellular volume (ECV) derived from computed tomography (CT) for predicting post-resection hepatic metastasis in patients with gastric adenocarcinoma.

### METHODS AND MATERIALS

We retrospectively collected 78 patients with confirmed gastric cancer in our hospital, and divided them into hepatic metastasis group (HM group,22 case) and non-metastatic group (NM group, 46 case) according to follow-up results. We recorded the age, sex,differentiation grade, Borrmann type, Lauren type, Tumor sites, Neurovascular invasion, tumor market lever(AFP,CA199, CA125, CEA, CA724), Surgical procedures (distal gastrectomy, proximal

gastrectomy, total gastrectomy), Postoperative adjuvant chemotherapy, erythrocyte volume in blood routine; We recorded the patient's CT-based TN stage, the spectral curve (?HU), iodine concentration(IC), normalized IC (NIC), effective atomic number (Zeff) of the tumor.The ECV fraction was calculated using the following equation : ECV fraction (%) = (1 - hematocrit) × (IDtumor/IDartery) × 100. In addition, We used two-independent sample T-test, Chi-square analysis and binary logistic regression for analysis.The statistical significance levels were all set as 0.05 with two-sided tests.

**RESULTS**

CT-derived ECV had a strong correlation with post-resection hepatic metastasis ($p = 0.002$). The HM group showed significantly higher CT-based TN stage,nerovascular invasion,levels of Cancer antigen125 (CA125), Cancer antigen724 (CA724), and IC,nIC in the delayed phase (DP) than the NM group ($p < 0.05$). Binary logistic regression was then used for further analysis, and the results showed the significance regression coefficients of the CT-based N stage and ECV were all < 0.05. Finally, the prediction probability of the binary logistic regression was made as ROC curve, which was displayedThe mixed model that combined ECV with CT-based N stage achieved an AUC of 0.835 (95% confidence interval (CI) = 0.725 - 0.914).

**CONCLUSION**

The mixed model that combined ECV with CT-based N stage contributes to the preoperative prediction of post-resection hepatic metastasis in patients with gastric adenocarcinoma.

**CLINICAL RELEVANCE/APPLICATION**

This study may help to explore energy spectrum information, combine ECV fraction, collect the risk characteristics of liver metastasis of gastric cancer, and establish a more effective and convenient prediction method to accurately predict the risk of liver metastasis at an early stage, so as to guide the individualized treatment of patients with gastric cancer and improve the survival benefits of patients.

## T7-SSRO03-5 IODINE QUANTIFICATION AND LI-RADS CLASSIFICATION IN SPECTRAL COMPUTED TOMOGRAPHY OF HEPATOCELLULAR CARCINOMA

Alessandro Barbaro (*Abstract Co-Author*) Nothing to Disclose
Paolo Marra, MD (*Abstract Co-Author*) Nothing to Disclose
Antonio Celestino, MD (*Abstract Co-Author*) Nothing to Disclose
Sandro Sironi, MD (*Abstract Co-Author*) Nothing to Disclose
Pietro A. Bonaffini, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The LI-RADS classification is widely adopted as a valid tool for evaluating nodules of hepatocellular carcinoma (HCC), although it’s based on a qualitative evaluation. This study aims to investigate the potential role of a quantitative assessment for HCC characterization, by using material density (MD) parameters of spectral computed tomography (SCT).

**METHODS AND MATERIALS**

Dual-energy SCT scans of nodules in cirrhotic patients between March 2022 and September 2023 were retrospectively reviewed. All the nodules were classified as LI-RADS 3, LI-RADS 4 or LI-RADS 5. MD maps were generated in the hepatic arterial phase (HAP) and in the portal venous phase (PVP). In each of the SCT phases iodine concentration density (ICD) was measured within a ROI placed in a homogeneously enhancing portion of the nodules (ICDnodule) and within a ROI placed in the non-nodular liver parenchyma (ICDliver). Lesion-to-normal liver ICD ratio (LNR) was calculated in the two different phases and compared.

**RESULTS**

A total of 69 patients were included (age 67 years ± 10 years, mean ± SD). 197 nodules (size 24.67 ± 23.11 mm, mean ± SD) were examined in 79 DECT exams, categorized under different LI-RADS classes as follows: 44 nodules as LI-RADS 3 (22.34%), 14 as LI-RADS 4 (7.11%), and 139 as LI-RADS 5 (70.56%). MD parameters on HAP, PVP and DP and the nodule difference in ICD could discriminate LI-RADS 3 nodules from LI-RADS 4 and LI-RADS 5 nodules ($p<0.05$). In particular, the median value of LNR in HAP was respectively 1.61 for LI-RADS 3, 1.91 for LI-RADS 4 and 2.29 for LI-RADS 5, while the LNR between HAP and PVP was respectively 1.76 for LI-RADS 3, 2.41 for LI-RADS 4 and 2.55 for LI-RADS 5.

**CONCLUSION**

MD parameters of HCC nodules measured in SCT scans of cirrhotic patients may be viable diagnostic tools to increase the radiologists’ confidence in LI-RADS class allocation.

**CLINICAL RELEVANCE/APPLICATION**

Quantification of iodine concentration of HCC in cirrhotic livers may support the diagnosis of HCC with potential value in prognostication and treatment response assessment.

## T7-SSRO03-6 HEPATOCELLULAR CARCINOMA BURDEN AND CYBERKNIFE ROBOTIC RADIOSURGERY: INVALUABLE INSIGHT FROM LMIC

Shaista Shoukat, MBBS (*Abstract Co-Author*) Nothing to Disclose
Kamran Saeed V, BMBS,DMRD (*Abstract Co-Author*) Nothing to Disclose
Urooj Kanwal, DMRD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Afnan SHOUKAT (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine the clinical and radiological treatment response on follow up imaging in post stereotactic body radiation therapy (SBRT) treated hepatocellular carcinoma (HCC) patients with contrast enhanced cross-sectional imaging in low and middle income countries.

**METHODS AND MATERIALS**

This prospective observational study was conducted at the department of radiology and cyber-knife robotic radiosurgery, JPMC Karachi from January 2019 to January 2023 of histologically proven HCC patients who treated with SBRT patients of either gender who presented with histological confirmation of HCC, child-pugh score of A or low B, those who were not the ideal candidates for surgical resection and the disease confined to liver were consecutively enrolled. Imaging and clinical assessment for treatment response were recorded at every follow up at three months, six months and after a year post-treatment and compared with baseline investigations. Radiological assessment was done by observing pattern of arterial phase enhancement on CECT performed with tri-phasic protocol while clinically ECOG performance, child-pugh scoring and platelet counts were monitored.

## RESULTS

All patients remain healthy and alive at 3 months, at 1year interval 51.5% (28) showed CR (complete response) with tumor volume reduction and lack of thick lobulated enhancement, 30% (20) showed PR (partial response) and remain stable with intra-tumoral necrosis, 5% (3) showed PD (progressive disease) radiologically. Among PD, patients showed up with >20% enhancement of already treated lesion on follow-up. Clinically, 61% (32) patients remain stable with ECOG performance level < 2, child-pugh score maintained at A or low B and platelet count near the baseline values, 30% (16) showed improvement with ECOG performance level 0 and improved platelet count while 5% (3) deteriorated showed up with high child pugh score and ECOG level >2.

## CONCLUSION

SBRT is a promising modality with least treatment related toxicity and CECT remains a standard imaging technique for response evaluation.

## CLINICAL RELEVANCE/APPLICATION

SBRT is emerging treatment option for various carcinomas one of which is hepatocellular carcinoma as well. Its main benefit is delivery of maximum radiation dose to the target lesion without local spread of disease, hence minimizing dose to adjacent organs without significant adverse effects.Key words: SBRT ( stereotactic body radiation therapy), HCC (hepatocellular carcinoma), CECT (contrast enhanced computed tomography), LMIC (low and middle income countries).

## T7-STCE1-2 RAPID MRI FOR APPENDICITIS IN PEDIATRIC PATIENTS CAN STREAMLINE WORKFLOW AND DECREASE PROVIDER COST

Shireen Hayatghaibi, PhD, MPH (*Abstract Co-Author*) Nothing to Disclose
Andrew T. Trout, MD (*Abstract Co-Author*) Author, RELX Author, Wolters Kluwer nv Research Grant, Canon Medical Systems Corporation Research Grant, Siemens AG Research support, Perspectum Diagnostics Ltd Consultant, Lantheus Holdings
Pradipta Debnath, MD (*Abstract Co-Author*) Nothing to Disclose
Rama S. Ayyala, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Use of MRI for appendicitis is increasing in the pediatric ED and this rapid exam can streamline workflow. Studies have shown MRI can be cost-effective for appendicitis if the associated charge is decreased. Our purpose is to highlight a single institution experience implementing rapid MRI for appendicitis in the ED and to model the associated cost.

### METHODS AND MATERIALS

In April 2021, MRI was introduced at our institution for second-line imaging after equivocal US. A three sequence, free breathing, non-contrast MRI is now routinely utilized for patients > 6 years old. For the period Dec 2022-Jun 2023, scan times (1st image to last image acquired) and diagnostic accuracy was calculated. A time-based driven activity cost (TDABC) analysis was performed to characterize the cost of rapid MRI for appendicitis relative to MRI exams that correspond to billing codes that are typically billed for MRI appendicitis (MRI pelvis w/o IV contrast, MRI abdomen/pelvis w/o IV contrast, and MRI abdomen/pelvis w/ IV contrast). Process maps were created by direct shadowing of exams (10 MRI appendicitis, 2 MRI pelvis, 8 MRI abdomen/pelvis). Additional information for 327 MRI exams was collected from the medical record. Practical capacity costs rates for personnel, equipment and facilities were calculated and combined with the mean duration of each step to generate a total cost for each MRI exam.

### RESULTS

369 MRI appendicitis exams were performed. The median scan duration was 5 minutes (range: 3-26). The sensitivity and specificity of MRI for diagnosis of appendicitis is 95% and 99% with positive predictive value 91% and negative predictive value 99%. The mean duration and provider costs for the compared MRI exams were: MRI appendicitis: 11 min, $20.03; MRI pelvis w/o IV contrast: 55 min, $105.99; MRI abdomen/pelvis w/o IV contrast: 65 min, $144.83; MRI abdomen/pelvis w/ IV contrast: 128 min, $236.99.

### CONCLUSION

Rapid MRI allows for quick and accurate diagnosis of appendicitis in the ED. Rapid appendicitis MRI has lower associated provider costs than other MRI exams billed with the same codes suggesting need for unique billing codes to allow implementation targeted at streamlining workflow.

### CLINICAL RELEVANCE/APPLICATION

With increasing utilization of rapid MRI for appendicitis in the emergent setting, it is important to collectively assess the impact of cost to the institution and the patient, the diagnostic accuracy of the exam, and the potential workflow improvements. This study does this and shows that a smarter, effective strategy for billing needs to be considered.

## T7-STCE2-2 THERANOSTICS IN THE COMMUNITY SETTING: ARE 177LU PSMA-617 TRIAL OUTCOMES APPLICABLE? YES, NO, AND MAYBE SO

James Cassuto (*Abstract Co-Author*) Nothing to Disclose
Emily R. Convery, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Compare early outcomes of a community hospital based Lu177-PSMA-617 program to those reported in landmark clinical trials.

### METHODS AND MATERIALS

Retrospective analysis of patients treated with Lu177-PSMA -617 (n=25) in a north-east USA community hospital between 10/2023 and 7/2024. Clinical and imaging therapy inclusion criteria and early outcomes were compared to those of select large and/or well know clinical trials in publication, including the VISION, TheraP, and LuPSMA trials.

### RESULTS

All patients met criteria for treatment according to the FDA Prescribing Information document. PSMA PET positive criteria was met by 100% of patients when compared to the VISION and LuPSMA trials, but only 28% compared to the TheraP trial. Twenty-eight percent of patients met PSMA PET negative exclusion criteria for the VISION trial. FDG PET was not used in patient evaluations, an inclusion requirement for TheraP and LuPSMA trials. Overall, 48% of patients met total body high PSMA SUV mean criteria, compared to 100% for trial populations. Except for death, treatment termination based on disease progression and persistent grade 3-5 adverse events were similar between study patients and those in the trials. Twenty-four percent of study patients died during treatment, or soon after terminating treatment, with 83% of these patients having received only 1 or 2 doses of therapy. These deaths only occurred during the first 5-months of the program. This is compared to study data where 7.7% of VISION trial patients died during therapy.

### CONCLUSION

Theranostic outcomes in the community hospital setting have the potential to be like trial data for patients fortunate enough to present for treatment while still meeting strict inclusion criteria. Despite many community patients presenting with more advanced and dedifferentiated disease when compared to trial populations, palliative and reduced side effect benefits of treating with Lu177-PSMA-617 persist (as reported in literature). Accordingly, it will be necessary to 1) Temper expectations for patients treated outside of trial selection criteria and 2) Educate referring physicians about the utility of incorporating nuclear medicine therapies earlier in their treatment plans to meet trial survival outcomes.

### CLINICAL RELEVANCE/APPLICATION

177Lu PSMA has been shown to significantly improve survival in patients with metastatic castration resistant prostate cancer when treatment is performed under ideal circumstances. However, ideal circumstances are not the norm in the community setting. Further research and targeted education is needed to help maximize theranostics outcomes in real world community settings and to support the delivery of this new and innovative care to these patients.

## T8-SSNMMI04-2 THE UTILITY OF HIGH-RESOLUTION SEMICONDUCTOR PET/CT IN THE ASSESSMENT OF BREAST CANCER EXTENT: COMPARISON WITH MR IMAGING

Rika Yoshida, MD (*Abstract Co-Author*) Nothing to Disclose
Takeshi Yoshizako, MD (*Abstract Co-Author*) Nothing to Disclose
Yasushi Kaji, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akina Miyamoto (*Presenter*) Nothing to Disclose

### PURPOSE

To retrospectively compare the usefulness of high-resolution semiconductor PET/CT (WB-SiPM-PET/CT) in prone position with MRI in diagnosing the extent of breast cancer.

### METHODS AND MATERIALS

76 patients with 82 breast cancers underwent WB-SiPM-PET/CT in prone position and dynamic MRI preoperatively without chemotherapy between September 2020 and November 2022. The lesions were histopathologically confirmed as breast cancer. Based on the PET accumulation values (SUVmean and standard deviation [SD]) of normal breast tissue, four tumor thresholds (SUVmean+2SD, SUVmean+3SD, 1.5SUVmean+2SD, 1.5SUVmean+3SD) were set and tumor sizes were measured semi-automatically for each threshold. The pathological size (invasive tumor and extensive intraductal components) was compared with MRI size and the four SUV thresholds sizes in relation to menopausal status and Ki-67.

### RESULTS

MRI successfully depicted all lesions, while WB-SiPM-PET/CT failed to visualize one lesion(a ductal carcinoma in situ of 6mm). There was a significant difference in the average SUVmean of normal breast tissue between premenopausal (0.865) and postmenopausal (0.767) patients ($p=0.029$). No significant differences were observed between MRI and the 1.5SUVmean+2SD or 1.5SUVmean+3SD thresholds in terms of imaging size / pathological size. All imaging size by MRI and the four SUV thresholds showed a strong correlation (the correlation coefficient > 0.6) with pathological size. The proportion of pathological size errors within 25% (pathological concordance rate) was highest for the 1.5SUVmean+2SD threshold among four thresholds, which was comparable to MRI. Especially, the percentage of pathological concordance rate of 1.5SUVmean+2SD was highest (68.2%, $p <0.05$) in premenopausal patients, while postmenopausal patients favored MRI (55.9%). In the low (=20%) Ki-67 group, the proportion of pathological concordance rate was low (3-50%) for all imaging. In the high (>21%) Ki-67 group, MRI (69.2%) and 1.5 SUVmean + 2SD (61.5%) showed high proportion of pathological concordance rate.

### CONCLUSION

The 1.5SUVmean+2SD threshold of WB-SiPM-PET/CT in breast cancer extent assessment exhibited diagnostic performance equivalent to MRI. The threshold was particularly useful in premenopausal patients, while MRI excelled in postmenopausal patients. The detection rates were low for all imaging in the low (=20%) Ki-67 group.

### CLINICAL RELEVANCE/APPLICATION

The 1.5SUVmean+2SD threshold of WB-SiPM-PET/CT in breast cancer extent assessment exhibited diagnostic performance equivalent to MRI. The threshold was particularly useful in premenopausal patients, while MRI excelled in postmenopausal patients. The detection rates were low for all imaging in the low (=20%) Ki-67 group.

## T8-SSNMMI04-4 PROSPECTIVE EVALUATION OF 18F-FLUOROESTRADIOL PET-CT FOR STAGING INVASIVE LOBULAR CARCINOMA

Samantha Salmon, MD (*Abstract Co-Author*) Nothing to Disclose
Sam Mitchell (*Abstract Co-Author*) Nothing to Disclose
Sophie Stolk (*Abstract Co-Author*) Nothing to Disclose
Jeffrey T. Yap, PhD (*Abstract Co-Author*) Nothing to Disclose
Andrew Kozlov, MD (*Abstract Co-Author*) Nothing to Disclose
Brandon Buckway (*Abstract Co-Author*) Nothing to Disclose
Zane Archibald (*Abstract Co-Author*) Nothing to Disclose
Regan Butterfield (*Abstract Co-Author*) Nothing to Disclose
Matthew Covington, MD (*Presenter*) Consultant, inviCRO, LLC

**PURPOSE**

Invasive lobular carcinoma (ILC) often poses challenges in detection with standard imaging including staging with CT, bone scan, and FDG-PET/CT. Considering that approximately 95% of ILC cases are estrogen receptor (ER) positive, the use of 18F-Fluoroestradiol-PET/CT (FES-PET/CT) for ER imaging could potentially enhance ILC detection. This study aims to determine the frequency of change in clinical staging for ILC when using FES-PET/CT. The primary endpoint is that FES-PET/CT will change clinical staging in at least 20% of patients, compared to standard of care imaging.

**METHODS AND MATERIALS**

This study is both IND and IRB approved. The analysis presented is based on data collected mid-way through study enrollment. We enrolled patients with biopsy-proven primary or locoregional ILC. FES-PET/CT was performed on all patients. Additionally, an optional FDG-PET/CT scan was offered if not already been performed within 4 weeks of enrollment. We documented positive sites of uptake using FES-PET/CT and, if available, FDG-PET/CT. We compared the AJCC clinical stage between the standard of care imaging assessment and FES-PET/CT.

**RESULTS**

FES-PET/CT was performed on 21 patients. A positive shift in clinical staging, according to the AJCC 8th edition, was noted in 29% (6 out of 21) of cases. In three instances (14%, 3/21), FES-PET/CT revealed unexpected distant metastatic disease in two patients with clinical stage 2A disease and another patient with stage 3A disease, subsequently confirmed through additional imaging or biopsy. All three had concurrent FDG-PET/CT that did not indicate stage IV disease. In two separate cases, FES-PET/CT detected axillary metastatic disease in patients who showed no abnormalities in axillary lymph nodes based on standard imaging. In one case, FES-PET/CT showed more axillary disease than was seen on MRI and ultrasound, upstaging from Stage 3A to 3C. A false negative assessment of axillary lymph nodes in pathologic staging was observed in 24% (5 out of 21). All five involved small nodal metastases identified on sentinel lymph node biopsy with no abnormal axillary FES uptake.

**CONCLUSION**

The preliminary mid-study analysis suggests FES-PET/CT may detect unsuspected stage IV disease in patients compared to standard imaging. However, it was unable to identify multiple metastatic axillary lymph nodes in comparison to sentinel lymph node biopsy. The mid-study analysis indicates a positive shift in clinical staging in up to 29% of cases, suggesting the primary study endpoint will be met..

**CLINICAL RELEVANCE/APPLICATION**

FES-PET/CT could benefit ILC staging by accurately upstaging disease. However, it may fail to detect metastatic axillary lymph nodes identifiable on sentinel node biopsy.

## T8-SSNMMI04-5 IRISIN-LOADED NANOPARTICLES ENHANCE ANTIGEN PRESENTATION TO OVERCOME TRIPLE-NEGATIVE BREAST CANCER RESISTANCE TO APD-1 THERAPY

Yufei Zhao, PhD (*Abstract Co-Author*) Nothing to Disclose
Xin-Gui Peng, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Xingzhe Tang (*Presenter*) Nothing to Disclose

**PURPOSE**

The efficacy of aPD-1 in treating triple-negative breast cancer (TNBC) is hindered by multiple factors, including disruption of antigen presentation. The lipid-rich TNBC microenvironment contributes to immune evasion by inhibiting activation of cyclic GMP-AMP synthase-stimulator of interferon genes (cGAS-STING) pathway in tumor cells, resulting in downregulation of major histocompatibility complex class I (MHC I) expression and consequential impaired antigen presentation. Irisin is a hormone involved in lipid metabolism regulation. But systemic administration of irisin might induce cachexia. Therefore, we aim to develop an Irisin-loaded nanoparticle to modulate tumor lipid metabolism disorder, enhance antigen presentation, thereby overcome TNBC resistance to aPD-1.

**METHODS AND MATERIALS**

Manganese oxide hybridized mesoporous organosilica nanoparticles (MMONs) are synthesized, subsequently, Irisin and Cy5.5 are loaded to yield MMONs-Irisin (MMOI) and MMOI-Cy5.5. To validate inhibitory effect of high-lipid microenvironment on antigen presentation and the capacity of MMOI to enhance antigen presentation, co-culture experiments involving 4T1 cells (representative TNBC cells), white adipocytes, and bone marrow derived dendritic cells (BMDC) are performed(Figure S1), and intervened with MMOI. Activation of cGAS-STING pathway and biomarkers associated with antigen presentation are evaluated. To evaluate the therapeutic efficacy of MMOI to TNBC, TNBC mice are established and intravenously administered with MMOI combined with aPD-1. The near-infrared imaging properties of MMOI-Cy5.5 allow for the evaluation of MMOI accumulation in tumor using an in vivo imager. Tumor volume is monitored over time and flow cytometric analysis of tumor-infiltrating T cells is conducted.

**RESULTS**

MMOI exhibits quasi-spherical morphology (Figure S2) with particle size of 152 ± 2.4 nm (Figure S3). Notably, MMOI activates cGAS-STING pathway in 4T1 cells (Figure S4), leading to significant upregulation of MHC I expression (Figure S5). Furthermore, MMOI promotes the maturation of BMDC co-cultured with 4T1 cells (Figure S6). Overall, MMOI enhances antigen presentation. In vivo near-infrared imaging demonstrates MMOI accumulates in tumor 6h post-injection (Figure S7). Compared to aPD-1 monotherapy, combined MMOI with aPD-1 significantly suppresses tumor growth (Figure S8), facilitates massive expansion of tumor-infiltrating effector T cells, and enhances tumor-killing capacity of CD8+ T cells (Figure S9).

**CONCLUSION**

MMOI effectively overcomes TNBC resistance to aPD-1 therapy and substantially enhances therapeutic efficacy.

**CLINICAL RELEVANCE/APPLICATION**

This study is relevant to the field of Nuclear Medicine Molecular Imaging.

### PURPOSE

To investigate the heterogeneity of prostate-specific membrane antigen (PSMA) expression in advanced prostate cancer using paired whole-body MRI (WB-MRI) and PSMA PET/CT.

### METHODS AND MATERIALS

Patients with advanced prostate cancer (APC) treated at one Institution between January 2017 and February 2024 who underwent both PSMA PET/CT and WB-MRI within a 30-day interval were included in this retrospective observational study. Image analyses were conducted by a consensus of paired experienced radiologist and nuclear medicine specialists. PSMA heterogeneity was defined as active lesions visible on MRI but show no PSMA uptake. Twenty-four potential sites were defined: 9 nodal stations, lung, liver, adrenal, prostate tumour, 10 bone sites and other. Each site of disease was categorised based on concordance between PSMA uptake and presence of active lesion on WB-MRI: complete agreement (same lesion count per site on both modalities), partial/no agreement (discrepancy in lesion count). Discrepancies arising from urinary uptake (PET), artefacts and subcentimetre nodes (affecting MRI diagnosis) were recorded.

### RESULTS

One hundred-seventeen patients were included, with a total of 170 metastatic sites. PSMA heterogeneity was observed in 16.2% of patients (19/117), encompassing 31.8% of metastatic sites (54/170). They were bone (63.0%; 34/54 sites), lymph nodes (16.7%; 9/54 sites), liver (13.0%; 7/54 sites), prostate tumour (5.5%; 3/54 sites) and intramuscular nodule in 1 case (1.8%). PSMA PET/CT failed to depict lesions in 3 cases (two local tumours and one bladder wall lesion), due to physiological uptake in the bladder masking these sites. Discrepancies leading to missed lesions on MRI were noted in 17.9% of patients (21/117), mostly due to subcentimetre nodes: mediastinal (8 cases), retroperitoneal (4 cases), pelvic and hilar nodes (3 cases).

### CONCLUSION

PSMA heterogeneity occurs throughout the body, especially in bone. Hence, using WBMRI -alone or together with PSMA PET/CT- can better define the presence of disease at all sites and provide deeper insight into tumour biology.

### CLINICAL RELEVANCE/APPLICATION

The PSMA heterogeneity in APC leads to suboptimal metastatic disease evaluation when relying solely on PSMA PET/CT, especially in bones. Awareness of these findings can contribute to a personalised diagnostic and therapeutic approach, tailored according to the prostate tumour imaging phenotype.

## W1-SSMS03-2 DIAGNOSTIC VALUE WHOLE-BODY MAGNETIC RESONANCE IMAGING (WBMRI) SHORT PROTOCOLS CAN BE USEFUL IN MULTIPLE MYELOMA PATIENTS

Teresa P. Giandola, MD (*Abstract Co-Author*) Nothing to Disclose
Davide Ippolito, MD (*Abstract Co-Author*) Nothing to Disclose
Paolo N. Franco, MD (*Abstract Co-Author*) Nothing to Disclose
Cesare Maino, MD (*Abstract Co-Author*) Nothing to Disclose

Davide G. Gandola, MD (*Abstract Co-Author*) Nothing to Disclose
Cammillo R. Talei Franzesi (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the effectiveness and accuracy of whole-body magnetic resonance imaging (WBMRI) short protocols for the overall assessment of bone marrow involvement in patients with multiple myeloma (MM), in comparison with standard whole-body MRI protocol.

**METHODS AND MATERIALS**

Sixty-four patients with biopsy-proven MM, who underwent an WBMRI with full body coverage (from vertex to feet) were retrospectively enrolled. WBMRI images were independently evaluated, by two expert radiologists. After identifying the infiltration pattern (normal, focal, diffuse and combined), the whole skeleton was divided into six anatomic districts: skull, spine, sternum and ribs, upper limbs, pelvis and proximal two-third of femur, remaining parts of lower limbs, and patients were grouped according to number(< 5, 5-20, and > 20) and location of the lesions.

**RESULTS**

Most of patients showed a focal (59%) and combined (33%) infiltration patterns with lytic lesions predominantly distributed in the spine (82%) and pelvis (67%). Locations less frequently involved by focal bone lesions were skull and lower limbs (12%, respectively). Excluding both the anatomic regions mentioned before from the standard MRI protocol, a short MRI protocol with a shorter execution time (saving about 14 minutes) could be obtained, maintaining a good sensitivity (89.9%), specificity (66.7%) and diagnostic accuracy (AUROC=0.881; 95%CIs: 0.797-0.965).

**CONCLUSION**

MRI short protocols could be proposed as an effective and reliable approach to reduce the examination time preserving a high diagnostic accuracy.

**CLINICAL RELEVANCE/APPLICATION**

WBMRI for MM evaluation can be more focused on the main involved districts, especially to reduce acquisition time without reducing the diagnostic accuracy

## W1-SSMS03-3 EXTRAMEDULLARY DISEASE AND CONCURRENT CANCER ON WHOLE-BODY MRI OF NEWLY DIAGNOSED MULTIPLE MYELOMA

Vicky J. Goh, MBBChir, FRCR (*Abstract Co-Author*) Research Grant, Siemens AG
Sarah Natas, BSc, FRCR (*Abstract Co-Author*) Nothing to Disclose
Andrew Refalo, BSc, MBChB (*Abstract Co-Author*) Nothing to Disclose
Olwen A. Westerland, MBBS (*Abstract Co-Author*) Nothing to Disclose
Matthew Streetly, MRCP,PhD (*Abstract Co-Author*) Nothing to Disclose
Roberta Dunn (*Presenter*) Nothing to Disclose

**PURPOSE**

The presence of extramedullary disease (EMD) and concurrent cancer affect the management of newly diagnosed myeloma. With more sensitive imaging including whole-body MRI and 18F-FDG PET/CT, detection may be higher than reported historically. This retrospective study aimed to assess the incidence of EMD and concurrent cancer in newly diagnosed myeloma on whole-body MRI and to compare this with 18F-FDG PET/CT in a subset of patients who had both imaging tests.

**METHODS AND MATERIALS**

Patients with newly diagnosed myeloma who underwent whole-body MRI (diffusion-weighted, T2-weighted, pre- and post-gadolinium T1-weighted sequences) between January 2014 and 2024 were included. MRI was assessed by two readers in consensus and 18F-FDG PET/CT by a single reader as per institutional practice. EMD (from hematogenous spread to organs and/or extension through the bone cortex), concurrent cancer, and site(s) of involvement were recorded for each modality. Tumor board review served as the reference standard. Clinicopathological findings were collated from the institutional electronic health records. Kaplan-Meier survival analysis was undertaken.

**RESULTS**

172 newly diagnosed myeloma patients were included (93 male; mean age 69 ± 12 years). 19/172 (11%) were classified as having EMD: 7/172 patients (4%) had EMD from hematogenous spread. The most common sites of EMD were lymph nodes (4), muscle (2), liver (2), spleen (1) and thyroid cartilage (1). 13/172 (8%) had a concurrent malignancy. There was 1 hematological (plasmablastic lymphoma) and 12 solid malignancies: prostate (n=4), melanoma (n=2), laryngeal (n=2), breast (n=1), cecal signet ring cell (n=1), lung (n=1), renal cell (n=1). MRI detected all sites of EMD and concurrent malignancy. 18F-FDG PET/CT (performed in 155/172, 90%) were available for a subset of patients with EMD 18/19 (95%) and concurrent primary malignancy 11/13 (85%). 5/18 (28%) were not classified as having EMD on 18F-FDG PET/CT. Concurrent cancer was identified in 11/11 (100%) patients. Median survival was 54 vs 52 vs 24 months (P=.004) for patients without EMD, with concurrent cancer and EMD, respectively.

**CONCLUSION**

This study provides contemporary data from whole-body MRI ± 18F-FDG PET/CT showing a higher incidence of EMD than historically reported. MRI was more sensitive than 18F-FDG PET/CT for EMD.

**CLINICAL RELEVANCE/APPLICATION**

We have highlighted that MRI is a sensitive modality for EMD, which carries a poorer prognosis. There is a paucity of literature comparing performance of imaging modalities and future work should address this.

## W1-SSMS03-4 A COMPARATIVE PROGNOSTIC ANALYSIS BETWEEN TWO TUMOR BURDEN MEASUREMENTS: TUMOR FRACTION ON LIQUID BIOPSY AND TOTAL TUMOR VOLUME ON CT SCANS IN 1065 METASTATIC PATIENTS

Alexandre Bone (*Abstract Co-Author*) Employee, Guerbet SA
Samy Ammari, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Littisha Lawrance (*Abstract Co-Author*) Nothing to Disclose
Nathalie B. Lassau, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lama DAWI, MD (*Abstract Co-Author*) Nothing to Disclose
Antoine Italiano (*Abstract Co-Author*) Nothing to Disclose
Paul-Henry Cournede (*Abstract Co-Author*) Nothing to Disclose
Ghina Jardali, MD (*Abstract Co-Author*) Nothing to Disclose
Jules Dupont (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the usefulness of tumor fraction (TF) of liquid biopsy and total tumor volume (TTV) for predicting overall survival (OS) at baseline in patients with advanced solid tumors, regardless of tumor origin and to compare the prognostic value of these two biomarkers.

**METHODS AND MATERIALS**

This retrospective cohort study enrolled 1065 patients between January 2021 and January 2023. Patients were eligible if they had metastatic solid tumors, regardless of their treatment type or disease stage at enrollment, with a liquid biopsy (LB) and with a chest-abdomen-pelvis CT scan at baseline, with a 90-day interval between CT scan/liquid biopsy and the start of treatment, and a 60-day interval between liquid biopsy and CT scan. TTV indicative of tumor burden in CT scans, was determined by adding the approximate 3D volumes of all lesions, and calculated using the following formula: Tumor volume = 2/3 x Surface x Minor Axis. The surface and minor axis were computed using pyradiomics. Two expert radiologists outlined each lesion on the largest surface on the axial view.Patients were divided into 3 groups for our analyses: first, based on LB: undetectable ctDNA with TF <10%, detectable ctDNA with TF <10% and detectable ctDNA with TF >10%. Each group was further divided based on their TTV. Second, based only on their TTV cutoff values. End-point of the analysis was OS. Analyses were performed using the univariate Cox proportional hazard models and the Kaplan Meier curves were used to visualize the separation between the populations with respect to the cut offs found using the ROC analysis and Youden's Index, and thresholds based on the best AUC for multiclass classification.

**RESULTS**

Among 1065 patients, 556 were selected for whom 31 763 lesions were annotated. Most common histological types were lung (16.2%) and colorectal adenocarcinomas (12.4%). Median OS was 11.24 months and median TTV was 96.87 cm3 (IQR: 240.63). Univariate analyses showed that TTV (p=2.905e-03) and TF (p=1.105e-10) were independent predictors of OS at baseline. TTV was significantly associated with the OS in the 3 patient groups divided according to TTV cut-offs: < 18.7 cm3, 18.7 cm3< TTV < 161.36 cm3, and > 161.36 cm3. High TTV (>161.36 cm3) and high TF (>10%) were independent predictive factor of worse OS (p=2.06e-07) and (p=9.42e-11) respectively. Patients with larger TTV (>161.36 cm3) and high TF (>10%) have shorter OS (6 months) versus those with smaller TTV (<18.7 cm3) and low TF (<10%) who have better OS (22 months).

**CONCLUSION**

Combining TTV and ctDNA stratifies patients well according to their survival at baseline.

**CLINICAL RELEVANCE/APPLICATION**

First study to compare the prognostic efficacy of tumor fraction (TF) with total tumor volume (TTV) in different types of metastatic solid tumors at baseline.

**PURPOSE**

To establish an advanced automatic bone marrow (BM) segmentation algorithm with robust performance on multicentric data sets with severe myeloma-related pathologies, and a subsequent radiomics prediction of the monoclonal protein (m-protein) level from whole-body (wb) MRI in multiple myeloma (MM).

**METHODS AND MATERIALS**

The study group comprised 284 datasets of 282 (smoldering) MM patients with wb-MRI performed at 8 different centers. A nnU-Net algorithm was established segmenting 30 individual BM compartments of the vertebra, pelvis, humeri and femora. For this task, 186 T1w wb-MRIs from center 1 were used in the training set. Two test sets included 12 smoldering MM T1w wb-MRIs from center 2 (I) and 9 MM T1w wb-MRIs from center 3-8 (II). The validated segmentation algorithm was then deployed to segment the BM in wb-MRIs of 184 datasets with corresponding information on m-protein, overlapping partly with annotated segmentation datasets. 127 datasets from center 1 were used to train the radiomics model for prediction of m-protein levels, which was tested on an independent test set containing 57 datasets from center 2-7. Features were selected by Maximum Relevance Minimum Redundancy and used to train a Random Forest Regressor. Model optimization and validation was performed using 5-fold cross-validation. The performance of the radiomics model was measured using the Pearson correlation coefficient (r) between predicted values and actual values of serum m-protein. Mean Dice scores were calculated to assess the accuracy of the automatic segmentations on the test sets and compared to an interrater variability reference established within a previous study.

**RESULTS**

The mean Dice score of the individual BM segmentations was 0.89 (test set I) and 0.88 (test set II), compared to the interrater reference of 0.88. The radiomics model predicted the m-protein levels on a multicentric external test set with an r-value of 0.30 and a significant Pearson correlation between predicted and actual m-protein levels on the test set ($p<0.05$).

**CONCLUSION**

The established BM automatic segmentation in wb-MRI showed an accuracy equal to the interrater reference performed by radiologists, even on heterogeneously acquired multicenter data with extensive pathologies. This groundwork can be utilized for further automatic analysis of the individual BM compartments in the future. Additionally, segmented wb-BM contained relevant myeloma-associated information as indicated by the moderate correlation of the radiomics model predictions with the m-protein values.

**CLINICAL RELEVANCE/APPLICATION**

Automatic models capturing the spatial heterogeneity of MM in MRI necessitate precise automatic wb-segmentation models. Subsequent radiomics analysis are capable to inform on tumor load.

## W1-SSMS03-6 AUTOMATIC SEGMENTATION AND LOCALIZATION OF PELVIC AND RETROPERITONEAL LYMPH NODES BASED ON DEEP LEARNING ON CT IMAGES

Yaofeng Zhang (*Abstract Co-Author*) Nothing to Disclose
Kexin Wang (*Abstract Co-Author*) Nothing to Disclose
Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaodong Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jinpeng Li (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the feasibility of automatic segmentation and localization of pelvic and retroperitoneal LNs by deep learning on CT images.

**METHODS AND MATERIALS**

956 pelvic and abdominal CT PVP scans develop 2 models (LN regions segmentation for model 1, LNs segmentation for model 2). 44 preoperative PVP CTs, 38 malignant tumor baseline PVP CTs evaluate models (hold-out test set 1 and 2). IOU, VS, PCK evaluate model 1. DSC evaluates segmentation efficiency of model 2. FROC, confusion matrix evaluate detection efficiency of model 2. BA analyze evaluate consistency of model 2's measurements with ground truth. Successful allocation partition, confusion matrix evaluate localization efficiency. SPE, SEN evaluate N-stage efficiency involving pelvic and retroperitoneal LNs.

**RESULTS**

Model 1 excelled in lymph node region segmentation, achieving the highest 0.95 of IoU in the inguinal region. VS and PCK-10.0mm medians surpassed 0.94 and 0.98. In hold-out tests, radiologists' satisfaction exceeded 90%, often reaching 100%. Model 2 also performed well in lymph node segmentation, with DSC values ranging from 0.75 to 0.86. At the lymph node level, DSC values improved as short diameter increased, peaking at 0.85 for LNs whose short diameters are greater than or equal to 1.0cm. In hold-out tests, DSC values approached 1.0 for larger LNs. Model 2 predicted LN volumes and diameters with high consistency with ground truth. For localization, the program successfully allocated 93.2-98.1% of detected LNs, with higher rates for larger LNs. The accuracy rates corresponding to the localization of these outputs were 98.0-100%. For detection, detection rates for all LNs or LNs whose short diameters are greater than or equal to 0.5cm, 0.8cm, 1.0cm in datasets were 78.8%-94.3%. FROC showed false positives well-controlled with high sensitivity. Localization-level detection was good except the sacral region. Patient-level detection was good in most datasets, but some patients with LNs whose short diameters are greater than or equal to 1.0cm in hold-out set 2 had false negatives. Unsuccessful detections/localizations were mainly in the sacral region. For N staging, binary classification sensitivity/specificity were 0.940/0.963 in the model construction set and 0.949/1.000 in hold-out set 1. Multi-classification sensitivity/specificity were 0.908/0.975 in the model construction set and 0.805/0.939 in hold-out set 1.

**CONCLUSION**

The automatic segmentation and localization of pelvic and retroperitoneal LNs model based on deep learning achieved good performance and can meet clinical needs in some scenarios.

**CLINICAL RELEVANCE/APPLICATION**

Automatic LNs segmentation and localization speeds up LNs evaluation, making tumor staging, prognosis, and treatment guidance more efficient.

Mohamed Tarek S. Ahmed, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Xingyu Nie, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To systematically compare the image quality of brain PET/CT images acquired with short versus long uptake time after administration of F-18 FDG in the same patient.

### METHODS AND MATERIALS

Brain F-18 FDG PET/CT studies performed in our institution between 1/31/2022 and 2/14/2024, using a Siemens Biograph mCT scanner, were reviewed, and only the ones who had two sets of brain PET images (short and long uptake) in the same patient were included in the study. Advanced neurology analysis using syngo.via (Siemens Healthcare, Erlangen, Germany) was performed for both sets of images, and regions of interest (ROIs) statistics were computed by comparing subject mean standardized uptake values (SUVs) to those of a normal database, generating z-scores. Paired t-tests were utilized to compare z-scores between the short- and long-uptake scans, as well as to compare their image qualities quantified by the Perception-based Image Quality Evaluator (PIQE) no-reference score, with statistical significance set at $p<0.05$.

### RESULTS

Eighty-five patients met our inclusion criteria. The average z-score of 196 ROIs across all patients decreased from -0.9±1.4 for short uptake to -1.2±1.4 for long uptake scans. In 76 ROIs (38.8%), the long-uptake scans exhibited significantly lower z-scores compared to the short-uptake scans. The most pronounced reductions were observed in the Amygdala (-0.8), Angular gyrus (-0.7), Anterior cingulate and paracingulate gyri (-0.7), Calcarine fissure and surrounding cortex (-0.7), Caudate nucleus (-0.6), Cerebellum (-0.5), and Cuneus (-0.5). For 47 subjects, the z-score of the long uptake scan was significantly lower, while for 15 patients, the z-score of the short uptake scan was significantly lower. Image quality testing using PIQE revealed slightly superior but significantly different image quality for the short uptake scan (63.5±8.6 vs 64.7±8.6, $p<0.0001$).

### CONCLUSION

Our data suggest an overall significant difference in the SUV and resultant z-score of brain F-18 FDG PET images acquired after a short versus longer uptake time. We also demonstrated a slight but significant difference in image quality between the 2 datasets. Limitations of the study include the potential disadvantage of the long-uptake scan being subject to motion artifacts as a result of the study design, the short- and long-uptake scans being acquired sequentially, which can lead to image degradation and distortion as well as misregistration during the database comparison workflow. Further studies are underway to improve the study design for better comparison and further investigate the clinical impact of these findings.

### CLINICAL RELEVANCE/APPLICATION

There was a significant difference in z-score between the short- and long-uptake datasets in brain F-18 FDG PET scans.

## W1-SSNMMI05-2 DYNAMIC AMYLOID PET: RELATIONSHIPS TO TAU PET AND COGNITION IN ALZHEIMER'S DISEASE

Tammie S. Benzinger, MD, PhD (*Abstract Co-Author*) Research Grant, Eli Lilly and Company;Investigator, Eli Lilly and Company;Investigator, F. Erik D. Roberson, MD, PhD (*Abstract Co-Author*) Research Grant, Eli Lilly and Company
Jordan Tzabari (*Abstract Co-Author*) Nothing to Disclose
Fabio Raman, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Neuroimaging biomarkers, such as positron emission tomography (PET) amyloid and tau and magnetic resonance (MR) hippocampal volume, have been associated with impaired cognition in individuals being evaluated for Alzheimer's disease. Information related to blood flow can be acquired during the early frames of amyloid PET (efAP) assessment: hippocampal efAP has recently been shown to be correlated with brain tau pathology measured with PET, and relative delivery (R1) is an established surrogate for blood flow derived from kinetic modeling to estimate brain perfusion. We hypothesized that both hippocampal efAP and R1 are similarly associated with [18F]flortaucipir (tau) PET deposition, and both can predict future cognitive trajectory more effectively than hippocampal volumes alone.

**METHODS AND MATERIALS**

257 participants with dynamic [18F]florbetapir amyloid PET/MR with at least 18 months of neuropsychological follow-up were selected from a retrospective cohort. Regression models were used to assess the longitudinal relationships between multidomain cognitive outcome measures and hippocampal efAP, R1, and volume.

**RESULTS**

Hippocampal R1 and efAP were both significantly associated with tau PET (rR1 = -0.59, refAP = -0.60, pR1/efAP < 0.0001) with strong predictive ability for tau PET positivity (AUCR1 = 0.926, AUCefAP = 0.913). Both R1 and efAP provided significant additive value above hippocampal volume in predicting attention and executive function aggregate Z-score (standardized effect size [ß]R1 = 4.079, ßefAP = 4.007) but not memory (ßR1 = 0.064, ßefAP = -0.891) or language (ßR1 = -0.679, ßefAP = -0.844). Additionally, R1 but not efAP, also better predicted the trajectory of semantic fluency (ßanimals / vegetables / MINT,R1 = 2.040 / 2.045 / 2.106, ßanimals / vegetables,efAP = 0.078 / -0.055 / 1.160), a component of language z-score, better than hippocampal volume alone. Hippocampal volume was the primary significant driver for memory z-score (ß = 2.238), but R1 provided an additional prediction of performance with the Selective Reminding Test (ß = -2.362).

**CONCLUSION**

Both hippocampal R1 and efAP, biomarkers acquired during the dynamic phase of amyloid PET, can be used to predict tau PET and provide additional information beyond hippocampal volume alone in predicting attention and executive function. Compared to efAP, R1 is less sensitive to bolus injection scheme, has significant association with semantic fluency and verbal learning and memory, but requires more sophisticated calculation methods.

**CLINICAL RELEVANCE/APPLICATION**

Successful development of this approach may increase utility of amyloid PET imaging and help predict who will respond best to therapy, especially with the recent FDA-approval of drugs targeting Aß plaques.

## W1-SSNMMI05-3 SUCCESSFUL RADIOLABELING OF THE NOVEL CURCUMIN ANALOG EF-24 WITH 68GA RESULTS IN INNOVATIVE PET-TRACER EXHIBITING SIGNIFICANT AFFINITY TO SYNTHETIC B-AMYLOID FIBRILS, SUGGESTING DIAGNOSTIC POTENTIAL FOR ALZHEIMER'S DISEASE

VASILIKI GIANNAKAKI (*Abstract Co-Author*) Nothing to Disclose
Kostas Marias, PhD (*Abstract Co-Author*) Nothing to Disclose
Eirini Saloustrou (*Abstract Co-Author*) Nothing to Disclose
Antonio Shegani (*Abstract Co-Author*) Nothing to Disclose
Georgios Z. Papadakis, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Curcuminoids have been reported to exhibit significant binding affinity for ß-amyloid plaques. EF-24 is an innovative synthetic curcumin analog with enhanced bioavailability and bioactivity presenting several biological activities, including neuroprotection. Aim of the current study was to successfully synthesize and characterize Gallium-68 EF-24 complex and explore its potential binding affinity to synthetic ß-amyloid fibrils.

**METHODS AND MATERIALS**

Firstly, DTC-EF-24 was synthesized and complexed with Gallium to form [Ga(DTC-EF-24)2 ]+. DTC-EF-24 was also radio-labeled with Gallium-68. The radio isotope was produced by reacting 68Ga3+ from a 68Ge/68Ga generator with 1mg/mL DTC-EF-24 solution. Reaction parameters (precursor amount, reaction temperature, and pH) were optimized to obtain high and reproducible radiochemical yield and purity. Quality controls and stability studies were performed by radio-TLC. Amyloid-beta (Aß) fibrils were prepared and incubated with the labeled complex. The binding affinity was estimated according to methods previously published (Asti Mattia et al,) . Displacement tests with an EF-24 solution were performed to evaluate specificity and interaction dynamics.

**RESULTS**

Synthesis and complexation of EF-24 with Gallium-68 were confirmed via comprehensive spectroscopic methods. Radiochemical purity (RCP) of 68Ga-complex was >95%, under best radio-labeling conditions. The identity of the [68Ga][Ga(DTC-EF-24)2 ]+ complex was confirmed by coelution with the equivalent natGa-complex in RP-HPLC analysis. The 68Ga-complex showed high and comparable stability to transchelation and transmetalation when challenged with DTPA solution or 0.9% NaCl solution or human serum. In all cases, the percentage of the intact complex remained >90% over 120 min of incubation. The [68Ga][Ga(DTC-EF-24)2 ]+ complex showed in vitro significant binding affinity to synthetic Aß fibrils, retaining 91.5 ± 2.0% radioactivity, markedly higher than the control. These results indicate the diagnostic potential of EF-24 complex in targeting amyloid-beta structures, a critical pathophysiologic feature in neurodegenerative diseases.

**CONCLUSION**

The current study reports the potential of 68Ga labeled EF-24 complexes as diagnostic tools in neurodegenerative diseases. The specificity towards amyloid-beta fibrils provides the groundwork for advanced in vivo studies.

**CLINICAL RELEVANCE/APPLICATION**

The development of a novel, highly specific 68Ga-radiolabeled PET-tracer with concomitant neuroprotective properties holds the potential of revolutionizing diagnostic/therapeutic approaches in the management of neurodegenerative disorders, such as the Alzheimer's disease.

## W1-SSNMMI05-5 DEVELOPMENT AND VALIDATION OF CLINICAL-RADIOMICS FOR PREDICTING IDH MUTATION AND WHO GRADE IN DIFFUSE GLIOMAS: A CONSECUTIVE L-[METHYL-11C] METHIONINE PET COHORT STUDY USING TWO SCANNERS

Wen Jianbo
(*Presenter*) Nothing to Disclose

**PURPOSE**

To build and validate radiomics models and clinical features incorporated nomogram for preoperative prediction of IDH mutation status and WHO grade of diffuse gliomas with l-[methyl-11C] methionine ([11C] MET) PET/CT imaging according to the 2016 WHO classification of tumors of CNS.

**METHODS AND MATERIALS**

Consecutive 178 preoperative [11C]MET PET/CT images were retrospectively studied for radiomics analysis. One hundred six patients from PET scanner 1 were used as training dataset, and 72 patients from PET scanner 2 were usedfor validation dataset. [11C]MET PET and integrated CT radiomics features were extracted, respectively; three independent predictive models were built based on PET features, CT features, and combined PET/CT features, respectively. The Select-KBest method, Spearman correlation analysis, Least Absolute Shrinkage and Selection Operator (LASSO) regression, and machine learning algorithms were applied for feature selection and model building, key clinical features were incorporated for the nomogram establishment.

**RESULTS**

The combined [11C]MET PET/CT radiomics model, which consisted of four PET features and eight integrated CT features, was significantly associated with IDH genotype ($p < 0.0001$ for both training and validation datasets). Nomogram based on the [11C]MET PET/CT radiomics score, patients' age, and dichotomous tumor location status showed satisfactory discrimination capacity, and the AUC was 0.880 (95% CI, 0.726-0.998) in the training dataset and 0.866 (95% CI,0.777-0.956) in the validation dataset. In IDH stratified WHO grade prediction, the final radiomics model consists of four PET features and two CT features had reasonable and stable differential efficacy of WHO grade II and III patients from grade IV patients in IDH-wildtype patients, and the AUC was 0.820 (95% CI, 0.541-1.000) in the training dataset and 0.766 (95% CI, 0.612-0.921) in the validation dataset.

**CONCLUSION**

Integrating [11C]MET PET and CT radiomics with clinical features into a nomogram enhances non-invasive IDH genotype prediction, offering insights into the efficacy and stability of radiomics in untreated diffuse gliomas

**CLINICAL RELEVANCE/APPLICATION**

Radiomics features from [11C]MET PET and integrated CT modalities could complement in non-invasive differentiation of IDH genotyping in diffuse glioma patients

## W1-SSNMMI05-6 UTILITY OF HIGH-RESOLUTION DEDICATED HEAD PET SYSTEM FOR CENTILOID SCALE CALCULATION IN AMYLOID PET

Kazunari Ishii, MD (*Abstract Co-Author*) Nothing to Disclose
Atsushi K. Kono, MD, PhD (*Abstract Co-Author*) Research Grant, General Electric Company
Hayato Kaida (*Abstract Co-Author*) Nothing to Disclose

Yasuyuki Kojita (*Abstract Co-Author*) Nothing to Disclose
Kohei Hanaoka (*Abstract Co-Author*) Nothing to Disclose
Daisuke Morimoto, RT, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Centiloid scale (CL), standardized semi-quantitative measures of amyloid imaging, is scaled from 0 to 100. The purpose of this study was to verify the impact of high-resolution dedicated head PET System on CL values calculated from amyloid PET using 18F-flutemetamol (FFM).

**METHODS AND MATERIALS**

This retrospective single-institution study received approval from our institutional review board, with the requirement for informed consent being waived. We obtained FMM PET images from 45 consecutive patients, suspected early dementia or mild cognitive disorders (mean age, 72 years; age range, 47-85 years), who participated in BATON study from April 2023 to March 2024 using a dedicated head PET system (BresTome; Shimadzu Corporation). High-resolution FMM PET images and FMM PET images with resolution equivalent to conventional PET/CT system were generated from an identical raw data set. FMM PET images were visually interpreted as positive/negative based on amyloid deposition in the cortex by two experienced nuclear medicine specialists. CL values were calculated from each image and compared using paired t tests.

**RESULTS**

The subjects comprised 31 positive and 14 negative cases of amyloid deposition as per visual evaluation. In the positive group, CL values of the high-resolution FMM PET images were significantly higher than those of the conventional FMM PET images (68.1 ± 19.2 vs 65.9 ± 19.1; $P < 0.001$). While in the negative group, there was no significant difference between CL values in high-resolution FMM PET images and those in conventional FMM PET images (-3.8 ± 14.3 vs -3.0 ± 14.5; $P = 0.91$).

**CONCLUSION**

CL values derived from amyloid PET with FFM using a high-resolution dedicated head PET were higher in the amyloid positive group than those obtained from a conventional PET/CT system, while the CL values in the negative group remain constant.

**CLINICAL RELEVANCE/APPLICATION**

Centiloid values procured from a high-resolution dedicated head PET system could augment visual reading in the early diagnosis of dementia, thereby enhancing diagnostic accuracy.

### PURPOSE

To evaluate the impact of optimized magnetic resonance (MR) facility design on outpatient brain and spine MR turnaround times and workflow efficiency compared to traditional MR facilities.

### METHODS AND MATERIALS

This IRB approved, HIPAA compliant retrospective study included 5,881 patients (mean age 54.9 ± 17.5 y; 2,393 male) who received MR scans of the brain with contrast (34%), pituitary gland with contrast (15%), cervical spine without contrast (16%) or lumbar spine without contrast (35%) from April 2022 to January 2024. All exams were performed on 3T MRI scanners (MAGNETOM Vida, Siemens Healthineers, Forchheim, GER) located either at one of two traditional reference facilities (RF 38%) or an optimized facility (OF 62%) featuring 3 scanners and 4 dedicated preparation bays with dockable scanning tables. Efficiency metrics, including the time of table preparation, adjustment sequences, scanner pauses, measurements, table turnover, and exam turnaround as well as on-time performance were obtained from MRI scanner logs and the electronic health record. Statistical analyses were performed in MATLAB using three-way ANOVA and chi-square tests to evaluate the impact of facility, anatomical region, and time. Times are provided as mean ± std error.

### RESULTS

For all anatomical regions, table preparation (2.4 ± 0.1 vs. 2.9 ± 0.1 min; $p<0.001$) and table turnover times (6.0 ± 0.2 vs. 10.3 ± 0.3 min; $p<0.001$) were significantly shorter at the OF compared to the RF, reducing exam turnaround times significantly ($p<0.001$) by 5.4 min (17%) for brain MR exams, by 6.7 min (19%) for pituitary MR exams, by 2.8 min (9%) for cervical spine MR exams, and by 2.3 min (9%) for lumbar spine MR exams. Mean measurement times for all exams were <20 min following protocol optimization (Lang M et al Acad Radiol 2021). Patient throughput was higher in the OF compared to the RF, with the total number of exams increasing over the observation period by 59% for the RF (from 112 to 178 scans per quartile per scanner) and by 81% for the OF (from 112 to 203 scans per quartile per scanner). On-time performance was significantly higher for OF with 77% vs. 60% for RF of exams starting within 5 min of the scheduled appointment ($p<0.001$).

### CONCLUSION

The OF design markedly improved the efficiency of brain and spine MR exams, as evidenced by significant reductions in table turnover and exam turnaround times. The higher throughput and on-time performance demonstrate the strategic value of optimized facility design in managing rising MR exam volume.

### CLINICAL RELEVANCE/APPLICATION

Optimized facility design increases patient throughput and on-time performance. Improving capacity and reliability of MR services enables better patient care by reducing wait times and making high-volume neurological MR exams more accessible.

## W1-SSNPM03-2 OPPORTUNISTIC SCREENING OF LOW BONE DENSITY ON X-RAY: EXPERIENCE AT AN ACADEMIC HOSPITAL

Anastasia Oikonomou, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Andrew Jayarajah, MBChB (*Presenter*) Nothing to Disclose

### PURPOSE

Osteoporosis is an often-overlooked but highly critical clinical disorder that leads to debilitating fractures, undesirable increase in healthcare usage and diminished quality of life. The current standard for diagnosis of osteoporosis and low bone mass is by clinical review of a patient's history and referral for dual-energy x-ray absorptiometry (DXA) if appropriate. We aimed to investigate the clinical adoption and perceived value of an artificial intelligence (AI) tool called Rho that opportunistically identifies patients at risk for low bone mineral density (BMD) when they undergo an x-ray for any clinical indication.

### METHODS AND MATERIALS

Patients aged 50 years and above (n=1142) were prospectively recruited and included if they underwent an x-ray for any clinical indication that included a body part eligible for Rho screening. Patients completed a pre-study questionnaire during the screening visit and a second study questionnaire at the end of the study. Family physicians of patients who had a Rho finding (likely low BMD) included in their x-ray report were asked to rate the effectiveness of Rho and provide feedback on an AI-screening tool for low BMD.

### RESULTS

Of 1142 patients screened, 589 were flagged as likely to have low BMD. Of these, 67% had not previously discussed osteoporosis or fracture risk with their doctor prior to the study. We expected that when these results were included in the x-ray report, a family physician might conduct a clinical risk assessment, and a portion would subsequently be referred for DXA. Within 6 months of the AI screen, 187 underwent DXA. Positive predictive value for low BMD was 77%, 19% had high fracture risk and 41% had moderate fracture risk. The family physician survey yielded 51 responses; 78% supported that Rho would be beneficial for patient care and 74% would use Rho screening information in their standard of care. Of patients who reported they had not discussed osteoporosis with their physician in the pre-study questionnaire, 29% had newly discussed osteoporosis with their physician by the post-study questionnaire, and 25% had newly prescribed osteoporosis medication.

### CONCLUSION

The Rho screening tool can identify patients at risk of low BMD in a real clinical setting. Radiologists incorporate the positive Rho results in their reports, and family physicians find these results useful for supporting the standard of care in osteoporosis management. Rho screening leads to additional DXA referrals for which there is a 77% PPV for low BMD.

### CLINICAL RELEVANCE/APPLICATION

Opportunistic screening for low BMD with Rho has the potential to help address low screening rates for fracture risk and osteoporosis.

## W1-SSNPM03-3 OPPORTUNISTIC, MULTILEVEL, BODY COMPOSITION ANALYSES OF EMERGENCY ABDOMINAL CT EXAMINATIONS IN TRICENARIANS: PREDICTION OF DISEASES AT AN 8-YEAR FOLLOW-UP

Subba R. Digumarthy, MD (*Abstract Co-Author*) Consultant, Merck & Co, Inc;Consultant, Pfizer Inc;Consultant, Bristol-Myers Squibb Company;Consultant, Novartis AG;Consultant, F. Hoffmann-La Roche Ltd;Consultant, Polaris;Consultant, Cascadian;Consultant, AbbVie Inc;Consultant, Gradalis, Inc;Consultant, Bayer AG;Consultant, Zai Lab Limited;Consultant, Biengen;Consultant, Riverain Technologies, LLC;Consultant, Resonance Health;Consultant, Annalise-AI Pty Ltd;Research Grant, Lunit Inc;Research Grant, General Electric Company;Research Grant, Qure.ai;Speaker, Siemens AG

Emiliano Garza Frias, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the role of opportunistic, multilevel, AI-based, single-click, body composition screening of emergency abdominal CT examinations in tricenarians for predicting major adverse cardiovascular events (MACE) and dyslipidemia with an 8-year follow-up.

### METHODS AND MATERIALS

Our study included 1277 patients (F:M 776:501; mean age 34 ± 3 years; age range 30-39 years) who underwent non-contrast or post-contrast abdomen-pelvis CT during their visit to the emergency department, regardless of the reason for examination. CT examinations were performed at one of the two quaternary and one community hospitals in the Greater Boston area between January 1, 2016, and December 31, 2016. The patients were identified from a Boolean search in the NLP-based radiology report search engine. We then queried Epic Datawarehouse using SQL queries to assess documentation of MACE and dyslipidemia over 8 years following CT examination (until April 2024). We used a single-click image-processing AI tool (ClariMetabo, Claripi.ai) for inferencing all de-identified CT examinations performed on multi-vendor CT equipment to obtain separate measures of CT attenuation values and volumes of subcutaneous and visceral fat, psoas, and all abdominal wall muscles, at T12-L4 vertebral levels. For the analysis, we used the anatomical measurements of each level and divided the patients according to their respective quartile at that level and anatomy location. These quartiles were used to do Cox Regression tests for different categories. We use the lowest quartile of anatomical measurement values as a reference to compare the hazard ratios (HR) for predicting MACE and dyslipidemia.

### RESULTS

Our study demonstrates that abdominal visceral (HR:1.7; $p< 0.02$) and waist circumference (HR:2; $p<0.03$) at multiple levels were the best and most significant predictors of MACE and dyslipidemia, respectively. Paradoxical protective HR (from -1.1 to - 1.6) for absolute CT attenuation values (high-fat attenuation offering protection against dyslipidemia) was likely related to a cofounder with smaller fat volumes in patients with higher fat attenuation ($p<0.001$ from ANOVA).

### CONCLUSION

Our study demonstrates the single-click, AI-based body composition analysis of emergency abdominal CT examinations in tricenarians for predicting major adverse cardiovascular events (MACE) and dyslipidemia.

### CLINICAL RELEVANCE/APPLICATION

Larger, prospective studies can help assess if opportunistic screening in young patients with an autonomous, efficient, single-click AI tool can increase the lead time for preventive steps to mitigate MACE and dyslipidemia.

## W1-SSNPM03-4 COUNTING COINS IN THE DARK - FUTURE DOCTORS VIEWS ON RADIOLOGY

Christoph J. Zech, MD (*Abstract Co-Author*) Nothing to Disclose
Ricardo Donners, MD (*Abstract Co-Author*) Nothing to Disclose
Magdalena Seng, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To capture the overall attitude of medical students towards “radiology”, their perceptions of the university curriculum, the clinical relevance, the future prospects of the specialty as well as reasons for and against seeking out radiology as a career.

### METHODS AND MATERIALS

An 18-question survey was distributed among 21 universities in Germany, Switzerland and Austria. It was returned by 1150 medical students (730 females) within one month. The survey encompassed sociodemographic inquiries, question regarding the university curriculum, perceptions of clinical relevance, job attractiveness, expectations regarding salary and work-life balance, the role of AI in radiology, and students' outlook on the future of the specialty.

### RESULTS

Among the participants, 688 (60%) expressed a desire for increased exposure to radiology within the medical curriculum, and 926 (80%) acknowledged the importance of radiology in their future clinical practice. However, 740 (65%) students definitively ruled out pursuing a career as a radiologist, citing limited patient interaction as the primary deterrent (n=723). Notably, 98% of participants considered the potential salary and work-life balance in radiology as significantly more favorable compared to other medical disciplines. Moreover, 694 (60%) of medical students expect a positive impact of increasing utilization of artificial intelligence in radiology, while only 15 (1%) took a pessimistic outlook regarding radiologists’ future prospects.

### CONCLUSION

While medical students recognize the clinical importance of radiology, the majority are disinclined to pursue a career as radiologists.

### CLINICAL RELEVANCE/APPLICATION

The findings suggest a need for educational initiatives to address misconceptions and enhance the attractiveness of radiology as a viable career option for medical graduates.

## W1-SSNPM03-5 THE AI LITERACY COURSE THREE YEARS LATER: INCREASING ACCESS TO AI TRAINING, VALIDATION OF IMPACT ON A GLOBAL SCALE

### PURPOSE

As artificial intelligence (AI) continues to change the practice of radiology, it has become all more important than ever to promote AI education in radiology training. To address the disparities in AI education in radiology, the AI Literacy Course has provided free, remote lecture series for radiology trainees in the US and internationally since 2021. In this project, we assess the trends in AI education, comfort with AI concepts and effect of the AI Literacy course on participant knowledge of fundamental AI terms and methods from 2021-2023.

### METHODS AND MATERIALS

The course is held remotely and broadcast to partner radiology programs in the US and internationally. An IRB approved pre- and post-course survey and evaluation is distributed to participants to collect demographic data, information on AI exposure, and the evaluation provides objective data on participant knowledge of AI terms and methods. Results of the evaluation data were compared using a student T-test.

### RESULTS

Since 2021 have been 728 participants in the AI Literacy Course from over 50 US radiology programs and over 30 countries. In the pre-course survey, the proportion of participants with prior AI experience has risen from 23% in 2021 to 64% in 2023. 22% of participants completed the AI literacy course previously, and only 15% of participants report that their home program has an AI education curriculum. Participants who took the course previously scored significantly higher on their pre-course evaluation (11 out of 15 vs. 9.0 out of 15, respectively (p=0.01)). Post-course evaluation scores increased significantly each year of the course, most recently increasing from 9.4 out of 15 to 10.4 out of 15 (p=0.02)

### CONCLUSION

The AI Literacy Course has contributed to the increasing accessibility of AI education. Participants in the course demonstrate an increased knowledge of AI terms and methods and an enduring understanding of core concepts of AI.

### CLINICAL RELEVANCE/APPLICATION

Free and accessible AI education is a critical step to ensuring an equitable integration of AI tools into radiology practice in the US and internationally.

## W1-SSNPM03-6 A HYBRID APPROACH TO SUBSPECIALTY TRAINING IN PEDIATRIC MUSCULOSKELETAL IMAGING: A NEW TOOL FOR OUTREACH, COLLABORATION AND FOSTERING COMMUNITY

Hansel J. Otero, MD (*Abstract Co-Author*) Nothing to Disclose
Maria A. Bedoya-Velez, MD (*Abstract Co-Author*) Nothing to Disclose

Hermon M. Derbew, MD (*Abstract Co-Author*) Nothing to Disclose

Monica Miranda-Schaeubinger, MD,MSc (*Abstract Co-Author*) Nothing to Disclose
Mohammad Jalloul, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Dedicated pediatric musculoskeletal (MSK) radiology fellowship programs are rare. Dedicating a year to subspecialty training might be taxing for colleagues in the USA and worldwide. While most pediatric radiologists interpret MSK imaging studies of children, who gets to be called a pediatric MSK radiologist is often left to the individual, their level of interest, and their organization. Recognizing the growing interest in the subspecialty and the desire to create a global community around their clinical interest, the World Federation of Pediatric Imaging developed a virtual pediatric radiology MSK clinical fellowship tailored for radiologists in Low- and middle-income countries. We detail our experience in establishing this program.

**METHODS AND MATERIALS**

The organizing committee recruited fellows through Sociedad Latino Americana de Radiologia Pediatrica. Mentors were recruited from USA institutions with dedicated pediatric MSK services. A curriculum was organized to include weekly hour-long live case-review sessions, complemented by learning management system modules, and a 4-week long observership at USA institutions. During each case session, mentors and fellows presented and discussed cases displaying multiple modalities. Feedback was solicited after each session. Fellows were given access to pediatric MSK radiology modules including pre-recorded lectures, articles, teaching cases, and questions. The year-long fellowship concluded with a 4-week, in-person visit to 3 collaborating institutions, allowing for hands-on experience.

**RESULTS**

The inaugural class featured 3 fellows (2 Argentina and 1 Uruguay) paired with 10 mentors from 5 US children’s hospitals. Throughout the year, 150 MSK cases were shared in 38 live sessions covering hip and pelvis, shoulder, upper and lower limbs, and multisystemic pathologies. MRI was the focus in most cases. Feedback from fellows emphasized the ease of transferring education, the good quality of images, and the organization of cases. Fellows perceived the cases to be fair to hard in difficulty. Overall, the content of the program was praised as "very good." A limitation of the program was the challenge of scheduling times due to the busy schedules of both mentors and fellows.

**CONCLUSION**

We showed a hybrid subspecialty training suitable for outreach, affordable in time and resources for international participants and US-based clinical specialists. Future iterations should optimize trainee, mentor, and institution numbers to maximize benefits and maintain high-quality education.

**CLINICAL RELEVANCE/APPLICATION**

The pediatric MSK radiology fellowship aims to enhance expertise and foster global collaboration, addressing the scarcity of dedicated programs in low- and middle-income countries.

## W1-SSVA03-2 PRECISE EVALUATION OF SUBSEGMENTAL PULMONARY THROMBOEMBOLISM IN CTEPH PATIENTS WITH CT PERFUSION IMAGING

Koray Hekimoglu (*Presenter*) Nothing to Disclose

### PURPOSE

Recovery of pulmonary artery thrombosis in chronic thromboembolic pulmonary hypertension (CTEPH) patients is the only curable form of pulmonary hypertension-CTEPH patients via surgery. Here we aim to demonstrate the impact of dual-energy computed tomography perfusion imaging (DE-CTPI) in SSPE diagnosis and investigate the quantitative differences between normal lung parenchyma and hypoperfused areas with and without corresponding dual-energy CT angiography (DE-CTA) findings in CTEPH patients.

### METHODS AND MATERIALS

Eighty-six consecutive CTEPH patients detected chronic SSPE with a DE-CTA examination and DE-CTPI were enrolled in this study. All DE-CTA and DE-CTPI examinations were acquired with a 3rd generation dual-source multidetector computed tomography scanner.Two radiologists reviewed DE-CTA and DE-CTPI images retrospectively and in consensus, blinded to radiology report, within two separate study groups. Iodine maps were evaluated for perfusion defects (which are represented as black areas of pulmonary parenchyma on the color-coded images) and locations of hypoperfused segments were noted. On each hypoperfused segment, three measurement regions of interest were placed for measuring mean lung parenchyma attenuation (HU), iodine density (mg/mL), and normalized uptake (HU) values.

### RESULTS

In 90 segments (55.6%) there was PE of the feeding segmental/subsegmental artery whereas for the remaining segments (n=72; 44.4%) there was a perfusion defect without any visible thrombus. Tamhane's T2 post-hoc analysis demonstrated mean lung attenuation values (HU) of hypoperfused areas with PE on CTA, were significantly different from normally perfused areas ($P<0.001$) (Figure 1).One-way ANOVA test and Tukey's post-hoc analysis demonstrated Iodine density and normalized uptake values of hypoperfused areas with PE were significantly lower than hypoperfused areas without PE on CTA. Iodine density of normal lung parenchyma, hypoperfused areas with PE on CTA were significantly different ($P<0.001$, $F=94.4$; $P<0.01$, $F=225$ respectively).

### CONCLUSION

Chronic SSPE could be not detected on routine CTA, and the regions of these vessels realized as hypoperfused segments on DE-CTPI due to different iodine densities. DE-CTPI iodine maps should be created in addition to CTA for precise diagnosis of SSPE in CTEPH patients.

### CLINICAL RELEVANCE/APPLICATION

DE-CTPI could reveal SSPE that is not visible on CTA and hypoperfused segments on DE-CTPI have significantly different iodine densities. DE-CTPI iodine maps should be created in addition to DE-CTA for precise evaluation and diagnosis of subsegmental small vessels.

## W1-SSVA03-3 VASCULAR IMAGING WITH PHOTON COUNTING DETECTOR CT IN THORAX: QUANTITATIVE AND QUALITATIVE ASSESSMENT FOR CT PULMONARY AND AORTA ANGIOGRAM

Nikahat Yasmine, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Nicole J. Martinez, MD (*Abstract Co-Author*) Nothing to Disclose
Ramandeep Singh, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Mostafa M. Abdelraheem, MD (*Abstract Co-Author*) Nothing to Disclose
Sravani Mannuru, MD (*Abstract Co-Author*) Nothing to Disclose
Natally AlArab, MD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

To assess quantitatively and qualitatively monoenergetic (ME) and poly energetic (T3D) reconstructions images on post contrast CT pulmonary angiography (CTPA, non-ECG-gated) and CT aorta angiography (CTAA, ECG-gated) optimized thoracic vascular imaging with photon counting detector CT (PCD-CT).

### METHODS AND MATERIALS

Our retrospective study (IRB-approved) analyzed 124 CT series of 62 adults (37M:25F; age: 61±13 years; mean BMI: 102±7 kg/m2) who underwent CTPA or CTAA scans (mean contrast volume 102±14 and 92±20 ml) on PCD-CT. Quantitative assessment and image quality analysis were conducted using ROIs (mean ROI: 130±11.5 mm2) in pulmonary artery, thoracic aorta, and pectoralis major muscle, evaluating artifacts on ME 55 keV and T3D images. SNR and CNR were computed. Two radiologists (11 and 6 years of experience) independently assessed images for artifacts and subjective image quality on a three-point scale (1=mild artifact, diagnostically excellent; 2=moderate artifact, diagnostically acceptable; 3=severe artifact, diagnostically compromised). Descriptive statistics and inter-class correlation were performed.

### RESULTS

ME images showed higher SNR in the pulmonary artery (CTPA 14±1; CTAA 16±1) and aorta (CTPA 7±1; CTAA 27±10) than T3D images (CTPA 14±1 and13±1; CTAA 6±1 and 20±70; p value <0.001). CNR and SNR at the site of artifacts was higher for T3D images than ME images for CTPA (ME CNR:1.6±1.2; SNR:2.2±1.1, T3D CNR:1.0±1.5; SNR:2.7±1.6, p<0.003) and CTAA (ME CNR:1.3±2.7; SNR:0.3±2.4, T3D CNR:0.6±1.7; SNR: 1.0±1.7, p <0.001). The artifacts (n=288 in 62 patients) detected were streak artifacts due to contrast 88/288 (31%), cross scatter 58/288 (20%), photon starvation 40/288 (14%), cardiac pacemaker 11/288(4%), port catheter 11/288(4%), and sternal wires 20/288 (7%). Qualitatively, the cross scattered artifacts were most mitigated on T3D (4-12%) compared to ME (42-62%) images with ICC of 0.87-0.99. Overall subjective image quality was significantly better on T3D compared to ME images for both CTPA and CTAA (ICC:0.89-0.99, p<0.001).

### CONCLUSION

A combined approach of monoenergetic 55 keV and poly energetic T3D reconstructions yields best objective and subjective image quality for vascular thoracic imaging with CT pulmonary (non-ECG gated) and aorta (ECG gated) angiography.

### CLINICAL RELEVANCE/APPLICATION

Incorporating a dual reconstruction strategy in thoracic vascular imaging by utilizing monoenergetic and polyenergetic T3D techniques on photon counting CT presents a promising avenue for enhancing image quality.

## W1-SSVA03-4 HUMAN-IN-THE-LOOP SUPERVISION OF A NEURAL NETWORK APPROACH TO AORTIC DIAMETER AND GROWTH MEASUREMENTS IMPROVES PERFORMANCE VERSUS MANUAL MEASUREMENTS

Gregory Spahlinger (*Abstract Co-Author*) Nothing to Disclose
Timothy Baker, PhD (*Abstract Co-Author*) Nothing to Disclose
Carlos Alberto Campello Jorge, MD (*Abstract Co-Author*) Nothing to Disclose
Nicholas S. Burris, MD (*Abstract Co-Author*) Royalties, ImBio, LLC
Nic Tjahjadi (*Abstract Co-Author*) Nothing to Disclose
Prabhvir S. Marway, BA, MBBChir (*Presenter*) Nothing to Disclose

### PURPOSE

Variability of manual diameter measurements (±3-5 mm) impedes accurate aortic diameter and growth assessments in ascending thoracic aortic aneurysm (aTAA). Our group has described a neural network (U-Net) approach for reliable and automated (~1 min) landmark localization and diameter measurements, but performance when integrated with human oversight has not yet been validated. We sought to compare performance of a U-Net with "human-in-the-loop" (HITL) validation for measuring static aortic diameters and diameter change (i.e., growth) during aTAA surveillance, versus manual clinical diameter measurements.

### METHODS AND MATERIALS

We included aTAA patients with >2 years between CT angiograms (CTA). Manual diameters were collected by 3D lab technicians at: sinus of Valsalva (SVS), sino-tubular junction (STJ), mid ascending aorta (AAo), and proximal, mid, and distal arch. An in-house U-Net - trained for multi-task segmentation and landmark localization on separate data - determined diameters at all locations and timepoints. A human rater verified U-Net derived landmarks and measurement planes. Highly discrepant (>5mm) static diameter measurements were adjudicated by a blinded 3rd expert rater. Growth was defined as the change in diameter at the same location over time. Ground-truth ascending aortic growth was derived from vascular deformation mapping (VDM), a validated method of 3D growth measurement with sub-millimeter accuracy. Accuracy of growth measurements was assessed by intraclass correlation coefficients (ICC).

### RESULTS

2028 unique diameters were collected by both manual and U-net measurements, from 338 CTAs in 169 patients (57% male, age 61 ± 6 years). 96% (1955) of U-net diameters passed HITL validation, ranging from 89% at the SVS to 100% at the AAo. After HITL validation, there was a 61% reduction (61 to 23) in >5 mm discrepancies between manual and U-Net diameters. Comparing remaining discrepancies to a 3rd expert rater showed a mean absolute error of 7.0 ± 2.9 mm for manual measurements vs. 2.2 ± 1.7 mm for U-net measurements (p <0.01). Considering aortic growth measurements, 43% of manual growth were negative compared to only 30% of U-net values (p <0.01). Compared to VDM-derived aortic growth, U-net yielded growth showed higher ICC agreement (0.74; 95% CI 0.62-0.80) versus manual growth (0.40; 95% CI 0.18-0.56).

### CONCLUSION

U-Net aortic diameters fail human validation at low rates (<4%) in a clinical aTAA population and show improved reliability and growth tracking accuracy compared to best-practice manual diameters.

### CLINICAL RELEVANCE/APPLICATION

Automated aortic measurements with HITL validation yielded superior reliability compared to manual measurements and may improve workflow efficiency and detection of disease progression.

## W1-SSVA03-5 MULTI-CENTER VALIDATION OF A DEEP LEARNING-BASED AORTIC DISSECTION AUXILIARY DIAGNOSIS SYSTEM

Chen Xia (*Abstract Co-Author*) Nothing to Disclose
Fule Wu (*Abstract Co-Author*) Employee, Infervision
Shaokang Wang (*Abstract Co-Author*) Nothing to Disclose
Dawei Wang, PhD (*Presenter*) Employee, Infervision

### PURPOSE

To validate the efficiency and validity of a deep learning (DL)-based auxiliary diagnosis system in aiding radiologists to diagnose aortic dissection.

### METHODS AND MATERIALS

A DL-based aortic dissection auxiliary diagnosis system (InferRead CT Aorta, Infervision) was employed and validated, including the fundamental segmentation performance of aorta and its branches as well as aortic dissection triage and Stanford subtype classification accuracy. 809 patients who underwent thoracoabdominal CTA examinations were enrolled from 8 hospitals. Two experienced radiologists annotated the aorta and the corresponding segments and their consensus serves as the reference standard. Diagnostics of aortic dissection and Stanford subtype were collected from electronic medical record system and further confirmed by the two participating radiologists. DICE and ICC were used to evaluate segmentation and subtype classification performance. The effect on triaging aortic dissection patients was evaluated by sensitivity and specificity.

### RESULTS

Segmentation of the aorta was performed on all 809 cases and the DICE index was 0.928. For the main aortic branches, the segmentation DICE reached 0.922, 0.922, and 0.923 for the brachiocephalic trunk, left common carotid artery, and left subclavian artery, respectively. Of note, there are 354 (43.76%) patients with aortic dissection in the collected dataset. The validated DL system displayed a sensitivity of 92.4% (95%CI: 89.6%-95.1%) and a specificity of 97.8% (95%CI: 96.5%-99.1%) when applied to triage patients with aortic dissection. No significant difference in triage performance was observed in age subgroups. Furthermore, the DL system performed well in classifying Stanford subtypes of aortic dissections as evidenced by an ICC of 0.82. In addition to the validated functions, the DL system could also automatically realize the curved plannar reconstruction, and even the three-dimensional aorta reconstruction, exerting application potential for surgery planning.

### CONCLUSION

The validated DL system is characterized by decent performance on aortic segmentation and aortic dissection triage and classification and is of great value in aiding the accurate and efficient diagnosis of aortic dissections.

### CLINICAL RELEVANCE/APPLICATION

As the commonly used diagnostic approach, thoracoabdominal CTA examination requires complex follow-up procedures to manually generate reference results for radiologists to give a report, which usually takes 30 minutes to an hour even for an experienced radiologist. The validated DL system has unique advantages in efficiency, accuracy, and reliability, and is of great clinical significance in assisting radiologists to provide the basis for clinical diagnosis and treatment.

## W1-SSVA03-6 AORTIC PERIVASCULAR FAT ATTENUATION INDEX CLASSIFIES DIAGNOSIS AND ACTIVITY OF TYPE I TAKAYASU ARTERITIS

Lele Cheng, DPhil, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Takayasu arteritis (TA), a rare granulomatous vasculitis affecting young people, is associated with considerable morbidity and premature mortality. Early diagnosis and evaluation of disease activity in TA helps inform therapy. Chronic inflammation is considered as main agent involved in TA pathogenesis. The peri-coronary fat attenuation index (FAI) is assessed using coronary computed tomography angiography (CTA), and it has emerged as a novel imaging biomarker of coronary inflammation. However, it is unclear whether the aorta-specific FAI provides incremental value to the diagnosis and activity classification of TA.

### METHODS AND MATERIALS

We consecutively enrolled 102 subjects with Type I TA, including 74 in the active phase and 27 in the inactive phase, and 77 matched controls underwent CTA examination. TA was diagnosed using clinical criteria for diagnosis of aortitis (ACR/EULAR Criteria 2022) and disease activity was assessed using the National Institutes of Health (NIH) criteria by experienced physicians. The aortic arch and 1cm above the arch were selected as the region of interest. Peri-aortic adipose tissue was defined as adipose tissue (-190HU to -30HU) within 1cm of the external vessel wall. The relationships between aorta-specific FAI and the presence and activity status of TA were evaluated.

### RESULTS

TA patients had higher FAI values than control individuals (-76.74±6.42HU vs. -80.34±6.43HU, $p<0.001$), and TA patients with activity had higher FAI values than those inactive (-75.64±5.08 HU vs. -79.74±5.60HU, $p<0.001$). Aortic wall thickness and erythrocyte sedimentation rate were higher in the active as group compared to the inactive group. FAI value was positively correlated with Kerr Clinical Activity Score ($r = 0.304$, $p = 0.002$), aortic wall thickness ($r = 0.305$, $p = 0.002$), and erythrocyte sedimentation rate ($r =0.278$, $p= 0.005$) and was higher in active vs. inactive TA (all $p< 0.05$). In the fully adjusted model, there was a 14.0% increase in the odds of TA activity status when the FAI increased by one unit (OR=1.14, 95% CI:1.02-1.27, $p=0.025$). Alone aorta-specific FAI above -78 HU had 67% sensitivity and 68% specificity for differentiating TA from controls and above -79 HU had 80% sensitivity and 60% specificity for differentiating active TA from all Type I TA patients.

### CONCLUSION

In this observational study, aorta-specific FAI demonstrated good diagnostic accuracy for Type I TA and was associated with clinical markers of inflammation and disease activity.

### CLINICAL RELEVANCE/APPLICATION

This finding suggests that quantitative assessment of aorta-specific perivascular FAI by CTA is of great significance for clinical practice in aiding the precise diagnosis and may be used to track activity assessment of Type I TA.

## W2-STCE1-1 LESSENING THE ENVIRONMENTAL IMPACT OF GADOLINIUM FROM BREAST MRI WITHOUT AFFECTING PATIENT OUTCOMES

Margarita L. Zuley, MD (*Abstract Co-Author*) Investigator, Hologic, Inc
Amy H. Lu, MD (*Abstract Co-Author*) Nothing to Disclose
Juhun Lee, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuying Cao, BSc (*Abstract Co-Author*) Nothing to Disclose
Federico Pineda, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Contamination by gadolinium-based contrast agents (GBCAs) has been found in waste, surface, and drinking water. Widespread adoption of MRI for breast cancer screening of women with dense breasts would mean a dramatic increase in the number of contrast-enhanced MRIs performed. The purpose of this work is to evaluate the effect of two strategies for reducing GBCA use in breast MRI: the use of a high relaxivity GBCA, and low-dose acquisitions followed by image enhancement via post-processing.

### METHODS AND MATERIALS

The first strategy was to compare screening MRIs acquired with a high relaxivity contrast agent (gadopiclenol) at 0.05mM/kg with priors in the same patient acquired with 0.1mM/kg gadoteridol. Signal enhancement was quantitatively compared between both imaging sessions in a sample of 7 patients. The second strategy for reduction of GBCA dosage was to administer 15% of a standard dose of gadobenate dimeglumine (0.015mM/kg) in 8 women with known enhancing lesions (suspected fibroadenomas). Several minutes later the remaining .085mM/kg was administered to obtain images at a "standard" dosage of 0.1 mM/kg. An image enhancement technique based on the Radon Cumulative Distribution Transform (RCDT) was applied to the low dose images. This technique highlights subtle changes in signal intensity. Lesion detection was evaluated using a detection algorithm trained on a publicly available dataset.

### RESULTS

Signal enhancement in the images acquired with 0.5mM/kg gadopiclenol was higher on average than in the priors acquired with 0.1mM/kg gadoteridol, though this difference was not significant. Relative signal enhancement was higher on average in the gadopiclenol images: 9.3% ± 10.2% in background parenchyma and 4.7% ± 20% in stable enhancing features. Using the RCDT, subtle signal enhancement in low dose images was highlighted better enabling detection of the enhancing lesions. Of the 11 lesions in the dataset, the detection algorithm detected 6 in both standard and low dose images, 3 in standard dose only, and 1 in low dose only.

### CONCLUSION

The preliminary results of imaging with gadopiclenol show that signal enhancement is not significantly affected by using half the dose of other GBCAs and may be in fact higher. Our results also suggest that the RCDT may be a useful tool in boosting lesion detection in images acquired with low doses of gadolinium. Improvements in the automatic lesion detection algorithm will allow us to better illustrate this technique's potential. Future work will evaluate the combination of both strategies for even greater reductions in the amount of Gd administered to patients and in-turn the amount of anthropogenic Gd present in the environment.

### CLINICAL RELEVANCE/APPLICATION

Increase in contrast-enhanced MRI use for breast cancer detection could have a significant environmental impact. Reducing the amount of GBCAs used in these examinations could help alleviate this impact. Our preliminary results suggest that strategies to reduce the dose of GBCAs administered by 50% to 85% could be an effective strategy for screening breast MRI.

## W2-STCE1-2 ALGORITHMIC FAIRNESS IN MEDICAL IMAGING: ASSESSING DEMOGRAPHIC BIAS IN A VISION-LANGUAGE MODEL

Dushyant Sahani, MD (*Abstract Co-Author*) Advisory Board, Koninklijke Philips NV;Advisory Board, Canon Medical Systems Corporation;Advisory Board, General Electric Company;
Avanti Gulhane, MD (*Abstract Co-Author*) Nothing to Disclose
Wei Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Yuzhe Yang (*Abstract Co-Author*) Nothing to Disclose
Domenico Mastrodicasa, MD (*Presenter*) Stockholder, Segmed, Inc;Consultant, Segmed, Inc

**PURPOSE**

To investigate the algorithmic fairness of a self-supervised vision-language foundation model, CheXzero, in chest X-rays across five radiology datasets (MIMIC, CheXpert, NIH, PadChest, and VinDr). Specifically, we tested the presence of demographic biases that could impact historically marginalized groups, potentially exacerbating health care disparities.

**METHODS AND MATERIALS**

The datasets included 858,804 chest X-rays with pathology labels and demographic data from 230,570 patients. CheXpert, PadChest, and VinDr datasets included radiologist labels, with CheXpert test set (n=666) and VinDr (n=5,323) including external annotations from radiologists (n=3). For fairness evaluation, we processed chest X-rays through CheXzero using specific text prompts for a wide range of pathologies (i.e., enlarged cardiomediastinum). Radiologist labels were used as benchmarks to evaluate diagnostic performance and fairness of CheXzero. Additionally, in a subset (n= 480) of the MIMIC dataset, the model's prediction of demographic attributes (sex, age, race) was compared to three additional board-certified radiologists. We compared false negative and false positive rates across demographic groups to quantify underdiagnosis disparities and identify potential biases in the model.

**RESULTS**

CheXzero achieved expert-level pathology detection accuracy but showed greater underdiagnosis disparities compared to radiologists. For instance, in detecting "enlarged cardiomediastinum" on the CheXpert dataset, CheXzero had an AUC of 0.92. However, underdiagnosis disparities were significant: sex 0.28 (p=1.280e-131), age 0.33 (p=2.510e-103), race 0.25 (p=8.790e-093), and sex-race intersection 0.36 (p=1.580e-206). CheXzero also achieved high AUCs for predicting sex (0.92), age (0.94), race (0.78), and intersectional subgroups (0.83), all substantially higher than random chance and outperforming the three radiologists, indicating robust demographic encoding.

**CONCLUSION**

CheXzero, tested across five independent radiology datasets, achieved high diagnostic accuracy but showed significant demographic biases, particularly underdiagnosing females, older adults, and racial minorities. The compounded biases in intersectional groups (i.e., Black females), highlight the need for targeted interventions before deploying vision-language models in clinical settings.

**CLINICAL RELEVANCE/APPLICATION**

Clinical deployment of vision-language foundation model with inherent demographic biases could exacerbate health care disparities, especially for marginalized groups. Our results highlight the importance of awareness of these biases and the need to intervene to mitigate them to achieve more equitable health care with AI models.

## W2-STCE1-3 METHODOLOGY TO EVALUATE THE ENVIRONMENTAL IMPACT OF CLINICAL TRIALS IN RADIOLOGY

Ehsan Samei, PHD (*Abstract Co-Author*) Research Grant, General Electric Company;Advisory Board, General Electric Company;Research Grant, Siemens AG;Advisory Board, Siemens AG;Advisory Board, medInt Holdings, LLC;Advisory Board, Metis Health Analytics;Research Consultant, Nanox Imaging Ltd;Royalties, General Electric Company;Royalties, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Mirion Technologies, Inc;Royalties, Cambridge University Press;Royalties, John Wiley & Sons, Inc
Francesco Ria, DMP (*Abstract Co-Author*) Metis Health Analytics
Liesbeth Vancoillie, PhD (*Abstract Co-Author*) Nothing to Disclose
Mina Mohammadi (*Presenter*) Nothing to Disclose

**PURPOSE**

In this study we assessed the environmental impact of a computed tomography (CT) clinical trial by focusing on five key dimensions: energy consumption, carbon footprint (CO2), methane (CH4), nitrogen (NOx) emissions, and water consumption. This evaluation identified areas for reducing the environmental impact of clinical research informing the implementation of sustainable practices.

**METHODS AND MATERIALS**

We developed a pipeline for estimating the environmental impact of clinical CT scan trial using the Greenhouse Gas (GHG) Protocol, defining three scopes for GHG accounting: Scope 1 covers direct emissions from the CT examination, cooling systems and idle scanner time; Scope 2 included indirect emissions from purchased energy; Scope 3 tracks the emissions from patient and staff transportation, hospital time, and waste.

**RESULTS**

Scope 1 showed a total energy consumption of 10.2± 5% kWh from CT usage, cooling systems, and idle time overhead, with no direct CO2, CH4, NOx emissions, or water usage. Scope 2 resulted in 4.3± 12% kg of CO2, 0.0004± 16% kg of CH4, and 0.00005± 19% kg of NOx, alongside a substantial water usage of 296± 58% kg. Scope 3 involved 28.1± 22% kWh of energy consumption, 0.008± 25% kg of CO2, 0.0003± 27% kg of CH4, 0.0002± 28% kg of NOx emissions, and 421± 62% kg of water usage. Overall, a single-patient clinical trial consumed 38.3± 16% kWh of energy, produced 4.3± 12% kg of CO2, 0.0007± 16% kg of CH4, 0.0002± 27% kg of NOx, and used 717.0± 44% kg of water. The total consumed energy, on average, is equivalent to powering an electric vehicle for 193 km, with a social cost of at least $240 per obtained image data. The environmental impact of clinical trials is further heightened by indirect water consumption and waste generated by disposable medical supplies.

**CONCLUSION**

The environmental impact of clinical trials in radiology is primarily driven by indirect activities (Scopes 2 and 3), including electricity sourcing, patient transportation and other material/energy usage. This results in a significant carbon footprint from fuel and hospital energy use, as well as GHG emissions from necessary travel. To reduce this impact, strategic actions are needed. One effective option is to replace some clinical trials with virtual trials, which can eliminate patient travel.

**CLINICAL RELEVANCE/APPLICATION**

Our project represents a pivotal step towards measuring the sustainability of clinical trials and promoting environmentally responsible practices within the radiology research community. We aim to create a more sustainable future for clinical research through interdisciplinary collaboration.

## W2-STCE2-1 PREDICTION OF AMYLOID POSITIVITY IN PARKINSON'S DISEASE USING THE EARLY-PHASE $^{18}$F-FP-CIT PET IMAGES

Suhong Kim, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to explore whether early-phase 18F-N-(3-fluoropropyl)-2ß-carboxymethoxy-3ß-(4-iodophenyl) nortropane (18F-FP-CIT) positron emission tomography (PET) images can predict ß-amyloid positivity on 18F-florbetaben (18F-FBB) PET scans in patients with Parkinson's disease (PD). Early-phase 18F-FP-CIT PET images (i.e., images acquired within the first 10 min after 18F-FP-CIT injection in a single PET session when diagnosing PD) reflect cerebral perfusion that may have significant associations with brain ß-amyloid load.

### METHODS AND MATERIALS

We reviewed the medical records of 54 patients with PD who underwent dual-phase 18F-FP-CIT PET scans and 18F-FBB PET scans upon initial diagnosis. Patients were divided into two groups based on 18F-FBB PET images: amyloid-positive group (n = 20) and amyloid-negative group (n = 34). We compared regional uptake in the early-phase 18F-FP-CIT PET images between the two groups. We further performed a linear discriminant analysis (LDA) to predict ß-amyloid deposition based on the standard uptake value ratios (SUVRs) of each region of interest on the Desikan-Killiany atlas.

### RESULTS

The amyloid-positive group exhibited decreased uptake in the inferior parietal and isthmus cingulate cortices and increased uptake in the insula and rostral anterior cingulate cortices as well as the caudate nucleus compared to the amyloid-negative group. The LDA prediction model using a stepwise selection of these region of interests demonstrated that SUVRs of the isthmus cingulate cortex and rostral anterior cingulate cortex optimally distinguished the amyloid-positive group from amyloid-negative group Wilk's lambda, 0.786; AUC, 0.796 [95% confidence interval, 0.678-0.913]; misclassification rate 33.2%; cross-validated misclassification rate, 33.2%).

### CONCLUSION

The present study demonstrated that decreased regional uptake in the isthmus cingulate cortex and increased regional uptake in the rostral anterior cingulate cortex on the early-phase 18F-FP-CIT PET images were associated with ß-amyloid deposition in patients with PD.

### CLINICAL RELEVANCE/APPLICATION

The early-phase 18F-FP-CIT PET can be used for prediction of ß-amyloid deposition in patients with PD.

## W2-STCE2-2 DETECTION OF OSSEOUS SPINAL METASTASES WITH T1-WEIGHTED DYNAMIC CONTRAST-ENHANCED PERFUSION MRI AND PET: ACCESSING AGREEMENT WITH POSITIVE BIOPSY

Eric Lis, MD (*Abstract Co-Author*) Nothing to Disclose
Julio Arevalo Perez, MD (*Abstract Co-Author*) Nothing to Disclose
Simone Krebs, MD (*Abstract Co-Author*) Nothing to Disclose
Andrei I. Holodny, MD (*Abstract Co-Author*) Nothing to Disclose

Onur Yildirim (*Abstract Co-Author*) Nothing to Disclose
Deeptha Bejugam, BS (*Presenter*) Nothing to Disclose

### PURPOSE

For patients suspected of metastatic spinal lesions, 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) and magnetic resonance imaging (MRI) are first-line imaging modalities. While conventional MRI provides morphological information, dynamic contrast-enhanced MRI (DCE-MRI) measures vascular perfusion parameters, including vessel permeability (Ktrans) and plasma volume (Vp), which are markers of viable tumors.Although DCE-MRI and PET are individually recognized for detecting tumors, no prior comparisons between Vp and PET maximum standardized uptake value (SUVmax) have been performed. This study evaluates the concordance between PET and DCE-MRI in identifying pathologically confirmed, untreated osseous spinal metastases and assesses DCE-MRI's non-inferiority to PET.

### METHODS AND MATERIALS

Eighty-five biopsy-confirmed, untreated osseous spinal metastases with DCE-MRI and PET scans were included. Exclusion criteria included intervals exceeding one year between DCE-MRI and PET, recorded radiation therapy within two vertebrae of the lesion, and systemic therapy between DCE-MRI and PET. Cases had an average time of 1.39 days between scans. DCE-MRI was performed using gadopentetate dimeglumine injection sequences, and mean Ktrans and mean Vp were calculated from the lesion's region of interest (ROI) using an extended Tofts pharmacokinetic model with NordicICE software. SUVmax, adjusted for patient body weight and liver function, was obtained from the 18F-FDG PET scans in the lesion's ROI. For DCE-MRI, a Vp threshold of 2.10 was used, based on previous literature, to detect spinal metastases; lesions with a Vp of 2.10 or more were classified as true positives for viable tumors. For PET SUVmax, thresholds of 2.00, 2.50, and 4.00 reported in the literature were examined. Agreement between Vp and each SUVmax threshold was assessed, and McNemar tests were used to determine any statistically significant differences in the number of metastases detected.

### RESULTS

At an SUVmax threshold of 2.00, Vp demonstrated a high agreement of 81.18% with SUVmax in detecting spinal metastases. Agreement with other SUVmax thresholds was lower, as expected. Compared to SUVmax thresholds, Vp identified the highest number of metastases ($p < 0.001$).

### CONCLUSION

In general, Vp from DCE-MRI and SUVmax from PET exhibit good agreement in detecting osseous spinal metastases. However, when common thresholds for these metrics are applied, Vp outperforms SUVmax in identifying viable tumors. Our study indicates that DCE-MRI plays a crucial role in detecting viable spinal metastases and, in some instances, more accurately classifies tumors compared to PET.

### CLINICAL RELEVANCE/APPLICATION

This study provides strong evidence for incorporating DCE-MRI in diagnoses of spinal metastases. While current practices utilize conventional MRI, PET-CT, and biopsies, the perfusion parameters measured by DCE-MRI offer further qualitative and quantitative evidence to support diagnoses. DCE-MRI's ability to detect spinal metastases may reduce the need for radiotracer-based imaging, effectively decreasing costs and patient radiation exposure. Recently, gadolinium-based contrast agents, like the agent used in this DCE-MRI technique, have emerged as theragnostic agents to treat cancers through conjugation with targeted, cytotoxic ligands. Imaging insights from our study indicate that DCE-MRI can complement established diagnostic practices and emerging theragnostic techniques to improve spinal metastasis diagnosis and treatment.

## W2-STCE2-3 A PHARMACOKINETIC MODEL DETERMINATION OF TIME ACTIVITY CURVES IN RADIOPHARMACEUTICAL THERAPY

Joseph Steiner, PHD (*Abstract Co-Author*) Nothing to Disclose
Farhad Jafari, PHD (*Abstract Co-Author*) Nothing to Disclose
Brandon Nguyen, BS, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Radiopharmaceutical therapy (RPT) dosimetry often requires activity measurements at discrete time points post-therapy to create time activity curves (TAC) for a given tissue (compartment). Unlike the current methods of determining TACs for each compartment independently using curve fitting, a single patient-specific pharmacokinetic (PK) model is developed to estimate the TAC for multiple compartments simultaneously. Model feasibility and validity was assessed using clinical data.

### METHODS AND MATERIALS

A PK model to determine intercompartmental rate constants from serial activity measurements of patient compartments following RPT was rigorously developed. The model was numerically implemented to determine the rate constants for a 3 compartment (blood, tumor, kidney) and a 4 compartment (adding an aggregate whole body compartment) model for activity measurements at 5 time points from publicly available data for 5 patients. An optimization algorithm (gradient descent) was used over the rate constant parameter space to minimize the least-square error (LSE) between the PK model and the patient data. The rate constants were used to generate TACs for each compartment; these TACs were compared to TACs generated by curve fitting the same data using single exponential (2 parameter) and bi-exponential (3 and 4 parameter) models.

### RESULTS

The LSE was calculated and compared for the TACs generated with the PK models and the exponential models. The average LSEs across all patients were 0.0486 for the single exponential model and 0.0192 for both bi-exponential models. These LSEs were comparable to the average LSE generated by the 3 compartment PK model (0.0178) and the 4 compartment PK model (0.0165). Graphical analysis of the TAC for the exponential and PK models additionally demonstrated comparability.

### CONCLUSION

A PK model framework was developed to estimate rate constants and TACs from post-therapy activity measurements in patients after RPT. The resultant average LSE for the PK models ranged from an order of magnitude less than to comparable to the average LSE from typical curve fitting, which demonstrates feasibility of the PK model to generate TACs treating the patient as a single system with interconnected compartments. Graphical analysis of the TAC additionally demonstrated comparability between the exponential and PK models.

### CLINICAL RELEVANCE/APPLICATION

Physiologically, the patient's organs and tissues are a single system that can be modeled if the intercompartmental rate constants are known. The PK model developed in this work provides a theoretical estimate of rate constants for any patient organ systems of interest. Knowledge of these rate constants may provide a new prognostic tool to guide patient-specific dosing, which is the future of RPT.

## W3-SSBR08-1 NON-MASS LESIONS BY CLINICAL INDICATION: PREDICTIVE VALUES OF US FEATURES AND COMPARISON BETWEEN REAL-WORLD BI-RADS CATEGORIES VS. A RISK STRATIFICATION SYSTEM

Kyunghwa Han, PhD (*Abstract Co-Author*) Nothing to Disclose
Seungchan Nahm (*Abstract Co-Author*) Nothing to Disclose
Ji Soo Choi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jiyoung Yoon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jung Hyun Yoon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Vivian Y. Park, MD (*Abstract Co-Author*) Nothing to Disclose
Miribi Rho, MD (*Abstract Co-Author*) Nothing to Disclose
Min Jung Kim, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze the performance measures of US features in non-mass lesions (NMLs) according to clinical indication and compare the performance of prospectively recorded BI-RADS categories vs. a recently proposed risk stratification system.

### METHODS AND MATERIALS

This retrospective study included 1152 women with 1183 pathologically confirmed NMLs from January 2014 to February 2021, which were prospectively categorized as NMLs prior to biopsy. Three breast radiologists independently reviewed US features and mammographic findings. Performance measures of US features were analyzed by clinical indication (screening, diagnostic, current breast cancer), and the performances of prospectively recorded BI-RADS categories vs. a risk stratification system were compared based on reader-averaged AUCs.

### RESULTS

Among 1183 NMLs, 766 (64.8%) were benign and 417 (35.2%) were malignant. Overall, the clinical indication, age, mammographic density, lesion size (=3cm), distribution, associated calcifications, posterior shadowing, abnormal ductal change, echogenicity, and positive mammographic findings were associated with malignancy (all p <.05). Multiple small cysts showed a negative association (p<.001). The PPVs of US features by indication subgroups (screening, diagnostic, current breast cancer) are as follows: distribution: 17.1%, 65.1%, 47.9%; calcifications: 50.0%, 70.8%, 77.0%; posterior shadowing: 12.0%, 58.6%, 59.4% and abnormal ductal change: 31.5%, 60.5%, 45.9%. The NPVs of multiple small cysts by indication were 89.6%, 54.5%, and 59.9%, respectively. BI-RADS categories from radiology reports showed an overall higher AUC than the risk stratification system (AUC 0.850 vs. 0.736) and for each indication subgroup (screening: 0.888 vs. 0.736, diagnostic: 0.880 vs. 0.766, current breast cancer: 0.717 vs. 0.614) (all p<.05).

### CONCLUSION

Previously reported US features were associated with malignancy in NMLs, but PPVs were lower in the screening subgroup. In all indication subgroups, radiologists' real-world BI-RADS classification demonstrated higher performance in the diagnosis of NMLs than the retrospective application of a risk stratification system.

### CLINICAL RELEVANCE/APPLICATION

US features were associated with malignancy in NMLs, but predictive values and diagnostic performance differed according to indication subgroup.

## W3-SSBR08-2 BREAST CANCER DETECTION USING CONTRAST-FREE ULTRASOUND QUANTITATIVE HIGH-DEFINITION MICROVASCULATURE IMAGING

Mostafa Fatemi, PhD, PhD (*Abstract Co-Author*) Nothing to Disclose
Azra Alizad, MD (*Abstract Co-Author*) Nothing to Disclose
Robert T. Fazzio, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Soroosh Sabeti, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To overcome the limitations of power Doppler in imaging angiogenesis, we investigated the utility of new quantitative biomarkers of a contrast-free ultrasound microvasculature imaging technique called quantitative high-definition microvasculature imaging (qHDMI) for differentiation of benign from malignant pathologies of breast lesions.

**METHODS AND MATERIALS**

In this prospective study, qHDMI was tested on 521 patients with 527 ultrasound-identified suspicious breast masses recommended for biopsy. The study was compliant with Health Insurance Portability and Accountability Act, and approved by our institutional review board (IRB). A signed informed IRB approved written consent was obtained from each patient. The histopathological results of breast core needle biopsy were used as the gold standard reference. Microvasculature images were generated through post-processing of the data, in a series of clutter filtering, denoising, and vessel enhancement steps. The extracted qHDMI biomarkers included number of vessel segments (NV), number of branch points (NB), vessel density (VD), vessel density ratio (VDR), spatial vascularity pattern (SVP), Murray's deviation (MD), fractal dimension (FD), diameter (D), bifurcation angle (BA), and tortuosity (t). Multivariable logistic regression analysis was used to study the performance of different prediction models trained with different sets of biomarkers in differentiating benign from malignant lesions.

**RESULTS**

The qHDMI biomarkers were statistically significantly different in malignant and benign lesions, regardless of tumor size. Models trained using all biomarkers showed an AUC, sensitivity, and specificity of 99.1% (95% CI: 98%-100%), 97.1%, 98.4%, respectively for lesions larger than 20mm. The classification was further improved by adding the BI-RADS score to the prediction model, showing an AUC, sensitivity, and specificity of 99.5% (95% CI: 99%-100%), 100%, 96.7%, respectively.

**CONCLUSION**

Without the help of contrast agents, through utilization of qHDMI on patients with breast masses, we were able to resolve tumor microvessels as small as 150 μm. We further showed that analysis of tumor vessel morphological parameters may improve the accuracy of ultrasound in differentiating malignant vs benign breast masses.

**CLINICAL RELEVANCE/APPLICATION**

qHDMI can offer a new means of detecting breast cancer when used as a complementary tool to standard ultrasound. The findings provide a translational rationale for the clinical implementation of qHDMI for breast cancer detection.

## W3-SSBR08-3 ASSESSING NONINFERIORITY OF QUANTITATIVE TRANSMISSION (QT) ULTRASOUND IMAGING COMPARED WITH DIGITAL BREAST TOMOSYNTHESIS (DBT): RESULTS FROM A MULTI-READER, MULTI-CASE (MRMC) OBSERVER STUDY

John C. Klock, MD (*Abstract Co-Author*) Officer, QT Imaging, Inc
Yulei Jiang, PhD (*Abstract Co-Author*) Research Grant, Delphinus Medical Technologies, Inc;Research Consultant, Delphinus Medical Technologies, Inc
Bilal Malik, PhD (*Presenter*) Consultant, QT Ultrasound, LLC

**PURPOSE**

Quantitative transmission (QT) imaging is a relatively new ultrasound breast imaging modality. Its inherent volumetric imaging allows for delineating overlapping breast tissue structures not differentiated well by mammography, specifically in women too young for screening mammography and in whom dense breasts are prevalent. Therefore, QT could potentially improve breast cancer detection and characterization in such a population. In this study, we present the results of a multi-reader multi-case (MRMC) study to compare radiologists' performance in interpreting QT vs digital breast tomosynthesis (DBT).

**METHODS AND MATERIALS**

The study utilized subject images obtained from HIPAA-compliant, institutional review board-approved prospective case collection studies conducted at four clinical sites. These images were interpreted by 24 board certified diagnostic radiologists. Adult females with either normal mammograms or mammographic abnormalities were enrolled and underwent QT scans after standard clinical DBT. DBT and QT images of both breasts were obtained for each subject, with bilateral images treated as separate cases for interpretation and analysis. The study image set comprised 177 cases, with 66 cases with cancer, atypia, or solid benign lesions and 111 normal cases or with non-solid benign lesions. Ground truth for abnormalities was established through biopsy or aspiration pathology results, while normal cases were determined by 1-year follow-up. The study tested the hypothesis that the area under the receiver operating characteristic curve (AUC) of QT imaging is non-inferior to that of DBT.

**RESULTS**

AUC of QT (0.746 ± 0.028, mean ± SD) was noninferior to DBT (0.700 ± 0.028) for AUC difference margin of -0.05 ($P < .05$). AUC difference was 0.046 ± 0.028 (95% CI: [-0.008, 0.101]). Sensitivity was 70.6 ± 7.2% for QT and 85.2 ± 6.4% for DBT, specificity was 60.1 ± 12.3% vs 37.2 ± 11.0%, with both differences statistically significant.

**CONCLUSION**

QT imaging holds promise as a possible substitute for mammography in screening for breast cancer among younger women who are not yet eligible for mammography.

**CLINICAL RELEVANCE/APPLICATION**

Although fewer than 5% of women with breast cancer are diagnosed before the age of 40, younger women often face the most aggressive forms with poorer survival rates. However, routine mammograms aren't advised for women under 40. QT imaging offers a promising alternative by more effectively imaging dense breast tissue and doing so without radiation exposure. The results of QT's non-inferiority to DBT demonstrate potential benefit of QT for younger women.

## W3-SSBR08-4 SUPPLEMENTARY ULTRASOUND AND MRI FOR DIAGNOSIS OF ABNORMAL CASES PRESENTING ARCHITECTURAL DISTORTION ON DBT

Meihao Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Jeon-Hor Chen, MD (*Abstract Co-Author*) Nothing to Disclose
Jiejie Zhou, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Xiao Chen (*Abstract Co-Author*) Nothing to Disclose
Yang Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose

Yan-Lin Liu (*Abstract Co-Author*) Nothing to Disclose
Min-Ying Su, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The presentation of architectural distortion (AD) has not been extensively investigated and not interpreted well in the BI-RADS lexicon, and the interpretation of AD remains challenging. The diagnosis for lesions that only present as pure AD without accompanying mass or microcalcifications is the most difficult. In this study, the diagnostic role of supplementary ultrasound (US) and MRI was investigated by evaluating their correlations and comparing their diagnostic performance.

**METHODS AND MATERIALS**

Pathologically confirmed 471 cases were investigated, 265 (56%) malignant and 206 (44%) benign. The DBT images were reviewed to identify the suspicious AD areas and to determine whether the lesion was pure AD or was accompanied by mass or microcalcifications. The US reports were reviewed to determine whether there were suspicious findings corresponding to the detected AD. The malignancy rate in patients with or without US findings was compared. In patients presenting as pure AD, the BI-RADS score distribution between DBT and US was correlated. In 57 patients who had DBT, US, and MRI, the diagnostic performance was compared.

**RESULTS**

Malignancy rate in DBT BI-RADS 5, 4C, 4B, 4A, and 3 groups were 100%, 86%, 57%, 37%, and 19%, respectively. Of 471 cases, 315 showed the corresponding abnormality on US, and the malignancy rate was 72%. In 156 cases without corresponding US findings, the malignancy rate was lower at 24% ($P < 0.001$). In US examination, irregular shape, non-circumscribed margin, low echo, heterogeneous echo, and larger tumor size were associated with malignancy. In 256 pure AD cases, there were 114 malignant (46%) and 139 benign (54%). In malignant cases, scores are mainly distributed in 4C to 4A, and 15 cases do not have suspicious US. In benign cases, scores are mainly distributed in 4B to 3, and 32 cases (23%) have US BI-RADS 2-3, and 47 cases (34%) do not have corresponding suspicious US findings. In 57 cases with three imaging, the diagnostic accuracy was 67% for DBT, and 74% for both US and MRI. MRI had the highest sensitivity of 90%, and US had the best specificity of 67%.

**CONCLUSION**

AD lesions identified on DBT that had corresponding US abnormalities had a much higher malignancy rate than those without. In pure AD, no corresponding US finding can rule out many benign lesions and spare patients from unnecessary biopsies. Supplementary MRI has the highest sensitivity; however, some benign lesions demonstrating enhancements would result in a false positive diagnosis. In these cases, the lack of US abnormality may improve the specificity.

**CLINICAL RELEVANCE/APPLICATION**

Diagnosis of lesions presenting as architectural distortion on DBT can be improved with more understanding of associated features, and with the correlation of features imaged by ultrasound and MRI.

## W3-SSBR08-5 ENHANCED DIAGNOSTIC PERFORMANCE OF SHEAR-WAVE DISPERSION IMAGING IN BREAST MASSES: COMPARISON WITH SHEAR-WAVE ELASTOGRAPHY ACCORDING TO LESION SIZE, DEPTH, AND BREAST THICKNESS

Sung Eun Song, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Eunkyung Woo (*Abstract Co-Author*) Nothing to Disclose
Kyu Ran Cho, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ok Hee Woo, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Min Sun Bae, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Bo Kyoung Seo, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Human breast tissue exhibits viscoelastic properties, but ultrasound (US) assessments have primarily focused on elasticity measurement. Shear wave elastography (SWE) is a commonly used US technique for quantifying tissue elasticity, but its accuracy can be affected by lesion size, depth, and breast thickness. Recent technological advancements allow for the automatic quantification of viscosity through the shear-wave dispersion slope (SWD) in SWE. This study aims to evaluate the diagnostic performance of SWD in distinguishing between benign and malignant breast masses and to explore its supplementary role.

**METHODS AND MATERIALS**

From August 2020 to August 2021, we retrospectively evaluated 606 consecutive patients scheduled for ultrasound-guided biopsy. We performed SWD and SWE before the procedure. A total of 630 breast masses were included in the study. For each mass, we measured the average tumor elasticity (Etumor) and tumor-to-fat elasticity ratio (Eratio) using SWE, as well as the average tumor dispersion (Dtumor) and tumor-to-fat dispersion ratio (Dratio) using SWD. We compared the diagnostic performance of SWE and SWD using the area under the curve (AUC). Additionally, we conducted a Mann-Whitney U test to determine whether lesion size, depth, and breast thickness independently affected the overall diagnostic performance.

**RESULTS**

Of the 630 masses, 395 were benign and 235 were malignant. Mean values of Etumor, Eratio, Dtumor, and Dratio were 11.5 kPa, 2.6, 11.2 m/s/kHz, and 2.1 for benign lesions and 79.5 kPa, 16.4, 27.1 m/s/kHz, 5.0 for malignant lesions ($p < 0.05$). The overall AUC was significantly superior in SWD (Dtumor vs. Etumor, 0.96 vs. 0.93; Dratio vs. Eratio, 0.95 vs. 0.93) ($p < 0.05$). In small masses = 10 mm, the sensitivity and positive predictive value of Dtumor were higher than Etumor (70% and 85% vs. 38% and 68%) with the preservation of high specificity (98% vs. 96%) ($p < 0.05$). In lesions of any depth and breast thickness, Dtumor showed the highest sensitivity and specificity.

**CONCLUSION**

SWD can enhance the diagnostic performance for distinguishing between benign and malignant breast masses compared to SWE across various lesion sizes, depths, and breast thicknesses.

**CLINICAL RELEVANCE/APPLICATION**

SWD, obtained automatically during SWE examination, could compensate for the shortcomings of SWE regarding variance in diagnostic performance according to lesion size, depth, and breast thickness.

## W3-SSBR08-6 SINGLE INSTITUTION INTERIM RESULTS OF NO AXILLARY SURGICAL TREATMENT IN CLINICALLY LYMPH NODE-NEGATIVE PATIENTS AFTER ULTRASONOGRAPHY (NAUTILUS) TRIAL

Woo Kyung Moon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jung Min Chang, MD (*Abstract Co-Author*) Research Consultant, Genoray Co, Ltd
Jung Oh Lee, MD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the interim results of axillary lymph node (LN) metastasis rate and the factors related to axillary LN metastasis in patients who underwent sentinel LN biopsy (SLNB) within the single-institution cohort participating in the No Axillary Surgical Treatment in Clinically Lymph Node-Negative Patients after Ultrasonography (NAUTILUS) trial.

**METHODS AND MATERIALS**

Between September 2020 and October 2022, patients with clinically and sonographically node-negative T1-2 breast cancer and who are expected to undergo BCS and whole-breast radiation in South Korea were invited in the NAUTILUS trial and randomized (1:1) to the axillary surgery omission and SLNB groups (NCT04303715). In this trial, patients with normal LNs (oval shape, smooth margin, and uniformly thin cortex < 3 mm) or one LN with cortical thickness = 3 mm, but biopsy proven negative were only included. Among these patients, we analyzed axillary LN metastasis rates of SLNB group in a single institution using clinical follow-up or pathologic data. The numbers of metastatic LNs were evaluated, and the differences in the distribution clinicopathological, and US features between patients with vs. without LN metastasis were analyzed using the t-test or the chi-square.

**RESULTS**

Among 617 women (median [IQR] age, 56 [48-66] years), 308 were randomized in axillary surgery omission group, and 309 in SLNB group. In 309 patients in SLNB group, the median (IQR) tumor size was 1.5 (0.5-1.9) cm, 258 (83.5%) had invasive ductal carcinoma, and 28 (9.1%) had invasive lobular carcinoma. The median (IQR) follow-up was 24 (19-28) months. Among these patients, there was 29 cases (9.4%, 29/309) of LN metastasis (one [n=24], two [n=2], three or more [n=3]). The median (IQR) index tumor size (1.8 [1.3-2.0] cm vs. 1.4 [1.0-1.8] cm, p=0.007) and cortical thickness of LN on US (2.0 [1.6-2.4] mm vs. 1.7 [1.4-2.0] mm, p=0.006) was significantly larger in patients with LN metastasis compared to patients without LN metastasis. Lymphovascular invasion was more frequently noted in patients with LN metastasis than without LN metastasis (10.3% vs. 2.1%, p=0.013). Age, menopausal status, tumor histology, Ki-67 index, hormone receptor or human epidermal growth factor receptor type 2 status were not correlated with LN metastasis.

**CONCLUSION**

Interim results from a single institution showed a 9.4% axillary LN metastasis rate in the SLNB group. The tumor size, cortical thickness of LNs, and lymphovascular invasion were significantly correlated with LN metastasis.

**CLINICAL RELEVANCE/APPLICATION**

The tumor size, cortical thickness of LNs on US could be helpful for decision of axillary surgery, although pathologic LN status may not be clinically relevant to patient management.

### PURPOSE

To optimize correlation between assessment of right ventricular (RV) stroke volume by cardiac MRI (CMR) and pulmonary artery forward flow (PAFF) using 4D flow MRI in patients with pulmonary hypertension (PH).

### METHODS AND MATERIALS

42 PH patients underwent right heart catheterization (RHC) and cardiovascular magnetic resonance (CMR) imaging, including 4D flow MRI, before and after surgery. Out of these, 31 patients with chronic thrombo-embolic PH (CTEPH) had pulmonary endarterectomy, while 11 patients with pulmonary arterial hypertension (PAH) had lung transplantation. CMR was performed using a 1.5T magnet. RV stroke volume was calculated conventionally (RVSV), and excluding hypertrophic RV trabeculations (RVSVt). Pulmonary artery forward flow (PAFF) was assessed conventionally at the mid-pulmonary artery trunk (MPAFF) and at the annular level (APAFF). Agreement between measurements was assessed using linear regression (Pearson), Blant-Altman analysis, Lin's concordance correlation coefficient, and intra-class correlation coefficients for interobserver reproducibility. The local ethics review board approved the study.

### RESULTS

Pre-operative mPAP significantly decreased from 44.5+/-12.7 to 22.5+/-5.2 mmHg after surgery ($p<0.001$). RV mass including trabeculations significantly decreased from 57.4+/-23.2 to 33.9+/-10.8g post-operatively ($p<0.001$). Pre-operatively, there was a significant difference between RVSV and RVSVt ($p=0.03$), and APAFF and MPAFF ($p=0.04$), with a strong correlation between RVSVt and APAFF ($r=0.90$, $p<0.001$), surpassing correlations with conventional RVSV and MPAFF measurements. Interobserver reproducibility was excellent for RVSV, RVSVt, APAFF and MPAFF, demonstrating high reliability of the assessment techniques. These differences were non significant post-operatively, indicating reliable RVSV assessment without need to exclude trabeculations after surgery.

### CONCLUSION

In PH patients, significant differences were demonstrated between RVSV and RVSVt, and MPAFF and APAFF, with a strong correlation between RVSVt and APAFF. After surgery, where RV reverse remodeling occured and decreased mPAP mitigated these differences. This study highlights the influence of excluding RV hypertrophic trabeculations and PA vortical flows that occur predominantly in mid-trunk PA, to assess RVSV and PAFF in PH patients.

### CLINICAL RELEVANCE/APPLICATION

The findings highlight the influence of the methodology to optimize the correlation between RVSV and PAFF assessment using CMR and 4D flow MRI in PH patients, underscoring the influence of excluding hypertrophic trabeculations to assess RVSV, and to avoid areas of vortical flows when assessing PA flows, for an optimal correlation between these measurements.

## W3-SSCA07-3 EVALUATION OF RIGHT VENTRICULAR DEFORMATION IN HYPERTROPHIC CARDIOMYOPATHY PATIENTS USING 1.5-T CARDIOVASCULAR MAGNETIC RESONANCE FEATURE TRACKING

Sanjeev Kumar, MBBS,MD (*Abstract Co-Author*) Nothing to Disclose
Priya Jagia, MD (*Abstract Co-Author*) Nothing to Disclose

Niraj N. Pandey, MBBS, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Right ventricular (RV) strain parameters have previously been used for prognostication in multiple cardiovascular diseases and are regarded as better markers of myocardium dysfunction compared to RV ejection fraction (RVEF). The present study sought to assess the global and regional RV deformation in hypertrophic cardiomyopathy (HCM) patients using 1.5-T cardiovascular magnetic resonance feature tracking (CMR-FT).

**METHODS AND MATERIALS**

Fifty-four HCM patients and 32 age- and sex- matched healthy controls were enrolled. HCM patients were divided into groups depending on the presence or absence of right ventricular hypertrophy (RVH), RV dysfunction, RV late gadolinium enhancement (RV-LGE), and left ventricular outflow tract obstruction (LVOTO), respectively. RV strain analysis by CMR-FT was performed using Circle Cvi42 software by automated and manual contouring of RV endocardial and epicardial surfaces.

**RESULTS**

The RV global longitudinal strain (LS), apical RS (radial strain), and mid and apical circumferential strain (CS) in HCM patients were significantly lower than those in controls ($p<0.05$). Compared to healthy controls, the RV global RS was significantly reduced in HCM patients even with absent RVH, the RV global CS and LS were significantly reduced in HCM patients even with normal RVEF, and the RV global RS and LS were significantly reduced in HCM patients even with absent RV-LGE ($p<0.05$). The RV global RS was significantly lower than that in HCM patients without RVH ($p<0.05$). The RV mid and apical CS and global, mid, and apical RS in HCM patients with RV-LGE were significantly lower than that in HCM patients without RV-LGE ($p<0.05$). No significant difference was found regarding RV strain parameters in HCM patients with LVOTO compared without LVOTO (all $p>0.05$) or among HCM patients with normal, reduced or hyperdynamic RVEF (all $p>0.05$).

**CONCLUSION**

CMR-FT can detect subclinical RV myocardial deformation, even in the absence of RVH, RVEF impairment, or RV-LGE; however, RV myocardial deformation in HCM patients is more severe in the presence of RVH and RV-LGE.

**CLINICAL RELEVANCE/APPLICATION**

CMR-FT may be used to detect subclinical RV myocardial deformation which in turn may aid in the prognostication of HCM patients.

## W3-SSCA07-4 THE FEASIBILITY OF HEMODYNAMIC FORCE ANALYSIS BY CARDIAC MAGNETIC RESONANCE FOR ASSESSMENT OF LEFT VENTRICULAR OUTFLOW TRACT OBSTRUCTION IN HYPERTROPHIC CARDIOMYOPATHY

Yang Peng (*Abstract Co-Author*) Nothing to Disclose
Lin Peng (*Abstract Co-Author*) Nothing to Disclose
Yu Feng (*Abstract Co-Author*) Nothing to Disclose
Yuying Chen (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the hemodynamic force (HDF) parameters by cardiac magnetic resonance (CMR) in patients with hypertrophic cardiomyopathy, and to assess their diagnostic value for left ventricular outflow tract (LVOT) obstruction.

**METHODS AND MATERIALS**

This study retrospectively included 81 HCM patients who underwent both CMR examinations with a 3.0 T scanner and color Doppler echocardiography within 2 weeks from January 2020 to November 2022. The patients were further diagnosed as non-obstructive HCM, occult obstructive HCM, or obstructive HCM according to color Doppler echocardiography. The HDF analysis were performed based on strain analysis of CMR cine images at long-axis views (2-chamber, 3-chamber, 4 chamber), including left ventricular longitudinal forces in the following phases: entire heartbeat, systole, diastole, systolic peak, systolic/diastolic transition, diastolic deceleration, as well as atrial thrust, and compared among the 3 groups. The multivariate analysis and receiver operating curve (ROC) analysis were performed to assess potential independent predictors of obstructive HCM.

**RESULTS**

Of the 81 HCM patients, there were 37 with non-obstructive HCM, 14 with occult obstructive HCM, and 30 with obstructive HCM. There was no significant difference in GLS among non-obstructive, occult obstructive and obstructive HCMs. HDF analysis revealed significantly higher forces in the entire heartbeat, systole, and diastole in obstructive HCM than those in non-obstructive HCM (all adjusted $P<0.05$). Peak systolic force was also higher in obstructive HCM than that in non-obstructive HCM (adjusted $P<0.05$). There was no HDF parameters revealing statistically significant difference between occult obstruction and the other two groups. At multivariate analysis, HDF in the entire heartbeat was confirmed as an independent predictor for obstructive HCM with an AUC of 0.738 (95% confidence interval:0.617-0.859, $P=0.001$). Its sensitivity and specificity were 53.3% and 81.1%, respectively.

**CONCLUSION**

HDF analysis indicated higher LV forces in obstructive HCM than that in non-obstructive HCM. HDF in the entire heartbeat showed the best predictive value for LVOT obstruction in HCM.

**CLINICAL RELEVANCE/APPLICATION**

LVOT obstruction in HCM was commonly assessed by LVOT gradient through color Doppler echocardiography or 4D flow CMR. This study revealed the potential value of HDF analysis by conventional CMR cine images in assessment of LVOT obstruction.

## W3-SSCA07-5 COMPARISON OF PULMONARY REGURGITATION FRACTION BETWEEN 2D PHASE CONTRAST AND 4D FLOW MRI IN ADULTS WITH REPAIRED TETRALOGY OF FALLOT

Michinobu Nagao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*) Support, Canon Medical Systems Corporation;Support, General Electric Company
Hirozumi Mori, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

It is known that adult patients with repaired tetralogy of Fallot can exhibit severe pulmonary arterial regurgitation, which significantly influences treatment decisions. Measurement of regurgitation fraction(RF) on cardiac MRI is a valuable non-invasive examination, and 4D flow offers advantages over 2D phase contrast sequence by enabling measurement at multiple cross-sections and retrospective determination while visually assessing flow

features such as turbulence. In this study, we compared the RF of the main pulmonary artery (MPA) using 2D phase contrast sequence and 4D flow at the same cross-section and evaluated whether RF rate measured at multiple cross-sections with 4D flow are affected by turbulence.

## METHODS AND MATERIALS

30 patients post-repaired of tetralogy of Fallot (44.3 ± 15.7 years, 18 females) underwent imaging with 3.0-Tesla MRI (Ingenia 3T, Philips Healthcare) using 2D phase contrast sequence and 4D flow. RF of the main pulmonary artery(MPA) was calculated from forward and backward flow using Intellispace Portal (ISP) and compared between the two imaging techniques. In 4D flow, RF was measured at positions matching those in 2D phase contrast sequence and proximal and distal positions, with up to five slices measured at 1 cm intervals on the 3D model shape.

## RESULTS

Forward flow was significantly higher with 2D phase contrast sequence compared to 4D flow (103.5 ± 26.7ml vs. 85.8 ± 31.0ml; paired t-test, p=0.01), while backward flow tended to be higher with 2D phase contrast sequence but was not statistically significant (44.5 ± 29.5ml vs. 33.14± 24.5ml; paired t-test, p=0.055). The distribution of RF between 2D phase contrast sequence and 4D flow showed a high correlation (40.0 ± 18.1% vs. 37.5 ± 19.7%: Spearman rank correlation, rs= 0.757).In 10 of the 30 cases, there was a noticeable variation in the RF measured in multiple slices in 4D flow, with a difference of more than 20% compared to the RF measured at the same location in 2D phase contrast sequence. Both forward and backward turbulence were evident in areas where the shape of the pulmonary arteries was complex.

## CONCLUSION

RF measured with 2D phase contrast sequences and 4D flow showed high agreement when aligning slice positions. However, in cases with significant turbulence, variations in measurements from 4D flow were noticeable.

## CLINICAL RELEVANCE/APPLICATION

While measurements in the MPA with 2D phase contrast sequence are typically performed at a single location, accurate measurement with 2D phase contrast sequence at a single slice is difficult in cases with complex pulmonary artery shapes. Therefore, measurement with 4D flow, allowing multi-section evaluation, is crucial for comprehensive evaluation and treatment decision-making.

## W3-SSER02-1 COMPARISON STUDY BETWEEN POSTMORTEM CT AND CONVENTIONAL AUTOPSY IN CORONER'S INVESTIGATIONS FORM THE PROVINCE OF QUEBEC, CANADA

Yann Daze (*Abstract Co-Author*) Nothing to Disclose
Gabriel Nadeau, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Martin Clavet (*Abstract Co-Author*) Nothing to Disclose
Luc Lacoursiere, MD, FRCPC (*Presenter*) Nothing to Disclose

### PURPOSE

To compare postmortem computed tomography (CT) and conventional autopsy in their capacity to determine the causes and manners of death and to detect anomalies, in coroner’s office investigations.

### METHODS AND MATERIALS

Postmortem CT was performed on 100 human corpses prior to conventional autopsy. The CT exams were read by a postmortem-trained and experienced radiologist and conventional autopsies (CA) performed by 4 forensic pathologists blinded to the CT results. All findings were recorded for each method and categorized by anatomic systems (soft tissue, bone, central nervous system (CNS), lungs, heart/vessels, abdomen). These findings were graded for their importance (essential, important, and fortuitous observations). The ability of each method to determine the cause of death and the primary anatomic system involved was also compared against coroner's final reports.

### RESULTS

Significant differences ($P < 0.05$) were observed in the detection of essential and important findings between CT and CA. Among all 378 findings, CT identified 271 (71.7%) compared to 309 (81.7%) for CA. Considering anatomic systems, there was a significant difference with CT performing better for CNS anomalies [90.2% (37/41) vs 65.9% (27/41)]. CA better detected heart/vessel anomalies [87.6 % (85/97) vs 57.7 % (56/97)] and abdominal findings [86.2 % (56/65) vs 47.7 % (31/65)]. Both CT and CA were of equal performance for detection of bone [93.9 % (62/66) vs 81.8 % (54/66)] and lung [78.6 % (44/56) vs 80.4 % (45/56)] anomalies. Kappa coefficient of agreement between CT and CA with coroner's final reports for the causes of death were: all causes of death (0.75), intoxication (0.59), natural causes of death (0.61), hypothermia (0.65), asphyxia (0.75), polytrauma (0.93), drowning (1), Fire (1), firearm and stabbing (1) and hanging (1). Kappa coefficient of agreement between CT and CA for the anatomic systems responsible for death were: all systems 0.73, heart 0.56, aorta and peripheral vessels 0.66, CNS 0.80, multisystem 0.86 and respiratory system 0.91.

### CONCLUSION

Postmortem CT and conventional autopsy are both effective in identifying most essential and important findings for determining the cause and manner of death. However, CT is better in detecting CNS anomalies, while conventional autopsy is better in detecting cardiovascular and abdominal anomalies. Agreement between both methods is considered near perfect or perfect for violent deaths and substantial for natural deaths.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrated the great value of postmortem CT in the context of coroner's investigations in which finding a probable cause of death is the main purpose and led to changes in investigating protocols for Quebec’s coroners.

## W3-SSER02-2 DIAGNOSTIC ACCURACY: SENSITIVITY AND SPECIFICITY OF DEEP LEARNING TOOL FOR AUTOMATIC CERVICAL SPINE FRACTURE DETECTION

Marlene SCUDELER (*Abstract Co-Author*) Nothing to Disclose
Vladimir Laletin, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yasmina Chaibi, PhD (*Abstract Co-Author*) Employee, Avicenna.ai
Angela Ayobi, MENG,MSc (*Abstract Co-Author*) Employee, Avicenna.ai
Charlotte Castineira (*Abstract Co-Author*) Nothing to Disclose
Mar Roca-Sogorb (*Abstract Co-Author*) Nothing to Disclose
Sarah Quenet, MD (*Presenter*) Employee, Avicenna.ai

**PURPOSE**

This study assessed the diagnostic performance of an artificial intelligence (AI) application for triage and prioritization of cervical spine fractures on CT scans. The validation was performed on scans across multiple clinical centers and CT vendors.

**METHODS AND MATERIALS**

This retrospective, multi-center, multinational and blinded study evaluated non-enhanced cervical CT images provided by three teleradiology organizations. The dataset encompassed various clinical centers in Europe and America and included scans from five different CT vendors. The study evaluated the efficacy of an AI-based application CINA-CSpine (Avicenna.AI, La Ciotat, France) in detecting cervical fractures. The performance of the AI device was compared against the Ground Truth, established by the consensus of three board-certified radiologists. The relevance for clinical workflow was equally assessed. Finally, the stratification analysis for several CT scan and patient parameters was performed.

**RESULTS**

328 scans (mean age: 55.3 yo ± 5.1 [SD]; 59.5% male) were reviewed. Among the 155 exams identified as positive for acute cervical spinal fracture by the experts, the device correctly identified 140, resulting in a sensitivity of 90.3% [95% CI: 84.5% - 94.5%]. Likewise, 159 out of 173 were correctly identified as negatives (specificity of 91.9% [95% CI 86.8% - 95.5%]). The Positive Predictive Value (PPV) and Negative Predictive Value (NPV) were 90.9% and 91.4%, respectively. Missed cervical spine fractures were attributed to poor image quality, osteophyte fractures, and vertebral degenerative diseases. False positives were associated with confounding conditions such as degenerative disease, chronic spinal fractures, acquisition artefacts and complex osteophytes. The overall mean time-to-notification for the automated tool was estimated at 2.9 ± 1.1 [SD] minutes. Sensitivity and specificity across multiple image acquisition parameters and patient characteristics exceeded 85%.

**CONCLUSION**

The AI-based algorithm, evaluated on real-world data CT scans, exhibited high accuracy in detecting cervical spine fractures, coupled with a rapid time-to-notification. These findings imply that incorporating AI into routine clinical practice could streamline the workflow, facilitating faster and more accurate diagnosis.

**CLINICAL RELEVANCE/APPLICATION**

This study sheds light on the high performance of an AI-based algorithm in clinical data triage and prioritization for routine detection of cervical spine fractures. The algorithm was tested on diverse data sourced from multiple clinical sites, highlighting its robustness and versatility. Future prospective assessments are needed to clarify the direct impact of this AI-based tool on patient outcomes.

## W3-SSER02-3 SHOCK THYROID: DOES IT EXIST? INCIDENCE AND RELEVANCE OF CT SIGNS OF SHOCK THYROID IN HEMODYNAMICALLY UNSTABLE PATIENTS

Ferco H. Berger, MD (*Abstract Co-Author*) Nothing to Disclose
Rawan Abu Mughli, MD (*Abstract Co-Author*) Nothing to Disclose
Sadia R. Qamar, MBBS (*Abstract Co-Author*) Nothing to Disclose
Jacques Du Plessis, MBChB, FFRad(D)SA (*Abstract Co-Author*) Nothing to Disclose
Matthew Mueller, MSc, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

CT signs of post-traumatic hypovolemic shock complex (HSC) in abdominal organs and vasculature correlate to existing/impending hypovolemic shock. Case reports described (non-) traumatic shock thyroid CT changes as peri-thyroid fluid, altered enhancement and swelling. This study aims to investigate the incidence of shock thyroid CT signs and correlate those with abdominal signs of HSC and patient outcome in trauma patients.

**METHODS AND MATERIALS**

This is a single-center, REB approved, retrospective study of CTs from 1051 hemodynamically unstable trauma patients at an academic Level-1 Trauma Center. CT scans of the neck, chest and abdomen/pelvis were retrospectively reviewed by a single reader blinded to outcome. Direct injury to the thyroid was excluded. Scoring included CT signs of acute thyroid changes (hypo-enhancement, heterogeneity, peri-thyroid fluid, and swelling), known abdominal visceral and vascular CT signs of HSC (IVC diameter; IVC halo; aortic diameter; and changes in enhancement to bowel wall, adrenals, renal cortex, and/or gallbladder wall), and clinical data.

**RESULTS**

This abstract reports on preliminary results of the first 135 patients or our cohort, the other 916 patient will be scored before presentation. 31/135 patients (23%) showed altered CT appearance of the thyroid. Patients were younger if thyroid abnormalities were present (41.8yrs vs 50.3yrs, $p = 0.035$). Striking peri-thyroid fluid correlated with a smaller IVC diameter (11.7 mm vs 14.9 mm; $p = 0.0154$). Of the 31 patients, only one showed visceral hypoperfusion signs on abdominal CT (altered enhancement of the gallbladder and renal cortex). Shock thyroid signs did not correlate with survival at discharge. Upon completion of scoring, further statistical analysis will be performed with subgroup stratification.

**CONCLUSION**

In hemodynamically unstable trauma patients, CT signs of shock thyroid could precede known abdominal CT signs. These preliminary results correlate striking peri-thyroid fluid with smaller IVC diameter, even without other CT HSC signs. Study completion will provide better insight of usefulness of shock thyroid CT signs for clinical management in post-traumatic hypovolemic shock.

**CLINICAL RELEVANCE/APPLICATION**

Signs of shock thyroid on CT may prove to be earlier imaging signs of existing/impeding hypovolemic shock in trauma patients, better guiding early trauma patient management and possibly improving survival.

## W3-SSER02-5 ANALYZING THE PREVALENCE OF INJURY AND VIOLENCE IN TRANSGENDER PATIENTS UTILIZING RADIOLOGY REPORTS

Bharti Khurana, MD, MBA (*Abstract Co-Author*) Consultant, General Electric Company;Editor, Wolters Kluwer nv;Author, Cambridge University Press;Consultant, ROKIT Healthcare, Inc
Rohan Chopra (*Presenter*) Nothing to Disclose

**PURPOSE**

Recent research indicates a concerning trend of increased violence against transgender individuals with significant underreporting. This study aims to investigate the prevalence and disparities in reported injuries and potential violence between transgender female and cisgender female patients by

analyzing radiology reports.

**METHODS AND MATERIALS**

Using our institution's Research Patient Data Registry, we identified 560 trans-female patients aged 18 and older, each confirmed by at least two specific transgender-related ICD codes. Among these individuals, 283 patients (cases) had at least one radiological study. We compared the imaging utilization, number, and types of injuries reported in the radiology reports of these transgender patients against those of 875 cisgender age-matched female control patients. Rates of injuries between cases and controls were compared using crude odds ratios and Fisher's Exact Tests.

**RESULTS**

In our study cohort, 20.5% (58/283) of cases sustained 85 distinct injuries, averaging 1.6 injuries per person (ranging from 1 to 4). In contrast, 11.4% (100/875) of controls experienced 119 injuries, averaging 1.2 injuries per person (ranging from 1 to 6). Fisher's Exact Test revealed a statistically significant difference in the likelihood of injury, with an odds ratio of 2.0 ($p = 0.0002$). Musculoskeletal (MSK) injuries dominated both groups (78.8% vs. 74.7%). Craniofacial injuries were more prevalent among cases, occurring in 18.8% (16/85) of injuries compared to 5% (6/119) among controls, with an odds ratio of 4.37 ($p = 0.002$). Of 2,294 radiological studies in cases, 55.2% (1267) were focused on MSK or neurological issues, significantly higher than the 30% (4039/13462) observed in the control group, yielding an odds ratio of 2.88 ($p < 0.0001$).

**CONCLUSION**

Our study demonstrates increased injury rates in trans-female patients despite lower imaging utilization compared to cisgender females, with a higher proportion of musculoskeletal and neurological imaging studies.

**CLINICAL RELEVANCE/APPLICATION**

The clinical significance of our study lies in its revelation of heightened injury rates among trans-female patients despite the underutilization of imaging services. The prevalence of musculoskeletal and neurological imaging among trans females indicates a propensity to seek medical attention primarily for injury-related concerns, potentially influenced by obstacles in healthcare access and hesitancy toward preventive healthcare measures. Addressing these disparities is pivotal for delivering equitable and comprehensive healthcare services to the transgender community, thereby fostering improved health outcomes and well-being.

## W3-SSER02-6 DOES AI ASSISTANCE IMPROVE CLINICIAN INTERPRETATION OF INPATIENT AND EMERGENCY DEPARTMENT CHEST X-RAYS?

Fergus V. Gleeson, FRCR,MBBS (*Abstract Co-Author*) Stockholder, Optellum Ltd
Ruchir Shah, MD, MBBS (*Presenter*) Nothing to Disclose

**PURPOSE**

This study evaluates a commercial AI product from Lunit and the effect on reader performance with AI assistance for clinicians from a variety of different specialities and grades on inpatient and emergency chest x-ray (CXR) interpretation.

**METHODS AND MATERIALS**

A multi-reader multi-case study design was used to evaluate the performance of 30 clinicians. These clinicians came from a variety of backgrounds (radiologists, reporting radiographers, emergency, general internal and intensive care physicians) and grouped into 3 different grades (1-4 years postgraduate, 5-8 years postgraduate, 8 years postgraduate). They were tasked to provide their interpretation on 500 adult inpatient and emergency department CXRs which were identified from 2 large teaching hospitals. Readers were asked to identify the presence of 10 pathologies and give a confidence score for each interpretation. This was done without and then with AI assistance after a 4 week washout period.The case ground truth was determined by 2 thoracic radiology consultants. Arbitration by a further senior thoracic radiology consultant was done in cases of disagreement. AUC and ANOVA analysis was performed using the MRMCaov r package.

**RESULTS**

Standalone AI performance on the dataset ranged from 0.83-0.99. For 8 pathologies the AI achieved AUC above 0.9. The AI assistance showed a statistically significant improvement in performance for 8 out of the 10 pathologies for readers. There was no statistically significant difference for pneumoperitoneum and mediastinal widening. The greatest improvement was demonstrated for fibrosis (delta AUC 0.193).

**CONCLUSION**

AI assistance can improve a variety of clinicians ability to interpret emergency and inpatient chest x-ray findings.

**CLINICAL RELEVANCE/APPLICATION**

Many AI solutions exist which aim to classify common pathologies on CXRs. There have been studies which evaluate various AI solutions performance in interpretation against expert radiologist as well as studies that explore how AI aids interpretation by radiologists. However, previous work has failed to explore how AI can aide clinicians from patient facing specialities and those of differing grades, in their interpretation of CXRs. As the volume and complexity of radiological investigations performed on patients presenting to hospitals increases at a pace faster than the availability of timely expert reporting and interpretation, the urgent clinical decisions based on CXR findings are made by the patient facing clinicians own judgement and interpretation. Patient facing clinicians can make better decisions by using AI to improve their interpretation of chest xrays.

## W3-SSGI12-1 DEEP-HCC: RADIOMIC FEATURES DIFFERENTIATE PATHOLOGICAL GRADE OF HEPATOCELLULAR CARCINOMA ON MULTIPHASE MRI

Xinyi (Mimi) Li (*Abstract Co-Author*) Nothing to Disclose
Pedram Keshavarz, MD (*Abstract Co-Author*) Nothing to Disclose
Kyunghyun Sung, PhD (*Abstract Co-Author*) Nothing to Disclose
Abhinav Suri, BA, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

Hepatocellular carcinoma (HCC) is one of the most common causes of cancer-related death worldwide. Pathological grading of these tumors on pre treatment biopsy can provide critical information about the likelihood of recurrence after local therapy. While the pre-treatment biopsy is rarely done, pre-treatment multiphase MR imaging prior is common. We aim to use radiomic features of tumors from four temporal phase T1-weighted MR images (pre-contrast, arterial, portal, delayed phase) to predict the pathological grade of HCC lesions.

### METHODS AND MATERIALS

In this retrospective study, we included 22 patients for analysis after exclusion criteria were applied (Figure 1a). Among these patients, 11 had well differentiated, 2 had moderately differentiated, and 9 had poorly differentiated lesions. 3D segmentations of the biopsy proven HCC lesions (verified by a radiologist with 30+ yrs experience) were performed on one MR series.For analysis, four temporal phase MRI images (pre-contrast, arterial, portal, delayed phase) were co-registered with each other based on imputed patient position. The HCC lesion segmentation on one image was propagated across all images and a bounding box was cropped around the segmentation (with a 5mm boundary). These values (Z score standardized relative to background) were input to PyRadiomics v3.1.0 to extract radiomic values for each MRI temporal phase. Additional values were generated by subtracting values for each pair of contrast phases and each radiomic feature (e.g., average[arterial] - average[delayed]) to generate a total of 644 features. These were used to select an optimal clustering algorithm (out of 9) that best-separated lesions by pathological grade (n clusters selected by elbow method using PyCaret v3.3.2, Figure 1b).

### RESULTS

K-Modes was found to be the best clustering algorithm (with n=2 clusters), achieving a complete separation between well-differentiated and poorly differentiated lesions (moderately differentiated lesions split between two clusters, Figure 1c). Out of the 110 features that were included (features with high collinearity and low variance were removed), 5 intensity-based features showed significant differences (t-test, $p<.001$) between the two clusters (Figure 1d).

### CONCLUSION

Radiomics features of HCC lesions on co-registered four phase MR images can successfully differentiate well from poorly differentiated HCC. Future directions of study include creating a prospective model for the prediction of lesion differentiation on imaging.

### CLINICAL RELEVANCE/APPLICATION

These radiomic values can be used to risk-stratify patients for therapeutics and monitoring based on initial imaging for HCC since pre-treatment biopsy has been shown to predict HCC recurrence rates.

## W3-SSGI12-2 LESION CO-REGISTRATION IN LIVER CT SCANS: A FULLY AUTOMATIC PIPELINE FOR RADIOLOGICAL FOLLOW-UP

Michael Uder, MD (*Abstract Co-Author*) Nothing to Disclose
Markus Kopp (*Abstract Co-Author*) Speakers Bureau, Siemens AG
Julia Rodriguez-Comas (*Abstract Co-Author*) Nothing to Disclose

Meritxell Riera I Marin (*Abstract Co-Author*) Nothing to Disclose
Daniel Canadas (*Abstract Co-Author*) Nothing to Disclose

Juan Moreno Vedia (*Abstract Co-Author*) Nothing to Disclose
Maximilian Schmidt (*Presenter*) Nothing to Disclose

**PURPOSE**

Radiological follow-up is a fundamental task for radiologists, requiring the analysis of multiple prior CT scans to assess lesion evolution and treatment efficacy. Within the complex abdominal anatomy, characterized by diverse structures and temporal changes, accurate co-registration of focal liver lesions across successive scans is crucial. In this study, we investigate the co-registration of liver lesions across different abdominal CT scans from individual patients, considering the lesions' temporal evolution. This method assigns a unique identification to each lesion detected at a single time-point and tracks its spatial position across consecutive imaging tests.

**METHODS AND MATERIALS**

This study presents a fully automatic end-to-end pipeline for analyzing changes in liver lesions across consecutive abdominal CT scans in oncology patients. The methodology integrates state-of-the-art registration methods for lesion co-registration. Lesions from subsequent studies are registered onto lesions in the first available study of the patient, and coincident lesions are assigned the same ID based on DICE score overlapping. To validate our method, we used a preliminary unique dataset from 68 clinical abdominal CT scans of 34 patients with a variety of focal liver lesions, expertly delineated by a radiologist.

**RESULTS**

The results demonstrate the efficacy of the proposed pipeline in accurately tracking lesions in the liver across successive CECT scans. In our preliminary results the pipeline exhibited excellent tracking accuracy, with a 100% mean accuracy rate in lesion co-registration. This level of precision facilitated the precise identification and tracking of individual lesions within the liver, enabling automated monitoring of lesion evolution, including changes in various parameters indicative of malignancy such as size, shape, or enhancement patterns.

**CONCLUSION**

The automated pipeline represents a promising approach to enhance the accuracy of clinical decision-making especially in radiological oncology. By streamlining liver lesion analysis and co-registration in abdominal CT scans, it offers valuable insights into disease progression and treatment effectiveness, ultimately leading to improved patient care.

**CLINICAL RELEVANCE/APPLICATION**

Comparing the development of liver lesions in CT scans over different time points represents a significant part of the daily work for many radiologists. An automated pipeline would greatly facilitate this task and at the same time enhance the quality of the comparison, by implying a wider range of metrics. These developments might be key in tackling future challenges such as rising number of studies or staff shortages.

## W3-SSGI12-3 HOW DOES ULTRASOUND COMPARE TO CROSS-SECTIONAL IMAGING IN THE WORKUP AND SURVEILLANCE OF FONTAN LIVER DISEASE

Ciara O'Brien, FRCPC, MBBCh (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance of ultrasound (US) for detecting liver cirrhosis and nodules in an adult population with Fontan circulation. To determine correlation between liver cirrhosis and mortality/transplantation. This is the 1st study to evaluate the diagnostic accuracy of US for the surveillance of Fontan liver disease in an adult population.

**METHODS AND MATERIALS**

This retrospective study, conducted at a single center. Patients with Fontan operation, older than 18 years old, followed at the our Adult Congenital Heart Disease Program between September 2015 and September 2022 who had a liver US and liver CT or MRI within 12 months apart, were included.The diagnostic accuracy of liver US for each liver finding was assessed against the cross-sectional imaging findings; sensitivity, specificity, positive predictive value , and negative predictive value were estimated for all variables. Agreement between the different methods was evaluated using the kappa index. A kappa value of 0-0.20 was considered slight agreement, 0.21-0.40 fair agreement, 0.41-0.60 moderate agreement, 0.61-0.80 substantial agreement, and 0.81-1.00 almost perfect agreement. All tests were considered significant in $p<0.05$.

**RESULTS**

131 patients met the inclusion criteria, mean age 34.4 ± 10.1 years, 57 (43.5%) females. The most common type of Fontan was an extracardiac conduit, 66 patients (50.3%). Liver US reported heterogeneous parenchyma, lobar redistribution, and surface nodularity in 85.4%, 72.5%, and 65.6%. Cross-sectional imaging reported the same features in 60.3%, 87.0% and 84.9%, respectively. US sensitivity was more than 0.75 for all variables, specificity was 0.21, 0.58 and 0.85 consequently. Liver US had sensitivity of 0.89 and specificity of 0.73 in defining hepatic nodules, with substantial agreement (kappa 0.64) between techniques. Liver cirrhosis was diagnosed in 78% and 90% of the population by US and cross-sectional respectively. Kappa agreement between techniques was 0.21. There was no correlation between presence of hepatic parenchymal changes or the presence of cirrhosis with mortality/transplantation.

**CONCLUSION**

US is appropriate for screening and surveillance of liver cirrhotic features in the adult Fontan population. Liver US accurately identifies small and large liver nodules. Liver cirrhosis does not correlate to mortality and transplantation.

**CLINICAL RELEVANCE/APPLICATION**

This study shows for the first time that US can be used accurately to detect features of liver cirrhosis and hepatic nodules in patients with Fontan circulation.

## W3-SSGI12-4 DIFFERENTIATING LIVER ADENOMA FROM FOCAL NODULAR HYPERPLASIA USING A NOVEL MECHANICAL TRANSDUCER FOR MRE: A PROSPECTIVE STUDY WITH GADOXETIC ACID-ENHANCED MRI AS THE REFERENCE STANDARD

Philipp Reschke, MD (*Abstract Co-Author*) Nothing to Disclose
Jan-Erik Scholtz, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study evaluates a novel mechanical Magnetic Resonance Elastography (MRE) transducer for differentiating focal nodular hyperplasia (FNH) from liver adenoma based on mechanical tissue properties.

**METHODS AND MATERIALS**

Sixteen patients (13 women, 3 men; median age 41; interquartile range 35-46) who had undergone gadoxetic acid-enhanced MRI for differentiating FNH from liver adenoma were enrolled in this prospective study. Two experienced radiologists with 35 and 16 years of experience in liver imaging provided a reference standard based on the contrast-enhanced MRI images. MRE exams were performed using a novel mechanical transducer 15 to 45 days following the MRI. Localization and volumetric analysis of lesions were conducted using the gadoxetic acid-enhanced MRI data. Unenhanced MRI, including T2-weighted and DWI-weighted imaging, aided in lesion localization. Mechanical properties (kPa) of each lesion were measured during MRE; mean kPa values were computed and compared using Student's t-test. Diagnostic accuracy was assessed through confusion matrices.

**RESULTS**

The mean stiffness for FNHs was 3.7 kPa (range, 3.2 - 4.2 kPa), and the mean stiffness for adenomas was 2.3 kPa (range, 1.9 - 2.7 kPa). There was no significant association between lesion size and stiffness values in both FNHs and adenomas ($P = 0.4$). No overlap in stiffness between FNHs and adenomas was noted. Utilizing a stiffness threshold of 3.05 kPa resulted in a diagnostic accuracy of 100%. Stiffness maps showed homogeneous stiffness in adenomas and increased peripheral stiffness in FNHs with reduced stiffness in the central scar area, mimicking the appearance in contrast-enhanced scans.

**CONCLUSION**

A novel mechanical transducer for MRE can accurately differentiate focal nodular hyperplasia from liver adenoma via estimation and visualization of lesion stiffness.

**CLINICAL RELEVANCE/APPLICATION**

We demonstrate that magnetic resonance elastography using a novel mechanical transducer can distinguish focal nodular hyperplasia and liver adenoma without the requirement for intravenous contrast agents. The stiffness maps generated are closely aligned with contrast-enhanced MRI visualizations of FNH. This method is particularly useful when contrast agents are unavailable or contraindicated, offering an alternative for liver lesion characterization.

## W3-SSGI12-5 PER ORAL GADOXETIC ACID ENHANCED LIVER MRI IN A MOUSE HEPATIC METASTASIS TUMOR MODELPER ORAL GADOXETIC ACID ENHANCED LIVER MRI IN A MOUSE HEPATIC METASTASIS TUMOR MODEL

Honsoul Kim (*Presenter*) Nothing to Disclose

**PURPOSE**

To establish a liver MRI protocol based on per oral gadoxetic acid (liver selective contrast agent which 50% is taken up by the hepatocytes) administration using a mouse liver tumor model.

**METHODS AND MATERIALS**

Our institutional IACUC approved this study. 37 female BALB/c nude mice (8 weeks old) were used, of which liver tumor model was generated in only 27 mice (but 3 mice failed to generate a gross tumor) in order to achieve a mixed pool of tumor bearing and non-bearing mice. Liver tumor model was generated by surgically implanting Lewis lung carcinoma cells in the liver. A 7T scanner (Biospec 70/30 USR, Bruker., Ettlingen, Germany) was used for MRI. For contrast enhancement, gadoxetic acid (0.3mmol/Kg body weight, dose was determined by an equation calculating the equivalent inter-species dose adjusting body surface area) was delivered via an orogastric tube. Precontrast and post-contrast (15, 30, 45, 60, 75 minutes) T1WI and T2WI with fat suppression were obtained. The degree of liver enhancement was quantitatively measured by placing regions of interest on the liver and paravertebral muscle calculating their mean signal intensity (SI). The liver-to-muscle signal intensity ratio of each enhancement phase was calculated according to the following equation: Signal intensity ratio(liver/muscle) = (ROILiver1+ROILiver2)/(2×ROIm). After MRI was complete, autopsy was performed to confirm the liver tumor. Paired t-test was performed to compare the relative SI ratio of each sequence. A P-value $<0.05$ was considered as statistically significant.

**RESULTS**

None of the tumors could be confidently identified on precontrast T1WI. Post-enhancement (75 minutes) T1WI revealed either focal tumor lesions (n=14) or multiple tumor lesions (n=6), but failed to detect tumor in 4 mice. The liver-to-muscle signal intensity ratio has statistically significantly increased at all time points ($P<0.01$) when compared with that of the precontrast sequence (precontrast=1; post-30 minutes=1.42±0.24, $P<0.01$; post-75minutes=1.54±0.31, $P<0.01$).

**CONCLUSION**

MRI based on per oral gadoxetic acid administration induced significant liver enhancement which considerably improved tumor delineation.

**CLINICAL RELEVANCE/APPLICATION**

1. Liver MRI protocol can be established based on per oral gadoxetic acid administration at least in mice, and if reproducible in human may be applied to abbreviated liver MRI to further enhance study feasibility and reduce study cost. 2. The gadoxetic acid bowel reabsorption capacities suggest a concept of pharmacokinetic enterohepatic reentry circuit which may serve to prolong gadoxetic acid clearance especially in patients with impaired renal function (and raise the risk of Gd retention complications).

## W3-SSGI12-6 ESTIMATING EFFICACY OF CONVERSION THERAPY ON PATIENTS WITH INITIALLY UNRESECTABLE COLORECTAL CANCER LIVER METASTASES BY USING MRI: DEVELOPMENT OF A PREDICTIVE SCORE

Jingjing Liu (*Presenter*) Nothing to Disclose

## PURPOSE

The conversion success rate (CSR) has crucial implication for clinical outcomes of initially unresectable colorectal liver metastases (CRLM) following conversion therapy. This study aimed to develop a simple predictive scoring model for identifying CSR according to baseline magnetic resonance imaging (MRI) features, and confirm its performance and prognostic significance in a validation cohort.

## METHODS AND MATERIALS

A total of 155 consecutive patients with initially unresectable CRLM were retrospectively reviewed in the study. A simple MRI-based predictive scoring model for identifying CSR was developed in the development cohort (n=104) by using multivariable logistic regression analyses. The diagnostic performance was evaluated for the predictive score. Thereafter, patients in the validation cohort (n=51) were stratified into groups with predicted high CSR or low CSR according to the score. The progression-free survival (PFS) and overall survival (OS) were compared between two groups using the log-rank test.

## RESULTS

The predictive score of CSR, named mrNISE, incorporated the number of CRLM = 10, the largest size = 50 mm, poorly defined tumor-liver interface, and peritumoral enhancement. The AUC of the mrNISE score was 0.845 for the development cohort and 0.776 for the validation cohort. According to the score, patients with predicted high CSR had better PFS and OS than those with low CSR in both development and validation cohorts.

## CONCLUSION

The predictive score demonstrated great performance for identifying CSR of initially unresectable CRLM.

## CLINICAL RELEVANCE/APPLICATION

The predictive score demonstrated great performance for identifying CSR of initially unresectable CRLM.

### PURPOSE

To assess the diagnostic performance of hemodynamic parameters measured with navigator-gated 4D flow MRI in the splanchnic vasculature for diagnosis of severe portal hypertension [hepatic venous pressure gradient (HVPG)=12 mmHg] and prediction of liver decompensation in patients with chronic liver disease.

### METHODS AND MATERIALS

56 patients (M/F 30/26, age 51±15y) with chronic liver disease and suspicion of portal hypertension (PH) were enrolled in our prospective study. Patients had transjugular liver biopsy with HVPG measurements (6±5 mmHg, 0-22 mmHg) within one month of multiparametric abdominal MRI at 1.5T. 4D flow MRI data was acquired 10 min. after injection of gadoxetic acid with a prototype respiratory navigator-gated pulse sequence, covering the abdominal vessels in coronal-oblique orientation (VENC=60 cm/sec, TR/TE/FA: 5.9 ms/3.4 ms/15°, 3 k-space segments/cardiac frame, 70.8 ms temporal resolution, 9-12 cardiac phases, 24 slices, resolution 2.5x2.5x2.5mm3). The portal (PV), superior mesenteric (SMV), splenic (SV) and middle hepatic veins (MHV), the supraceliac aorta and its celiac branches were segmented (Fig.1) by two independent observers. Time-averaged vessel cross-section area, through-plane time-averaged velocity and flow, and peak velocity were compared between patients with/without severe PH, and with/without future liver decompensation (varices, ascites or hepatic encephalopathy) by Mann-Whitney U test and ROC analysis.

### RESULTS

25 (45%) patients had PH, of which 8 (14%) had severe PH. Decompensation was diagnosed in 7/52 (13%) patients within 619±220 days from MRI. Celiac trunk peak velocity [AUC(95%CI)=0.90(0.81-0.99)] and superior mesenteric vein area [AUC= 0.89(0.79-0.99)] identified severe PH with the highest diagnostic performance. A logistic regression model combining peak velocity in the celiac trunk and superior mesenteric vein flow identified severe PH with AUC=0.950, sensitivity=1 and specificity=0.89. Superior mesenteric vein flow [AUC(95%CI)=0.79(0.66-0.94)] and area [AUC(95%CI)=0.78(0.63-0.94)], as well as hepatic artery area [AUC (95%CI)=0.74 (0.55-0.93)] predicted decompensation with good diagnostic performance.

### CONCLUSION

Splanchnic 4D flow MRI measurements have excellent performance for diagnosing severe PH and good performance for predicting liver decompensation. The elevated hemodynamic parameters in patients with severe PH are consistent with hyperdynamic circulation in portal hypertension.

### CLINICAL RELEVANCE/APPLICATION

Hemodynamic measurements in the splanchnic circulation with 4D flow MRI reflect compensatory mechanisms in PH, and have the potential to non-invasively diagnose severe PH and predict liver decompensation.

## W3-SSGI13-2 LIVER STIFFNESS VS. GADOXETATE HEPATOBILIARY UPTAKE SCORES FOR PREDICTION OF OUTCOME IN PATIENTS WITH ADVANCED CHRONIC LIVER DISEASE

### PURPOSE

To correlate MRI-based markers including liver stiffness (LS), liver/spleen volumes, and gadoxetate uptake scores: FLIS (Functional Liver Imaging Score) and Liver to Spleen Index (LSI) both measured on hepatobiliary phase (HBP) with liver function in patients with advanced CLD (ACLD); as well as to compare the performance of MRI-based markers to blood tests for prediction of outcomes in the same patients.

### METHODS AND MATERIALS

This was a single-center retrospective study in which we assessed 87 patients (M/F 56/31, mean age 57±14y) with ACLD and histopathologic fibrosis stage of F3/F4 (advanced fibrosis/cirrhosis), who underwent gadoxetate-enhanced MRI with MRE and clinical follow up of at least 2y. Additionally, laboratory values were collected (within 3m from index MRI). LS was measured using 2D GRE/EPI MRE. FLIS (qualitative score determined by liver enhancement, portal vein intensity and biliary excretion at HBP, LSI=signal intensity (SI) liver at HBP/SI spleen at HBP, liver/spleen volume were also measured by 2 observers. Outcomes such as hepatic decompensation, HCC occurrence, transplant and death were collected.

### RESULTS

Patients were classified at baseline as compensated (cACLD, n=52) and decompensated (dACLD, n=35). 32 decompensation events were observed during follow-up in 24 patients (including 16 from baseline dACLD), additionally 36 outcomes (HCC occurrence, transplant, and death) were observed. FLIS (Fig. 1) outperformed all MRI markers in diagnosing decreased liver function based on MELD and Child-Pugh scores (CPS) with AUC up to 0.86 [CI, 0.77-.096], LS (Fig. 2) had lower performance with max AUC of 0.69 [0.53-0.84]. LS was a significant predictor of decompensation with AUC of 0.74 [CI, 0.63-0.85] equivalent to FIB-4 (0.73 [0.62-0.84]) and MELD-Na (0.71 [0.59-0.83]) whereas FLIS did not do as good with AUC of 0.68 [CI, 0.56-0.79]. CPS had the best performance for decompensation with AUC of 0.84 [0.75-0.92]. As for prediction of transplant or death the best MRI predictors were Liver/spleen volume ratio with AUC 0.76 [CI, 0.64-0.89] and FLIS with AUC of 0.71 [CI, 0.51-0.91] respectively. Multivariable logistic regression showed excellent performance when combining FIB-4, CPS and LS with AUC of 0.89 [0.82-0.96] for predicting decompensation.

### CONCLUSION

Our preliminary results suggest that FLIS is a better marker of decreased liver function than LS, while LS is superior to FLIS for prediction of decompensation in patients with ACLD. Future work will focus on assessing advanced markers such as spleen stiffness and 3D MRE markers.

### CLINICAL RELEVANCE/APPLICATION

Gadoxetate MRI and MRE can be used to assess liver function and predict outcome in patients with ACLD.

## W3-SSGI13-4 DEEP LEARNING RECONSTRUCTION OF PROSPECTIVELY ACCELERATED MR IMAGING OF THE PANCREAS: CLINICAL EVALUATION OF SHORTENED BREATH-HOLD EXAMINATIONS WITH DIXON FAT SUPPRESSION

Sebastian Werner, MD (*Abstract Co-Author*) Nothing to Disclose
Maryanna Chaika (*Abstract Co-Author*) Nothing to Disclose

Judith Herrmann, MD (*Abstract Co-Author*) Nothing to Disclose
Haidara Al Mansour, MD, MEng (*Presenter*) Nothing to Disclose

### PURPOSE

Deep-learning (DL)-enabled MRI reconstructions can enable shortening of breath-hold examinations and improve image quality by reducing motion artifacts.Prospective studies with DL reconstructions of accelerated MRI of the upper abdomen in the context of pancreatic pathologies are lacking. In a clinical setting, the purpose of this study is to investigate the performance of a novel DL-based reconstruction algorithm in T1-weighted volumetric interpolated breath-hold examinations with partial Fourier sampling and Dixon fat suppression (hereafter, VIBE-DixonDL) and to analyze its impact on acquisition time, image quality, pancreatic lesion conspicuity and diagnostic confidence.

### METHODS AND MATERIALS

This prospective study included participants with various pancreatic pathologies who gave written consent from Jan 2023 to Sep 2023. During the same session, each participant underwent two MRI acquisitions using a 1.5 Tesla scanner: conventional pre-contrast and post-contrast T1-weighted VIBE acquisitions with Dixon fat suppression (VIBE-Dixon, reference standard) using fourfold parallel imaging acceleration and sixfold accelerated VIBE-Dixon acquisitions with partial Fourier sampling utilizing a novel DL reconstruction tailored to the acquisition. Image analysis was performed by four readers. Acquisition time, overall image quality, diagnostic image noise and artifacts, diagnostic confidence as well as pancreatic lesion conspicuity and size were compared.

### RESULTS

Thirty-two participants were evaluated (mean age, 62 years ± 19 [SD]; 20 men). The VIBE-DixonDL method enabled up to 52% reduction in average breath-hold time (7 seconds for VIBE-DixonDL vs 15 seconds for VIBE-Dixon, $P < .001$). A significant improvement of image sharpness, overall image quality, diagnostic confidence and pancreatic lesion conspicuity were observed in the images recorded using VIBE-DixonDL ($P < 0.001$). Furthermore, a significant reduction of image noise and motion artifacts were noted in the images recorded using the VIBE-DixonDL technique ($P < 0.001$). In addition, for all readers there was no evidence of a difference in lesion size measurement between VIBE-Dixon and VIBE-DixonDL. Interreader agreement between VIBE-Dixon and VIBE-DixonDL regarding lesion size was excellent (ICC > 90).

### CONCLUSION

The prospectively accelerated, deep learning (DL)-enhanced VIBE with Dixon fat suppression was clinically feasible. It enabled a 52% reduction in breath-hold time and provided superior image quality, diagnostic confidence, and pancreatic lesion conspicuity.

### CLINICAL RELEVANCE/APPLICATION

This technique might be especially useful for patients with limited breath-hold capacity and might improve MR throughput and patient experience.

## W3-SSGI13-5 PREDICTING POSTOPERATIVE PANCREATIC FISTULA AFTER MAJOR PANCREATIC SURGERIES USING CONTINUOUS-TIME RANDOM-WALK DWI MODEL AND VIRTUAL MR ELASTOGRAPHY

Xinming Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Yongjian Zhu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Wei Cai (*Presenter*) Nothing to Disclose

### PURPOSE

Clinically relevant postoperative pancreatic fistula (CR-POPF) is the most clinically problematic complication after major pancreatic surgeries. The aim of this study was to investigate the performance of continuous-time random-walk (CTRW) diffusion model and virtual MR elastography (vMRE) for predicting the risk of CR-POPF in patients undergoing major pancreatic surgeries.

### METHODS AND MATERIALS

One hundred twenty-four patients with pancreatic tumors were recruited in this study. All patients underwent pancreatic MRI including multi-b-value (Mb) DWI sequence. The Mb-DWI data were acquired using ss-EPI sequence with 14 b values from 0 to 3000 s/mm2. Diffusion-based shear modulus (μDiff) from vMRE was calculated as: μDiff (kPa) = -9.8 · ln(S200/S1500) + 14. CTRW model parameter maps of temporal diffusion heterogeneity (a), spatial diffusion heterogeneity (ß), and anomalous diffusion coefficient (Dm) can be described as equation: Sb/S0 = Ea·[-(b·Dm) ß]. Mean values of maps in pancreatic parenchyma were obtained. The conventional apparent diffusion coefficient (ADC) maps were also calculated. CR-POPF is defined as grade B or C POPF. The differences in clinical-pathological features and quantitative parameters between CR-POPF and non-CR-POPF groups were analyzed. Multivariate logistic regression was used to build the combined prediction model for CR-POPF. The predictive performance was evaluated using ROC analysis.

### RESULTS

Twenty-six out of 125 patients were CR-POPF. BMI, albumin (ALB), pancreatic texture, operative blood loss, fibrosis grading, pancreatic thickness, and main pancreatic duct (MPD) diameter showed significant difference between the two groups (all $p < 0.05$) (Table 1). The CR-POPF group had higher ADC, ß, Dm, and μDiff values than non-CR-POPF (all $p < 0.05$) (Table 2) (Figure 1 and Figure 2). Clinical model was constructed by BMI, ALB, and MPD diameter. MRI model was built using ß, Dm, and μDiff. Combined model was constructed by employing the above six significant predictors and visualized using a nomogram (Figure 3). μDiff exhibited the best predictive performance among individual parameters with an AUC of 0.779 (Table 3). The combined nomogram significantly improved the predictive performance with an AUC, sensitivity, specificity, in identifying CR-POPF were 0.925, 84.61%, 94.95%, respectively (Figure 4).

### CONCLUSION

The CTRW diffusion model, vMRE, together with clinical features, offers a new method for preoperative assessment the risk of CR-POPF noninvasively.

### CLINICAL RELEVANCE/APPLICATION

For patients receiving major pancreatic surgeries, CTRW diffusion model and vMRE can provide noninvasive assessment of CR-POPF with good accuracy and high specificity.

## W3-SSGI13-6 EVALUATING LIVER FIBROSIS: PROSPECTIVE ASSESSMENT OF A NOVEL MECHANICAL TRANSDUCER FOR MAGNETIC RESONANCE ELASTOGRAPHY IN COMPARISON WITH TRANSIENT ULTRASOUND ELASTOGRAPHY

Simon S. Martin, MD (*Abstract Co-Author*) Nothing to Disclose
Vitali Koch, MD (*Abstract Co-Author*) Nothing to Disclose
Omar Darwish (*Abstract Co-Author*) Nothing to Disclose
Ralph Sinkus (*Abstract Co-Author*) Nothing to Disclose
Christian Booz, MD (*Abstract Co-Author*) Speaker, Siemens AG
Jennifer Gotta (*Abstract Co-Author*) Nothing to Disclose
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Leon D. Gruenewald, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate a novel mechanical Magnetic Resonance Elastography (MRE) transducer in comparison to acoustic transducers and transient ultrasound elastography for the non-invasive quantification of tissue biomechanics in patients with histologically confirmed metabolic dysfunction-associated steatohepatitis (MASH) and liver fibrosis.

### METHODS AND MATERIALS

Seventy-six participants (45 men, 31 women; mean age 53, SD 12.8) with suspected or confirmed liver disease were enrolled in this prospective study. MRE was conducted using a novel mechanical transducer (MT), established acoustic transducers (AT), and transient ultrasound elastography (TE) within a 30-day interval. Patient records and histopathological samples were reviewed if sampled within three months of MRE or AT assessments. Generalized additive models (GAMs) analyzed relationships and predictive values for fibrosis classification using MT, AT, and TE. Multiclass ROC analysis with micro-averaging determined AUC values for precise fibrosis classification. ROC analysis was repeated after dichotomization of fibrosis into low-grade (0-2) and high-grade (3-4). Agreement between device-based classifications and histopathological grading was assessed using Cohens Kappa.

### RESULTS

Twenty-eight patients who underwent MT, AT, and TE had histopathological samples taken within 3 months (14 men, 14 women; mean age 57, SD 14). Agreement between histopathological fibrosis grading and MT, AT, and TE were 0.85, 0.77, and 0.71, respectively. GAMs showed an almost linear relationship between MT and TE up to 6 kPa; beyond this, TE values plateaued despite increased stiffness in MT. ROC analysis confirmed excellent discriminatory value in differentiating low-grade from high-grade fibrosis (MT: 0.99, AT: 0.97, TE: 0.96). In multiclass ROC, AUC values were 0.90, 0.87, and 0.85. Ordinal GAMs indicated a higher predictive value for MT (deviance explained 86.7%, AIC 31.4) and AT (deviance explained 80.4%, AIC 37.3) compared to TE (deviance explained 54.5%, AIC 60.0).

## CONCLUSION

The novel mechanical transducer for MRE shows better alignment with histopathological samples compared to acoustic transducers and transient elastography to further enhance the diagnostic accuracy and predictive value in the non-invasive assessment of liver fibrosis.

## CLINICAL RELEVANCE/APPLICATION

We demonstrate that magnetic resonance elastography using a novel mechanical transducer provides more precise fibrosis grading compared to established acoustic transducers and transient ultrasound elastography. Adopting this transducer can offer a reliable alternative for the early detection of liver fibrosis and the assessment of fibrosis progression in patients with MASH.

## W3-SSGI14-1 COLORECTAL CANCER DETECTION ON ROUTINE ABDOMEN/PELVIS CT

Omar Hassan, MD (*Abstract Co-Author*) Nothing to Disclose
Spencer C. Behr, MD (*Abstract Co-Author*) Grant, Cancer Targeted Technology;Scientific Advisory Board, Novartis AG;Research Consultant, GenVivo
Stephen G. Wahlig, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the performance of routine abdomen/pelvis CT in detecting colorectal cancer.

### METHODS AND MATERIALS

A retrospective dataset consisting of 204 routine abdomen/pelvis CTs was compiled based on review of our institution's pathology/imaging archives. 64 cases had pathologically confirmed colorectal cancer, while 140 cases had no colonic neoplasms on colonoscopy. Two radiologists blinded to the patient history and imaging indication reviewed the cases independently. They scored each case for any colonic abnormality which could represent colorectal cancer. The imaging abnormality location, morphology, presence of regional lymphadenopathy, and degree of diagnostic confidence were recorded.

### RESULTS

Reviewers demonstrated a sensitivity of 64-77% and specificity of 83-86% for detection of colorectal cancer. Detected tumors were significantly larger than missed cancers, with mean maximum diameter of 5.2-5.7 cm for detected cancer (n=81) and 2.8-2.9 cm for missed cancer (n=25) (reviewer 1 $p<.001$; reviewer 2 $p=.02$). Positive predictive value (PPV) strongly correlated with diagnostic confidence, with 100% of pooled cases (39/39) reported as 5 (Almost Certainly Neoplastic) positive for cancer compared to 53% of cases (17/32) reported as 3 (Could be Benign or Neoplastic). The presence of regional lymphadenopathy was a strong predictive feature, with 94% of pooled cases with identified lymphadenopathy (48/51) positive for cancer compared to 51% (42/82) without lymphadenopathy ($p<.001$). Abnormalities characterized as polypoid intraluminal masses and exophytic masses demonstrated pooled PPV of 92% (11/12) and 100% (4/4) respectively, compared to 76% (25/33) for asymmetric wall thickening and 60% (50/84) for circumferential wall thickening. Cases classified as false negatives included low rectal tumors, tumor within a collapsed segment of colon, and cases with regional lymphadenopathy in the absence of discernable colonic wall abnormality on CT. False positives primarily consisted of colonic wall thickening secondary to an acute inflammatory pathology such as diverticulitis or perforated appendicitis.

### CONCLUSION

While colorectal cancers greater than 3 cm were detected with relatively high specificity, abdomen/pelvis CT performed poorly with lesions smaller than 3 cm. In our cohort, radiologist-reported diagnostic confidence was strongly associated with diagnostic accuracy. Regional lymphadenopathy, polypoid intraluminal masses, and exophytic masses are each highly specific findings, although insensitive.

### CLINICAL RELEVANCE/APPLICATION

Routine abdomen/pelvis CT may be helpful for identifying advanced cancer requiring further workup but is not sensitive enough to replace optical colonoscopy or CT colonography.

## W3-SSGI14-2 DEVELOPMENT OF MESENTERIC PANNICULITIS FOLLOWING BRAF/MEK INHIBITOR TREATMENT

### PURPOSE

In recent years, BRAF/MEK inhibitors (BRAFi/MEKi) together with PD-1 and CTLA-4 immune checkpoint inhibitors (ICI) have changed therapeutic strategy in advanced malignant melanoma and significantly improved patients' clinical outcome. However, these therapies can also be associated with immune-related side effects. While recent studies reported an increased rate of panniculitis of the skin following BRAFi/MEKi treatment, data on the development of mesenteric panniculitis (MP) are scarce. Because MP has been reported to mimic malignancy, we investigated the development of MP following BRAFi/MEKi treatment compared to ICI treatment in advanced melanoma.

### METHODS AND MATERIALS

In a monocentric retrospective study, abdominal CTs of patients [n = 486 patients] with malignant melanoma >= stage IIIa were evaluated for the development of MP. Patients were either treated with BRAFi/MEKi (Dabrafenib/Trametinib, Vemurafenib/Cobimetinib, Encorafenib/Binimetinib) or ICI (Nivolumab, Ipilimumab, Pembrolizumab, Nivolumab/Ipilimumab). Occurrence of MP was analyzed only during first-line treatment with either BRAFi/MEKi or ICI. MP was defined as the detection of at least three out of five imaging criteria (increased mesenteric density, increased number of lymph nodes, fat-ring sign, pseudocapsula, displacement of bowel segments). Explorative data analysis was performed and groups were compared using chi-square test. $p<0.05$ indicated statistical significance.

### RESULTS

100 BRAFi/MEKi first-line therapy periods (median follow-up 303 d, IQR: 379d) in 100 patients (41 women, median age at therapy start 58yrs, IQR: 18yrs) and 436 ICI first-line therapy periods (median follow-up 165 d, IQR: 256 d) in 386 patients (162 women, median age at therapy start 61yrs, IQR: 21yrs) were evaluated. Incidence of MP was significantly higher following BRAFi/MEKi therapy compared to ICI (6.4% vs. 2.5%, $p=0.044$). No significance was detected comparing time until MP development from therapy start (214d, IQR: 235d [BRAFi/MEKi] vs. 243d, IQR: 317d [ICI], $p>0.05$).

### CONCLUSION

Our study demonstrates a significant correlation between the development of mesenteric panniculitis and treatment with BRAF and MEK inhibitors compared to immune checkpoint inhibitors in patients with malignant melanoma. Since this benign condition can mimic malignancy, awareness of its appearance is important.

### CLINICAL RELEVANCE/APPLICATION

BRAF/MEK inhibitor treatment is associated with a significant higher rate of mesenteric panniculitis in malignant melanoma patients. Because it can mimic malignancy, awareness of this benign finding is important.

## W3-SSGI14-3 A STUDY ON DOSE CALIBRATION METHODS FOR CONSTANT RADIATION DOSE MANAGEMENT IN SINGLE PHASE ABDOMINAL-PELVIC CT SCAN

Chang Min Dae (*Abstract Co-Author*) Nothing to Disclose
Jinhee Lim (*Abstract Co-Author*) Nothing to Disclose
Yong Hwan Chung, RT (*Abstract Co-Author*) Nothing to Disclose
Joohyun Kim, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

CT Equipment varies between manufacturers and models with respect to components such as the X-ray tube, detector, and Automatic Exposure Control (AEC) modes. However, if the radiation dose required to achieve similar image quality is significantly higher compared to other equipment, it may indicate a potential error in the protocol. The purpose of this study is to conduct dose calibration for each equipment to minimize the differences in patient radiation dose between equipment, and to manage the radiation dose received by patients during Single phase Abdominal-Pelvic CT (SAPCT) scan.

### METHODS AND MATERIALS

The study included eight CT scanners from two manufacturers, featuring seven models, ranging from 64 to 512-slice MDCT (A~H). To compare the Dose Length Product (DLP) values of 8 scanners, the SAPCT protocol was performed 5 times using an anthropomorphic abdominal phantom (Kyoto Kagaku). Additionally, DLP values of 1679 patients who underwent SAPCT from October to November 2023 was extracted using the dose management system (DoseM, INFINITT). Median DLP values were analyzed using a Box Whisker Plot chart (MedCalc, version 10.0). The Target DLP was set based on Diagnostic Reference Levels (DRLs) provided by the Korea Disease Control and Prevention Agency (KDCA), and the target mAs was calculated according to the proportional equation. We identified the equipment that needed calibration and then applied the target mAs to perform phantom tests and patient SAPCT (100 patients per equipment, from February to March 2024). Median DLP values from which dose calibration was performed were compared with the DRLs value. Phantom image quality was evaluated using Signal-to-Noise Ratio (SNR), and patient image quality was evaluated by three radiologists using a Likert scale.

### RESULTS

Before calibration, the mean DLP from phantom tests ranged between 190.1 and 327.7 mGy*cm, and the median DLP from patient SAPCT was between 298.3 and 494.4 mGy*cm. The set target DLP was 400 mGy*cm, and the equipment identified as requiring calibration are models A and D, for which the Target mAs was calculated as 303 and 307, respectively. Post-calibration results showed that the mean DLP for phantom tests was 261.5 and 260.7 mGy*cm, respectively, while the median DLP for patients was 374.8 and 389.8 mGy*cm. Regarding image quality, SNR decreased from an average of 11.5 to 9.8, with a Likert scale rating of 4.7.

### CONCLUSION

If the methods described in this paper are applied to periodically verify and calibrate the dose for each equipment, it will be possible to minimize dose variations among different equipment and manage them in an integrated manner.

### CLINICAL RELEVANCE/APPLICATION

For patient safety, this approach can be utilized as one of the methods to optimize medical radiation dose.

## W3-SSGI14-4 ONE STEP CLOSER TO THE K-EDGE: PIONEERING CLINICAL FINDINGS OF 60 KVP LOW-DOSE CONTRAST-ENHANCED ABDOMINAL CT WITH ARTIFICIAL INTELLIGENCE ITERATIVE RECONSTRUCTION

Guozhi Zhang (*Abstract Co-Author*) Nothing to Disclose
Yixuan Zou, MS (*Abstract Co-Author*) Employee, Shanghai United Imaging Healthcare Co, Ltd
Peng Liu (*Abstract Co-Author*) Nothing to Disclose
Wenjie Sun (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic image quality and radiation dose of 60 kVp low-dose abdominal contrast-enhanced CT with artificial intelligence iterative reconstruction (AIIR).

### METHODS AND MATERIALS

A total of 57 patients (No. of male: 25, age: 18-82 y, body mass index: 17.3-27.6 kg/m2) were prospectively enrolled to undergo both standard- (120 kVp, 100 mAs) and low-dose (60 kVp, 200 mAs) four-phase abdominal enhanced CT scans on a 320-row scanner within a week. Each scan contained

non-enhanced, arterial, venous, and delayed phase acquisitions. Standard-dose data were reconstructed with hybrid iterative reconstruction (HIR) served as the reference (Group Ref), while low-dose data were reconstructed using AIIR (Group A) and HIR (Group B). Image contrast and diagnostic confidence were evaluated using 5-point Likert scales (1-poor, 5-good) and compared between any paired groups via Wilcoxon signed-rank test. The diagnostic performance of Groups A and B in benign-malignant classification was analyzed using receiver operating characteristic (ROC) analysis on both per-patient and per-lesion basis. Consensus criteria from three radiologists based on Group Ref image were employed as diagnostic standard. Additionally, image noise on lesions was recorded and compared.

**RESULTS**

For the 57 patients, 60 kVp low-dose acquisition significantly reduced the mean effective radiation dose by 78.9% compared to the standard-dose acquisition (4.8 ± 1.1 mSv vs. 22.8 ± 3.3 mSv). No significant difference was found between Groups A and Ref in terms of image contrast (4.6 ± 0.5 vs. 4.7 ± 0.4, p = 0.083) and diagnostic confidence (4.8 ± 0.3 vs. 4.9 ± 0.2, p = 0.157). Based on Group Ref image, a total of 18 lesions were identified in 15 patients, with 8 lesions were classified as malignant. Group A demonstrated superior diagnostic performance in benign-malignant classification compared to Group B, with the area under the curve (AUC) being 0.93 (95% CI, 0.67-0.99) vs. 0.57 (95% CI, 0.30-0.82) on a per-patient basis and 0.94 (95% CI, 0.74-0.99) vs. 0.56 (95% CI, 0.32-0.77) on a per-lesion basis (p = 0.012 and p = 0.003, respectively). No statistical difference was observed between Groups A and Ref regarding image noise on lesions (26.8 ± 9.9 HU vs. 25.9 ± 5.0 HU, p = 0.776).

**CONCLUSION**

The 60 kVp low-dose acquisition combined with AIIR can significantly lower radiation exposure in abdominal contrast-enhanced CT without compromising image quality and diagnostic performance.

**CLINICAL RELEVANCE/APPLICATION**

The 60 kVp low-dose acquisition with AIIR has the potential to revolutionize CT abdominal screening by significantly reducing radiation exposure while maintaining high diagnostic performance.

## W3-SSGI14-6 HEART-LIVER MRI FOR THE EVALUATION OF MYOCARDIAL INFLAMMATION AND FIBROSIS IN AN ANIMAL MODEL OF LIVER CIRRHOSIS

Narine Mesropyan, MD (*Abstract Co-Author*) Nothing to Disclose
Oliver M. Weber (*Abstract Co-Author*) Nothing to Disclose
Franziska Schneider (*Abstract Co-Author*) Nothing to Disclose
Christoph Katemann (*Abstract Co-Author*) Employee, Koninklijke Philips NV

Dmitrij Kravchenko, MD (*Abstract Co-Author*) Nothing to Disclose
Johannes Chang (*Abstract Co-Author*) Nothing to Disclose
Alexander Isaak, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore and characterize cardiovascular abnormalities using multiparametric heart-liver MRI in an experimental animal model of liver cirrhosis.

**METHODS AND MATERIALS**

Cholestatic cirrhosis was induced in male Sprague-Dawley rats by bile-duct ligation (BDL). Sham-operated rats served as controls. Heart-liver MRI at 3T was performed in BDL rats after 3 weeks (3w-BDL group) and after 5 weeks (5w-BDL group) as well as in controls. Myocardial function was assessed using cine imaging in standard axes. Myocardial and hepatic T1, T2, and extracellular volume fraction (ECV) values were assessed. After the MRI scan, in-vivo portal pressure was measured. Serum biomarkers, gene expression studies, and histological examinations were performed to evaluate fibrotic and inflammatory abnormalities of the heart and liver.

**RESULTS**

BDL groups showed higher cardiac index (53±11 vs 67±23 vs 77±18 ml/min/m²; p=0.009), elevated left ventricular end-diastolic volume index (325±38 vs 375±57, 421±77 µl/m²; p<0.001) and elevated LV mass (321±34 vs 393±103, 395±69 mg/m²; p=0.021) compared to controls (sham vs BDL-3w vs BDL-5w). Myocardial T1, T2 and ECV values were elevated in BDL groups (T1: 946±29 vs 952±39 vs 987±39 msec; p=0.014; T2: 23±4 vs 32±3 vs 33±4 msec; p<0.001; ECV: 27±3 vs 32±3 vs 37±5; p<0.001; sham vs BDL-3w vs BDL-5w) and correlated with serum NT-proBNP levels (e.g., for T2: r=.560, p<0.001 or ECV: r=.537, p<0.001), myocardial CCL-3, MMP-9, and IL1b (e.g., for myocardial T2: r=.825, p<0.001). Interorgan correlations were found between quantitative myocardial parameters and parameters of hepatic fibrosis (e.g., hepatic CCL-3 and myocardial ECV: r.=552, p<0.001), inflammation (e.g., hepatic IL1b and myocardial T2: r=.678, p<0.001) and portal pressure (myocardial T2: r=.678, p<0.001). Quantitative cardiac MRI provides noninvasive, sensitive detection of hepatic cardiomyopathy, particularly diffuse myocardial edema/inflammation.

**CONCLUSION**

Functional cardiac remodeling and elevation of inflammatory and fibrotic biomarkers of the myocardium were found in preclinical models of cirrhosis. A marked increase in inflammatory gene expression suggests that hepatic cardiomyopathy is predominantly driven by systemic inflammation. Quantitative cardiac MRI provides noninvasive, sensitive detection of hepatic cardiomyopathy, particularly diffuse myocardial inflammation.

**CLINICAL RELEVANCE/APPLICATION**

This study may lay the groundwork for further clinical application of multiparametric MRI of the liver-heart axis and may reveal potential therapeutic approaches for cirrhotic cardiomyopathy.

### PURPOSE

To develop an artificial intelligence (AI) algorithm to assess axial T2W prostate MRI scans for motion corruption and overall quality to determine rescan necessity.

### METHODS AND MATERIALS

This three-site retrospective study included a total of 1412 axial T2W prostate MRI scans (median age, 67 years). Four experienced uro-radiologists (NT, AF, AK, JL) provided quality scores of the scans on an interval scale from 0-3 (0: uninterpretable, 1: marginally interpretable, 2: adequately diagnostic, 3: more than adequately diagnostic) with 65 of the scans scored by all four reviewers and 138 scans scored by exactly two reviewers. These scores were then collated and used as ground truth labels for a convolutional neural network (CNN). The 203 scans scored by two or more reviewers were left as a test set. The remaining data was split into a training set (1007 scans) and a validation set (203 scans). Of the 12 models developed, the chosen model was a 3D-DenseNet of depth 169, and performance was evaluated using Cohen's ? scores, accuracy, and area under the receiver operating characteristic curve (AUC). Results were binned into non-diagnostic (0 or 1) and diagnostic (2 or 3) to assess the model's ability to predict whether a rescan is required. These rescan predictions were then compared to the number of rescans performed clinically on a subset of 174 exams at one of the sites.

### RESULTS

On the test set, the chosen model accurately predicts expert radiologist quality assessment scores with a Cohen's ? of 0.658, indicating moderate agreement. This is comparable to the inter-rater reliability among the four reviewers (Cohen's ? scores between 0.688 and 0.791). The model also yielded rescan predictions at similar reliability to radiologists (model Cohen's ? = 0.537, reviewer ? between 0.577 and 0.703). The rescan prediction AUC was 0.867, suggesting a very strong ability to differentiate between diagnostic and non-diagnostic scans. Using the model, the clinical unnecessary rescan rate could be reduced by 35%.

### CONCLUSION

The proposed deep learning model accurately mimics expert radiologist image quality scores for axial T2W prostate MRI scans. Compared to the clinical operating point, the model could be used to guide MR technologists and decrease unnecessary rescans while maintaining the same rate of correct rescanning.

### CLINICAL RELEVANCE/APPLICATION

To optimize time management for prostate MRI, it is pertinent to ensure that scans are repeated only when necessary. In our clinic, the decision to rescan is made subjectively by an MR technologist during an exam. Guiding that process using the proposed AI model could greatly reduce the unnecessary rescan rate without compromising appropriate rescans.

**PURPOSE**

Evaluate potential improvements to false-positive rates when combining prostate MRI AI-based decision support, clinical data and radiologists' PI-RADS scores for the detection of Gleason grade group (GGG) =2 cancers.

**METHODS AND MATERIALS**

Clinical data (MRI, PSA, histopathology) and PI-RADS scores were obtained retrospectively. AI software was developed using biparametric (bpMRI) data from 5 study sites together with PROSTATEx (794 patients, GGG=2, prevalence 34%) to calculate prostate and transition zone (TZ) volume for PSA density (PSAD), segment lesions and score patients for likelihood of GGG=2 disease. Histological data from biopsy were used as ground truth, with MRI-negative patients not undergoing biopsy assumed negative. The impact of clinical data integration was tested using a blinded validation set of data from 6 sites (252 patients, 42 per site, 31% GGG=2), including 6 scanner models from 2 vendors, with different field strengths (1.5T/3T) and acquisition protocols. One site was unseen during development, and validation data from the other sites were from a later period than the development set. Models combining bpMRI AI, PSAD and PI-RADS data were trained using the development data. Validation data was used to obtain AUC metrics, and specificity was interpolated from a fixed sensitivity of 0.9. 95% confidence intervals were obtained via bootstrapping.

**RESULTS**

On the validation set, GGG=2 was detected by bpMRI AI with an AUC of 0.90 (0.87-0.94). Whole prostate PSAD alone had an AUC of 0.85 (0.8 - 0.89), and TZ-PSAD an AUC of 0.86 (0.82-0.90). At a sensitivity of 0.90, combining AI score with TZ-PSAD significantly improved specificity from 0.72 (0.55-0.80) to 0.81 (0.57-0.86, KS test p-value<0.001) and AUC to 0.91 (0.88-0.94). The original PI-RADS =3 scores, given by the radiologists working in a multidisciplinary team setting, had an AUC 0.95 (0.92-0.97). At a sensitivity of 0.90, incorporating AI, TZ-PSAD and PI-RADS scores significantly improved specificity from 0.88 (0.85-0.9) to 0.90 (0.86-0.94, KS tes p-value<0.001) and AUC to 0.96 (0.95-0.98, DeLong test p-value 0.013). GGG=2 cancer was found in 4/27 patients with PI-RADS 3. For this group, the model combining PI-RADS, AI score and TZ-PSAD missed 2 GGG=2 cancers but would have allowed 21 negative patients (12% of negative patients in the validation set) to avoid biopsy.

**CONCLUSION**

Combining PI-RADS, PSAD and AI offers substantial specificity improvement compared to AI or PI-RADS assessments alone. The use of AI and PSAD to risk-stratify is particularly relevant for PIRADS 3 cases.

**CLINICAL RELEVANCE/APPLICATION**

Specificity improvements through integration of AI in the clinical setting can potentially reduce false positive cases, further aiding patient selection for biopsy using MRI.

## W3-SSGU05-3 EVALUATION OF ARTIFICIAL INTELLIGENCE-ASSISTED TRANSPERINEAL BIOPSY PLANNING FOR PROSTATE CANCER DIAGNOSIS: A PROSPECTIVE COHORT STUDY

Anwar R. Padhani, MBBS, FRCR (*Abstract Co-Author*) Advisory Board, Siemens AG;Speakers Bureau, Siemens AG;Advisory Board, Lucida Medical Ltd;Stockholder, Lucida Medical Ltd
Tobias Penzkofer, MD (*Abstract Co-Author*) Researcher, Aprea Therapeutics AB;Researcher, Astellas Group;Researcher, AstraZeneca PLC;Researcher, Bristol-Myers Squibb Company;Researcher, Genmab A/S;Researcher, Incyte Corporation;Researcher, Lion Biotechnologies, Inc;Researcher, Takeda Pharmaceutical Company Limited

Charlie A. Hamm, MD,PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to evaluate the diagnostic efficacy of an FDA-cleared computer-assisted diagnosis (CAD) software compared to PI-RADS reporting in identifying prostate cancer (PCa) in men undergoing transperineal MRI-transrectal ultrasound fusion biopsies (MRI-TRUS TPB).

**METHODS AND MATERIALS**

Between January and July 2022, 262 patients were prospectively enrolled. Targeted biopsies were conducted based on radiological findings from reports of 27 different radiological practices and regions of interest (ROI) identified by the CAD software. Additionally, systematic biopsies were performed using a reduced scheme. The primary objective was clinically significant (cs)PCa detection based on PI-RADS and CAD reporting. Secondary objectives included evaluating agreement between the localization of index lesions in MRI reports and the CAD software, PCa detection in additional ROIs, and false positive rates for PI-RADS and CAD software reporting. Performance was assessed using free-response receiver operating characteristic curves and the exact Fisher-Yates test.

**RESULTS**

The median patient age was 68 years (IQR: 61-74), PSA level was 6.57ng/ml (4.98-10.73), and prostate volume was 46ml (33-62). Overall, csPCa was detected in 56% (146/262) of men, with a sensitivity of 92% and 97% (p=0.007) for PI-RADS- and CAD-directed TPB, respectively. In 4% (10/262) of cases, csPCa was solely detected by CAD-directed biopsies, while in 8% (22/262) additional csPCa lesions were identified. However, the number of targeted lesions increased by 54% (518 vs. 336), and the false-positive rate doubled (0.66 vs. 1.39; p=0.009).

**CONCLUSION**

The CAD-tool tested for TPB planning enhances csPCa detection but results in an increased number of sampled lesions and false positives.

### CLINICAL RELEVANCE/APPLICATION

AI-assisted biopsy planning improves sensitivity and detects multifocality of prostate cancer in men but increases biopsy targets by 54% and doubles false-positive cores. This may enable more personalized biopsy planning based on urological and patient preferences.

## W3-SSGU05-4 DEEP LEARNING-ACCELERATED ULTRAFAST MR IMAGING OF THE PELVIS TO IMPROVE SCREENING OF PELVIC METASTASES IN PATIENTS WITH SUSPICION FOR PROSTATE CANCER

Ralph Strecker (*Abstract Co-Author*) Employee, Siemens AG
Hannes Engel, MD (*Abstract Co-Author*) Nothing to Disclose

Tobias Scheef, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to compare the image quality and diagnostic confidence of prospectively accelerated deep learning (DL) reconstructed T1-weighted (T1w) imaging with conventional accelerated T1w imaging for the screening of pelvic metastases in prostate MRI.

### METHODS AND MATERIALS

In this prospective study, consecutive patients with clinical suspicion of prostate cancer were included. All patients underwent PI-RADS conform multiparametric MRI at 3T. In addition to the conventional T1w VIBE Dixon sequence, a research DL-accelerated sequence was acquired after intravenous contrast administration, both with 2 mm slice thickness. Image quality (sharpness, subjective noise, artifacts, and overall image quality) and diagnostic confidence regarding lymph nodes and bone lesions were assessed independently by two radiologists in random order and blinded to the type of sequence using a 5-point Likert scale (5=excellent). For quantitative assessment, signal homogeneity was measured in the piriformis muscle by calculating the coefficient of variation (CV). Wilcoxon signed-rank tests were used to compare the different image sets and the CV.

### RESULTS

A total of 50 patients were included (mean age 68±6.6). The DL-accelerated sequences showed a significantly shorter acquisition time (0:15 vs. 2:23 min; p-value < 0.001). Qualitative ratings revealed a higher overall image quality and sharpness compared to the conventional sequence for both readers (p-value < 0.01). One reader reported significantly fewer artifacts with the DL-accelerated sequence. The diagnostic confidence for lymph nodes and bone lesions was excellent for both sequences, with significant difference only for lymph nodes in favor of the DL-accelerated sequence for one reader (p-value < 0.05). There was no significant difference between the CV (0.031 for the DL-accelerated sequence and 0.029 for the standard sequence).

### CONCLUSION

DL-accelerated ultrafast T1w VIBE Dixon imaging demonstrated superior image quality and improved or equal diagnostic confidence for pelvic lymph nodes and bone lesions in patients with suspicion for prostate cancer compared to conventional T1w VIBE Dixon imaging with a tremendously shorter acquisition time.

### CLINICAL RELEVANCE/APPLICATION

In recent years, there has been a growing demand for prostate MRI, a trend that is expected to continue with the establishment of systematic screening programs worldwide. To meet this demand, DL-accelerated sequences are emerging as a compelling option. Here, we show that DL-accelerated ultrafast T1w VIBE Dixon sequences allow screening for pelvic metastases in a fraction of the original scan time, while providing superior image quality and improved or equal diagnostic confidence compared to conventional imaging.

### PURPOSE

To assess the performance of a biparametric MRI (bpMRI)-based AI model in estimating overall prostate cancer (PCa) and clinically significant prostate cancer (csPCa) volume on whole-mount (WM) histopathology using detailed histopathological mapping.

### METHODS AND MATERIALS

This single-center retrospective study included patients who underwent multiparametric MRI and subsequent radical prostatectomy between January 2014 and November 2021. All scans underwent prospective assessment by an expert genitourinary radiologist who volumetrically contoured each intraprostatic lesion. An automated prostate lesion detection model which was developed on a multi-institutional dataset of 1240 treatment-naļve patients on bpMRI was tested using thresholds set at 50% (flexible), 63% (default), and 75% (strict). A genitourinary pathologist delineated all tumors on digitized WM slides and assigned Gleason Grade Groups (GG) to each neoplastic focus. WM tumor volumes were determined from histopathological

annotations, incorporating a shrinkage correction factor of 1.15. csPCa was defined as GG=2. Volumetric contours by the radiologist and AI at several thresholds were compared to WM specimen volumes using the Wilcoxon signed-rank test and Kendall t coefficient.

**RESULTS**

A total of 108 patients (median age, 63; interquartile range [IQR], 57-68 years) with a median prostate-specific antigen of 7.3 ng/mL (IQR, 5.4-10.7 ng/mL) were included. The median tumor burden on WM was 2.3 mL (IQR, 1.2-4.9 mL) for overall PCa and 2.3 mL (IQR, 1.1-4.9 mL) for csPCa. The median volume per radiologist contours (2.1 mL) were higher than that of flexible (1.2 mL, P<.001), default (0.9 mL, P<.001) and strict (0.7 mL, P<.001) AI thresholds. The WM volume demonstrated significant correlations with flexible (tPCa=0.51, tcsPCa=0.49), default (tPCa=0.51, tcsPCa=0.49), strict AI (tPCa=0.49, tcsPCa=0.47) thresholds and with the radiologist (tPCa=0.47, tcsPCa=0.46). Bland-Altman analyses revealed the highest concordance between radiologist-delineated contours and WM volumes for both PCa and csPCa, with the strict-threshold AI showing the least agreement. In patients with PI-RADS 4 index lesions (n=39), the radiologist estimate (1.3 mL) was similar to median tumor volumes on WM for PCa (1.3 mL, P=.20) and csPCa (1.2 mL, P=.35).

**CONCLUSION**

A bpMRI-based AI model achieved the best performance for PCa volume estimation at the flexible threshold. Expert-derived volumetric contours are more representative of the actual tumor burden compared to the AI segmentations.

**CLINICAL RELEVANCE/APPLICATION**

An automated prostate lesion detection model could be used to estimate the tumor volume at a flexible threshold on whole-mount pathology without utilizing dynamic contrast enhanced MRI.

### PURPOSE

The Brain Tumor Segmentation - Metastases (BraTS-METS) challenge focuses on volumetric assessment metastatic disease to the brain using MRI. It addresses the significant variability in lesion size, appearance and post-treatment changes. While BraTS-METS 2023 challenge include pre-treatment cases showing promising results, BraTS-METS 2024 is an extension of the 2023 challenge to add post-treatment cases and evaluate segmentations based on lesionwise detection across the different algorithms.

### METHODS AND MATERIALS

The BraTS-METS dataset is a retrospective collection of MRI from patients scanned on varying MRI imaging quality across different vendors and different sites. The scans are pre-processed using different algorithms then refined by a pool of annotators with different expertise in medical imaging. The dataset is finally reviewed carefully by two independent board certified neuroradiologists. The data is divided into Training, validation and testing dataset. The challenge will be evaluated based on weighted lesionwise detection score of enhancing tumor, whole tumor, tumor core and post-treatment changes.

### RESULTS

Data was collected from 9 different sites includes MRI of patients with brain metastasis on either pre-treatment or post-treatment scans. There are 2,712 cases received from various institutions. 966 cases were released during BraTS-METS 2023 challenge contain 3,433 brain lesions. The rest will be released as part of BraTS-METS 2024 challenge containing post-treatment cases. Seven different teams enrolled in the challenge during MICCAI conference. The top teams detect 70% of the brain metastasis with 80% senstivity of detection small lesions. We are currently in the recruitment phase for the 2024 challenge which will be held in October 2024. Plans are made to hold the challenge beyond 2024 and to include more labels, more data from different sites and timepoints.

### CONCLUSION

Throughout the 2023 BraTS-METS challenge, we have confronted both technical and practical challenges in the development and application of machine learning algorithms for BM segmentation. The challenge has highlighted the critical need for algorithms capable of detecting even the smallest lesions, which are often overlooked due to human error or obscured by the limitations of imaging data.

### CLINICAL RELEVANCE/APPLICATION

The development of refined segmentation algorithms that effectively balance sensitivity with specificity is therefore essential. The BraTS-METS challenge has been instrumental in advancing these developments, pushing forward the creation of models that are robust and adaptable across varied clinical environments. This endeavor not only tests the precision of these algorithms but also evaluates their practical applicability.

## W3-SSIN05-2 LEARNING WITHOUT FORGETTING FOR CONTINUAL ABDOMINAL MULTI-ORGAN AND TUMOR SEGMENTATION

Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Yixiao Zhang (*Abstract Co-Author*) Nothing to Disclose
Xiaoxi Chen, MD (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To enable AI to learn new classes of organs and tumors while retaining previously learned classes, preventing forgetting.

### METHODS AND MATERIALS

We propose a novel continual multi-organ and tumor segmentation method that overcomes the forgetting problem with little memory and computation overhead. First, we propose to generate soft pseudo annotations for the previous classes on new data. This enables us to keep old knowledge without saving the old data. Second, we propose image-aware class-specific heads for each class on top of the shared encoder and decoder. These heads allow a single backbone and easy extension to new classes while bringing little computational cost. Third, we propose to encode the class names with CLIP, which encodes semantic information of each class through large-scale image-text co-training. We evaluate our method using three abdominal CT datasets, i.e., BTCV, LiTS, and JHH. We define two learning trajectories. (1) First segment 13 organs in the BTCV dataset and then segment liver tumors in the LiTS dataset. (2) Segment 13 organs in the JHH dataset, followed by continual segmentation of 4 gastrointestinal tracts (GT), and 6 cardiovascular system structures (CSS).

### RESULTS

We compare the proposed method with baseline methods LwF, ILT, and PLOP. On the JHH dataset, our method achieves a Dice of 0.783 on old organ classes, 0.3% better than the best baseline, and a Dice of 0.695 on GT and 0.636 on CSS, higher than the best baseline by a margin of 4.2% and 15.2%, respectively. On the BTCV and LiTS datasets, our method also achieves a Dice of 0.817 on old organ classes and 0.466 on the new tumor class, 1.8% and 1.0% better than the best baseline models, respectively. Empirical results show the proposed method enjoys the least forgetting in old classes and a better ability to adapt to new classes. We further conduct ablation studies on the proposed organ-specific heads and CLIP encoding on the JHH dataset. The use of organ-specific heads brings a 1.0% improvement in old organ classes and a 14.4% improvement in new GT classes. Using CLIP encoding further brings a 1.0% improvement in old organ classes and 2.1% in new GT classes.

### CONCLUSION

We propose a continual multiple organ and tumor segmentation method in 3D abdominal CT images. The proposed method is evaluated on public and private datasets in continual learning. Empirical results demonstrate that the proposed method outperforms the continual learning baseline methods in this challenging task.

### CLINICAL RELEVANCE/APPLICATION

Due to privacy regulations, institutions usually have limited access to the data for a pre-trained model from another source. The proposed method offers the ability to extend a pre-trained model to new data with little forgetting of its knowledge of previous data.

## W3-SSIN05-3 TRAJECTORIES OF BODY COMPOSITION IN THE GENERAL POPULATION: REFERENCE VALUES FROM OVER 66.000 INDIVIDUALS

Jakob Weiss, MD (*Abstract Co-Author*) Nothing to Disclose
Susanne Rospleszcz (*Abstract Co-Author*) Nothing to Disclose
Michael T. Lu, MD, MPH (*Abstract Co-Author*) Stockholder, NVIDIA Corporation;Institutional Research Grant, Kowa Company, Ltd;Institutional Research Grant, AstraZeneca PLC;Stockholder, Advanced Micro Devices, Inc;Stockholder, Intel Corporation

Matthias Jung, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Imaging-based body composition (BC) measures play an important role for risk estimation in patients with cardiometabolic disease and cancer. With advances in AI, automated and accurate quantification of BC from imaging studies has become feasible, but reference values for BC measures are still missing. Here, we developed and tested a fully automated deep learning framework to quantify BC from magnetic resonance imaging (MRI) to calculate normative reference curves similar to the concept of growth charts in pediatric care.

### METHODS AND MATERIALS

The framework was developed to quantify BC from whole-body MRI using data from the UK Biobank (UKBB) and the German National Cohort (NAKO). Whole-body BC was derived as 3D segmentation masks for (i) subcutaneous (SAT), (ii) visceral (VAT), (iii) skeletal muscle (SM), SM fat fraction (SMFF), and (iv) intramuscular adipose tissue (IMAT). The 3D BC segmentation masks were used to compute changes in each BC measure across age, stratified by sex and body height. Normative reference curves based on age, sex, and height were generated for each BC measure using generalized additive models.

### RESULTS

Among 66,608 individuals (mean age: 57.7±12.9 years; mean BMI: 26.2±4.5 kg/m2, 48.3% female) BC analysis revealed sex differences in volumes and distributions with stepwise increases in SAT, VAT, SMFF, and IMAT over age decades, and stepwise decreases in SM (all $p < 0.001$). Spatial craniocaudal distribution analysis revealed age- and sex-related shifts in BC distribution: With increasing age, SAT shifted from the gluteal region to the chest, VAT from the pelvis to the abdomen, SM from the gluteal region to the trunk and chest in females and from the chest to the gluteal region in males. Paraspinal IMAT shifted from the lower lumbar spine to the upper thoracic spine. Normative BC reference curves based on age, sex, and body height showed that BC variance and volume were significantly more body height dependent in males than in females.

### CONCLUSION

This study provides normative reference curves, similar to growth charts in pediatric care, for body composition from a large general population. These are key to tracking normal and abnormal changes in BC across the lifespan.

### CLINICAL RELEVANCE/APPLICATION

As there is increasing evidence that changes in BC over the course of diseases may provide important prognostic information in cardiometabolic and oncologic diseases and may be related to treatment tolerability, the normative curves provided in this study may help clinicians and researchers to quantitatively assess abnormal BC. Reference curves will be made publicly available via a tool that allows researchers and clinicians to normalize and compare BC metrics of their own datasets to reference values of a large Western-European population.

## W3-SSIN05-4 DEEP LEARNING TO PREDICT MORTALITY FROM WHOLE-BODY MAGNETIC RESONANCE IMAGING IN THE GENERAL POPULATION

Fabian Bamberg, MD, MPH (*Abstract Co-Author*) Speakers Bureau, Bayer AG;Speakers Bureau, Bracco Imaging;Speakers Bureau, Siemens AG;Research Grant, Siemens AG
Hanna Rieder (*Abstract Co-Author*) Nothing to Disclose
Vineet K. Raghu, PhD (*Abstract Co-Author*) Nothing to Disclose
Michael T. Lu, MD, MPH (*Abstract Co-Author*) Stockholder, NVIDIA Corporation;Institutional Research Grant, Kowa Company, Ltd;Institutional Research Grant, AstraZeneca PLC;Stockholder, Advanced Micro Devices, Inc;Stockholder, Intel Corporation
Jakob Weiss, MD (*Abstract Co-Author*) Nothing to Disclose
Marco Reisert (*Abstract Co-Author*) Nothing to Disclose
Matthias Jung, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Manually extracted single-slice (2D) body composition (BC) measures have shown associations with clinical outcomes in patients with cardiometabolic disease and cancer. With advances in artificial intelligence, fully automated 3D segmentation approaches are now possible, but whether these measures carry prognostic value to predict mortality in the general population is unknown. Here, we developed and tested a deep learning framework to automatically quantify 3D BC from whole-body magnetic resonance imaging (MRI) and investigated their prognostic value to predict mortality in the general population.

### METHODS AND MATERIALS

The framework was developed using data from two large population-based cohort studies, the UK Biobank (UKBB) and the German National Cohort (NAKO). BC was defined as subcutaneous (SAT), visceral (VAT), skeletal muscle (SM), SM fat fraction (SMFF), and intramuscular adipose tissue (IMAT). The prognostic value of the BC measures was assessed in the UKBB only using Cox regression analysis. In addition, we extracted 2D BC areas for every level of the thoracic and lumbar spine 1) to compare the proposed 3D approach to the currently established 2D approach on the height of the L3 vertebra and 2) to investigate the correlation between 3D volumes and 2D single slice areas on the level of each vertebral body.

### RESULTS

In 36,317 UKBB participants ( 65.1±7.8y, 51.7% female; 1.7% [633/36,317] all-cause deaths; median follow-up 4.8 years), Cox regression revealed an independent association between 3D SM (aHR: 0.71, 95% CI [0.58-0.86], p<0.001), 3D SMFF (aHR: 1.2, 95% CI [1.06-1.36], p=0.004), and 3D IMAT (aHR: 1.12, 95% CI [1.03-1.21], p=0.009) and mortality after adjustment for demographics (age, sex, BMI, race) and cardiometabolic risk factors (alcohol consumption, smoking status, hypertension, diabetes, history of cancer, blood serum markers). This signal was not seen when using traditional 2D measures, despite high correlation between 3D and 2D metrics including R=0.96 at L5 for SAT, 0.95 at L5 for SMFF and at L3 for VAT (R=0.98), SM (R=0.94), and IMAT (R=0.76) (all p<0.001). A similar pattern was found in 23,725 NAKO participants (53.9±8.3y, 44.9% female). No significant association was found between SAT or VAT and all-cause mortality.

### CONCLUSION

Automated 3D BC assessment from whole-body MRI predicted mortality in the general population beyond traditional clinical risk factors. 2D were highly correlated with 3D measures but the association with mortality attenuated after multivariable adjustment.

### CLINICAL RELEVANCE/APPLICATION

As 3D BC measures are increasingly accessible using automated techniques, they could help to identify high-risk individuals to improve personalized prevention and lifestyle interventions.

## W3-SSIN05-5 ABDOMENATLAS: AI AND RADIOLOGISTS UNITE TO MAP THE ABDOMEN

Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Wenxuan Li, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To leverage the synergy between medical professionals and artificial intelligence algorithms to create the largest annotated multi-organ dataset to date.

### METHODS AND MATERIALS

We have developed the largest annotated CT dataset, named AbdomenAtlas, which includes 22,532 three-dimensional CT volumes from 94 hospitals, providing 684,752 high-quality masks of anatomical structures.The annotation involved 20 radiologists at JHU and associated institutes—14 senior radiologists with 8-15 years of experience and 6 junior radiologists with 3-5 years of experience. Typically, senior radiologists spent 30-60 minutes annotating each organ or tumor in a CT volume. To reduce this workload, we developed an efficient annotation method using a blend of three AI models trained on public datasets of labeled abdominal scans to minimize bias. These AI models initially annotated unlabeled datasets, highlighting key areas with color-coordinated attention maps for focused manual review by radiologists. This iterative process of AI prediction followed by human verification accelerated the annotation rate by a factor of 168, achieving a quality comparable to that of manual annotations by experienced radiologists.

### RESULTS

Three editions of AbdomenAtlas have been developed: (I) AbdomenAtlas 1.0 is publicly accessible, licensed under CC BY-NC-ND, and represents the largest public CT dataset currently available. Collected from 26 centers, 1.0 provides per-voxel annotations for 9 anatomical structures for 5,195 CT volumes (1.9M images). (II) AbdomenAtlas 2.0, set for full release in late 2024 with a CC BY-NC-ND license, includes per-voxel annotations for 73 anatomical structures and seven tumor types (e.g., liver, pancreas, kidney, colon, lung) for 9,262 CT volumes (3.5M images), collected from 88 centers.

(III) AbdomenAtlas Pro is reserved for internal studies at JHU and includes per-voxel annotations for 142 anatomical structures and all types of tumors for 22,682 CT volumes (8.5M images). Pro was collected from 102 centers.

## CONCLUSION

Creating datasets of such scale (22K CT volumes) conventionally requires an impractical 209.5 years of continuous annotation by a single radiologist. Our study demonstrates that AI significantly streamlines this process by pre-annotating clear boundaries and time-intensive sections. This human-AI collaboration dramatically reduces the time required, making the annotation of extensive medical datasets feasible within a manageable timeframe for expert radiologists (e.g., 1.25 years to create AbdomenAtlas).

## CLINICAL RELEVANCE/APPLICATION

AbdomenAtlas automates the identification and delineation of 142 anatomical structures, significantly reducing manual contouring efforts for organ shape/volume measurement.

Printed on: 05/28/25

## W3-SSIN06-1 LARGE LANGUAGE MODEL-ENHANCED PREDICTION OF COMBINED INTRAPARENCHYMAL HEMORRHAGE AND INTRAVENTRICULAR HEMORRHAGE EXPANSION FROM CT DATA AND CLINICAL INFORMATION

Liting Shi (*Abstract Co-Author*) Nothing to Disclose
Lequn Zhu (*Abstract Co-Author*) Nothing to Disclose
Lei Shi (*Abstract Co-Author*) Nothing to Disclose
Yinyu Lan (*Abstract Co-Author*) Nothing to Disclose
Hui Xu (*Abstract Co-Author*) Nothing to Disclose
Yulong Yang (*Abstract Co-Author*) Nothing to Disclose
Zhenwei Yao (*Abstract Co-Author*) Nothing to Disclose
Jianlin Wang (*Abstract Co-Author*) Nothing to Disclose
Xianjing Zhao (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to evaluate the effectiveness of using a Large Language Model (LLM) to predict combined intraparenchymal hemorrhage (IPH) and intraventricular hemorrhage (IVH) growth, consequential complications of intracerebral hemorrhage (ICH) that significantly impact patient outcomes. The study will explore the potential of incorporating CT reports and clinical information to improve the predictions made by LLM. Additionally, the study will compare the performance of LLM with predictions made by a senior doctor and a junior doctor separately, to assess its accuracy.

### METHODS AND MATERIALS

This retrospective multicenter study included radiological and clinical data from ICH patients across three hospitals. Non-contrast CT scans were used to determine IPH volume, IVH volume, IPH location, and IPH markers, while the presence of subarachnoid hemorrhage was also noted. CT reports were included as inputs for the model. Clinical presentations included age, gender, time interval from symptom onset to baseline CT, and Glasgow Coma Scale (GCS) score upon admission. Ground truth for IPH and IVH expansion was determined from 24-hour follow-up CT scans, where an increase in IPH volume of =6ml and/or any expansion of IVH was considered significant. The dataset was divided into training and testing sets in an 8:2 ratio. The LLaMa 7B model was chosen, and the LoRA fine-tuning method was used for optimization. The predictions of one senior doctor and one junior doctor, with 3 and 20 years of experience in neuroradiology respectively, were independently compared with the predictions made by the LLaMa 7B model. The performance of the LLaMa 7B model was evaluated using area under the receiver operating characteristic curve (AUC), precision, recall, and F1 score. The DeLong test compared AUCs of the model and two doctors.

### RESULTS

A total of 718 patients (median age: 62 years; majority male) were included in the study. The LLaMa 7B model achieved an AUC of 0.741, precision of 0.686, recall of 0.889, and F1 score of 0.774. The junior doctors' predicted AUC was 0.574, while the senior doctor's predicted AUC was 0.704. The LLM outperformed the predictions made by the junior doctors significantly (p=0.027). Although the AUC of the LLaMa 7B model was slightly higher than that of the senior doctor's predictions, the difference was not statistically significant (p=0.518).

### CONCLUSION

LLM demonstrated superior performance in predicting IPH and IVH expansion, outperforming the prediction made by junior doctors.

### CLINICAL RELEVANCE/APPLICATION

LLM has the potential to enhance the prediction of combined intraparenchymal hemorrhage and intraventricular hemorrhage expansion.

## W3-SSIN06-2 CLINICAL IMPLEMENTATION OF ARTIFICIAL INTELLIGENCE IN THE DIAGNOSIS OF ACUTE PULMONARY EMBOLISM

Matthew A. Barish, MD (*Abstract Co-Author*) -[Stockholder, Blackford Analysis Ltd]; -[Consultant, Calyx.AI]; -[President,SBQ Radiology]; -[Medical Advisory Board, Nuance]
Rakesh D. Shah, MD (*Abstract Co-Author*) Nothing to Disclose
Pina C. Sanelli, MD, MPH (*Abstract Co-Author*) Research support, Siemens AGInvestigator, Siemens AG
Amir Gandomi (*Abstract Co-Author*) Nothing to Disclose
David S. Hirschorn, MD (*Abstract Co-Author*) Nothing to Disclose
Shlomit Goldberg-Stein, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Evaluate concordance rates between radiologists and an AI algorithm for detection of acute pulmonary embolism (PE) on PE protocol CT (CTPE) across an integrated healthcare network.

**METHODS AND MATERIALS**

This IRB approved prospective observational study included consecutive CTPE exams in adults (9/9/21-2/20/23). In our clinical workflow, CTPE were evaluated by an FDA-approved AI algorithm (AIDOC) and subsequent interpretation by radiologists, who were aware of AI results at the time of interpretation. Disagreements between AI and interpreting radiologists were resolved by expert adjudicators. We calculated concordance between interpreting radiologists and AI and analyzed adjudicator concordance with interpreting radiologists or AI. Confidence intervals for proportions and Clopper-Pearson method via the 'beta' method in Python's library was used.

**RESULTS**

A total of 32,501 CTPE exams were included in the analysis and yielded 97.82% (CI 97.66,97.98) concordance between interpreting radiologists and AI for the diagnosis of acute PE. For the remaining 2.18% (n=708), adjudicators agreed with the interpreting radiologist in 76.98% (n=545); these agreements were higher for positive PE (n=392, 71.93%) vs. negative PE (n=153, 28.07%). Of 485 cases where the interpreting radiologist diagnosed PE where AI did not, adjudicators agreed with the interpreting radiologist in 85% of cases (n=392). There were 3,137 positive exams for acute PE, after expert adjudication of discordant cases. Overall, the rate of enhanced PE detection by the interpreting radiologist alone (where AI did not diagnose PE) was 12.5% (n=392) of all positive PE exams (n=3,137). The rate of enhanced PE detection by AI alone (where interpreting radiologists did not diagnose PE), was 2.96% (n=93) of all positive PE exams (n=3,137).

**CONCLUSION**

There was high concordance of AI with interpreting radiologists (98%) for acute PE detection. AI enhances radiologists' diagnosis of acute PE in the clinical environment, adding 3% of positive PE not detected by the radiologist. Radiologists should not be swayed against a positive diagnosis of PE when not detected by AI, given high concordance with adjudicators for positive PE (85%). What remains unknown is the true added value of AI in detection of PE that would otherwise go undetected by radiologist since radiologists were aware of AI results prior to interpretation.

**CLINICAL RELEVANCE/APPLICATION**

This is the largest study to date evaluating clinical implementation of AI for acute PE, allowing for subset analysis, and a deeper understanding of optimal utilization of AI in clinical practice.

## W3-SSIN06-3 IDENTIFY AND MITIGATE BIASES IN SYNTHETIC IMAGING DATA TO IMPROVE RELIABILITY OF AI DIAGNOSIS MODELS

Jules H. Sumkin, DO (*Abstract Co-Author*) Research Grant, Hologic, Inc;
Margarita L. Zuley, MD (*Abstract Co-Author*) Investigator, Hologic, Inc
Dooman Arefan, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Degan Hao, MS (*Abstract Co-Author*) Intern, F. Hoffmann-La Roche Ltd
Shandong Wu, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

With the surge of generative AI, an increasing amount of synthetic medical imaging data are being produced. Synthetic data can increase sample sizes and benefit machine learning, but the generation of synthetic data may inherent/amplify potential biases in the original real data or introduce new biases (e.g., spurious correlations), leading to degraded model performance or integrity. This study aims to develop a new method to identify and mitigate potential spurious correlation biases in synthetic data to improve AI model training.

**METHODS AND MATERIALS**

This IRB-approved study employed a convolutional neural network on mammogram images from 1,284 patients (per biopsy, 366 breast cancer and 918 benign/negative cases) for breast cancer diagnosis. These patients have 4,346 real mammogram images, and a generative adversarial network was trained to generate another set of 4,346 synthetic images with several different settings of inserting or removing tumorous tissues on images to create various new samples. We propose a novel method, namely, Bias-Resilient Fine Tuning (BRFT; see attached figure) to mitigate biases in synthetic data to improve model training. BRFT identifies robust features on real and synthetic data, measures feature correlation, and uses a feature swapping strategy to improve training. In experiments we first follow regular training to train a model only using real or synthetic data to examine potential biases, then we incorporate BRFT for training to evaluate the corresponding model effects. The model's performance is measured by Area Under the ROC Curve (AUC) under five-fold cross-validation.

**RESULTS**

Regular training on real data alone shows a test AUC of 0.615 ± 0.016, but on the synthetic data alone the test AUC is 0.946 ± 0.074 on synthetic test data, indicating a seriously skewed performance due to spurious correlation biases in the synthetic data. When BRFT is applied, it leads to a synthetic data test AUC of 0.610 ±0.040 (which is close to the real data AUC of 0.615), showing BRFT can effectively mitigate biases in the synthetic data to reduce inflated AUCs. In addition, the use of BRFT also increases the real data test AUC from 0.615 ± 0.016 to 0.633 ± 0.015, showing the improved model performance attributed to use of the additional synthetic data.

**CONCLUSION**

Generative AI and synthetic data are being promoted for medical imaging applications, where detecting and mitigating potential biases in synthetic data are critical to ensure reliability and fairness of AI models for clinical uses.

**CLINICAL RELEVANCE/APPLICATION**

Generative AI and synthetic data are being promoted for medical imaging applications, where detecting and mitigating potential biases in synthetic data are critical to ensure reliability and fairness of AI models.

## W3-SSIN06-5 AUTOMATED ELECTRONIC HEALTH RECORDS TOOLS FOR IMPROVING HEPATOCELLULAR CARCINOMA SCREENING AND SURVEILLANCE

Soudabeh Fazeli, MD,MPH (*Abstract Co-Author*) Nothing to Disclose
Julie Y. An, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Diagnostic imaging plays a critical role in the detection and diagnosis of hepatocellular carcinoma (HCC). Patients with cirrhosis and/or chronic hepatitis B are at elevated risk for developing HCC and are recommended 6-months interval screening/surveillance imaging exams. With the ever-growing busy clinical practice and advancements in EHR capabilities, we saw an opportunity to build an integrated tool to aid in improving compliance of imaging-based HCC surveillance.

**METHODS AND MATERIALS**

Our collaborative team of physicians and IT specialists developed a population-health-based framework within the EHR to identify and mark eligible patient due for surveillance imaging. We then defined specific criteria, based on published recommendations and subspecialty expertise, to trigger a Best Practice Advisory (BPA) for patients due or overdue for imaging. This allowed clinicians to review clinical data quickly and place orders within the tool. Feedback was solicited at each design and implementation step. EHR use-data and clinical outcomes were collected post-implementation (11/13/23-3/6/24). A secondary patient-reported assessment evaluated potential barriers to surveillance and patient attitudes towards potential reminders.

**RESULTS**

Qualitative feedback led to modifications in the framework, including refining patient inclusion/exclusion criteria and optimizing the human-machine workflow. Clinicians reported overall improvement in workflow but noted multiple false positive BPA alerts due to initial over-inclusion. Among 225 eligible patients who received a BPA during clinical encounters, 136 (60%) resulted in imaging orders (62% US, 28% MRI, 7% CT, and 4% abbreviated MRI). Of the completed exams after a 3-month follow-up, 2/81 were diagnostic of HCC, and 1/81 was considered indeterminate (LI-RADS 3), requiring short interval follow-up. In the secondary analysis of patient-reported preferences, 100% (20/20) of patients desired direct reminders via their mobile app for future HCC surveillance exams, which could be incorporated in future updates.

**CONCLUSION**

An automated, EHR-integrated tool can help improve compliance of in preventative care measures. In our implementation study, we created and deployed a tool built into our EHR system which provided targeted reminders to clinicians managing the care of at-risk patients. Our tool improved HCC screening/surveillance compliance above that of

**CLINICAL RELEVANCE/APPLICATION**

Modern EHR tools can be optimized to aid in accurate tracking and reminding of recommended health maintenance tasks, including imaging-based HCC surveillance. We hope our experience will provide a framework for others interested in similar efforts.

## W3-SSIN06-6 AI-ENABLED RADIOGRAMMETRY FOR OPPORTUNISTIC OSTEOPOROSIS SCREENING: A REAL-WORLD FEASIBILITY STUDY

Jyhwen Chai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Qingzong TSENG (*Abstract Co-Author*) Nothing to Disclose
SHENG CHE HSIAO (*Abstract Co-Author*) Nothing to Disclose
CHENG WEI LIN (*Abstract Co-Author*) Nothing to Disclose
Hsuan-Yin Lin, BMedSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Osteoporosis(OP), characterized by reduced BMD and increased fragility fracture risk, is a growing epidemic due to aging populations. Despite the potential for prevention, it remains underdiagnosed due to DXA access. Opportunistic screening, utilizing existing medical images, offers a cost-effective way for OP identification. While AI-assisted radiogrammetry has been explored, pelvic and hip X-rays are not routinely obtained in standard health examinations and chest X-rays lack hip BMD data - critical for assessing fracture risk. Plain abdomen X-rays (KUB), however, are routinely ordered and provide both lumbar and hip information. This study aims to validate the use of AI to facilitate OP screening using KUB radiographs.

**METHODS AND MATERIALS**

The institutional review board approved this prospective study (TCVGH-IRB No. SF23547B). The performance of an AI software (DeepXray Coxa, Alpha Intelligence Manifolds, Inc.) was first validated using retrospectively collected data of DXA BMD values and KUB obtained at Taichung Veterans General Hospital between 2011-2022. The study used DXA BMD measurements conducted on a Lunar iDXA (GE, Chicago, USA). After excluding images with incomplete femur or implants on the region of interest (ROI) (n=15784), tags on the ROI (n=1577) and suboptimal quality (n=855), 3,850 paired DXA-KUB were enrolled for further AI analysis [78% Female; mean age 71.8 ± 11.8 years]. This study then employed the AI algorithm combining the feature extraction capabilities of a convolutional neural network with established radiogrammetric principles, for prospective BMD estimation.

**RESULTS**

34.97% of KUB are eligible for AI analysis. On the internal test set (942 hips from 365 individuals), the AI model demonstrated a root mean square difference (RMSD) of 0.059 g/cm² and a Pearson correlation of 0.88 compared to DXA-measured BMD, achieving an AUROC of 0.924 for predicting T-scores = -2.5 (PPV/NPV: 84%/87%, OP prevalence: 27%). In a subsequent prospective feasibility study (116 hips from 61 patients), the AI model maintained an RMSD of 0.062 g/cm² and a Pearson correlation of 0.87. To minimize false positives and unnecessary referrals, we employed a conservative detection threshold of T-score = -2.8. The AI model achieved a 100% PPV and 83.6% NPV.

**CONCLUSION**

This paper presents an AI model that is capable of using routine KUB to estimate hip BMD, which is highly correlated with DXA measurements. A prospective study confirms its effectiveness in opportunistic screening for high-risk OP cases in a real-world setting while minimizing false alarms.

**CLINICAL RELEVANCE/APPLICATION**

This AI model enables opportunistic OP screening using a widely available method, potentially facilitating early treatment and reducing medical financial burdens.

## W3-SSMK08-1 ULTRA-PROCESSED FOOD CONSUMPTION IS ASSOCIATED WITH HIGHER INTRAMUSCULAR FAT INFILTRATION IN INDIVIDUALS WITHOUT RADIOGRAPHIC OSTEOARTHRITIS OR FREQUENT PAIN IN THE KNEE AND HIP: DATA FROM THE OSTEOARTHRITIS INITIATIVE

Gabby B. Joseph (*Abstract Co-Author*) Nothing to Disclose
Wynton Sims (*Abstract Co-Author*) Nothing to Disclose
Zehra Akkaya (*Abstract Co-Author*) Nothing to Disclose

Katharina Ziegeler, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The loss of contractile muscle tissue is associated with poor health outcomes in a variety of diseases, including osteoarthritis (OA). While lifestyle factors may impact muscle quality, little is known about the influence of low-quality nutrition, specifically ultra-processed foods (UPF). The aim of this study was to assess the association of UPF intake and intramuscular fatty degeneration.

### METHODS AND MATERIALS

Participants from the Osteoarthritis Initiative at risk of but without radiological hip/ knee OA (KL grade =1) or self-reported knee/hip pain on either side at enrollment were included in this cross-sectional study. Participants without 3T thigh MRI or plausible dietary data based on Block Brief 2000 food frequency questionnaire (FFQ) were excluded. Intramuscular fat was assessed using semi-quantitative 5-level Goutallier grades (GG), ranging between 0 (no fatty streaks in the muscle) to 4(>50% fatty signal), on axial T1W images. Each muscle was scored on both thighs per participant; sum GG scores across all muscles (GGall), bilateral flexors (GGflex) (semimebranosus, semitendinosus, biceps femoris), extensors (GGext) (rectus femoris, vastus medialis, vastus lateralis, vastus intermedialis), and adductors (GGadd) (adductors, gracilis, sartorius) were calculated. Standardized values for UPF proportion in overall annual diet (%) were extracted from the FFQ based on the NOVA Classification, which classifies food and beverages into 4 groups based on their level of processing. UPF represents NOVA group 4, indicating industrial-scale processing for increased palatability and shelf-life. Linear regression models were used to assess the relationship between dietary UPF and GG. All models were adjusted for age, sex, race, BMI, total daily caloric intake, physical activity, depression, education, and income levels.

### RESULTS

There were 666 participants (45% men, mean age 59.9 [±9] years, mean BMI 27.1 [±4.3] kg/m2). Mean GG scores and UPF are presented in Table 1A. Highest and lowest GG scores were noted for extensors and flexors, respectively (Table 1A). The relationship between UPF and GG scores was significant for GGall (ß 0.86 [95% CI 0.13, 1.58], p=0.021), indicating an increase of GG by almost 1 grade for each SD increase in UPF. Significant results were also found for GGadd and GGflex but not for GGext (Table 1B).

### CONCLUSION

In a normative cohort of patients, at risk for but free of knee or hip OA by radiographic and clinical criteria, the consumption of UPF is associated with higher intramuscular fat, independent of total daily caloric intake, physical activity, or BMI.

### CLINICAL RELEVANCE/APPLICATION

Quality of nutrition may impact muscle quality and represents a potential target for non-invasive or preventive therapeutic approaches.

## W3-SSMK08-2 SCAN-RESCAN REPEATABILITY OF QUANTITATIVE T1RHO MAPPING ON EXTRAOCULAR MUSCLES IN A HEALTHY COHORT

Min Deng (*Abstract Co-Author*) Nothing to Disclose
Winnie C. Chu, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Yiyou Sun (*Abstract Co-Author*) Nothing to Disclose
Weitian Chen (*Abstract Co-Author*) Nothing to Disclose
Ziqiang Yu (*Abstract Co-Author*) Nothing to Disclose
Ziqin Zhou, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

This prospective study aims to assess the different-day same-scanner repeatability of T1rho mapping on extraocular muscles (EOMs), and to present the normative values of EOMs T1rho in healthy cohort.

**METHODS AND MATERIALS**

Sixteen healthy volunteers (age: 24-32 years; 8 women and 8 men) underwent 3 repeated orbit MRI exams on day 1(baseline), day 2 (short-term repeat), day 7(mid-term repeat). Native T1rho weighted images were acquired on a 3T MR scanner using B1 and B0 compensated spin-lock preparation pulses at spin-lock frequency of 500Hz, with spin-lock times (TSL) of 0, 10, 30 and 50ms. Single-shot turbo spin echo with Half-Fourier sampling was used to accelerate image acquisition, while minimizing EOMs distortion due to eyeball motion. T1rho maps were depicted by fitting images at different TSL to a mono-exponential decay model on pixel-by-pixel basis (Fig 1). Regions of interest were manually drawn by a trained analyst on bilateral EOMs, i.e., medial, lateral, superior, inferior rectus (MR, LR, SR, IR), temporalis (TM) and white matter (WM), excluding observable vessels and artifacts. Repeatability was estimated by intraclass correlation coefficient (ICC), Bland-Altman plots, within-subject coefficient of variation (CV).

**RESULTS**

EOMs showed overall good T1rho scan-rescan repeatability (ICCs:0.766-0.891), comparable to WM (ICCs: 0.813-0.830) and inferior to TM (ICCs: 0.914-0.954). Short-term ICCs were nearly equivalent in four recti (0.818-0.891). Mid-term ICCs remained favorable in MR, LR, and SR (0.842-0.880), but declined in IR with large 95% confidence interval of 0.416-0.919 (Table 1). 95% limits of agreement in the short-term were -7.0 to 6.1 for MR, -8.0 to 5.6 for LR, -10.2 to 8.7 for SR, -29.2 to 32.3 ms for IR, respectively; and in the mid-term were -6.6 to 8.5 for MR, -9.9 to 10.7 for LR, -8.7 to 7.0 for SR, -43.4 to 32.4 ms for IR, respectively (Fig 2), indicating that satisfactory repeatability was gained on all recti except for IR. EOMs scan variability was lowest in MR and highest in LR (short-term CVs: 3.4 -9.3%; mid-term CVs: 4.1-14.5%). When omitting the IR having relatively poor reliability in presence of strong susceptibility near air-filled sinuses, normative T1 rho value was similar in recti (68.99, 69.01, 66.38 ms in MR, LR, SR, respectively; mean: 68.16 ms) (Table 1).

**CONCLUSION**

Orbit T1rho mapping at 3T enables repeatable T1rho measures of EOMs in healthy adults. However, there is still room for improvement in repeatability on IR susceptible to strong B0 inhomogeneity.

**CLINICAL RELEVANCE/APPLICATION**

Quantitative T1rho MRI has been first extended to small-sized EOMs. This paves the way for translating T1rho metric to a new clinically applicable imaging biomarker reflective of EOMs impairments, like inflammation and degeneration.

## W3-SSMK08-3 EVALUATING THE RELATIONSHIP BETWEEN LUMBAR SPINE 4 BONE MARROW FAT FRACTION AND ABDOMINAL/PARASPINAL MUSCLE FAT INFILTRATION: INSIGHTS FROM MRI AND QCT IN PEOPLE LIVING WITH HIV AND HEALTHY INDIVIDUALS

**PURPOSE**

This study investigates the relationships between bone marrow fat fraction (BMFF) at the lumbar spine and abdominal muscle quality, specifically intramuscular fat area and lean muscle area in the psoas, lateral abdominal, rectus, and paraspinal muscles.

**METHODS AND MATERIALS**

52 People Living with HIV(PLWH) and 52 seronegative controls were included in our study. Chemical shift-based water-fat separation MR images were obtained with a 3T GE scanner; BMFF was calculated from mean density fat fraction maps within the L4 vertebral body. Single slice abdominal QCT images at the L4 level were obtained on a GE scanner; fat and lean areas within segmented muscle groups were calculated using in house segmentation software. Linear regression models were utilized to examine the associations between BMFF and intramuscular fat and lean areas. All models were adjusted for age and sex, with additional sensitivity analyses for group (PLWH and controls).

**RESULTS**

The mean age of individuals was 59.2 ± 4.92 years. Of the total cases, 60 (58%) were males. The analysis of fat infiltration in the paraspinal muscles revealed a significant positive correlation with vertebral BMFF, even after adjusting for age and sex. This association remained robust across sensitivity analyses for PLWH status (coeff=0.63, 95% CI: 0.23-1.04, p-value=0.002). Similarly, fat infiltration in the psoas muscle exhibited a positive association with vertebral BMFF. Although not statistically significant, the effect size was larger (coeff=1.01, 95% CI: -1.71-3.75; p=0.46). Conversely, lean area of the paraspinal and psoas muscles demonstrated a negative association with vertebral BMFF. This was significant in the psoas, even after adjustments and sensitivity analyses (coeff=-0.36, 95% CI: -0.64- -0.07; p=0.01).In the lateral abdominal and rectus muscles, no significant associations were found between vertebral BMFF and fat and lean areas.

**CONCLUSION**

Our findings revealed positive associations between vertebral BMFF and fat infiltration within the psoas and paraspinal muscles, which are anatomically close to the lumbar spine as compared to lateral abdominal and rectus muscles. We also found negative associations between vertebral BMFF and muscle lean area within the psoas and paraspinal muscles. These findings were independent of HIV status.

**CLINICAL RELEVANCE/APPLICATION**

Our results suggest that fat infiltration across marrow and muscle may develop from a common mechanism, and that anatomical proximity may determine the extent of similarity in fat infiltration across tissues. Combined with the established inverse association between BMFF and bone quality, these findings have clinical implications for understanding, preventing, and treating vertebral bone loss.

## W3-SSMK08-4 3D COLOR-RENDERED MR NEUROGRAPHY HEATMAPS IN VISUALIZING NORMAL LUMBOSACRAL (LS) PLEXUS AND INCREASING CONSPICUITY OF LS PLEXOPATHY

### PURPOSE

To determine whether color-rendered 3D MR neurography (MRN) images (heatmaps) improve diagnostic accuracy, reader confidence levels, and time savings to assess lesions compared to the conventional greyscale images.

### METHODS AND MATERIALS

A cross-sectional study included adults of all genders with MRN of LS plexus and known reference standards of normal or neuropathy (plexopathy / radiculopathy). Heatmaps were constructed using 3D MRN STIR images and color rendered with higher intensity to yellow and lower intensity to darker-red colors in 1-2 minutes and were available on PACS for the readers. 2D plus 3D greyscale MIP images and 2D plus 3D MIP heatmaps were analyzed by four musculoskeletal radiologists (two faculty and two fellows) in 2 separate rounds blinded to the final diagnosis. Readers evaluated: neuropathy and number of nerves affected (neuropathy score: 0 - normal; 1 - one nerve affected; 2 - two or more nerves affected); final diagnosis; confidence levels; and time taken to evaluate the studies.

### RESULTS

Among 70 MRNs from 70 patients, there were 32 males and 38 females with average age ± SD of 54.8 ± 20.1 and 49.9 ± 16.6 years, respectively. There were 30 normals and 40 of LS plexus lesion scans. Interreader agreements were moderate to good for conventional imaging and heat maps (Conger's kappa: 0.65; 95% CI: 0.55, 0.73 and 0.59; 95% CI: 0.47, 0.69), respectively. The mean neuropathy score and final diagnosis accuracies were similar in both rounds 85.7% ± 0.1% vs 83.2% ± 0.1% (P=0.13), and 83.6% ± 0.1% vs 80.0% ± 0.1%; P=0.16), respectively. Time savings were significant when using heatmaps for all readers (P<0.001). Time savings using heatmaps ranged from 57.7%-74.6% and 56.3%-75% of the original time for the fellows and faculty respectively. Average confidence levels for neuropathy score significantly increased using heatmaps for one fellow and one faculty ($P < 0.05$), while average confidence levels for final diagnosis improved for both fellows and one faculty ($P < 0.05$).

### CONCLUSION

3D color-rendered MRN heatmaps show comparable diagnostic accuracy to conventional MRN imaging but with significant time savings to identify LS plexus lesions.

### CLINICAL RELEVANCE/APPLICATION

3D color-rendered heatmaps increase time efficiency in evaluating MRNs of LS plexus, allowing for improved radiologist productivity and diagnostic confidence.

## W3-SSMK08-5 NEUROFIBROMATOSIS TYPE 1(NF1)-RELATED PRE-MALIGNANT/MALIGNANT PERIPHERAL NERVE SHEATH (MPNST) TUMORS: CAN MRI PREDICT HISTOLOGY?

Laura M. Fayad, MD (*Abstract Co-Author*) Nothing to Disclose
Jenifer Pitman, MD (*Abstract Co-Author*) Nothing to Disclose
Shivani Ahlawat, MD (*Abstract Co-Author*) Nothing to Disclose
Ali Ghasemi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the qualitative and quantitative anatomic and functional magnetic resonance imaging (MRI) features of atypical/low-grade MPNST (managed with marginal resection) versus high-grade MPNST (managed with wide excision and/or chemotherapy or radiotherapy) in patients with neurofibromatosis type 1 (NF1).

### METHODS AND MATERIALS

This retrospective single-center study enrolled consecutive participants with NF1 with histological diagnosis of atypical (atypical neurofibromatous neoplasm of unknown biologic potential), low-grade MPNST and high-grade MPNST, and pre-diagnosis MRI from 02/2014-02/2024. In addition to demographic data, qualitative (heterogeneity, architecture ("target sign"), margins, and surrounding plexiform tumor at T2-weighted, T1-weighted pre-contrast, and T1-weighted post-contrast images) and quantitative (size and minimum apparent diffusion coefficient (ADC min) on diffusion weighted imaging (DWI)) MRI features were recorded. Chi square and Spearman's correlation tests were used accordingly for statistical analysis.

### RESULTS

A total of 41 tumors in 40 patients were included (20 (49%) females [median age: 38, range: 14-66] with high-grade (n = 29) and ANNUBP/low-grade (n = 12) MPNSTs). The presence of intralesional necrosis, perilesional edema, and perilesional enhancement ($p = 0.001$, $p = 0.007$, and $p = 0.005$, respectively); a higher largest diameter and average diameter (Spearman's $?=0.363$ ($p=0.02$), and $S? = 0.374$ ($p = 0.016$), respectively); and a lower ADCmin ($S? = -0.509$ ($p = 0.001$)) were associated with high histologic grade. The remaining qualitative and quantitative features, including the presence of a "target sign" on T2 or DWI ($p = 1.0$) or a plexiform background ($p = 0.631$), did not correlate with the grade.

### CONCLUSION

The presence of intralesional necrosis, perilesional enhancement and edema, larger diameters, and a lower ADCmin are associated with high-grade NF1-related MPNSTs when compared with atypical/low-grade MPNSTs.

### CLINICAL RELEVANCE/APPLICATION

MRI using qualitative and quantitative routine anatomic and advanced functional sequences can distinguish premalignant/low-grade MPNST from high-grade MPNST in patients with NF1. The addition of DWI/ADC mapping to a routine MRI protocol reliably distinguishes benign from pre-malignant/low-

grade MPNST in patients with NF1. In the absence of serial imaging with volumetric tumor measurements or PET imaging, a single-time point MRI with DWI will potentially impact therapy and may be useful for the development of imaging-based prognostic features.

## W3-SSMK08-6 CORRELATING DIFFUSION TENSOR IMAGING PARAMETERS WITH LUMBAR PARASPINAL MUSCLE FAT INFILTRATION: IMPLICATIONS FOR SARCOPENIA DIAGNOSIS

Wenshuang Zhang, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to investigate the correlation between DTI quantitative parameters and the extent of fat infiltration in paraspinal muscles, as measured by the Dixon proton density fat fraction (PDFF). The goal is to identify DTI imaging biomarkers that accurately depict paraspinal muscle degeneration and atrophy, providing a fresh perspective for the diagnosis and evaluation of sarcopenia.

### METHODS AND MATERIALS

This study enrolled 16 volunteers with chronic lumbar discomfort (5 males and 11 females) with an average age of 45.2±13.4 years. Participants underwent MRI examinations, including T1-vibe, Q-dixon, and DTI sequences. To analyze the data, at L5/S1 and L4/5 levels, precise delineation and measurement of ROIs were carried out on both side of the paravertebral muscles for each subject, totaling 64 ROIs. The steps to determine the ROIs in detail were as follows: Firstly, DWI was registered to T1-weighted images to ensure precise anatomical matching. For accurate ROI delineation at the L5/S1 and L4/5 levels, the central intervertebral discs were identified as anatomical landmarks on T1-weighted MRI. Subsequently, the paravertebral muscles on each side, including the erector spinae and multifidus, were individually outlined, with the intermuscular fascia included to maintain the integrity of the muscle groups in the analysis. Post-processing of DTI and Q-Dixon data was conducted using FSL, ITK-SNAP, and DSI Studio software. Scatterplots and Spearman correlation coefficients were employed to assess the relationship between DTI quantitative measurements and Q-Dixon PDFF.

### RESULTS

This study successfully demonstrated the feasibility of employing DTI for fiber tracking within the lumbar paraspinal muscles. The three-dimensional visualization of fiber tracking (Figure1) vividly showcased the fibrous structure of the paraspinal muscles, offering clear and notable insights. An analysis of the 64 regions of interest (ROIs) yielded histograms illustrating the distribution of PDFF, FA, MD, AD, and RD values (Figure2). Additionally, scatterplots unveiled significant positive correlations between FA values and PDFF, MD, AD, and RD values (all $p < .01$), as detailed in Figure 3.

### CONCLUSION

This study demonstrates that DTI quantitative parameters are associated with the extent of fat infiltration in lumbar paraspinal muscles, presenting novel tools for the imaging diagnosis of muscle degenerative diseases, such as sarcopenia.

### CLINICAL RELEVANCE/APPLICATION

The study reveals a correlation between DTI imaging parameters and lumbar paraspinal muscle fat infiltration, highlighting their potential as imaging biomarkers for diagnosing muscle degeneration and sarcopenia, with further implications for clinical application.

Carlos Dier, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In clinical practice, aneurysm wall enhancement (AWE) relies on visual adjudication, which can be biased and not very reproducible. Therefore, a novel three-dimensional (3D) method for quantifying the aneurysm wall's signal intensity (SI) can help experts' AWE assessment. We compared visual and objective determination of AWE.

### METHODS AND MATERIALS

Patients with saccular intracranial aneurysms (IAs) were imaged with 3T magnetic resonance imaging (MRI) between May 2018 and November 2023 at the University of Iowa. Clinical information was retrieved and morphological metrics such as size, size ratio, aspect ratio, and shape were obtained using digital subtraction angiography. Images were reviewed on Carestream viewer. AWE was visually determined by three experienced neuroradiologists if the degree of enhancement was equal or higher than the pituitary stalk and was not present before gadolinium (Gd) administration. 3D segmentations of the IAs were created utilizing 3D Slicer. A previous MATLAB pipeline was used to calculate the SI distribution across the aneurysm wall. A region of interest was marked in the corpus callosum for SI normalization. On T1+Gd MRI, the mean SI was computed and defined as the objective measurement. If this metric was higher than one, an aneurysm was objectively “enhancing.” Cohen’s kappa coefficient was used to analyze the inter-rater variability of AWE adjudication. Univariate regressions were performed to identify which morphological characteristics influenced accurate visual adjudication of AWE based on 3D quantification of SI.

### RESULTS

A total of 113 IAs were reviewed, and the agreement among experts on AWE visual assessment was moderate (k = 0.631). Out of these, 49.5% of IAs (56) were classified as "enhancing" and 50.5% (57) as "non-enhancing". However, there was minimal consensus between the visual assessment of AWE and the 3D method for SI quantification (K= 0.163, p = 0.021). The visual adjudication of enhancement was less accurate (PPV: 25%) compared to the 3D method. However, neuroradiologists were reliable in adjudicating the absence of enhancement (NPV: 91%). Experts were more likely to visually adjudicate as "enhancing" IAs larger than 7 mm (OR: 0.33, CI 0.15 - 0.72, p= 0.006), as well as those with a higher size ratio (OR: 0.69, CI: 0.49 - 0.95, p=0.027) despite being objectively "non-enhancing".

### CONCLUSION

Visual assessment of AWE varies among readers; however, it is reliable when adjudicating the absence of enhancement. 3D quantification of SI can avoid overestimating enhancement, particularly when evaluating aneurysms larger than 7 mm.

### CLINICAL RELEVANCE/APPLICATION

Three-dimensional quantification of SI of the aneurysm wall can improve experts' accuracy on AWE assessment.

## W3-SSNR10-3 ADVANCING CSVD DIAGNOSIS: INTEGRATING QUANTITATIVE SUSCEPTIBILITY MAPPING WITH MRI-BASED RADIOMICS

Xianglin Li (*Abstract Co-Author*) Nothing to Disclose
Meng Li (*Abstract Co-Author*) Nothing to Disclose
Changhu Liang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Lingfei Guo, MD (*Abstract Co-Author*) Nothing to Disclose
Zhenyu Cheng (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the potential of combining quantitative susceptibility mapping (QSM) and radiomics features as a quantitative imaging marker for diagnosing cerebral small vessel disease (CSVD), and to investigate how features from specific brain regions correlate with cognitive impairment (CI).

### METHODS AND MATERIALS

A total of 118 CSVD patients and 127 healthy controls underwent quantitative susceptibility mapping (QSM) and 3D-T1 scans, and all completed multiple cognitive tests. Lasso regression was used to select features, and the radiomics model was constructed based on the regression coefficients of these features. The test set was used to evaluate the effectiveness of the diagnostic criteria for CSVD, and the area under the receiver operating characteristic curve (AUC) was calculated. A hybrid model was constructed by combining the radiomics model with clinical cognitive and motor tests. All models were cross-validated to analyze the generalization ability of the models. Partial Least Squares (PLS) was used to screen the brain regions related to the cognitive tests in the model, and hierarchical regression was used to explore the effect of structural changes on cognitive performance and whether this relationship was changed by CSVD.

### RESULTS

A total of 245 participants were divided into training set, internal test set and validation set. The AUCs of radiomics and hybrid model were 0.80 and 0.87 in the internal test set, and 0.77 and 0.79 in the validation set, demonstrating the superior decision-making efficiency of the hybrid model. The Trail-Making Test (TMT), which is used to enhance the diagnostic performance of the model, is associated with multiple brain regions, especially the right cortical nuclei and the right fimbria. The volume reduction of these brain regions is related to the role of TMT in enhancing the diagnostic performance.

### CONCLUSION

The hybrid model based on radiomics features and cognitive tests can achieve quantitative diagnosis of CSVD and improve the diagnostic efficiency. Furthermore, the reduced processing capacity due to atrophy of the right cortical nucleus and right fimbria suggests the importance of these regions in improving the diagnostic accuracy of the model.

### CLINICAL RELEVANCE/APPLICATION

The hybrid model combining QSM, radiomics features and cognitive tests provides a highly accurate tool for the diagnosis of CSVD. This model can achieve early detection and quantitative diagnosis of CSVD, which is essential for timely intervention and management. In addition, it identifies specific brain regions associated with cognitive impairment, which may provide a reference for clinical treatment.

## W3-SSNR10-4 INCREASED DIAGNOSTIC ACCURACY AND QUANTITATIVE MEASUREMENT CONSISTENCY OF SMALL INTRACRANIAL ANEURYSMS USING ULTRA-HIGH-RESOLUTION PHOTON-COUNTING DETECTOR CT ANGIOGRAPHY

Zhihan Xu, MD (*Abstract Co-Author*) Nothing to Disclose
Yong Lu (*Abstract Co-Author*) Nothing to Disclose
Fuhua Yan, MS (*Abstract Co-Author*) Nothing to Disclose
Naying He, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Haiying Lyu, MD, BMedSc (*Presenter*) Nothing to Disclose

### PURPOSE

1) To assess the accuracy of ultra-high-resolution (UHR) photon-counting detector CT angiography (PCCTA) for diagnosis of cerebral aneurysms 5mm or smaller, compared with standard-resolution (SR) PCCT, with digital subtraction angiography (DSA) as the reference standard. 2) To evaluate the aneurysms quantitative measurement consistency between UHR PCCTA and DSA, and between SR PCCTA and DSA.

### METHODS AND MATERIALS

In this prospective study (IRB approved), a total of 54 consecutive patients were included, who underwent UHR PCCTA with SR reconstruction and subsequent DSA examination within a month. We assessed the diagnostic performance with DSA as the reference standard through calculation of sensitivity, specificity, and accuracy on a per-aneurysm basis. And we also compared the quantitative measures of intracranial aneurysm on PCCTA, including absolute height (AH), perpendicular height (PH), neck diameter (ND), aspect ratio (AR), size ratio (SR), etc., to the same variables measured on DSA by two blinded readers, and the intraclass correlation coefficients (ICC) were also calculated.

### RESULTS

Of 54 patients, 28 patients had a total number of 34 aneurysms at DSA. By using DSA as the reference standard, the respective sensitivity, specificity, and accuracy of PCCTA for detection of aneurysms were 100% vs 67.65% (UHR vs SR) and 96.77% vs 77.42% and 98.46% vs 72.31%, and those for detection of small aneurysms (5mm or smaller) were 100% vs 60.71%, and 96.77% vs 77.42%, and 98.31% vs 69.49% using UHR PCCTA, and SR PCCTA, respectively. The sensitivities of UHR PCCTA were higher for detection of small aneurysms, even for those smaller than 3mm. Quantitative aneurysm measurement consistency of PCCTA and DSA was also much better in UHR PCCTA (ICC: 0.89-0.98) than that of SR PCCTA (ICC: 0.21-0.82).

### CONCLUSION

UHR PCCTA has sufficient diagnostic accuracy and quantitative ability for small intracranial aneurysms compared with conventional SR PCCTA, with DSA as the gold standard.

### CLINICAL RELEVANCE/APPLICATION

Owing to its higher resolution and increased contrast-to-noise ratio, the photon-counting detector CT angiography can sufficiently improve the visualization of intracranial aneurysms and increase the diagnostic confidence for small intracranial aneurysms.

## W3-SSNR11-2 SHORT TERM COMPARISON BETWEEN INTRAARTICULAR INJECTION AND MEDIAL RAMUS NERVE BLOCK IN LUMBAR FACET JOINT SYNDROME

Fernando Ruiz Santiago, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This work in progress compares the effectiveness of intraarticular injection versus facet test by blocking the medial branch of the dorsal rami of the spinal nerve to diagnose and treat facet joints syndrome, at 1 month of follow-up.

### METHODS AND MATERIALS

This is an evaluator-blinded randomized trial including 54 patients (30 females). 26 patients with facet joints syndrome were randomly allocated to bilateral intraarticular injection of L3-L4 to L5-S1 (group 1) and 28 to bilateral medial branch of the dorsal rami nerve block from L4 to S1 (group 2). The procedures were performed under CT guidance.Included patients were assessed clinically by VAS score and the modified Oswestry index. Injection consisted of 10 ml of 1% mepivacaine and 40 mg of triamcinolone distributed in the six locations (6 joints, or 6 transverse process bases).Follow-up was performed by phone calls, at 1 month of follow-up. VAS score, Oswestry index, and a 4-point Likert scale were used for clinical assessment.Statistical analysis was performed by unpaired Student’s t-test and chi-square test.

### RESULTS

No age or clinical measures differences were found at presentation between groups 1 and 2 (VAS: 8.54± 0.3 versus 8.46± 0.2).Improvement in VAS score was superior in the nerve block group than in the intraarticular group (2.14± 0.5 versus 3.85± 0.6; p=0.41), but no statistical differences in the Oswestry index were found. The percentage of satisfaction was 85.7% in the nerve block versus 69.2% in the intraarticular group, although reaching no statistical significance.

### CONCLUSION

Although intraarticular injection and nerve block are useful methods to diagnose and treat facet joints syndrome, nerve block is superior in relieving pain.

### CLINICAL RELEVANCE/APPLICATION

This work confirms that the nerve block of the medial branch of the dorsal rami of the spinal nerve is superior to intraarticular injection in relieving pain and should be the preferred method to diagnose and select patients for further procedures, such as rhizolysis.

## W3-SSNR11-3 SHIFTING PATTERNS IN SINGLE-LEVEL VERTEBRAL AUGMENTATION PROCEDURES: A DECLINE IN VERTEBROPLASTY UTILIZATION COMPARED TO KYPHOPLASTY FROM 2010 TO 2021

Philip Ratnasamy (*Abstract Co-Author*) Nothing to Disclose
Albert Rancu (*Abstract Co-Author*) Nothing to Disclose
Jonathan Grauer (*Abstract Co-Author*) Nothing to Disclose
Rahul Jayaram, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Vertebral augmentation procedures, such as kyphoplasty and vertebroplasty, are common interventional spine procedures performed to treat vertebral compression fractures. While these procedures are often studied together, literature comparing trends, utilization, and costs of kyphoplasty relative to vertebroplasty is limited. The current study aimed to characterize trends in usage, predictive factors, and overall reimbursements of kyphoplasty compared to vertebroplasty using a large, national, multi-insurance, administrative database.

### METHODS AND MATERIALS

Cases of single-level kyphoplasty and vertebroplasty were identified using the 2010 to 2021 PearlDiver M161 database. Numerical and proportional utilization of these procedures were assessed for each year over the study interval. Univariate and multivariate logistic regression analyses were performed to identify clinical factors (age, sex, and Elixhauser Comorbidity Index [ECI]) and non-clinical factors (insurance and geographic region) for undergoing kyphoplasty over vertebroplasty. Average 90-day overall reimbursements of kyphoplasty and vertebroplasty were calculated and compared.

### RESULTS

From 2010 through 2021, 135,840 kyphoplasties and 31,891 vertebroplasties were performed. The proportional utilization of kyphoplasty compared to vertebroplasty increased from 2010 to 2021 (69.79% versus 87.55%, p<0.001). Independent predictors of having kyphoplasty relative to vertebroplasty included: age (per decade increase odds ratio [OR] 1.01), ECI (relative to 0, incrementally greater for ECI 1-2 [OR 1.28], ECI 3-4 [OR: 1.41], and ECI = 5 [OR: 1.51]), insurance plan (relative to commercial, Medicare [OR 0.97]), and geographic variation (compared to Midwest, West [OR 1.24], South [OR 1.98], and Northeast [OR 1.80]) (p<0.001 for all). There was no difference in 90-day overall reimbursement.

### CONCLUSION

Kyphoplasty increased from 69.79% of vertebral augmentation procedures in 2010 to 87.55% in 2021 (corresponding to a decreased utilization of vertebroplasty). Variations in utilization of one versus the other were associated with both clinical and non-clinical factors.

### CLINICAL RELEVANCE/APPLICATION

Drawing upon a vast national database, the current study is the largest to date to evaluate trends and predictive factors for utilization of single-level kyphoplasty versus vertebroplasty. Given similar overall healthcare system costs/reimbursements, evolving to best practices seems indicated.

## W3-SSNR11-4 ASSESSING THE IMPACT OF AN AI-ASSISTED PRIORITIZATION SYSTEM ON CERVICAL SPINE FRACTURE DETECTION THROUGH CT IMAGING IN THE OUTPATIENT SETTING

Arash Mahdavi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to assess the workflow impact of a computer-aided detection and prioritization artificial intelligence (AI) algorithm in the outpatient (OP) setting for suspected cervical spine fracture in patients undergoing cervical spine CT. By evaluating the impact of this AI algorithm on reducing wait times for radiologist interpretation of positive cervical spine fractures, we seek to explore its potential for expediting case diagnosis.

### METHODS AND MATERIALS

Prospective OP imaging data was collected between September 2023 and March 2024 at a multisite, quaternary care, academic healthcare system. Cervical spine CT studies processed with an FDA-approved AI algorithm for detecting cervical spine fracture were selected. For all cases included, a wait time metric measuring the duration from the completion of study acquisition to the time a radiologist initiated the case for dictation was calculated. Median wait times were compared between AI-positive and radiologist-notified cases (AI+) and cases determined as negative and not flagged by the AI system (AI-). Statistical testing for differences between the AI+/AI- groups was performed using Mood's median test.

### RESULTS

A total of 2,009 CT scans of the cervical spine were included, with 1,938 (96.5%) categorized as AI- and 71 (3.5%) as AI+. The AI+ scans exhibited a significantly reduced median wait time of 99.0 minutes (IQR: 458.9) compared to 225.7 minutes (IQR: 1187.6) for the AI- scans. This resulted in an observed wait time reduction of 126.7 minutes (56.1%, p<0.05).

### CONCLUSION

The integration of a computer-aided detection and prioritization AI solution led to a statistically significant reduction in wait times for radiologist review initiation in patients with suspected cervical spine fractures.

### CLINICAL RELEVANCE/APPLICATION

The utilization of an AI-powered solution for prioritizing CT scans showing positive cervical spine fractures in the OP setting demonstrated a reduction in wait times. Faster interpretation for spine fractures has potential clinical implications, as it enables faster communication and management, which might lead to improved patient outcomes and resource utilization.

## W3-SSNR11-5 UTILITY OF AN ABBREVIATED MRI PROTOCOL IN SCREENING FOR ACUTE CORD COMPRESSION

Marie Hausner, ARRT, RT (*Abstract Co-Author*) Nothing to Disclose
Jay K. Pahade, MD (*Abstract Co-Author*) Consultant, General Electric Company;Consultant, Clario Medical Imaging, Inc;
Rudra V. Joshi, MD (*Abstract Co-Author*) Nothing to Disclose
Josiah Sherman (*Abstract Co-Author*) Nothing to Disclose
Amit Mahajan, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

Acute cord compression (ACC) of the spinal cord is a surgical emergency and may cause permanent neurological deficits if not treated promptly. ACC may be due to multiple etiologies that are often nonspecific by history physical. MRI is considered the gold standard for spinal cord evaluation, but can be time-consuming and may delay surgical decompression. To minimize the resources necessary to evaluate ACC while ensuring time-sensitive diagnosis and treatment, we aimed to evaluate the efficacy of a limited non contrast two-sequence total spine screening protocol MRI to detect ACC.

### METHODS AND MATERIALS

Medical records were reviewed of patients who underwent a shortened, two-sequence total spine MRI protocol to screen for ACC after presenting to a large academic tertiary medical center emergency department from April 2018 to August 2022. The findings of the MRI were recorded, in addition to patient discharge disposition/admission status, receipt of surgery for ACC treatment, whether a repeat spine MRI using the standard spine protocol was performed within 15 days of the screening MRI, and if so, if undetected significant findings were subsequently identified.

### RESULTS

A total of 363 patients underwent the ACC protocol. 297 (82%) did not undergo further spine MRI within 15 days. 155 (43%) had no additional spine MRI within study period while 134 (64%) had additional spinal MRI done after 15 days. 66 patients underwent an additional spine MRI within 15 days, prior to

further disposition. 131 patients (44%) had no evidence of ACC on MRI, while 24 (15.5%) had findings of ACC on MRI. Of the 24 patients who demonstrated evidence of ACC on screening MRI, 19 (79%) underwent surgical decompression while 5 (21%) were treated conservatively. Of the 66 patients who required repeat imaging within 15 days, 16 (22%) underwent nonemergent surgical decompression, while 21 had no cord compression.

**CONCLUSION**

Most (80%) ED patients undergoing an abbreviated total spine ACC protocol had no imaging findings of acute cord compression. The ACC protocol is effective at ruling out and ruling in ACC with 79% of patients in our cohort undergoing operative decompression. Additional studies are necessary to quantify the cost benefit of using screening MRI protocols for evaluate ACC in the ED.

**CLINICAL RELEVANCE/APPLICATION**

In the current state of healthcare with high demand for imaging resources, throughput must be balanced with providing appropriate care. Our study demonstrates that an abbreviated screening protocol can allow for prompt diagnosis and free up more time for other high acuity cases to be scanned. If necessary, additional protocols can be added at the radiologist's discretion to guide characterization. Abbreviated protocols may allow for improved triaging of surgical emergencies.

## W3-SSNR11-6 RATES OF CERVICAL SPINE FRACTURES IN PATIENTS YOUNGER OR OLDER THAN 65

David M. Yousem, MD, MBA (*Abstract Co-Author*) Royalties, RELX;Speaker, MRI Online;Board Member, MRI Online;
Shuchi Zinzuwadia, MD (*Abstract Co-Author*) Nothing to Disclose
Armin Tafazolimoghadam (*Abstract Co-Author*) Nothing to Disclose
Mahla Radmard, MD (*Abstract Co-Author*) Nothing to Disclose
Akua Amoah, MD, MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

There was a distinction made in the 2001 Canadian Cervical Spine Rule (CCR) regarding patients 65 and over and younger than 65 studied from 1996-1999 as far as indications for cervical spine computed tomography (CSCT) scanning in the trauma setting. We sought to determine if the data on fracture differences and age are still relevant in 2024. Should age 65 and older alone be an indication for CSCT in the ED?

**METHODS AND MATERIALS**

This IRB-approved retrospective study reviewed five years of cervical spine CT data from trauma patients in two emergency departments. We analyzed variables including age, fracture types and sites, treatments, and injury mechanisms, categorizing patients by symptomatic status and age (above/below 65 years). Asymptomatic patients were cognitively capable with no indications of cervical spine injuries. Results from 2018-2023 were compared with historical data from 1996-1999, which identified fracture rates of 1.7% in patients under 65 and 6.6% in those 65 and older (NEJM, 2003).

**RESULTS**

In the 65 and older age group, we found 190 fractures (2.0%) among 9455 CSCTs (112 females); 29 (0.3%) were in asymptomatic patients. In the age group less than 65 there were 199 (1.6%) fractures out of 12531 CSCTs of which 19 (0.15%) were asymptomatic. Looking at subsets of the data, the rates of fractures in the 65-75 age range (1.7%) paralleled the 1.7% quoted in the less than 65 age group in 2003. There were no distinguishing features as to the mechanism of injury, cervical spine level, or part of the vertebra fractured between asymptomatic and symptomatic patients. The older age group showed more C1 and C2 fractures [52 (27.4%) and 78 (41.1%) respectively] and fewer motor vehicle collisions [23 (12.1%) compared to the younger group (89 (44.7%)] as a cause of their fractures. Patients < 75 years old who are asymptomatic showed rates of fractures that were less than 0.25%; those 40 years old or less had a less than 0.1% asymptomatic fracture rate (Table 1).

**CONCLUSION**

The difference in fracture rates reported from the data that inspired the CCR (1.4-1.7%) fracture rate in trauma patients < 65 and 5.2%-6.6% in = 65 years old) differ from our data collected in 2018-2023. Our cohort at age 65-70 has a similar rate of fractures (1.7%) to the CCR < 65 group. Because of successful aging, healthier elderly, and safety features now in cars, it may be appropriate to extend the CCR age criterion to 70-75 years old.

**CLINICAL RELEVANCE/APPLICATION**

The study supports updating the Canadian Cervical Spine Rule to raise the age threshold for CSCT scans in trauma patients, which could reduce unnecessary scans and optimize emergency department resources.

Wenxuan Li, BS (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate how well an AI algorithm generalized to out-of-distribution datasets from other resources on the task of detecting pancreatic neoplasms including Pancreatic Ductal Adenocarcinoma (PDAC), Cysts, and Pancreatic Neuroendocrine Tumors (PNET).

### METHODS AND MATERIALS

We collected and annotated 2,599 dual-phase contrast-enhanced CT scans to create our in-house JHH datasets, and split it to training (N=1,594) and test (N=1,005) sets. The JHH dataset was used to train AI algorithms and conduct internal validation. Moreover, we collected five datasets of normal patients, i.e., BTCV (N=47), Pancreas-CT (N=42), CHAOS (N=20), TraumaDet (N=4,706), and HeidelbergN (N=364), to assess AI's Specificity and three datasets of pancreatic tumor patients, i.e., MSD-Pancreas (N=89), JHH-OUT (N=389), and HeidelbergP (N=196), to assess AI's Sensitivity. These external datasets were sourced from various hospitals worldwide. To enhance AI generalizability, we developed three strategies: data augmentation, an improved AI algorithm, and post-processing. Our data augmentation included rotations, translations, and intensity variations. The AI algorithm leverages the strengths of both CNN and transformer architectures to enhance algorithmic capacity. Post-processing was applied to eliminate predicted tumors located outside the pancreas or those with a radius less than 4mm. Furthermore, synthetic tumors supplemented the annotated data for training, providing the AI with additional training examples of small tumors, which are rare and difficult to detect in most datasets.

### RESULTS

For internal validation, our AI achieved a sensitivity of 95.2% and a specificity of 95.7%. On the MSD-Pancreas dataset, the sensitivity was 91.0%. For external validation, our AI yielded a Sensitivity of 91.8% and 92.3% when detecting pancreatic tumors on JHH-OUT and HeidelbergP, respectively. When dealing with normal patients, the AI showed a Specificity of 100%, 90.0%, 95.2%, 91.3%, and 96.4% on BTCV, CHAOS, Pancreas-CT, TraumaDet, and HeidelbergN.

### CONCLUSION

The performance of AI algorithm on external datasets showed a slight decrease compared to the JHH dataset but remained within acceptable ranges, demonstrating notably better results on two external datasets. This indicates AI algorithm exhibits strong generalizability and can be integrated into clinical routines, aiding radiologists in making reliable and, possibly, near-perfect detections.

### CLINICAL RELEVANCE/APPLICATION

The encouraging results from our study, achieved using CT scans from a variety of scanners and protocols for external validation, suggest that AI algorithms could eventually be incorporated into clinical practice.

## W3-STCE1-2 EVALUATING OPEN AND CLOSED-SOURCE LANGUAGE AND VISION-LANGUAGE MODELS FOR MULTICENTER IMAGE-BASED DIAGNOSIS IN RADIOLOGY: A COMPARATIVE STUDY WITH READER PERFORMANCE

Chang Min Park, MD, PhD (*Abstract Co-Author*) Research Grant, Lunit Inc;Stock options, Lunit Inc;Research Grant, Coreline Soft, Co Ltd;Stock options, Coreline Soft, Co Ltd;Stockholder, Promedius Inc
Ji Young Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Dabin Min (*Abstract Co-Author*) Nothing to Disclose
Kyungmin Jeon (*Abstract Co-Author*) Nothing to Disclose
Donguk Kim (*Abstract Co-Author*) Nothing to Disclose
Gihun Cho, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate open and closed-source Large Language Models (LLMs) and Vision-Language Models (VLMs) for multicenter image-based diagnosis in radiology, assessing fine-tuning impact and comparing with reader performance.

### METHODS AND MATERIALS

We analyzed 9,409 Radiopaedia cases (19 body systems, 13 modalities, 592 centers, 61+ countries) and 175 Korean Society of Thoracic Radiology (KSTR) chest cases (2 modalities, 1 center). Radiopaedia data was split into 7,527 training and 1,882 test cases; KSTR cases were used only for testing. We evaluated seven open-source LLMs (include Llama3), two open-source VLMs (include OpenFlamingo), and two closed-source models (GPT-4 and Claude) under three input settings: History and Findings (HF, text-only), Image, History and Findings (IHF), and Image and History (IH). Models were tested in both zero-shot and fine-tuned scenarios. Diagnostic accuracy (DxAcc) was defined as the proportion of GPT-4's perfect 5-point scores, with a radiologist validating a subset of these scores. We created a 200-case multiple-choice question (MCQ) from Radiopaedia for circular evaluation, measuring consistent correct answers across four iterations with rotated options. Additionally, we compared model performance with reader accuracy on 162 KSTR cases.

### RESULTS

A radiologist's review validated the DxAcc metric, showing 98.79% (408/413) agreement. Claude outperformed other models, achieving DxAcc of 64.8% (Radiopaedia, IHF), 60.0% (KSTR, HF), and 89.5% accuracy (MCQ, HF). Among open-source models, Llama3-70B performed best with DxAcc of 53.5% (Radiopaedia, HF), 38.6% (KSTR, HF), and 78.5% accuracy (MCQ, HF). Fine-tuning improved open-source models' DxAcc by 9.2%±4.3 on Radiopaedia, 3.8%±3.2 on KSTR, and accuracy by 9.7%±11.8 on MCQ. Notably, while Claude surpassed reader accuracy (41.8%±26.9) on KSTR in HF/IHF settings ($P < .001$), all models underperformed readers in the IH setting ($P < .001$). Closed-source models showed slight improvements in IHF versus HF (GPT-4: 59.4% to 62.2%, Claude: 60.2% to 64.8% on Radiopaedia). All models showed significant performance degradation in IH settings compared to IHF ($P < .001$), with Claude's DxAcc dropping by 38.2% on Radiopaedia and 50.3% on KSTR.

### CONCLUSION

LLMs and VLMs show potential for image-based radiology diagnosis, with fine-tuning improving performance. While open-source models showed lower performance compared to closed-source alternatives, all models, including closed-source ones, underperformed readers particularly when image findings were not provided.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrates the potential for AI integration in radiology workflows, highlighting both the promise and the limitations of LLMs/VLMs in diagnosis.

## W3-STCE1-3 BEYOND BMI: AI-DRIVEN INSIGHTS ON BODY COMPOSITION'S IMPACT ON BRAIN HEALTH

Saqib Basar (*Abstract Co-Author*) Nothing to Disclose
Madhurima Datta (*Abstract Co-Author*) Nothing to Disclose
Thanh Duc Nguyen (*Abstract Co-Author*) Nothing to Disclose
Nasrin Akbari (*Abstract Co-Author*) Nothing to Disclose
Sam Hashemi, MSc (*Abstract Co-Author*) Nothing to Disclose
Saurabh Garg (*Abstract Co-Author*) Nothing to Disclose
Ahmed Gouda, MSc (*Abstract Co-Author*) Nothing to Disclose
Soojin Lee (*Presenter*) Nothing to Disclose

### PURPOSE

While BMI is commonly used to determine obesity, it does not account for body composition and relies solely on body weight and height. This study investigates the impact of body composition on brain health using quantitative metrics from AI models applied to whole-body MR imaging.

### METHODS AND MATERIALS

We used 3D nnU-Net segmentation models to analyze 1.5T whole-body MRI scans from 2,839 participants across the US and Canada. Total skeletal muscle mass percentage (SMP) and fat mass percentage (FMP) were derived by converting segmentation volumes to mass and normalizing by weight. Volume- and thickness-based 97 brain metrics were normalized by intracranial volume.We matched 300 pairs of participants for age, sex, height, BMI, type 2 diabetes, and hypertension, but differing in SMP by over 5%. Participants with higher SMP were classified into the HighSMP group, while their matched counterparts were placed in the LowSMP group. The two groups were compared using two-sample t-tests with false discovery rate correction. We used multiple linear regression to examine brain metrics in relation to SMP and FMP, controlling for the aforementioned participants' characteristics as well as pack year and alcohol intake.

### RESULTS

The HighSMP and LowSMP groups differ significantly not only in body composition characteristics but also in 48.5% of brain metrics. The LowSMP group had reduced total brain ($p < .001$) and hippocampus ($p < .001$) volumes and increased inferior lateral ventricle volume ($p < .001$). Cortical thickness, particularly in the temporal lobe, was also lower in the LowSMP group ($p < .001$). These differences were consistent in both normal and overweight participants. Regression analysis showed brain volumes and thickness positively associated with SMP and negatively with FMP, with the effect size of SMP being around four times greater.

### CONCLUSION

Even with the same BMI, body composition significantly impacts brain volumes and cortical thickness. Higher SMP is linked to greater brain volume and cortical thickness, regardless of BMI categories. The influence of skeletal muscle mass on brain metrics surpasses that of fat mass.

### CLINICAL RELEVANCE/APPLICATION

AI-based automated segmentation holds significant potential for identifying cross-organ correlations. Our study demonstrates that body composition offers crucial insights, surpassing the traditionally used BMI measure in assessing brain health.

## W3-STCE2-1 EFFECTIVENESS AND FEASIBILITY OF MOBILE MRI USE IN THE PUBLIC HEALTH SYSTEM. EIGHTEEN YEARS OF EXPERIENCE. "ACTIONS SPEAK LOUDER THAN WORDS"

Alfonso Iglesias, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Alfonso Iglesias Arias (*Abstract Co-Author*) Nothing to Disclose
Mercedes Arias Gonzalez, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to evaluate the effectiveness and feasibility of mobile magnetic resonance imaging (MRI) in providing diagnostic imaging services in remote and underserved areas in a public health system environment.

### METHODS AND MATERIALS

Mobile MRI units were deployed to various locations, including seven second level hospitals with no in-house magnets and five third level hospitals with in-house magnets in order to reduce waiting lists. During the last 18 years, 279.143 MR scans in 231.210 patients were performed using a 1.5T MRI system, with standardized protocols to ensure image quality. Quality was assessed with annual surveys of patients and requesting doctors. Operational metrics, including setup time, patient throughput and kilometers avoided by patients were recorded.

### RESULTS

Mobile MRI units reached mean satisfaction levels of 95% in the patient survey and 98% in the survey of requesting doctors. The most common indications for MRI included neurological conditions (60%), musculoskeletal disorders (31%), and abdominal issues (9%). Operationally, the mobile units demonstrated an average setup time of 25,5 minutes and a patient throughput of 24 scans per day, with minimal logistical challenges reported. More than 16 million of kilometers of travel were avoided to patients.

### CONCLUSION

Mobile MRI is a viable solution for delivering high-quality diagnostic imaging in remote and underserved populations in a public health system environment. The study demonstrates that mobile MRI can achieve comparable image quality to fixed-site facilities while significantly improving accessibility and equity to the MRI technique.

### CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of mobile MRI to enhance access to essential imaging services, improve patient care, accessibility and equity to the MRI technique in underserved areas.

## W3-STCE2-2 BENEFITS OF QUANTUM MRI COILS FOR LOW-FIELD MRI

Grum Teklemariam, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

A major challenge faced by low-field MRI (LFM) is the low signal-to-noise (SNR) of the signal received from the subject. Despite this issue, there has been significant advances in the development of LFM scanners for more than a decade. A notable example is the success of Hyperfine Inc offering a head only, portable MRI scanner able to be transported on wheels and used in point-of-care (PoC) settings. Other similar applications have been developed from diagnosing NASH (Livivos Inc) to portable MRI Mammography systems and dedicated prenatal scanners. In all these applications, a rf coil receiver with significant SNR increases over current performance would be extremely beneficial. The SNR of any sensor depends on a fundamental level on the coupling strength between the detector, the MRI coil, and the signal, the electromagnetic field generated by the subject nuclei or spin [1]. Amongst other factors, such as coil geometry and noise, there is an intrinsic quantum coupling strength set by vacuum electromagnetic fluctuations. Aspects of this interaction can be enhanced by engineering the properties of a resonator to increase the SNR through a stronger spin coupling [2].

### METHODS AND MATERIALS

Model: A theoretical model for the room temperature quantum enhancement was developed confirming the SNR increase. Based on this, a study was conducted of a low pass, rf head birdcage coil using Ansys HFSS 2023. To demonstrate the enhancement effect, both a conventional birdcage coil and a quantum enhanced birdcage type coil was built. The comparisons were conducted on bench tests and phantom tests on a Siemens Avanto 1.5T scanner. Coil Designs: For fast prototyping, the formers were 3D printed using PETG and the conductors were directly placed on these formers with the necessary tuning and matching reactive elements.

## RESULTS

The scanner tests were conducted on an Avanto 1.5T (63.6 MHz) on a standard 2-liter phantom. SNR measurements were done using a gradient echo (GRE) sequence. The scan parameters are listed below: The scanner results confirm our expected doubling of the measured SNR as shown below. To protect the scanner from potential spurious signals, the receiver gain was set to low. In some instances, additional interface cabling was required to match the input impedance of the scanner preamp for optimal SNR performance.

## CONCLUSION

The central axial signal of a birdcage coil has been shown to have near optimal SNR under ultimate intrinsic SNR theory. Comparing these coils using a birdcage coil shows that indeed the spin coupling is being enhanced. In the images above, we used the same ROIs to compare across the three coils we scanned. The flex coil gives us a reference signal since a surface coil with a smaller diameter inherently yields a higher signal. Based on these results, an improved design has been developed that shows factor of 2 increase over the current quantum coil and a new enhanced coil is being built to test in a scanner to confirm the bench test results.

## CLINICAL RELEVANCE/APPLICATION

These developments affect all MRI scanners but can be of great benefit for low-field MRI scanners.

# W3-STCE2-3 UTILIZING 0.55T MRI FOR THE EVALUATION OF EMERGENCY DEPARTMENT PATIENTS PRESENTING WITH RIGHT UPPER QUADRANT PAIN- PRELIMINARY EXPERIENCE

Hero K. Hussain, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Christopher Fung (*Abstract Co-Author*) Nothing to Disclose
Jacob Richardson (*Abstract Co-Author*) Nothing to Disclose
Vikas Gulani, MD, PhD (*Abstract Co-Author*) Research support, Siemens AG;Consulting, Cook Group Incorporated
Nicole Seiberlich, PhD (*Abstract Co-Author*) Royalties, Siemens AG;Research support, Siemens AG
Radhika Rajeev, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To assess performance of standard and deep-learning (DL) reconstructed unenhanced 0.55T MRI in Emergency Department (ED) patients presenting with right upper quadrant (RUQ) pain, and compare MRI diagnoses with standard-of-care imaging (CT/US) and clinical diagnosis.

## METHODS AND MATERIALS

IRB-approved prospective study of patients presenting to ED with acute, nontraumatic RUQ pain. After undergoing standard-of-care imaging tests (CT and/or US) patients underwent standard unenhanced MRI abdomen and pelvis on commercial 0.55T MRI (MAGNETOM Free.Max, Siemens Healthineers AG, Erlangen, Germany). Imaging protocol: coronal and axial T2w HASTE, axial fat suppressed T2w BLADE, axial DWI (b=50, b=800 s/mm2), axial OP/IP GRE, axial FS T1w 3D VIBE, and 3D T2w TSE MRCP. In the latter phase of the study, the coronal axial HASTE, axial FS T2w TSE, and DWI b50 ,b800 sequences were replaced with deep-learning (DL) versions of the same sequences applying super-resolution processing that uses neural networks trained with high-resolution images. 2 abdominal radiologists blinded to standard-of-care imaging independently interpreted images and rendered a diagnosis. Each radiologist's interpretation was assessed for agreement with standard-of-care imaging study and final clinical diagnosis. Interrater reliability was assessed with Cohen's kappa. The acquisition time of standard 0.55T and DL-0.55T sequences were compared.

## RESULTS

15 patients were scanned, initial 10 with standard 0.55T sequences and last five with DL-sequences. Standard of care imaging (only CECT n=4, only USG-n=4, USG and CECT n= 4, combination of USG, CT and MRI 1.5T- n=2, USG and HIDA n=1) was performed in all patients. Clinical diagnoses were: acute pyelonephritis(n=2), acute appendicitis (n=1), acute cholecystitis (n=1), acute small bowel obstruction (n=1) gallstone pancreatitis, (n=1), cholangitis and liver abscess (n=1), pancreatic head mass (n=1), mild diffuse colitis (n=1) and no cause was identified on MRI (n=1). At standard 0.55T MRI, concordance between radiologists' interpretation of 0.55T images and standard-of-care imaging was 8/10 cases (reader 1) and 9/10 cases (reader 2). Both radiologists diagnosed acute pyelonephritis before it was visualized on CT/ clinically diagnosed. Both radiologists missed acute pancreatitis on MRI which was detected on USG and clinical diagnosis. Concordance between clinical diagnosis and 0.55T MRI was 8/10 and 9/10, respectively. Agreement between the two radiologists was 90% (kappa = 0.61). For 0.55T DL-MRI, the clinical diagnoses were: cholelithiasis (n=4) and acute cholelithiasis (n=1). Concordance between radiologists' interpretation and standard-of-care imaging was 4/5 cases (readers 1 and 2). Both radiologists did not report cholelithiasis seen on USG. Concordance between clinical diagnosis and DL-0.55T was 5/5 for both readers. Agreement between the two radiologists was 100% (kappa =1). MRI revealed findings not visible on CT (pyelonephritis, small abscess in ruptured appendicitis and small liver abscess in patient with cholangitis). Average acquisition time for standard 0.55T was 64.4 ± 9.05 mins. with FS T2w TSE being longest (11.56 ± 4.33 mins) compared to 58.2 ± 5.32 mins for DL-0.55T. Compared to standard 0.55T sequences, acquisition times of the DL-0.55T sequences were shorter for coronal HASTE (47% decrease) and axial HASTE (45% decrease), and longer for DWI (15% increase) and FS T2W TSE (12% increase).

## CONCLUSION

Low-field unenhanced MRI is a viable alternative to establish cause of RUQ pain in ED patients and has potential to replace standard-of-care enhanced CT and US. Deep learning algorithm reduced acquisition time of the HASTE sequence only.

## CLINICAL RELEVANCE/APPLICATION

Unenhanced MRI at 0.55T has potential to replace contrast enhanced CT and US for the definitive diagnosis of suspected hepatobiliary and pancreatic disease in patients presenting to the ED with RUQ pain.

Takeshi Matsumoto (*Abstract Co-Author*) Nothing to Disclose
Takeshi Sato (*Presenter*) Nothing to Disclose

### PURPOSE

To verify the proportion of complete response (CR) achieved using selective conventional transarterial chemoembolization (cTACE) with a porous glass membrane pumping emulsification device in hepatocellular carcinoma (HCC).

### METHODS AND MATERIALS

Between January 2021 and June 2023, 50 cases of HCC with tumor diameter =5 cm and liver function classified as Child-Pugh A or B were enrolled in a multicenter clinical trial (jRCTs052200095). An emulsion, created by mixing epirubicin solution and lipiodol using the emulsification device, was injected into the feeding arteries of the target lesions followed by embolization with gelatin sponge particles. The primary endpoint was the proportion of CR at three months post-treatment. Secondary endpoints included the proportion of CR at one month and the incidence of adverse events. Results were compared using the exact binomial test with a prior study using an emulsion prepared by a three-way stopcock method (JIVROSG-1302).

### RESULTS

Two cases were deemed ineligible after registration, leaving 48 subjects (SS) who underwent the protocol treatment. An additional three cases were found ineligible post-TACE, creating an analysis set (FAS) of 45 subjects. Both one-month and three-month CR rates in the FAS were 97.9% [95% confidence interval: 88.2, 99.9], which was significantly higher than in the prior study (75.2% at three months, 84.2% at one month; $P<0.001$, $P=0.008$). The incidence of serious adverse events in SS included increased AST (50.0%), increased ALT (29.2%), decreased platelets (2.1%), and decreased ALP (2.1%), showing no significant difference compared to the prior study. The deterioration rate of the ALBI score at three months post-TACE in the FAS was 17.8%.

### CONCLUSION

Selective cTACE using an emulsion prepared with a porous glass membrane pumping emulsification device for HCC demonstrated a higher CR rate compared to traditional methods using a three-way stopcock, with equivalent safety, suggesting its efficacy and security in clinical use.

### CLINICAL RELEVANCE/APPLICATION

cTACE utilizing W/O emulsion achieves an impressive 98% complete response rate, indicating its efficacy.The incorporation of glass membrane emulsification device technology contributes to enhancing the outcomes of TACE, suggesting its potential to increase the power of cTACE.

## W6-SSIR03-2 FACTORS IMPACTING SURVIVAL AFTER TRANSARTERIAL RADIOEMBOLIZATION IN PATIENTS WITH UNRESECTABLE INTRAHEPATIC CHOLANGIOCARCINOMA: A COMBINED ANALYSIS OF THE PROSPECTIVE CIRT AND CIRT-FR STUDIES

Peter Reimer, MD, MBA (*Presenter*) Nothing to Disclose

**PURPOSE**

This combined analysis of the prospective observational CIRT (CIRSE Registry for SIR-Spheres Therapy) and CIRT-FR (CIRSE Registry for SIR-Spheres Therapy in France) studies aimed to tackle the challenges as to what is the best timing for transarterial radioembolization (TARE) with Yttrium-90 resin microspheres for intrahepatic cholangiocarcinoma (ICC) in multimodal treatment approaches

**METHODS AND MATERIALS**

174 ICC patients from CIRT (120) and CIRT-FR (54) enrolled between Jan 2015-Dec 2017 and Aug 2017-Aug 2020, respectively were analysed. Patient characteristics and treatment-related data were collected at baseline. Four treatment groups based on the position of TARE in the treatment strategy were assessed. Safety and follow-up data were collected every three months.

**RESULTS**

Statistically significant differences in overall survival (OS) across different treatment groups were found (p=0.0028). Patients receiving first-line TARE in addition to any systemic treatment had a median OS of 32.5 months. Patients selected for first-line TARE alone showed a median OS of 16.2 months, whereas TARE as 2nd or further treatment-line resulted in a median OS of 12 and 9.3 months, respectively. Partition model dosimetry was an independent predictor for better OS (p=0.0259). Overall, 89 patients (51.1%) experienced =1 adverse event, while grade 3-4 adverse events occurred in 28 (16.1%) patients.

**CONCLUSION**

Results from this combined analysis point towards the benefits of TARE in combination with systemic therapy for the treatment of unresectable ICC and consolidate the evidence on safety and effectiveness of TARE in this cohort. Adequate dose-determination techniques play an important role in the effectiveness of TARE.

**CLINICAL RELEVANCE/APPLICATION**

TARE in combination with systemic therapy shall be considered for the treatment of unresectable ICC. Personalized dosimetry improves OS ensuring higher dose requirements for ICC.

## W6-SSIR03-4 TOWARD A "NO-MAPPING" PROTOCOL IN THE ERA OF ABLATIVE RADIOEMBOLIZATION: A RETROSPECTIVE STUDY OF 235 SOLITARY HEPATOCELLULAR CARCINOMAS

Charles Hua, MD,MS (*Abstract Co-Author*) Nothing to Disclose
Hugh McGregor (*Abstract Co-Author*) Nothing to Disclose
Sandeep Vaidya, MD (*Abstract Co-Author*) Nothing to Disclose
Grace Laidlaw, MD (*Abstract Co-Author*) Nothing to Disclose

Wayne L. Monsky, MD, PhD (*Abstract Co-Author*) Research Consultant, Merit Medical Systems, Inc
Harika Barri, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Toward the goal of identifying patients with hepatocellular carcinoma (HCC) in which mapping angiography can be omitted before radioembolization, the purpose of this study was to identify patient and tumor characteristics associated with low hepatopulmonary shunting and predictable treatment volumes.

**METHODS AND MATERIALS**

All yttrium-90 transarterial radioembolizations (TARE) for solitary HCC performed from 2019 to 2023 were reviewed. Clinical and laboratory data including patient age, presence of cirrhosis, and prior TIPS procedures were recorded. Imaging data including tumor size, tumor distance from the liver capsule, and macrovascular invasion were obtained from pre-procedural imaging. Lung shunt fraction (LSF) obtained from planar scintigraphy after Tc-99m MAA infusion was recorded. Treatment volume was measured on post-treatment Bremsstrahlung SPECT/CT images. Univariable and multivariable analyses of clinical and imaging data were performed to identify variables associated with high LSFs (>10%) and large treatment volumes (>300 mL).

**RESULTS**

235 patients with solitary HCC underwent TARE during the study period. Mean age was 68 +/- 10 years (range 24 to 92) and 219 patients had cirrhosis. 9 patients had previously undergone TIPS. Mean tumor size was 3.7 +/- 2.3 cm (range 1.0 to 13.7). 8 tumors were central in location (>4 cm from liver capsule). Macrovascular invasion was present in 15 patients. Mean LSF was 4.5 +/- 3.8% (range 0.6 to 25.8). Mean treatment volume was 208 +/- 232 mL (range 25.1 to 2068.1). Previous TIPS and macrovascular invasion were associated with a LSF >10%, with odds ratios (OR) of 6.9 and 11.1 respectively. Tumor size >5 cm and central location were associated with treatment volumes >300 mL, with ORs of 40.8 and 3.8 respectively. 162 patients had peripheral tumors <5 cm without macrovascular invasion and had no history of TIPS. In this group, the maximum treatment volume was 297.9 mL and the maximum LSF was 9.7%. Using a partition dosimetry model with a tumor to normal parenchyma vascularity ratio of 2:1, 1.7 GBq of Y90 microspheres would be required to reach a tumor dose of >400 Gy. The lung dose in this scenario would be 9.6 Gy.

**CONCLUSION**

In patients without macrovascular invasion or history of TIPS, peripheral solitary HCCs <5 cm in size have predictable LSFs and treatment volumes. Safe lung doses and ablative tumor doses may be achieved by ordering a standardized activity in these cases, without the need for mapping angiography.

**CLINICAL RELEVANCE/APPLICATION**

Maximum lung dose and minimum tumor dose can be predicted based on clinical and imaging characteristics in solitary HCC. Mapping angiography prior to TARE in a subset of patients may not be necessary, saving time and resources while maintaining safety and efficacy.

## W6-SSIR03-5 PORTAL VEIN EMBOLIZATION AND HEPATIC VEIN EMBOLIZATION VERSUS PORTAL VENOUS EMBOLIZATION ALONE IN CIRRHOTIC AND NON-CIRRHOTIC SWINE

**PURPOSE**

To evaluate the efficacy of portal vein embolization (PVE) combined with hepatic vein embolization (HVE) versus PVE alone in inducing growth of the future liver remnant (FLR) in a porcine model.

**METHODS AND MATERIALS**

Sixteen swine were divided into two groups: eight with induced cirrhosis (CG) and eight with healthy livers (NCG). In both the CG (n = 8) and the NCG (n = 8), two subjects were subjected to a sham procedure, while three subjects underwent either PVE only or a combined HVE and PVE. For PVE, 100-300µm microspheres (BeadBlock, Boston Scientific, Marlborough, MA, USA) were injected via an ipsilateral approach, and 5-12mm detachable coils (Interlock Embolization Coils, Boston Scientific, MA, USA) were placed at the right and right-middle lobe portal vein origins. HVE was performed by deploying a vascular plug in the right hepatic vein (Amplatzer Vascular Plug II, Abbott Medical, MN, USA). Portal pressures and non-targeted liver biopsies were obtained before each procedure. Computed tomography (CT) scans with intravenous contrast of the liver were acquired on the day of as well as two and four weeks after the procedure. Total liver and left lobe volumes were segmented on portal-venous phase CT scans using the 3D Slicer software (Version 5.0.3 r30893 / 7ea0f43, Harvard University National Institutes of Health, Boston, USA). Student's t-tests were used with the significance level set at $P < 0.05$. All statistical analyses were carried out in GraphPad Prism (Version 9.5.1; GraphPad, CA, USA).

**RESULTS**

Hepatic cirrhosis was achieved in all swine of the CG and confirmed on histological staining with Masson's trichrome. In all swine, the FLR was greater after the combination procedure of PVE and HVE (24.12% [95% CI: 15.36%, 32.88%]) compared to PVE only (12.75% [95% CI: 7.43%, 18.07%]) ($P = 0.021$) two and four weeks after embolization (23.23% [95% CI: 15.79%, 33.47%] and 15.08% [95% CI: 9.98%, 20.87%] ($p=.043$). Similarly, in the CG, the degree of hypertrophy was greater after PVE combined with HVE (20.85% [95% CI: 14.40% 27.30%]) than PVE alone (8.66% [95% CI: 6.47%, 10.86%]) ($p=.0089$) at two as well as four weeks after embolization (19.27% [95% CI: 17.87%, 20.67%] and 13.33% [95% CI: 9.23%, 13.33%]) ($p=.0003$).

**CONCLUSION**

PVE combined with HVE resulted in a greater degree of hypertrophy of the FLR in this porcine model than PVE alone two and four weeks after embolization. This combination also achieved a greater degree of hypertrophy in cirrhotic swine.

**CLINICAL RELEVANCE/APPLICATION**

Combined PVE and HVE may achieve more effective hypertrophy than PVE alone in patients with cirrhosis who require a larger future liver remnant after partial hepatectomy. This could improve resectability in cirrhotic patients with significant liver tumor burden.

## W6-SSNMMI06-1 INITIAL EXPERIENCE WITH [177LU]LU-PSMA-617 POST-APPROVAL FOR METASTATIC CASTRATION-RESISTANT PROSTATE CANCER AT A MAJOR U.S. ACADEMIC CENTER: EFFICACY, SAFETY, AND OUTCOME PREDICTION

Somya Shesadri, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The goal of our study was to investigate efficacy, safety, and outcome predictors of [177Lu]Lu-PSMA-617 at a major U.S. academic center, since its approval from the FDA in March 2022.

### METHODS AND MATERIALS

Metastatic castration-resistant prostate cancer patients who received [177Lu]Lu-PSMA-617 (Pluvicto) at Johns Hopkins Outpatient Center outside clinical trials were screened for inclusion. Patients who completed treatment or received 4 cycles of [177Lu]Lu-PSMA-617 and had outcome data available were included. Outcome data included PSA response (50% decline), PSA progression-free survival (PSA-PFS), and overall survival (OS).Baseline circulating tumor DNA (ctDNA) mutational status in homologous recombination deficiency (HRD), PI3K alteration pathway, and aggressive variant prostate cancer (AVPC)-associated genes were tested for associations with treatment outcome. Baseline PSMA-PET/CT images were analyzed using SelectPSMA, an artificial intelligence algorithm, to make treatment outcome predictions, and associations with observed outcome were evaluated.

### RESULTS

Of 86 screened metastatic castration-prostate cancer patients who received [177Lu]Lu-PSMA-617, 76 (88%) met inclusion criteria. PSA response was achieved in 30/74 (41%) patients. The median PSA-PFS was 4.1 months (95%CI, 2.0-6.2) and the median OS was 13.7 months (95%CI, 11.3-16.1). Mutational status in HRD, PI3K pathway, or AVPC genes was not associated with treatment outcome. 18/71 (25%) patients classified by SelectPSMA as non-responders had significantly lower rates of PSA response (6% vs 51%; $p<0.001$), shorter PSA-PFS (median: 1.3 vs 6.3 months; $p<0.001$), and shorter OS (median: 6.3 vs 14.5 months; $p=0.046$) compared to patients classified as non-responders.

### CONCLUSION

[177Lu]Lu-PSMA-617 offered in real-world setting after regulatory approval in the U.S. showed similar efficacy and toxicity profile with previously reported German real-world data. Artificial intelligence-based analysis of baseline PSMA-PET/CT images may improve patient selection.

### CLINICAL RELEVANCE/APPLICATION

In this study we evaluated, to our knowledge, for the first time the efficacy and toxicity of [177Lu]Lu-PSMA-617 in real-world setting in the U.S. in post-approval era. Additionally, identifying candidates for [177Lu]Lu-PSMA radioligand therapy who are unlikely to benefit from treatment is an urgent unmet need and this study attempted to investigate a sensitive screening test modality to enhance patient selection.

### PURPOSE

LuPSMA (177Lu-vipivotide tetraxetan) is an effective therapy for metastatic castration-resistant prostate cancer (mCRPC), providing well-tolerated systemic radiation delivery1. While the advantage of LuPSMA therapy is the ability to treat systemic disease with radiation, additional localized disease control may be required2. In this context, targeted external beam radiation therapy (RT) may be used as an adjunct, but the indications, efficacy, and safety/toxicity of combining RT with LuPSMA are unclear3. Here, we report our experience with RT in patients receiving LuPSMA therapy and assess local disease control/palliation outcomes.

### METHODS AND MATERIALS

This retrospective IRB-exempted study reviewed patients who received LuPSMA therapy at 2 academic cancer centers in 5/2022-3/2024. Inclusion criteria required patients to receive RT within 6 months of starting LuPSMA and complete at least 1 cycle. The study examined parameters such as RT rationale, lesion locations, symptoms, and outcomes.

### RESULTS

We reviewed 52 out of 244 mCRPC patients receiving LuPSMA across our institutions who met the above criteria at the time of analysis. Patients received radiation doses and techniques tailored to their specific disease conditions. 28/52 (48%) patients received RT before LuPSMA, 7 during, 14 after, and 3 underwent RT twice with LuPSMA. RT was administered to 33 patients for impending pathological fractures, and 15 for intracranial and epidural diseases. Notable adverse effects based on the PRO-CTCAE and CTCAE criteria included general pain in 11.5% of patients at severity level =1, and thrombocytopenia in 3.8% at severity level =3. At a median follow-up of 5 months, 32 individuals showed symptom improvement, and 20 died from disease progression. At the time of review, 38% (20/52) of patients demonstrated a =50% PSA reduction from baseline at any time during RT/LuPSMA therapy (PSA50) - this was slightly lower but not significantly different compared to the general LuPSMA population reviewed at our institutions (PSA50 of a subset of the general population:50%, 122/244, Chi-squared proportional test: p=0.13). Furthermore, the PSA response was markedly heterogeneous (best PSA% change median: 70%, range: 2- 86.3%).

### CONCLUSION

In our clinical experience, RT was mainly indicated for localized tumor control and symptom management, especially for osseous and CNS lesions. In these settings, patients tolerated RT with limited toxicity, which likely facilitated their LuPSMA treatment.

### CLINICAL RELEVANCE/APPLICATION

Our findings suggested that the integration of RT with LuPSMA effectively controls localized disease and manages symptoms, enhancing patients' quality of life and functional status while enabling uninterrupted LuPSMA treatment.

### PURPOSE

Optimal thresholds for PET-based patient selection criteria for 177Lu-PSMA-617 (LuPSMA) therapy are yet to be defined. Landmark VISION and TheraP trials introduced different imaging criteria. TheraP used higher PSMA uptake threshold and required an additional pre-treatment FDG-PET to exclude patients with discordant findings, likely helping to increase the PSA50 response rate (66% vs 46%) at the cost of higher screen failure (28% vs 12.6%). In this study, we aimed to evaluate the association of PSMA and FDG PET-based eligibility criteria defined by the TheraP trial and its subgroups with the outcomes in VISION-eligible patients.

### METHODS AND MATERIALS

Consecutive patients treated with LuPSMA who met criteria for treatment as defined in the VISION trial were included in this analysis. Patients had pre-treatment PSMA and FDG PET and were blindly classified by two nuclear medicine physicians as TheraP eligible (TheraP-E) and TheraP ineligible (TheraP-I). Further subclassification was made based on reasons of ineligibility: low PSMA and discordant findings. The endpoints of interest were PSA50 response (i.e. =50% decline in PSA from baseline), PSA progression-free survival (PFS), and overall survival. Odds ratio (OR) and hazard ratio (HR) were computed using logistic and Cox regressions, respectively.

### RESULTS

A total of 75 patients with a median age of 74 years (IQR, 70-79) were included. 69/75 (92%) patients received chemotherapy prior to LuPSMA (38/75[51%] 1 regimen, 31/75[41%] 2 or more regimens). Median follow-up time was 14.5 months (95% confidence interval [CI] 12.2,17). TheraP-I patients had a lower PSA50 rate compared to TheraP-E patients (28% vs 67%, OR= 0.19, 95% CI 0.06-0.52, p= 0.002) and lower PSA PFS (HR= 2.0, 95% CI 1.2-3.3, p= 0.007). Overall survival in the TheraP-I group was numerically shorter than in the TheraP-E group but the comparison was only marginally significant (10.4 vs not reached [NR] months, HR= 1.9, 95% CI 1.0-3.7, p= 0.054). Patients classified as TheraP-I due to low PSMA had no statistically significant different risk of death (p=0.9) compared to the TheraP-E group, but patients with discordant findings had statistically significantly higher risk of death (HR=2.3, 95% CI1.1-4.6, p=0.02).

### CONCLUSION

In VISION-eligible patients who were treated with LuPSMA, TheraP-ineligible patients due to discordant FDG PET findings had lower PSA50, PSA-PFS, and possibly shorter OS. Our study suggests that the shorter OS of TheraP-I patients is mainly driven by the presence of FDG-avid discordant disease.

### CLINICAL RELEVANCE/APPLICATION

Understanding the value of PSMA expression thresholds and the influence of dual tracer imaging findings will allow more appropriate patient selection for LuPSMA

## W6-SSNMMI06-5 IS ALKALINE PHOSPHATASE OR PROSTATE SPECIFIC ANTIGEN A BETTER BIOMARKER OF PSMA-AVID DISEASE IN PATIENTS TREATED WITH LUTETIUM-177 PSMA?

### PURPOSE

Prostate-specific antigen (PSA) is a widely used marker for prostate cancer, however, its role and accuracy for disease progression has yet to be vetted. Alkaline phosphatase (ALP) has been shown to be a useful biomarker for osseous disease burden, especially in patients receiving radium-223 dichloride. There is a paucity of data on each biomarker and their role in evaluation for treatment response. This study aims to determine the role of PSA and ALP as biomarkers in patients undergoing Lutetium-177 PSMA therapy (Pluvicto).

### METHODS AND MATERIALS

All patients with PSMA-avid metastatic castration-resistant prostate cancer undergoing Pluvicto were enrolled. Baseline and follow-up PSMA (F-18 DCFPyL) PET/CTs were segmented using MIM Software® (Beachwood, OH) to analyze total, osseous and soft tissue tumor burden and activity. PSA and ALP levels prior to starting Pluvicto (200 mCi, every 6 weeks) therapy, and 4 weeks after each cycle were recorded. Total, osseous and soft tissue tumor volumes (TV), lesion activity (LA) and PSMA expression (SUVmax, SUV mean, SUVmin) were correlated with Spearman correlation to measure the relationship between pre-therapy, post-therapy and the difference between pre-and post-therapy.

### RESULTS

A total of 47 patients were identified, of which 20 patients had two consecutive PSMA PET/CTs. Both the PSA and ALP measurements (spearman correlation and p value, respectively) showed significant correlation with baseline total TV (0.62 and 0.50, p-values <.001) and change in total TV (0.71 vs 0.66, $p<0.001$), however only ALP was correlated with follow-up PET/CT total TV (0.51, $p=0.02$). While both biomarkers showed correlation with bone TV in pre-, post-therapy and difference between pre and post values, ALP had a stronger correlation than PSA ($p<0.05$). Both PSA and ALP had mild-to-moderate correlation total LA and bone LA, except for PSA in post-therapy PET/CTs. PSA demonstrated a mild correlation with soft tissue TV (0.53, $p=0.01$) and soft tissue LA (0.5, $p=0.02$), whereas ALP did not show any correlation with neither soft tissue TV nor LA. Neither of the biomarkers showed any correlation with SUVmax, SUVmean or SUVmin.

### CONCLUSION

This study supports that both PSA and ALP have significant roles in pre-therapy, post-therapy and treatment response evaluation for Pluvicto therapy. Our results support the use of ALP in bone tumor burden measurement over PSA, and PSA for soft tissue disease burden over ALP.

### CLINICAL RELEVANCE/APPLICATION

ALP and PSA values have an important role in evaluation of PSMA PET/CTs. This study shows that ALP can be used to detect changes in bone tumor volume throughout the treatment course. PSA is also accurate in terms of total tumor burden and for the evaluation of soft tissue disease burden.

## W6-SSNMMI06-6 PERFORMANCE OF CHATGPT-4 AND GEMINI CHATBOTS IN RESPONDING TO COMMON PATIENT QUESTIONSON PROSTATE CANCER $^{177}$LU-PSMA-617 THERAPY

### PURPOSE

As artificial intelligence (AI) chatbots are becoming increasingly popular, many patients are expected to turn to them as a rapid source of health information. This raises important questions about the reliability and effectiveness of AI chatbots in delivering accurate and understandable information. The aim of this study was to evaluate and compare the accuracy, conciseness, and readability of responses from OpenAI's ChatGPT-4 and Google's Gemini (formerly known as Bard) to patient inquiries concerning the novel LuPSMA therapy for prostate cancer.

### METHODS AND MATERIALS

Two experts listed the 12 most commonly asked questions by patients on LuPSMA therapy. These twelve questions were prompted to ChatGPT-4 and Gemini. AI-generated responses were distributed using an online survey platform (Qualtrics) and blindly rated by eight experts. The performances of the AI chatbots were evaluated and recorded across three domains: accuracy, conciseness, and readability. Accuracy and conciseness of responses were

evaluated on a 4-point scale, and readability was assessed on a 3-point scale. Additionally, potential safety concerns associated with AI-generated answers were also examined. Responses with an accuracy score of = 2 were categorized as misleading answers. The Mann-Whitney U and chi-square (?²) tests were utilized to compare the performances of AI chatbots.

**RESULTS**

Eight experts participated in the survey, evaluating 12 AI-generated responses across the three domains of accuracy, conciseness, and readability, resulting in 96 assessments (12 responses x 8 experts) for each domain per chatbot. ChatGPT-4 provided more accurate answers than Gemini (2.95 ± 0.671 vs 2.73 ± 0.732, p=0.027). Gemini's responses had better readability than ChatGPT-4 (2.79 ± 0.408 vs 2.94 ± 0.243, p=0.003). Both ChatGPT-4 and Gemini achieved comparable conciseness scores (3.14 ± 0.659 vs 3.11 ± 0.679, p=0.798). Experts categorized the AI-generated responses as incorrect or partially correct at a rate of 16/96 for ChatGPT-4 and 28/96 for Gemini. Gemini's answers contained significantly more misleading information than those of ChatGPT-4 (p = 0.039).

**CONCLUSION**

While Gemini's responses were assessed as easier to understand, ChatGPT-4 demonstrated higher accuracy. However, neither provided completely accurate answers to all questions.

**CLINICAL RELEVANCE/APPLICATION**

AI chatbots have gained significant attention, and their performance is continuously improving. Nonetheless, these technologies still need further improvements to be considered reliable and credible sources for patients seeking medical information on LuPSMA therapy.

### PURPOSE

To evaluate the efficacy of rectal contrast gel to assist in pelvic MRI detection of rectal endometriosis

### METHODS AND MATERIALS

Before 3/2018, our institution routinely administered rectal contrast gel (RCG) in our MRI pelvis protocol to assess endometriosis. We subsequently discontinued the use of RCG but maintained the remaining protocol. We included 71 consecutive adult patients who had MRI pelvis with RCG for pelvic pain or endometriosis and surgical/pathologic follow up within 1 year. As a comparison, we included 73 consecutive patients who had MRI pelvis without RCG, matched by surgical findings and meeting the same inclusion/exclusion criteria. The exams were anonymized, randomized and presented on our clinical PACS to 3 readers (R1 18 yrs, R2 3 yrs, and R3 1 yr experience). Readers evaluated for rectal lesions, mural involvement, and overall disease severity utilizing deep pelvic endometriosis index system. Comparison of rectal lesion detection to the gold standards of surgical findings were made and sensitivity (Sn), specificity (Sp), positive predictive value (PPV), and negative predictive value (NPV) were obtained and compared between with and without RCG for each reader using Fischer's Exact test. Fleiss' Kappa was obtained for all readers for all studies, with RCG only, and without RCG only.

### RESULTS

Diagnostic statistics for WITH and WITHOUT RCG respectively: R1 (Sn 0.58, 0.75 (p=0.67), Sp 0.69, 0.72 (p=0.84), PPV 0.28, 0.35 (p=0.76), NPV 0.89, 0.94 (p=0.49); R2 (Sn 0.42, 0.58 (p=0.68), Sp 0.90, 0.87 (p=0.78), PPV 0.45, 0.47 (p=0.31), NPV 0.88, 0.91 (p=0.76); R3 (Sn 0.42, 0.75 (p=0.21), Sp 0.83, 0.82 (p=1.00), PPV 0.33, 0.45 (p=0.73), NPV 0.88, 0.94 (p=0.32). Kappa for readers in detecting bowel lesions with RC: 0.51; without RC: 0.71. Kappa for readers in disease severity with RC: 0.61; without RC: 0.62. % of lesions proximal to level of RCG: R1: 39%, R2: 58%, R3: 48%.

### CONCLUSION

RCG does not significantly impact detection and diagnosis of rectal lesions in deep endometriosis. Readers agreement on detecting lesions is better without RCG than with RCG. Agreement on assessing disease severity is similar with or without RCG.

### CLINICAL RELEVANCE/APPLICATION

Administering RCG requires time, extra budget, and skilled personnel without benefits of improved lesion detection or interreader variability. Other interventions may be considered for optimal imaging of rectal endometriosis.

## W6-SSOB03-2 ADVANCING ENDOMETRIOSIS DETECTION: A DEEP LEARNING-ENHANCED MULTI-SEQUENCE MRI ANALYTICAL MODEL

**PURPOSE**

To evaluate the efficacy of deep learning (DL) tools in enhancing the accuracy of multi-sequence MRI-based detection of endometriosis.

**METHODS AND MATERIALS**

We gathered a patient cohort from our institutional database, composed of patients with surgically and pathologically confirmed endometriosis from 2015-2024. We collected their gynecologic MRIs three months prior to the diagnostic surgery. We also created an age-matched control group that underwent a similar MR protocol but without a diagnosis of endometriosis. For our analysis, we used sagittal T1-weighted(T1) pre- and post-contrast, as well as T2-weighted(T2) MRIs. We allocated one-eighth of the dataset for testing and conducted seven-fold cross-validation on the remainder. MR images were analyzed using various convolutional neural network (CNN) architectures. Simultaneously, two abdominal radiologists and one fellow reviewed a random selection of images and documented their endometriosis detection.

**RESULTS**

594 patients were included in the case and control group. The final DenseNet-121 classifier model demonstrated robust performance. Our findings indicated the most accurate predictions were obtained from T1 pre- and post-contrast images in our validation sets, employing seven-fold cross-validation across 520 cases. In this setup, the model achieved average values on 7 folds as follows: F1 Score of 0.792, area under the receiver operating characteristic curve (AUROCC) of 0.898, sensitivity of 0.854, and specificity of 0.861. Further testing on the separate set of 74 cases using T2 and T1 pre- and post-contrast MRI and ensemble technique resulted in an F1 Score of 0.911, AUROCC of 0.881, sensitivity of 0.976, and specificity of 0.720. In addition, occlusion map visualizations provided insights into the model's focus areas, further confirming the model's diagnostic accuracy in identifying endometriosis lesions. Our radiologist readers achieved an 86.66% accuracy in disease detection.

**CONCLUSION**

The study introduced the first DL model to use multi-sequence MRI on a large cohort, showing results nearly equivalent to human detection in identifying endometriosis. Further external validation of the model is in progress.

**CLINICAL RELEVANCE/APPLICATION**

Endometriosis, a condition characterized by the growth of endometrial-like tissue outside the uterus, affects 5-10% of women of reproductive age, leading to chronic pelvic pain, infertility, and malignancy. Despite its prevalence, the diagnosis of endometriosis through imaging remains challenging and requires at least 2 years of specialized training. Advances in DL, particularly through CNNs, are changing the diagnosis and management of this complex condition and fostering patient-centered treatment.

## W6-SSOB03-3 AUTOMATED DETECTION, QUANTIFICATION AND ENUMERATION OF OVARIAN FOLLICLES ON T2-WEIGHTED MR IMAGING IN A LARGE PATIENT COHORT OF 2781 REPRODUCTIVE AGE WOMEN

Yosef G. Chodakiewitz, MD (*Abstract Co-Author*) Nothing to Disclose
Sam Hashemi, MSc (*Abstract Co-Author*) Nothing to Disclose
Ahmed Gouda, MSc (*Abstract Co-Author*) Nothing to Disclose

Siavash Khallaghi (*Abstract Co-Author*) Nothing to Disclose
Saqib Basar (*Abstract Co-Author*) Nothing to Disclose
Soojin Lee (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to develop an automated deep learning model to quantify and enumerate ovaries and follicles, providing valuable insights into women's reproductive health, aiding clinical decision making.

**METHODS AND MATERIALS**

We utilized a U-Net semantic segmentation network trained on 328 sagittal T2-weighted pelvis scans to detect ovaries, enabling quantification of ovarian volume and extraction of the ovarian region of interest (RoI) mask. Subsequently, a Retina U-Net instance detection network was trained on 198 ovarian RoIs from sagittal T2-weighted pelvis scans of 99 patients to detect individual follicles within each ovary. During inference, ovarian RoIs were obtained using the U-Net network, and individual follicles within each ovarian RoI were detected using the Retina U-Net solution. Normative aging- and menstrual-cycle curves were derived based on the models' predictions over a large general population (N=2781) of patients aged 20 to 55 years, with the last menstrual period (LMP) within the past 29 days. This allowed for comparison of ovarian and follicle measurements against the general population by age and days since the LMP and monitoring of the dominant follicle development throughout the cycle.

**RESULTS**

The normative graphs depict expected trends in ovarian volume and follicle size across the reproductive lifespan of women. Ovarian volume typically increases until around age 25, reflecting peak fertility, before gradually decreasing. Additionally, the dominant follicle's volume and dimensions tend to increase leading up to ovulation midpoint, then decrease post-ovulation.

**CONCLUSION**

Leveraging the power of artificial intelligence, our model enables the automated detection and quantification of ovarian follicles using T2-weighted pelvic MRI.

**CLINICAL RELEVANCE/APPLICATION**

Analyzing detected follicles across a large population yields normative curves for follicle count and distribution, offering valuable insights into ovarian function and reproductive health. This approach provides an efficient tool for clinical research, enabling reliable assessment of ovarian characteristics and their variations within populations. The automated approach also facilitates longitudinal monitoring of ovarian follicle development, enabling personalized interventions and fertility management strategies. Further, by analyzing the follicle distribution pattern using the proposed tool, the model may assist clinicians with identifying characteristic features associated with polycystic ovary syndrome (PCOS).

## W6-SSOB03-4 EVALUATION OF ROUTINE TRANSVAGINAL ULTRASOUND FOR DETECTING ENDOMETRIOSIS: RETROSPECTIVE COHORT STUDY BASED ON SRU CONSENSUS CLASSIFICATION

Priyanka Jha, MBBS (*Abstract Co-Author*) Nothing to Disclose
Richa D. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Luyao Shen, MD (*Abstract Co-Author*) Nothing to Disclose
Stephan Altmayer, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Aya Kamaya, MD (*Abstract Co-Author*) Royalties, RELX;Research Grant, Canon Medical Systems Corporation
Martina Z. Francisco, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The recent Society of Radiologists in Ultrasound (SRU) Consensus on routine pelvic ultrasound (US) for endometriosis has established the clinical criteria to perform augmented pelvic US (APU). Our goal was to evaluate a retrospective cohort of patients undergoing routine transvaginal US (TVUS) to identify findings suggestive of endometriosis.

**METHODS AND MATERIALS**

We performed a retrospective cohort including consecutive patients aged 16 to 55 years old undergoing TVUS for any cause in December 2019 to allow for at least 4 years of follow-up. Our exclusion criteria were obstetric US or technically inadequate US. We implemented the SRU consensus classification for the interpretation of US: normal (APU-1), equivocal for endometriosis (APU-2), positive for endometriosis (APU-3). Two readers with 5 and 10 years of experience evaluated the imaging findings in consensus. Medical records were evaluated to determine if APU was indicated at the time of the routine US according to the SRU consensus criteria. Follow-up imaging or procedures were also evaluated to determine if the patient was ever diagnosed with endometriosis before or after the routine US.

**RESULTS**

A total of 76 consecutive patients were identified with a mean age of 44.6 years (SD 8.1 years). Among the total, 24 patients (31.5%) would have met clinical criteria for performance of APU at the time of the exam. Five patients (6.6%) had imaging findings equivocal for endometriosis on routine TVUS, two of which were found to have prior history of endometriosis, while the other three have not yet established a diagnosis. Sixteen patients (21.0%) had imaging findings positive for endometriosis. Of those, three (18.7%) had a known history of endometriosis, two (12.5%) had a follow-up MRI consistent with endometriosis, and the remaining eleven (68.7%) have not yet established a diagnosis of endometriosis during the follow-up. Among the 21 patients with equivocal or positive findings on routine TVUS, eleven (52.3%) met clinical criteria for performance of APU. Of the 24 patients who met clinical criteria for performance of APU, eight (33.3%) were classified as positive for endometriosis.

**CONCLUSION**

Nearly 29% of patients undergoing routine TVUS for any cause were found to have equivocal or positive US findings of endometriosis. Most of these patients have not yet established the diagnosis of endometriosis. Among the patients who met clinical criteria for performance of APU, 33.3% were classified as positive for endometriosis (APU-3).

**CLINICAL RELEVANCE/APPLICATION**

Endometriosis often goes undiagnosed for many years. A significant proportion of routine pelvic ultrasounds performed for any reason demonstrate signs suggestive of endometriosis, which may assist in early diagnosis.

## W6-SSOB03-6 DW MRI RADIOMICS IN PREDICTING THE HISTOPATHOLOGICAL RISK FACTORS AND MOLECULAR CLASSIFICATIONS FOR 2023 FIGO STAGING OF ENDOMETRIAL CANCER

Yu-Fu Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Gigin Lin, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The study aims to construct a radiomics risk model utilizing standard DW MRI to predict the histopathological factors and molecular classifications for the 2023 FIGO staging of endometrial cancer.

**METHODS AND MATERIALS**

From 2015 to 2023, a total of 541 patients were enrolled, age 52+/-11 years, with each patient having 105 volumetric radiomic features extracted from their whole tumor on pre-treatment DW MRI. Radiomic risk scores (Rad-Scores) were formulated using the LASSO regression model to predict risk factors pertinent to the 2023 FIGO staging of endometrial cancer in a training cohort (n=433), and subsequently validated in an independent testing cohort (n=108). A significance level of $P < .05$ was employed for statistical analysis.

**RESULTS**

In the testing dataset, the Rad-Scores exhibited precise predictions of histopathological factors, achieving accuracies accuracy of 0.74 for aggressive histological type, 0.77 for deep myometrial invasion, 0.74 for cervical stromal invasion, 0.78 for adnexal involvement, 0.72 for lymphovascular space invasion (LVSI), and 0.73 for lymph node metastasis. Moreover, the Rad-Scores demonstrated promising capabilities in forecasting molecular classifications, attaining accuracies of 0.83 for DNA polymerase epsilon mutation (POLEmut), 0.80 for mismatch repair deficient (MMRd), and 0.65 for p53 abnormal (p53abn). These Rad-Scores histopathological factors and molecular classifications translated into the prediction of overall survival and disease-free survival ($P < .05$).

**CONCLUSION**

DW MRI radiomics exhibits promising potential in predicting histopathological factors and molecular classifications of endometrial carcinoma. Integration of radiomics with the 2023 FIGO staging system could offer a more evidence-based framework for treatment recommendations, thus enhancing outcomes and survival rates.

**CLINICAL RELEVANCE/APPLICATION**

By developing a radiomic risk score using routine DW MRI and establishing its association with histopathological factors and molecular classifications for the 2023 FIGO staging, this study shows promising translational relevance in providing a personalized approach to therapy selection for endometrial cancer patients.

## W6-SSPH10-2 PORTABLE BRAIN CT MOTION CORRECTION USING GENERATIVE DIFFUSION MODEL

Dufan Wu, PhD (*Abstract Co-Author*) Nothing to Disclose
Rajiv Gupta, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Quanzheng Li, PhD (*Abstract Co-Author*) Nothing to Disclose
Quirin Strotzer, MD (*Abstract Co-Author*) Nothing to Disclose
Rehab N. Khalid, MBBS (*Abstract Co-Author*) Nothing to Disclose
Zhennong Chen, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Portable Computed Tomography (CT) for brain often encounters motion artifacts due to the prolonged scanning time and critically ill patients who are unable to cooperate or hold still. We proposed a generative diffusion model to reduce motion artifacts in portable brain CT images.

### METHODS AND MATERIALS

The model is a 3D conditional diffusion model that progressively generates a corresponding motion-free 3D brain CT under the guidance of a motion-corrupted 3D brain CT volume using the diffusion sampling process. 3D patch-wise training was employed for training efficiency, but the model was applied to the entire full-resolution volume during testing. The training data were generated from 80 motion-free CT volumes acquired from fixed CT scanners, where 10 samples of motion-corrupted volumes were simulated from each volume using the portable CT geometry. All CT images were reconstructed using the soft-tissue kernel.The trained model was first tested on 200 simulated motion-corrupted CT volumes from 20 different patients for quantitative evaluation. It was then tested on 30 motion-degraded portable brain CT scans acquired by CereTom (Neurologica, USA) from ICU patients. Two radiologists reviewed each dataset before and after the correction and scored the corrected images for motion artifacts, diagnostic value, and preference in the range of -2 to +2. The reviewers scored the pre- and post-correction images, in a randomized, blinded fashion after a washout time to account for recollection bias.

### RESULTS

Our method demonstrated significant correction of motion artifacts in both skull and brain. In simulated testing data, our method significantly reduced MAE from 183+-40HU to 54+-16HU, reduced RMSE from 353+-61HU to 130+-37HU, improved SSIM from 0.62+-0.11 to 0.95+-0.03, ($p<0.01$ under one-tailed t-test). It achieved the same level of contrast-to-noise-ratio as motion-free ground truth images. Our method also outperformed the convolutional neural network (CNN)-based method quantitatively and visually.In the real testing data, the motion corrected CT had better or equal score than the original CT on all the 30 scans for all 3 criteria. Out of the 30 scans, Radiologist-A rated motion-corrected images to be superior 29:1 in terms of artifacts, 25:5 for overall image quality, and 17:13 for improved diagnostic value. For Radiologist-B, these scores were 26:4, 26:4, and 23:7, respectively.

### CONCLUSION

A generative diffusion model can significantly reduce motion artifacts in portable brain CT scans.

### CLINICAL RELEVANCE/APPLICATION

Motion artifacts is one of the major image limitations in portable brain CT scans. Our method can significantly reduce its motion artifact and enhance the diagnostic value of portable CT in all clinical settings.

## W6-SSPH10-3 MOTION-COMPENSATED BLADE-MRI IMAGE RECONSTRUCTION USING GENERATIVE NEURAL NETWORKS

Daniel Rueckert, PhD (*Abstract Co-Author*) Consultant, IXICO Limited;Consultant, HeartFlow, Inc
Sergios Gatidis, MD (*Abstract Co-Author*) Nothing to Disclose
Kerstin Hammernik, MSc (*Abstract Co-Author*) Nothing to Disclose
Konstantin Nikolaou, MD, MBA (*Abstract Co-Author*) Advisory Panel, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Siemens AG;Advisory Panel, Bayer AG;Speakers Bureau, Bayer AG;Research Grant, Bayer AG
Thomas Kuestner, DIPLENG (*Abstract Co-Author*) Nothing to Disclose
Bin Yang, PhD,DIPLENG (*Abstract Co-Author*) Nothing to Disclose
Andreas Peter Wagner, MD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Motion artifacts originating during MRI acquisition pose a problem in the clinical field. In the abdomen, respiratory-induced motion artifacts limit the diagnostic value. In free-breathing acquisitions or in scan conditions when navigator triggering fails, the complex and highly localized deformations are challenging to compensate by current techniques (e.g., BLADE).

**METHODS AND MATERIALS**

Deep Learning-based (DL) generative approaches currently show promising results in compensating motion artifacts. However, current approaches do not guarantee data fidelity to the acquired k-space.We propose the reformulation of motion correction as an image reconstruction task and present a reconstruction network incorporating a generative learnable regularizer and data consistency layers within an adversarial training. Investigations are carried out for T2 weighted abdominal BLADE imaging. A supervised training with simulated motion artifacts is used during network training in a cohort of 113 patients. Testing is performed on prospective data acquired under free-breathing in 8 patients.

**RESULTS**

The performance of the proposed network is evaluated on simulated motion (breathing as cosine waveforms) and actual motion (free-breathing patients). It achieves high qualitative and quantitative (SSIM, PSNR, NMSE) performance on simulated and actual motion in comparison to common neural networks or compressed sensing reconstruction. Fidelity to the acquired data was achieved.

**CONCLUSION**

Formulating the task of motion compensation as a reconstruction problem yields feasible results with superior image quality to comparable neural networks or classical motion reconstruction methods.Prior motion estimation and optimization is needed for high performance scanner integration. For understanding and controlling the motion correction capabilities, further analysis, e.g., uncertainty estimation, is needed.

**CLINICAL RELEVANCE/APPLICATION**

The number of multiple breath-hold maneuvers during acquisition could be reduced or eliminated, resulting in increased diagnostic value in patients who are unable to perform extensive breathing maneuvers due to their condition.Due to the similarity of the problems, undersampled data acquisition and downstream compensation in the pipeline could accelerate the whole MRI examination, allowing more patients to be examined and costs to be reduced.

**PURPOSE**

Low-dose CT simulation is needed to assess reconstruction and dose reduction techniques. Projection domain noise insertion requires manufacturers' proprietary information. Image domain methods have been established for filtered back projection (FBP) but are hard to extend to iterative and deep-learning reconstruction and different reconstruction settings. We aim to address these challenges using a scalable physics informed generative neural network for simulating scanner- and algorithm-specific low dose CT exams (PALETTE)

**METHODS AND MATERIALS**

PALETTE included physics-based noise prior generation (NPG), Noise2Noisier (N2Nr) network, and noise texture synthesis (NTS) network. NPG injected Poisson noise in forward projection of routine dose images and created a noise prior via back projection. N2Nr derived the bias prior at low dose. NTS used noise and bias prior as inputs to predict difference images between routine and reference low dose images. PALETTE used custom transformers to harmonize different sampling frequencies at variable field of view. The encoded reconstruction types were used as an input to modulate intrinsic filter response to differentiate noise texture types in networks. Custom regularizations were developed, including constraints on noise correlations and frequency distribution. We evaluated PALETTE using data from 3 CT scanners, including 1 photon counting CT. For each scanner, 30 patient cases were collected (10 training, 20 testing). A clinically validated projection domain noise insertion tool was used to create the lower dose references (50% and 25% dose). FBP and 3 iterative reconstruction algorithms were used, including 6 filters / denoising strengths and various field-of-views (FOV diameter 340 - 460 mm). Phantom data was acquired to assess noise power spectra (NPS) using peak frequency and mean absolute error (MAE). In patient cases, local and global noise texture and the corresponding frequency distributions were inspected. Noise level was compared in uniform liver parenchyma using mean absolute percent difference (MAPD)

**RESULTS**

PALETTE-derived and reference NPS showed consistent peak frequency and MAE < 0.7 HU2cm2. In patient cases, PALETTE-simulated images were well matched to the reference across all reconstruction settings, showing similar local and global noise structure and frequency distribution (mean Jensen-Shannon divergence <0.1). MAPD of noise level was <6% and not statistically significant (Student's t-test $p>0.05$)

**CONCLUSION**

PALETTE generalized well across reconstruction algorithms and settings on different CT scanners

**CLINICAL RELEVANCE/APPLICATION**

PALETTE can provide high quality scalable low dose CT simulation using only image data to facilitate optimizing CT protocols and dose

## W6-SSPH10-5 A NOVEL APPROACH TO DENOISE CT IMAGES USING A LATENT DIFFUSION-BASED DEEP LEARNING MODEL: A PHANTOM STUDY COMPARED TO A DEEP LEARNING RECONSTRUCTION METHOD

Won Chang, MD (*Abstract Co-Author*) Nothing to Disclose
Yoon Jin Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Young Hoon Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Jungheum Cho, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jongmin Jee, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to evaluate the denoising performance of CT images using a latent diffusion-based deep learning model (LDM), compared to a deep learning-based image reconstruction method (DLR, TrueFidelity™).

**METHODS AND MATERIALS**

Our proposed model utilized an encoder-decoder architecture enhanced by a latent diffusion process, with training structured in two phases. Initially, the encoder-decoder architecture was trained to extract and reconstruct features from the input data. Then, the latent diffusion model was trained using a cold diffusion process to align the diffusion endpoint with the latent space of low-dose CT images. The transformed latent representation was synthesized by the decoder into a denoised image. The model was trained on 100 patient datasets, which included routine-dose (100%) and simulated low-dose abdominal CT images (13%, 25%, and 50%). The model's performance was evaluated using a multi-sized image quality phantom acquired under six different radiation dose levels (0.48, 0.97, 1.93, 3.87, 7.74, and 15.47 mGy). The images were reconstructed using filtered back projection (FBP) and three strength levels of the DLR (low, medium, high). The FBP images were denoised using the LDM. We compared the detectability index (d'), a task-based detection performance metric that reflected spatial resolution and noise properties, between LDM and DLR using these images. The d' values were obtained under various combinations of three target sizes (10, 5, and 1 mm), five inlet contrasts (CT value differences with the background: -895, 50, 90, 335, and 1000 HU), and five phantom diameters (36, 31, 26, 21, and 16 cm). An increase in d' was observed in LDM compared to DLR-low, DLR-medium, and DLR-high.

**RESULTS**

The overall mean d' values measured in LDM increased by 86% (range: -21~297%) compared to DLR-low, by 56% (-31~240%) compared to DLR-medium, and by 22% (-49~164%) compared to DLR-high. Overall, there was an improvement in performance, but occasionally, a few values suffered at high contrast inlets with low dose conditions.

**CONCLUSION**

The mean detectability of the LDM was shown to be superior to that of the vendor-specific DLR at all strengths.

**CLINICAL RELEVANCE/APPLICATION**

This denoising model may provide a potential solution for enhancing the detectability of low-contrast objects while simultaneously preserving diagnostic details, thereby improving clinical outcomes.

## W6-SSPH10-6 CONSISTENCY OF LARGE LANGUAGE MODEL (LLM)-AIDED MODEL FOR FIVE-YEAR POST-CYSTECTOMY SURVIVAL PREDICTION OF BLADDER CANCER PATIENTS

Heang-Ping Chan, PhD (*Abstract Co-Author*) Nothing to Disclose
Di Sun, MEng, BEng (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the performance consistency of a large language model (LLM)-aided survival prediction model that combined clinical, radiomic, and deep learning (CRD) information, for 5-year post-cystectomy survival prediction of bladder cancer patients.

**METHODS AND MATERIALS**

With IRB approval, we identified 781 patients with bladder cancer. Inclusion criteria were (1) having undergone neoadjuvant chemotherapy (NAC); (2) having CT Urogram (CTU) before and after NAC; (3) having undergone radical cystectomy; and (4) having a known 5-year survival status post-cystectomy that could be used as ground truth. The criteria were met by 163 patients, and they were split into three sets: training (56%: 55 alive (A); 37 deceased (D)); validation (4%: 4 A; 3 D); and test (40%: 20 A; 44 D). The predictive model, CRD, was based on clinical descriptors, including pathological stage, lymph nodes stage, and lymphovascular invasion status, extracted by GPT-4 from the medical records, and radiomics and deep-learning features extracted from CTU images. The clinical and imaging information were fused with a neural network to provide survival prediction. We tested the performance consistency of the trained CRD model due to the variabilities in information extraction by GPT-4 when different prompts were used or repeated queries with the same prompt by different users. We designed two prompts for information extraction: Prompt1 (P1, concise) and Prompt2 (P2, detailed and with constraints). P2 was used by two users (User1 and User2) to test the reproducibility of GPT-4. The area under the ROC curve (AUC) was used to assess the CRD model classification performance on the test set. The Kaplan-Meier survival analysis was used to evaluate the CRD predictions. The consistency of CRD predictions when using different prompts or when repeated queries were performed was evaluated by the Intraclass Correlation Coefficient (ICC).

**RESULTS**

The CRD model achieved AUCs of 0.86±0.05 (P1), 0.83±0.05 (P2-User1), and 0.86±0.05 (P2-User2). Regardless of the prompt or the users, the model could significantly stratify the deceased and alive groups ($p<0.001$). The agreement of CRD prediction between (1) P1 and P2-User1 and (2) P2-User1 and P2-User2 was ICC=0.979 and ICC=0.995, respectively.

**CONCLUSION**

While larger data sets are needed for further validation, this study demonstrates the robustness of the CRD model in terms of different prompts and repeated queries with the same prompt, in predicting the 5-year survival of bladder cancer patients post-cystectomy.

## CLINICAL RELEVANCE/APPLICATION

Accurate five-year survival prediction for bladder cancer patients post-cystectomy can provide valuable information for treatment planning, patient counseling, decision-making, and resource allocation.

## W6-STCE1-1 ASSESSING THE IMPACT OF THE COVID-19 PANDEMIC ON RADIOLOGY IMAGING VOLUMES AND EFFICIENCY: A QUALITY IMPROVEMENT REPORT

Judy Burleson (*Abstract Co-Author*) Nothing to Disclose
Mike Simanowith (*Abstract Co-Author*) Nothing to Disclose
Mythreyi Bhargavan-Chatfield, PhD (*Abstract Co-Author*) Nothing to Disclose
Matthew S. Davenport, MD (*Abstract Co-Author*) Royalties, Wolters Kluwer nv
Haniyeh Zamani, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the effects of the COVID-19 pandemic on radiology imaging volumes and radiologist productivity. The study focuses on changes in efficiency, sustainability, and health equity across diverse radiology facilities in the United States.

### METHODS AND MATERIALS

A comprehensive analysis was conducted on imaging volumes from 197 radiology facilities and 1,600 radiologists across 23 states, including academic institutions (N=5), community hospitals (N=79), multi-specialty clinics (N=5), freestanding imaging centers (N=109), and other facilities (N=5). Data from 12.4 million imaging examinations were collected from December 1, 2017, to February 28, 2023, covering pre-pandemic, pandemic, and post-pandemic periods. Six modalities were analyzed: computed tomography (CT), mammography, magnetic resonance imaging (MRI), X-ray, ultrasound, and positron emission tomography (PET)-CT. Workforce numbers, workload, non-physician practitioner (NPI) attrition, and turnover were tracked quarterly using the American College of Radiology (ACR) General Radiography Improvement Database (GRID), with National Provider Identifiers (NPIs) used to identify individual radiologists.

### RESULTS

Of the 1,600 radiologists, 804 (50%) participated throughout the study, with 581 (36%) maintaining a consistent volume of at least 100 examinations per quarter. The average number of exams read per day increased by 1.4% from 2017 to 2023 (from 49.5 to 50.9), following a notable 35% decline per quarter during the peak pandemic period (March-May 2020, from 2,015,150 to 1,304,748). High-productivity radiologists experienced a 25.4% increase in exams read per day (from 52.3 to 65.6) and a 24.4% rise in clinical days worked per quarter (from 37.7 to 46.9) from 2017 to 2022. Despite significant turnover, the number of unique radiologists grew from 997 to 1,144, with days worked per NPI per quarter remaining stable (40 days vs. 39 days).

### CONCLUSION

The study reveals a full recovery in radiology imaging volumes and improved efficiency post-pandemic, with notable increases in productivity among high-volume radiologists. These findings highlight the resilience of radiology practices and underscore the need for a sustainable solution to the mismatch between imaging demand and radiologist supply.

### CLINICAL RELEVANCE/APPLICATION

The insights gained can inform policy-making and operational adjustments to better address future disruptions and support radiology care delivery into the future.

## W6-STCE1-2 COMPARATIVE ANALYSIS OF ENERGY CONSUMPTION FOR VIRTUAL AND CLINICAL TRIALS IN RADIOLOGY

Francesco Ria, DMP (*Abstract Co-Author*) Metis Health Analytics
Mina Mohammadi (*Abstract Co-Author*) Nothing to Disclose
Ehsan Samei, PHD (*Abstract Co-Author*) Research Grant, General Electric Company;Advisory Board, General Electric Company;Research Grant, Siemens AG;Advisory Board, Siemens AG;Advisory Board, medInt Holdings, LLC;Advisory Board, Metis Health Analytics;Research Consultant, Nanox Imaging Ltd;Royalties, General Electric Company;Royalties, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Mirion Technologies, Inc;Royalties, Cambridge University Press;Royalties, John Wiley & Sons, Inc
Liesbeth Vancoillie, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluate and compare the energy consumption of virtual computed tomography (CT) simulations versus real clinical CT studies, to assess the potential sustainability advantages of virtual trials.

### METHODS AND MATERIALS

We analyzed energy consumption for a clinical abdominal CT scan and a virtual chest-abdomen CT scan. For the virtual scan, we selected an anthropomorphic computational XCAT phantom from a previously established database. The phantom was imaged using a scanner-specific CT simulator (DukeSim, Duke University) running on a cluster with 8 GPUs. The baseline energy consumption of the cluster during idle time needed to be calculated by measuring the energy usage without any active jobs. These results were compared to clinical abdominal CT imaging energy consumption data reported in literature.

### RESULTS

Running the simulation on the cluster, we recorded a total energy consumption of 0.305 kWh over 52 minutes, including a baseline consumption of 0.085 kWh for idle time and 0.221 kWh for active usage. In comparison, literature estimates for clinical abdominal CT scans range from 0.2 kWh to 11.4 kWh, depending on whether only the scan time or the total patient room time is considered. Including the total patient room time accounts for the idle time of the CT scanner as well. A typical clinical patient room visit took around 20 minutes, with only about one minute dedicated to the scan itself. This places the energy consumption of virtual trials at the lower end of the clinical range. Notably, the idle time for the cluster (0.085 kWh) is considerably lower than the energy consumption for patient room time with a CT scanner (2.9 kWh). The virtual simulation, instead, required longer time (52 minutes), but ran in the background with minimal direct human intervention.

### CONCLUSION

Virtual trials demonstrate comparable energy consumption to clinical CT scans, and even significantly lower consumption when accounting for the idle time. Because virtual trials offer time, cost, ethical, and sustainability benefits, they can be implemented to design and test optimization actions before clinical applications. Additionally, imaging physical phantoms in virtual environments could further reduce both energy consumption and runtime due to their simpler structure.

### CLINICAL RELEVANCE/APPLICATION

Integrating virtual simulations into clinical research not only provides known advantages in terms of time, cost, and ethics but also offers significant sustainability benefits. Hospitals seeking optimization or innovation should strongly consider initial investigations through virtual trials.

## W6-STCE1-3 GLOBAL VALIDATION OF OSTEOPOROSIS SCREENING ON CHEST RADIOGRAPHS

Namkug Kim, PhD (*Abstract Co-Author*) Stockholder, Anymedi, Inc
Miso Jang (*Abstract Co-Author*) Nothing to Disclose
Minjee Kim (*Abstract Co-Author*) Nothing to Disclose
Jinhoon Jeong (*Presenter*) Nothing to Disclose

### PURPOSE

Osteoporosis, a global health concern, affects 19.7% of the population worldwide, with a higher prevalence in developing countries. Previous studies suggest that osteoporosis screening can effectively reduce societal costs by preventing osteoporotic fractures. The incidence of fragility fractures and their associated healthcare expenditures are expected to increase in the coming years due to demographic shifts towards an aging population. To address this issue, we propose a cost-effective screening method utilizing chest radiographs, which offer superior accessibility and cost-efficiency compared to other diagnostic tools.

### METHODS AND MATERIALS

We evaluated our osteoporosis screening model using four external datasets, which comprised chest radiograph (CXR) data paired with dual-energy X-ray absorptiometry (DXA) results from individuals aged over 50 years. We utilized data from four distinct external datasets. Dataset A is sourced from a tertiary university hospital. Dataset B originates from a secondary care hospital specializing in spine and joint care, which has a relatively lower proportion of osteoporosis patients. Dataset C is from a hospital for veterans, representing diverse settings within the healthcare system and featuring a higher proportion of males and elderly individuals. Datasets A, B, and C are all based in South Korea. Conversely, dataset D was obtained from a global medical imaging platform, with most data sourced from the United States and Brazil. A commercial AI tool (PROS® CXR: OSTEO, PROMEDIUS INC, Seoul, Korea) was retrospectively applied to CXRs to predict osteoporosis. CXR manufactures of each hospital were very different .The accuracy of this AI tool was assessed by comparing its predictions to osteoporosis diagnoses made using DEXA scans, which served as the reference standard. We evaluated the area under the receiver operating characteristic curves (AUCs), sensitivity, specificity, and F1 score.

### RESULTS

Dataset A comprised 1,089 individuals, with 969 females (mean age 58 years) and 120 males (mean age 59 years), and an osteoporosis prevalence of 29.2%. Dataset B included 3,338 individuals, with 1,854 females (mean age 59 years) and 1,484 males (mean age 59 years), showing an osteoporosis prevalence of 6.0%. Dataset C consisted of 937 individuals, with 411 females (mean age 72 years) and 526 males (mean age 74 years), with an osteoporosis prevalence of 24.9%. Dataset D included 295 individuals, with 288 females (mean age 66 years) and 7 males (mean age 69 years), and an osteoporosis prevalence of 18.3%. In the A dataset, the performance was AUC 0.89, sensitivity 0.84, specificity 0.76, and F1 score 0.70. In the datasets B, C, and D, AUC was 0.92, 0.89, and 0.81, sensitivity was 0.71, 0.85, and 0.39, specificity was 0.92, 0.77, and 0.94, and F1 score was 0.48, 0.67, and 0.47, respectively.

### CONCLUSION

Osteoporosis screening using CXR demonstrated excellent performances of general usability across a variety of quality and multiple machines of chest radiographs from multiple hospitals with various conditions.

### CLINICAL RELEVANCE/APPLICATION

Osteoporosis diagnosis is critical for initiating timely interventions to prevent fractures. This study proposes leveraging CXRs, which are widely accessible and routinely performed, as an innovative screening tool for osteoporosis, particularly in resource-constrained settings. This approach has the potential to expand diagnostic capabilities and promote earlier treatment initiation across a broader patient demographic, thereby improving detection of osteoporosis and reducing the burden of osteoporotic fractures especially in developing countries.

## W6-STCE2-2 CARDIAC MRI AND ENDOMYOCARDIAL BIOPSY IN FULMINANT MYOCARDITIS: INSIGHTS FROM DIAGNOSIS TO PROGNOSIS

Minjie Lu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shihua Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Yining Wang (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to compare the role of cardiac magnetic resonance imaging (MRI) and endomyocardial biopsy (EMB) findings in the diagnosis, choice of therapeutic strategy, and risk stratification of patients with FM.

### METHODS AND MATERIALS

Data were collected from 75 adult patients with clinically suspected myocarditis who underwent both 3.0T cardiac MRI and EMB. Receiver operating characteristic curves were used to assess the ability of cardiac MRI parameters to diagnose FM, and the cut-off values obtained were used to establish the MRI criteria. Major adverse cardiovascular events were defined as cardiac death and cardiac transplantation. The impact of the selected variables on prognosis was analyzed using univariate Cox analysis and Kaplan-Meier survival curves.

### RESULTS

32 patients (42.7%) were assigned to the FM group, of which 24 (75.0%) were confirmed by EMB and 29 (90.6%) by cardiac MRI, with areas under the curve of 0.90 and 0.63, respectively. Patients who meet the MRI criteria were more likely to undergo temporary mechanical circulatory assistance, and patients confirmed by EMB used corticosterone and or immunoglobulin more often. After a median of 912 days of follow-up, 12 patients experienced adverse cardiovascular events, including 9 cardiac deaths and 3 heart transplants. Giant cell myocarditis, left ventricular anterior wall late gadolinium enhancement (LGE), and transmural LGE were the strongest prognostic predictors.

### CONCLUSION

By providing a comprehensive assessment of myocardial with more precise tissue characterization, cardiac MRI will help cardiologists and intensive care unit doctors to quickly confirm FM and identify high-risk patients. The combination of imaging information and pathological findings will also help to better determine the severity of myocardial inflammation and improve therapeutic strategies accordingly.

### CLINICAL RELEVANCE/APPLICATION

By providing information on myocardial tissue characteristics, cardiac magnetic resonance imaging can accurately diagnose fulminant myocarditis, as well as provide further prognostic and therapeutic guidance, complementing endomyocardial biopsy. Early imaging and pathological examination and universal access to certain technologies, such as quantitative parametric mapping and immunohistochemistry, will provide important insights for the effective management of the disease. Future efforts could target the different roles of cardiac MRI and EMB in the diagnosis and prognostic prediction of FM, as well as standardizing and updating the management guidelines of myocarditis to maximize patient benefits.

## W6-STCE2-3 PERILESIONAL ENHANCEMENT ON MRI PREDICTS PROGNOSIS IN PATIENTS UNDERGOING IMMUNOTHERAPY FOLLOWED BY RADICAL SURGERY FOR INTRAHEPATIC CHOLANGIOCARCINOMA

Liheng Liu (*Abstract Co-Author*) Nothing to Disclose
Jingjing Liu (*Abstract Co-Author*) Nothing to Disclose
Tingting Mu (*Abstract Co-Author*) Nothing to Disclose
Gengyun Miao (*Presenter*) Nothing to Disclose

### PURPOSE

Intrahepatic cholangiocarcinoma (ICC) is a highly invasive cancer with a poor prognosis, where surgery is often the only curative option. Due to the advanced stage at which ICC is often diagnosed, neoadjuvant therapy can transform locally advanced or unresectable tumors into resectable ones. Recently, immunotherapy has gained attention as a treatment strategy for ICC. This study aimed to investigate the correlation between imaging features and the prognosis of patients with ICC who received immunotherapy before surgery.

### METHODS AND MATERIALS

This retrospective study included 77 patients with surgically resected ICC who had undergone immunotherapy prior to surgery. All patients underwent magnetic resonance imaging (MRI) before immunotherapy. Qualitative and quantitative MRI characteristics evaluated included tumor morphology,

intrahepatic duct dilatation, hepatic capsule retraction, target sign on diffusion-weighted imaging (DWI), arterial-phase enhancement pattern, venous- and delayed-phase enhancement patterns, perilesional enhancement, tumor size, number of tumors, and the mean apparent diffusion coefficient. Additional clinicopathological features were also assessed for their prognostic value. Univariate and multivariate Cox proportional hazards models were used to analyze the relationship between MRI features and ICC prognosis, with P values < 0.05 indicating statistical significance.

**RESULTS**

Univariate Cox analysis identified the number of tumors, perilesional enhancement, and microvascular invasion (MVI) on pathology as being correlated with prognosis (P = 0.031, 0.032, and 0.001, respectively). Multivariate Cox analysis demonstrated that perilesional enhancement and pathologic MVI were independent risk factors for poor prognosis in ICC patients (P = 0.031, 0.004, respectively).

**CONCLUSION**

The number of tumors, perilesional enhancement, and pathologic MVI are significant predictive factors for prognosis in ICC patients who received immunotherapy before surgery. Specifically, perilesional enhancement and pathologic MVI are independent risk factors for poor prognosis in these patients.

**CLINICAL RELEVANCE/APPLICATION**

Identifying predictive factors for prognosis in patients with intrahepatic cholangiocarcinoma (ICC) undergoing immunotherapy followed by radical surgery is crucial for optimizing treatment strategies and improving patient outcomes. This study demonstrates that perilesional enhancement on MRI and pathologic microvascular invasion (MVI) are significant independent risk factors for poor prognosis in this patient population. Clinically, these findings suggest that incorporating MRI-based evaluation of perilesional enhancement into preoperative assessment protocols can help in stratifying patients based on their risk and guiding treatment decisions. Furthermore, recognizing patients with high-risk features such as perilesional enhancement and patho-MVI may prompt closer monitoring and more aggressive therapeutic approaches post-surgery, ultimately enhancing the management and survival rates of patients with ICC.

### PURPOSE

To compare the relative performance of three domains of breast cancer risk models—the Mirai mammography artificial intelligence (AI) algorithm, the Breast Cancer Surveillance Consortium version 3 (BCSC v3) clinical risk model, and a polygenic risk score (PRS)—alone and in combination over 15-year time horizon.

### METHODS AND MATERIALS

A prospective cohort was drawn from >400,000 patients enrolled in a large research study as part of an integrated US health system between 2008 and 2011. Women with a history of breast cancer were excluded. At enrollment, participants answered a health survey, which was used with data from the electronic health record to generate the BCSC v3 5-year risk score. The full-field digital screening mammogram performed closest in time to enrollment as part of routine care was used to generate the Mirai algorithm 5-year risk score. The mammogram date defined the study index time. Participants also provided saliva that was genotyped with an Affymetrix Axiom array and used to generate a PRS. Incident cancer outcomes were ascertained using the regional Tumor Registry. Cancers occurring in the first 3 months after the mammogram were removed to separate the effect of future risk vs. AI-aided detection. Risk estimates for incident breast cancer 0.25 to 15 years after the initial mammographic examination were calculated using a time-dependent area under the receiver operating characteristic curve (AUC). Combined models using two or more individual risk models were fit using a Cox model, with 10-fold cross-validation used to estimate the time-dependent AUC.

### RESULTS

We present preliminary analysis for 42,098 women with complete data for Mirai AI, BCSC v3 risk score, and in-progress genotype data. There were 2055 incident cancers. The time-dependent AUC for BCSC vs. Mirai was 0.63 vs. 0.68 at 5 years, 0.60 vs. 0.65 at 10 years, and 0.58 vs. 0.67 at 15 years. The top 30% of Mirai risk predicted 50% of cancers, whereas the top 30% of BCSC risk predicted 41% of cancers. The AUCs for the combined Mirai and BCSC models were lower than for the Mirai model alone.

### CONCLUSION

The Mirai model risk model predicts future risk of breast cancer better than the BCSC v3 clinical model out to 15 years. Performance of all models decreased at 10- and 15-year time horizons, but Mirai continued to have relatively higher performance than BCSC. The addition of BCSC to Mirai in a combined model worsened performance. PRS results are near completion and will be shared if accepted for presentation.

### CLINICAL RELEVANCE/APPLICATION

Mirai mammographic AI model continues to demonstrates strong long term future breast cancer risk prediction at a 15 year time horizon, better than the BCSC clinical risk model.

## W7-SSBR09-2 DEEP LEARNING EXTRACTION OF BREAST DENSITY RELATED FEATURES FOR RISK PREDICTION

Daan Van Den Oever (*Abstract Co-Author*) Nothing to Disclose
Ioannis Sechopoulos, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation;Research Grant, Sectra AB;Research Grant, ScreenPoint Medical BV;Research Grant, Volpara Health Technologies Limited
Raneim Nabil Hossni Mohamed (*Presenter*) Nothing to Disclose

### PURPOSE

To capture the intrinsic patterns of fibroglandular tissue from a single mammogram as an initial step towards quantifying longitudinal dense tissue pattern changes for improved breast cancer risk prediction.

### METHODS AND MATERIALS

The study was conducted on retrospectively collected raw and processed digital mammography exams (N = 3,000) of women participating in the Dutch breast cancer screening program between 2008 and 2018. Density maps were generated from the raw mammograms with a commercially available automated software program. The maps represent the amount of fibroglandular tissue in mm. A modified U-Net was trained to extract features from mammograms by predicting the density map from the processed mammogram. The density features are extracted from the last layer of the encoder part of the network. To ensure that the features are density related, the model is trained with a loss combining the mean square error (MSE) of the density map and a cosine embedding loss. The cosine embedding loss compares the features of the proposed network to the features of a helper U-Net, pre-trained to compress density maps. The performance of the density map generation was evaluated using the structural similarity index measurement (SSIM) (0: no similarity, 1: perfect similarity) and MSE inside the breast region. The similarity between features of the network with the helper network was measured by using the cosine similarity. All values are given in median (95% confidence interval).

### RESULTS

The model achieved an SSIM of 0.87 (0.86 - 0.87) and an MSE of 4.17 (3.35 - 4.99). The helper network, compressing density maps, achieved an SSIM of 0.99 (0.99 - 0.99) and an MSE of 0.49 (0.18 - 0.82). The cosine similarity between the features was 0.82 (0.81 - 0.82). Visual inspection shows similar density patterns between predicted density maps and ground truth.

### CONCLUSION

The proposed model was able to extract features from processed mammograms similar to those of the helper model. Simultaneously, the model generates realistic density maps. This indicates that the model can generate features from processed mammograms that capture density patterns.

### CLINICAL RELEVANCE/APPLICATION

The proposed model could be leveraged as an initial step for downstream tasks such as predicting breast cancer risk, treatment effects, and recurrence based on changes to the dense tissue pattern in mammograms.

## W7-SSBR09-3 PROGNOSTIC VALUE OF DL-BASED QUANTIFICATION OF BREAST ARTERY CALCIFICATION FROM ROUTINE MAMMOGRAPHY FOR CARDIOVASCULAR DISEASE AND MORTALITY RISK PREDICTION

### PURPOSE

Breast artery calcification (BAC), often incidentally detected during mammography, is rarely reported or quantified by radiologists, despite its potential as an independent cardiovascular disease (CVD) risk factor. This study evaluates the prognostic value of BAC in predicting CVD outcomes and mortality in a population who underwent cardiac CT scans to identify populations that may benefit most from BAC quantification.

### METHODS AND MATERIALS

We included 4,668 patients who underwent cardiac CT (Coronary Artery Calcium [CAC] Scoring CT or Coronary CT Angiography [CCTA]) and had a screening mammogram between 2010 and 2023. Structural CTAs were excluded. If a patient had multiple mammograms, the mammogram closest to the cardiac CT was included. First Cardiovascular Event (angina, atherosclerosis, transient ischemic attack, etc), Hard Event (MACE), and Death were studied as primary outcomes. Patients were grouped into: screening population with CAC scoring only (Screening), Screening Subgroup with CAC score of zero (CAC-zero), symptomatic patients with CCTA +/- CAC scoring (Symptomatic), and Symptomatic Subgroup with Heart Failure (Symptomatic-HF). Using a previously validated deep learning (DL) model, we calculated BAC area using the mediolateral oblique (MLO) views of screening mammograms and categorized patients into three BAC grades (<10 mm2, 10-40 mm2, and >40 mm2). Univariable and multivariable Cox Proportional Hazard (CPH) and Hazard Ratios (HR) were calculated.

### RESULTS

In the Screening group, all BAC grades were strong univariate and multivariate predictor for First Event, Hard Event, and Death. For prediction of Hard Events, HR for BAC was greater (2.84 (95%CI: 1.36 - 5.92, p=0.01) than CAC score (HR: 1.88, 95%CI: 1.35-2.63, p<0.005). In the CAC-zero group, BAC was a strong univariable predictor for First Event (HR: 1.95, 95%CI: 1.14 - 3.33, p=0.02) and Hard Event (HR: 7.98, 95%CI: 2.02 - 31.58, p<0.005). BAC was also a strong univariate (HR: 5.59, 95%CI: 2.06-15.19, p<0.005) and multivariate (HR: 3.69, 95%CI: 1.17-11.65) predictor for Hard Events in the Symptomatic group. BAC was not a significant predictor of events in the Symptomatic-HF subgroup in both univariate and multivariate analysis.

### CONCLUSION

Our study underscores the significant prognostic value of BAC in predicting CVD outcomes and mortality, particularly in populations where CAC scoring is not feasible or when patients have no detectable CAC.

### CLINICAL RELEVANCE/APPLICATION

DL-based BAC quantification can serve as a screening tool available to over 40M women annually who undergo screening mammography. This would enable early identification and risk stratification of CVD in females who are primarily underdiagnosed compared to their male counterparts.

## W7-SSBR09-4 CHALLENGES IN AI-BASED DIAGNOSTIC IMAGE QUALITY ASSESSMENT OF MAMMOGRAMS

Tina Santner, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

In mammography, diagnostic image quality with high positioning accuracy is substantial. The rise of artificial intelligence (AI) in radiology could open up new opportunities to facilitate, accelerate and objectify diagnostic quality assessment in daily routine.Purpose of the present work was to compare results from a prototype AI software to those of human expert readers as a framework for AI-based quality assessment.

### METHODS AND MATERIALS

From an extensive multicenter PGMI case collection (13 institutions, 3 vendors), 130 random cases (520 images) and 70 challenging cases (280 images) were selected. Three expert radiographers and one screening radiologist classified all images by consensus review using the PGMI system (perfect, good, moderate, inadequate). For comparison, a deep-learning based prototype software, trained in a multi-task manner for segmentation, detection, and classification of quality features was used.The PGMI categories from human and AI reading were analyzed for agreement using Cohen's Kappa and Landis and Koch classification. Frequency and reasons for disagreement were evaluated.

### RESULTS

CC view: "Pectoral muscle visibility" showed best values with substantial to almost perfect agreement. Most other categories showed fair agreement in the random sample, decreasing to slight or poor in the challenging sample. "Medial gland" and "lateral gland" showed slight and poor agreement in both samples.MLO view: "Pectoralis angle" showed moderate agreement in the random and fair agreement in the challenging sample. The other categories showed fair or slight agreement in the random sample, decreasing to poor agreement for the "pectoralis nipple line" and "nipple in profile" in the challenging sample.Skinfold detection was not an available feature of the AI software at the time of the study.The summary PGMI grade per image showed a total agreement and difference in one grade in 50.77% and 44.04% in the random sample and 49.64% and 43.93% in the challenging sample.Total agreement on inadequate images showed 6/51 cases in the random and 7/69 cases in the challenging sample, with difference in one grade in 30 and 54 cases, respectively.The work-up of disagreement identified misinterpretations of anatomical landmarks and causality issues in the categorization.

### CONCLUSION

Transformation of the PGMI system into a fully automated AI algorithm is challenging and may differ substantially between subcategories.

### CLINICAL RELEVANCE/APPLICATION

AI-based diagnostic quality evaluation of mammograms showed total agreement in PGMI classification of only about 50% and needs further refinement before full integration as an objective real-time quality management tool.

## W7-SSBR09-5 DEVELOPMENT OF MACHINE LEARNING MODELS FOR PREDICTION OF PATHOLOGIC COMPLETE RESPONSE IN BREAST CANCER USING CLINICAL, MRI-RADIOMIC AND MRI-QUALITATIVE DATA

Corinne Balleyguier, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Samy Ammari, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tarek Assi (*Abstract Co-Author*) Nothing to Disclose
Charles Aboudaram (*Abstract Co-Author*) Nothing to Disclose
Nathalie B. Lassau, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Rami Hajri, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Pathological complete response (pCR) is considered to be a prognostic surrogate endpoint for superior long-term clinical outcomes in some histological subtypes of breast cancer patients treated with neoadjuvant therapy. The objective of this study is to develop and evaluate machine learning-based biomarkers to predict pCR and recurrence-free survival (RFS).

### METHODS AND MATERIALS

This retrospective, monocentric analysis included 235 women (mean age 46) with non-metastatic breast cancer, treated with neoadjuvant therapy. We performed an analysis of the clinical features (age, genetic mutations, TNM staging, hormonal receptors expression, HER2 status and histological grade), in addition to morphologic and radiomic data extracted from pre-treatment MRI. We developed different models trained on these three sources of data and their combinations: clinical features, qualitative analysis of breast MRI by the radiologist according to ACR BI-RADS Atlas (size, analysis of T2 signal and surrounding edema), and the radiomic data extracted from the conventional pre-therapeutic MRI sequences (T1-weighted contrast-enhanced and T2-weighted images). Patients were separated into a training group and a test group with different MRI models to ensure the reproducibility of the results. A customized Machine Learning pipeline was used to handle these different types of data consisting of a feature selection and a classifier.

### RESULTS

The prediction ability of the best model was superior using radiomics features, with the best model achieving an AUC of 0.72. A split into subgroups in the cohort was performed in order to reflect the differences according to the molecular profiles. The optimal performance was recorded among triple-negative

(AUC of 0.80) and HER2+ subgroups (AUC of 0.65). Due to short follow-up of patients and low sample size, the prediction of RFS was promising with relatively acceptable AUC values, but lacked statistical power.

**CONCLUSION**

This study suggests that machine learning models based on clinical data and pre-treatment MRI morphologic and radiomic data can help predict the pCR in breast cancer patients receiving neoadjuvant therapy, regardless of MRI's model.

**CLINICAL RELEVANCE/APPLICATION**

With potentially growing indications of neoadjuvant therapy in breast cancer patients, prediction of the pCR could eventually lead to optimized treatment tailoring thus improving the personalization of therapeutic strategies and may even in the future avoid surgery in some cases.

## W7-SSBR09-6 CLINICAL APPLICATION OF NOVEL MOBILE AI SOLUTION FOR REAL-TIME DETECTION AND DIFFERENTIAL DIAGNOSIS IN BREAST ULTRASOUND: A FIRST PROSPECTIVE FEASIBILITY STUDY

Won Hwa Kim, MD, PhD (*Abstract Co-Author*) Stockholder, BeamWorks
Hye Jung Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Jaeil Kim, PhD (*Presenter*) Stockholder, BeamWorks, Inc.

**PURPOSE**

Conventional artificial intelligence (AI) solutions for breast ultrasound are designed to aid in the process of differential diagnosis, serving as computer-aided diagnosis (CADx) systems. However, prior to conducting a differential diagnosis, ultrasound requires the process of detection to ensure that clinically significant lesions are not missed during scanning. We suggest a mobile AI solution to supports detection (CADe) and differential diagnosis (CADx) in real-time during scanning. This study aims to evaluate the feasibility of a mobile AI solution prospectively in real-world clinical settings.

**METHODS AND MATERIALS**

From August to December 2023, a feasibility study was conducted in tertiary medical center of Taiwan using mobile AI solution (CadAI-B for breast, BeamWorks Inc., Korea). CadAI-B is connected to an ultrasound equipment using tablet PC. It supports healthcare providers to detect suspicious breast lesions by highlighting suspicious area during breast ultrasound scanning, and to make a differential diagnosis by providing BI-RADS categories and malignancy score (0-100%). The rate of real-time detection in malignancies and area under the receiver operating characteristic curve (AUC) was calculated. Distribution of BI-RADS categorized by CadAI-B were compared with those by breast imaging experts on independent review.

**RESULTS**

The analysis included 33 patients with an average age of 47 years (IQR, 44 - 62). There were 14 malignancies, 17 benign lesions, and 2 normal cases, and 30 patients (90.9%) underwent biopsy. For patients with malignancies, CadAI-B successfully identified all malignancies. Overall diagnostic performance, as AUCs calculated by the malignancy score and BI-RADS, was 0.835 and 0.850, respectively. The per-patient sensitivity of CadAI-B was 100.0%, while the specificity was 52.6%. The BI-RADS distribution between CadAI-B and expert was the same in malignant cases. In benign cases, CadAI-B categorized 9 cases (50.0%) as C4A or C4B, while experts classified 13 cases (72.2%), indicating a potential reduction in the need for biopsy.

**CONCLUSION**

This study demonstrates that real-time processing capabilities of CadAI-B enable the identification of critical lesions during breast ultrasound, helping to reduce unnecessary biopsy. These findings may helpful in diagnostic decisions and training of non-experts in clinical settings and offer the potential to improve workflow efficiency.

**CLINICAL RELEVANCE/APPLICATION**

This mobile real-time AI solution could aid in diagnostic decision-making and the training of non-experts. Of particular significance is the potential to facilitate ultrasound-based triage for breast cancer screening in low-resource settings or remote areas.

Thomas Geyer, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Existing methods for risk stratification in patients with hypertrophic cardiomyopathy (HCM) are imperfect. The objective of this study was to develop a machine learning (ML)-based model to identify individual HCM patients who are at high risk of developing major adverse cardiac events (MACE).

### METHODS AND MATERIALS

In this single center study, adult patients who had undergone cardiac MRI for evaluation of HCM between 2015-2022 were retrospectively evaluated. Cardiac MRI was performed at 1.5T or 3T (Siemens, Germany) including balanced cine steady state-free precession (bSSFP), native T1 and T2 mapping, and late gadolinium enhancement (LGE). Native T1 and T2 were converted to z-scores using scanner-specific local reference values. The primary outcome of MACE was defined as a composite of cardiovascular death, resuscitated sudden cardiac death, or heart failure hospitalization. A ML algorithm was applied including clinical, cardiovascular risk factors, demographic, genetic, echocardiography and cardiac MRI variables using 250 repeats of repeated random sub-sampling cross-validation (80% training and 20% testing splits). For each training set a random forest model was trained using ML (n=34 variables), and validated on the testing set. A feature map using Shapley Additive exPlanation (SHAP) values was created. The performance of this model was compared to the sudden cardiac death risk model by the European Society of Cardiology (ESC). Performance statistics were calculated across splits.

### RESULTS

604 patients were included (69% male, mean age 52±15 years). Median follow-up time was 3.0 years. The random forest model exhibited favorable predictive performance for MACE (area under the receiver operator characteristic curve [95% CI]: 0.70 [0.45-0.86]), surpassing that of the ESC risk model (0.63 [0.53-0.72]), although the difference did not reach statistical significance (p=0.078). SHAP values showed that native T1 z-scores had the highest impact on model performance, followed by indexed left ventricular mass, indexed left ventricular end-systolic volume, and left atrial diameter.

### CONCLUSION

A ML-based prediction model comprised of routinely available clinical and cardiac MRI variables performed well in predicting risk of MACE in patients with HCM.

### CLINICAL RELEVANCE/APPLICATION

Further study is needed to determine the value of this ML model for risk-stratification in patients with HCM in independent samples.

## W7-SSCA08-2 EPICARDIAL FAT VOLUME PREDICTS OBSTRUCTIVE CORONARY ARTERY DISEASE AND MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS WITH "ZERO" CORONARY ARTERY CALCIUM SCORE

Vidiyala Pujitha, MBBS (*Abstract Co-Author*) Nothing to Disclose
Priya Jagia, MD (*Abstract Co-Author*) Nothing to Disclose
Sanjeev Kumar, MBBS,MD (*Abstract Co-Author*) Nothing to Disclose
Niraj N. Pandey, MBBS, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study sought to investigate the role of epicardial fat volume (EFV) in prediction of the presence of obstructive coronary artery disease (CAD) and occurrence of major adverse cardiovascular events (MACE) in patients with "zero" coronary artery calcium score (CACS).

### METHODS AND MATERIALS

799 consecutive patients referred for coronary CT angiography with atypical chest pain and clinical suspicion of CAD were included in this retrospective analysis. 477 (59.7%) patients had a "zero" CACS and were included in the final analysis. Quantification of EFV was performed on non-contrast images used for CACS estimation. CT angiography was evaluated for presence of obstructive CAD. Patients were followed up on subsequent outpatient visits or on phone using standard questionnaire or by review of medical records, for occurrence of MACE.

### RESULTS

Of 477 patients (median age [interquartile range; IQR]: 50 [45-57] years, 51.4% males) with "zero" CACS, obstructive CAD (=50% stenosis) on CT angiography was present in 51 (10.7%) patients. Of the 341 patients for whom follow-up was available, MACE was observed in 37 (10.9%) patients (median follow-up: 15 months [IQR: 12-19 months]). A significantly higher EFV was seen in patients with obstructive CAD (158.2mL [IQR: 114.6-195.1] vs. 120.9mL [IQR: 93.4-153.0]; p=0.0001) and in patients experiencing MACE (165.2mL [IQR: 124.4-202.1] vs. 117.5mL [IQR: 91.8-151.5]; p<0.0001). EFV showed a significant association with obstructive CAD (unadjusted Odd's ratio (OR) [95%CI]: 1.0114 [1.0056-1.0171]; p=0.0001) and MACE (unadjusted OR [95%CI]: 1.0165 [1.0095-1.0236] in univariate analysis, which remained significant in multivariate analysis. Adding EFV to conventional coronary risk factors in the pre-test probability models increased the area-under-curve (AUC) for prediction of both obstructive CAD (AUC [95%CI]: 0.814 [0.776-0.848] vs. 0.796 [0.757-0.832]) and MACE (AUC [95%CI]: 0.961 [0.935-0.979] vs. 0.942 [0.912-0.964]), although not reaching statistical significance.

### CONCLUSION

A "zero" CACS does not exclude obstructive CAD nor the occurrence of MACE. EFV is an independent predictor of obstructive CAD and MACE in patients with "zero" CACS. Addition of EFV to traditional cardiovascular risk factors improves estimation for pretest probability of obstructive CAD and MACE.

### CLINICAL RELEVANCE/APPLICATION

Addition of EFV to traditional cardiovascular risk factors offers a more accurate prediction of obstructive CAD and MACE, which may help to improve the initial management of patients with atypical chest pain. Since EFV is derived from the same dataset used for quantifying CACS, it may also allow for better definition of cardiovascular risk in patients undergoing only coronary artery calcium scoring.

## W7-SSCA08-3 CARDIAC MRI-BASED RIGHT AND LEFT VENTRICULAR BLOOD POOL T2 RATIO: A NOVEL POTENTIAL PREDICTOR OF POOR PROGNOSIS IN PATIENTS WITH DILATED CARDIOMYOPATHY

Yangzhen Hou (*Abstract Co-Author*) Nothing to Disclose
Jing Luo (*Abstract Co-Author*) Nothing to Disclose
Hui Zhou, MD (*Abstract Co-Author*) Nothing to Disclose
Ji Yang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the prognostic value of right-to-left ventricular blood pool T2 ratio (RV/LV T2 ratio) in patients with dilated cardiomyopathy(DCM).

### METHODS AND MATERIALS

This retrospectively study enrolled consecutive 128 patients with DCM who underwent cardiac magnetic resonance(CMR) from January 2019 to December 2021. Thirty healthy controls were also included for comparison. LV and RV blood pool T2(RVT2) values were measured by placing circular ROIs within the LV and RV blood pools in the basal, middle and apical short-axis view. The average values were used and calculated RV/LV T2 ratio. The primary endpoint of major adverse cardiac events(MACE) was defined as composite of all-cause mortality, heart failure-related hospitalizations, and aborted sudden cardiac death.

### RESULTS

RVT2 value and RV/LV T2 ratio were significantly decreased in DCM patients compared to healthy controls ($p < 0.001$). 38 patients reached the primary endpoint (median follow-up: 30 [IQR: 19.0-37.8] months). The area under the curve(AUC) analysis showed that the primary endpoints were associated with RV/LV T2 ratio (AUC, 0.73 [95% CI: 0.65, 0.81], P <0 .001) and RVT2 value (AUC, 0.67 [95% CI: 0.59, 0.75], P <0 .001). Notably, RV/LV T2 ratio (above or below 0.49 based on the cutoff value) was associated with the outcome, irrespective of RVT2 value, suggesting that RV/LV T2 ratio was the most discriminating T2 mapping derived parameter. According to Kaplan-Meier analysis, the risk of MACE increased significantly with decreasing RV/LV T2 ratio tertiles (log-rank $p < 0.001$). Kaplan-Meier analysis of patients stratified by the highest and lowest tertiles of RV/LV T2 ratio showed that patients with the lowest RV/LV T2 ratio tertile had a significantly higher incidence of MACE, irrespective of LVEF and late gadolinium-enhanced(LGE) extent. After adjustment for clinical and imaging risk factors, RV/LV T2 ratio (HR: 1.77 per 0.1 decrease, p=0.002) was independent predictors of MACE. A model combining RV/LV T2 ratio with other clinical and conventional imaging risk factors (C statistic, 0.758; likelihood ratio, 35.24) showed improved discrimination and calibration for the primary endpoints compared with models with clinical variables (C statistic, 0.719; likelihood ratio, 25.85; both $P < 0.01$).

### CONCLUSION

RV/LV T2 ratio was an independent predictor of MACE in patients with DCM, providing incremental prognostic value when combined in a model with clinical and conventional CMR risk factors.

### CLINICAL RELEVANCE/APPLICATION

CMR T2 mapping derived RV/LV T2 ratio may be a convenient prognostic indicator for patients with DCM, which is better than LVEF and LGE and can be easily acquired during routine scanning without specialized commercial software and complex post-processing capabilities.

## W7-SSCA08-4 PROGNOSTIC SIGNIFICANCE OFCARDIAC MRI IN GENE-POSITIVE ARRHYTHMOGENIC CARDIOMYOPATHY

Kate Hanneman, MD, MPH (*Abstract Co-Author*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Melanie Care (*Abstract Co-Author*) Nothing to Disclose
Sarin Lekchuensakul (*Abstract Co-Author*) Nothing to Disclose
Danna Spears (*Abstract Co-Author*) Nothing to Disclose
Farah Cadour, MD, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Cardiac MRI is frequently used to assess tissue and functional abnormalities in patients with arrhythmogenic cardiomyopathy (ACM). However, there is limited data on the prognostic significance of cardiac MRI findings in gene-positive ACM in relation to various genotypes. The purpose of this study was to evaluate the prognostic significance of cardiac MRI findings in patients with gene-positive ACM in relation to genetic variants.

### METHODS AND MATERIALS

In this retrospective cohort study, consecutive adult patients with a pathogenic or likely pathogenic variant in a gene associated with ACM and meeting clinical criteria for ACM with at least one cardiac MRI between 2004-2023 and minimum 1 year follow-up were included. Cardiac MRI evaluation included quantification of left ventricular (LV) and right ventricular (RV) volumes and function, late gadolinium enhancement (LGE) and native T1/T2 mapping. Major adverse cardiac events (MACE) was defined as a composite of sustained ventricular tachycardia, appropriate ICD discharge, heart transplantation, hospital admission for heart failure requiring therapy, and cardiac death. Statistical analysis included Cox proportional hazard models.

### RESULTS

213 ACM patients were included (101 women, mean age 39±16 years) with pathogenic or likely pathogenic variants in desmosomal genes in 103 (48%) and non-desmosomal genes in 110 (52%). With respect to Padua phenotype, 13% were right-dominant, 23% left-dominant, 34% biventricular, and 29% indeterminant. After median clinical follow-up of 5.4 years (IQR 2.8, 9.4), 49 (24%) patients experienced MACE which varied between phenotypic groups (37% biventricular vs 28% left-dominant vs. 21% right-dominant vs. 3% indeterminant, p<0.001). After adjusting for patient age, sex, genotype and phenotype group, each 1% increase in LVEF was associated with a 2% reduction in the hazard of MACE (HR 0.98, 95%CI 0.96-0.99, p=0.03), each 1 unit increase in T2 mapping z-score was associated with a 37% increase in the hazard of MACE (HR 1.37, 95%CI 1.08-1.75, p=0.011), and presence of LGE was associated with 4 times higher hazard of MACE (HR 4.00, 95%CI 1.75-9.17, p=0.001). Native T1 and LV/RVEDV did not independently predict MACE.

### CONCLUSION

Gene-positive ACM with biventricular phenotype is associated with worst prognosis compared to other phenotypes. Cardiac MRI parameters including LVEF, LGE and native T2 add independent prognostic value even after adjustment for clinically relevant potential confounders.

### CLINICAL RELEVANCE/APPLICATION

Given the independent prognostic value of LGE in gene-positive ACM, LGE sequences should be included in all ACM protocols at least at baseline evaluation. Future study is needed to determine the prognostic value of LGE extent and progression.

## W7-SSCA08-5 OPPORTUNISTIC ASSESSMENT OF AORTIC ARTERY CALCIFICATION USING ARTIFICIAL INTELLIGENCE (AI) AND ITS ASSOCIATION WITH CORONARY ARTERY CALCIFICATION AND CARDIOVASCULAR EVENTS

Soterios Gyftopoulos, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Eduardo Iturrate (*Abstract Co-Author*) Nothing to Disclose
Jeffrey Berger (*Abstract Co-Author*) Nothing to Disclose
Michael P. Recht, MD (*Abstract Co-Author*) Nothing to Disclose

Malte Westerhoff (*Abstract Co-Author*) Employee, Pro Medicus Limited;Stockholder, Pro Medicus Limited
Judy Zhong (*Abstract Co-Author*) Nothing to Disclose
Miriam A. Bredella, MD, MBA (*Presenter*) Nothing to Disclose

### PURPOSE

Cardiovascular disease (CVD) is the leading cause of death in the US and coronary artery calcium (CAC) scanning using ECG-triggered CTs can discriminate coronary artery disease and predict major adverse cardiovascular events (MACE). Abdominal CT is commonly performed in adults at risk for CVD, and aortic artery calcification (AAC) can be quantified automatically using artificial intelligence (AI) on CTs performed for other clinical purposes (opportunistic CT). The purpose of our study was to determine the clinical utility of fully-automated AAC quantification for the development of MACE.

### METHODS AND MATERIALS

A fully-automated AI algorithm to quantify AAC using the Agatston score was retrospectively applied to a cohort of patient that underwent both abdominal and CAC CT scanning. Subsequent MACE (death/MI/stroke/coronary revascularization) and clinical risk factors were identified via electronic health record (EHR) review. Kaplan-Meier Curve analyses and Cox proportional regression were performed to evaluate associations between AAC and CAC and the development of MACE.

### RESULTS

Our cohort included 3662 patients (median age: 60 (Interquartile Range 11) years, 62% male, 74% White) who had an evaluable abdominal CT and cardiac CT. There was a positive correlation between presence of CAC and AAC (r=0.56, p<0.001). MACE occurred after CT in 324 patients (9%). The incidence of MACE was 0.85 (95% CI 0.64-1.11) and 2.85 (95% CI 2.53-3.21) per 1000 person-month in the AAC absent and AAC present groups, respectively (P<0.001). Following adjustment for age, sex, race/ethnicity, BMI, diabetes mellitus, hypertension, and statin use, presence of AAC was associated with a significant risk of MACE (adjHR 2.24, 95% CI 1.51-3.32, P<0.001).

### CONCLUSION

AAC, quantified on opportunistic abdominal CT using a fully-automated AI algorithm, correlates significantly with CAC and is independently associated with incident MACE. These data support the use of opportunistic imaging in patients for cardiovascular risk assessment. Future studies should investigate whether opportunistic imaging can help guide appropriate cardiovascular prevention strategies.

### CLINICAL RELEVANCE/APPLICATION

Opportunistic CT using a fully-automated AI algorithm can be used to screen for abdominal aortic calcifications, thereby allowing for the initiation of therapy to prevent future major adverse cardiovascular events.

## W7-SSCA08-6 BREAST ARTERIAL CALCIFICATIONS DETECTED BY ARTIFICIAL INTELLIGENCE MODEL ARE ASSOCIATED WITH SIGNIFICANT PREVALENCE OF CARDIOVASCULAR DISEASE: A STUDY OF OVER 18,000 WOMEN

Alyssa T. Watanabe, MD (*Presenter*) Officer, CureMetrix, Inc;Stockholder, CureMetrix, Inc

### PURPOSE

We studied the correlation between breast arterial calcification presence on mammograms and the prevalence of various acute and chronic cardiovascular events and risk factors in 18,092 women.

### METHODS AND MATERIALS

A retrospective study examined a dataset containing 33,167 digital mammogram screening exams, involving 18,092 women (with a mean age of 56.8 +/- 11 years), alongside electronic health records collected from 2007 to 2016 at a sole academic institution. BAC presence was determined using an

artificial intelligence (AI) device (cmAngio, San Diego, CA). Logistic regression analyses were employed to calculate odds ratios (OR) between BAC presence and different health conditions, adjusting for age and Framingham covariates.

## RESULTS

The overall prevalence of BAC at the time of patients' first recorded mammograms was 19.7%. Age-adjusted analyses revealed significant associations between BAC presence and the prevalence of various health conditions. Individuals diagnosed as BAC-positive exhibited notably higher correlation with the prevalence of acute and chronic conditions. For instance, the OR for pooled acute conditions was 2.37 (95% CI: 1.91-2.94), and for pooled chronic conditions, it was 1.51 (95% CI: 1.39-1.65). The OR for specific conditions such as heart failure, heart attack, and chronic kidney disease exceeded 2.0, indicating a strong correlation between BAC presence and disease prevalence.

## CONCLUSION

Opportunistic reporting of BAC presence on mammogram reports could aid in improved risk stratification for women potentially leading to and early intervention strategies for asymptomatic women and improved cardiovascular outcomes.

## CLINICAL RELEVANCE/APPLICATION

Opportunistic reporting of BAC presence on mammogram reports could aid in risk stratification and early intervention strategies for asymptomatic women, potentially leading to improved patient outcomes.

### PURPOSE

Given that CVD and lung cancer share several common risk factors, many lung cancers are detected in asymptomatic patients undergoing Coronary Artery Calcium Score Computed Tomography (CACCT) exams. Our study aims to demonstrate the utility of CACCT for opportunistic detection of early-stage lung cancer, which is usually diagnosed at a late stage such as Stage 3 or Stage 4, after it has spread to nearby tissues or distant organs. Early detection is crucial, as survival rates are significantly higher for lung cancer diagnosed at Stage 1 or Stage 2. We also explored the role of reviewing full field of view reconstructions when interpreting CACCT exams.

### METHODS AND MATERIALS

We conducted a retrospective review of 30,679 consecutive patients who underwent CACCT between January 1, 2013, and February 29, 2019, under an IRB-approved study protocol. The patient population was cross-referenced with an existing cancer registry through natural language processing (NLP) and checked against the Electronic Medical Record for pathologically confirmed cancers. Subset analyses were conducted focusing on the sex, smoking history, and cancer stage within the cohort diagnosed with lung cancer. The imaging was also reviewed for distribution of the lung cancers on small (cardiac) FOV versus wide FOV exams by board certified radiologist.

### RESULTS

Out of 30,679 individuals who underwent a CACCT, 2,887 (9.4%) had a cancer diagnosis at the time of scan. Among this subset, 170 patients (5.9% of the total cancer cases) had lung cancer detectable via CACCT. Of these lung cancer cases, 55 patients (16 males, 39 females) had their lung malignancy first identified through the CACCT scan. The smoking status distribution among these 55 cases was as follows: 25 were former smokers (45.4%), 18 had an unknown smoking status (32.7%), 10 were never smokers (18.2%), and 2 were current smokers (3.6%). Stage-wise analysis revealed that 39 (70%) were diagnosed at Stage 1B or earlier, and 52 (94.5%) were diagnosed earlier than Stage 4. FOV data analysis revealed that 18 out of these 55 cases (32.7%) would have gone undetected in the absence of full FOV reconstruction.

### CONCLUSION

The study findings reveal that coronary artery calcium score computed tomography (CACCT) can identify a substantial number of lung cancers at an early stage, with approximately 70% of cases diagnosed at Stage 1B or earlier, offering patients a significant opportunity for complete cure. It also highlights the importance of utilization of wide FOV image reconstruction.

### CLINICAL RELEVANCE/APPLICATION

Our study underscores the importance of incidental lung nodule observation, reporting, and follow-up in calcium score exams for early lung cancer detection and treatment.

## W7-SSCH07-3 UTILIZING CT-DERIVED BODY COMPOSITION TO PREDICT LUNG NODULE MALIGNANCY AND DYNAMIC GROWTH IN SCREENING SETTINGS

Tong Yu (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to explore whether incorporating body composition can improve the assessment of malignancy in screen-detected indeterminate pulmonary nodules (IPNs) and elucidate the potential impact of body composition on the dynamic growth of such nodules.

### METHODS AND MATERIALS

A dataset of 216 subjects from a low-dose CT lung cancer screening program was used in this study. These subjects had IPNs identified at baselines and at least one follow-up CT scans. Artificial intelligence algorithms were used to automatically segment and quantify IPNs and five body compositions depicted on baseline and follow-up CT scans. Logistic Regression (LR) analyses were performed. The area under the receiver operating characteristic curve (ROC-AUC) was used to assess the performance via the 10-fold cross-validation method. Average feature importance was evaluated in several machine learning models. Causal relationships were analyzed and visualized using a novel directed graph method. Correlation analyses were employed to study the association between body composition features and malignancy at baseline, as well as the relationship between body composition dynamic changes and nodule growth rate with the last CT examinations. Gender was emphasized in all analyses.

### RESULTS

The feature skeletal muscle density showed statistically significance in both men and women in univariate analysis. The multivariate LR model, incorporating body composition and nodule features, yielded a maximum AUC of 0.87 (95% CI: 0.82 - 0.91). In terms of feature importance, skeletal muscle density, intramuscular adipose tissue mass and density were high-ranked among body tissue features, with skeletal muscle density retaining its significance even after adjusting clinical and nodule features. The causal AI method identified two nodule features, mean Intensity, and irregularity, and one body tissue feature, skeletal muscle density, as directly (causally) linked to malignancy. Correlation analysis identified several nodule dynamic growth indicators, including nodule features, irregularity, mean diameter and mean intensity, and body tissue features, skeletal muscle density, and intramuscular adipose tissue density in both men and women.

### CONCLUSION

The body compositions, notably skeletal muscle density, hold significant promise in distinguishing between malignant and benign nodules, as well as evaluating the dynamic growth of nodules over time. Integrating body composition with nodule features can significantly improve the assessment of an IPN’s malignancy.

### CLINICAL RELEVANCE/APPLICATION

Approximately 96% of IPNs detected in lung cancer screening turn out to be false positives, which often lead to unnecessary follow-up procedures, such as follow-up imaging and biopsy.

## W7-SSCH07-4 IMPLICATIONS OF 2D SINGLE SLICE VS. 3D WHOLE-CHEST BODY COMPOSITION PHENOTYPING ON OUTCOME PREDICTION: INSIGHTS FROM THE NATIONAL LUNG SCREENING TRIAL

Fabian Bamberg, MD, MPH (*Abstract Co-Author*) Speakers Bureau, Bayer AG;Speakers Bureau, Bracco Imaging;Speakers Bureau, Siemens AG;Research Grant, Siemens AG
Jakob Weiss, MD (*Abstract Co-Author*) Nothing to Disclose
Matthias Jung, MD (*Abstract Co-Author*) Nothing to Disclose
Marco Reisert (*Abstract Co-Author*) Nothing to Disclose
Fabian Bernhard Pallasch, MD (*Abstract Co-Author*) Nothing to Disclose
Johannes Jahn, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Measures of body composition (BC) are associated with clinical outcomes in patients with cardiovascular (CV) disease and cancer. BC is typically estimated from a single slice at the 3rd lumbar vertebra, given the high correlation with whole-body volumes. Standardized heights for chest imaging are not well-established, and whether 3D volumes can further improve prognostication is unknown. Here, we used a fully automated deep learning network 1) to investigate the correlation between 2D single slice areas and 3D whole-chest volumes and 2) to explore the association between these BC measures with mortality in heavy smokers.

### METHODS AND MATERIALS

We used data from the first screening round of the National Lung Screening Trial (NLST). Body composition was estimated on chest CT and defined as skeletal muscle (SM), intramuscular (IMAT) and subcutaneous adipose tissue (SAT). First, the highest correlation between 2D slices for each thoracic vertebra and 3D chest volumes was explored. Second, the association between BC measures and mortality was assessed for both approaches. The primary outcome was all-cause mortality; additional outcomes were CV and lung cancer mortality. Kaplan-Meier survival curves were calculated (categories <15%; 15-85%; >85%) to investigate time to mortality. Cox regression assessed the association between BC measures and mortality adjusted for demographics and CV risk factors.

### RESULTS

Among 23,319 individuals (mean age 61.4±5, 41.9% female), 1,590 (6.8%) all-cause deaths occurred over a median follow-up of 6.3 years. The best correlation between single slice and the 3D volumes was observed at the T4 vertebra for SM and IMAT, and at T7 for SAT. For 3D volumes, Kaplan-Meier curves showed higher rates of mortality for low SM and high IMAT groups (all $p<0.0001$). No effect was found for SAT. Univariable Cox regression revealed an association between the low SM and high IMAT group, which remained robust after multivariable adjustment for risk factors (aHR: 1.34, 95% CI 1.18-1.52, $p<0.001$ and aHR: 1.58, 95% CI: 1.39-1.81, $p<0.001$, respectively). No significant association was found for SAT. Survival analyses for the 2D measures yielded similar results as for the 3D approach. Largely similar patterns were found for CV and lung cancer mortality for both 3D and 2D measures.

### CONCLUSION

Low SM and high IMAT are independent predictors for mortality in heavy smokers beyond traditional clinical risk factors. 3D and 2D measures showed largely similar results and can be used interchangeably.

### CLINICAL RELEVANCE/APPLICATION

Automated and opportunistic quantification of BC from chest CT may help to identify high-risk individuals participating in lung cancer screening with the potential to improve personalized prevention beyond established strategies.

## W7-SSCH07-5 USEFULNESS OF AUTOMATIC DEEP LEARNING-BASED LUNG CT ANALYSIS IN PREDICTING THE OCCURRENCE OF SYMPTOMATIC RADIATION PNEUMONITIS AFTER STEREOTACTIC BODY RADIOTHERAPY FOR LUNG MALIGNANCIES

Hajime Sakuma, MD, PhD (*Abstract Co-Author*) Research Grant, Eisai Co, Ltd;Research Grant, FUJIFILM Holdings Corporation;Research Grant, Guerbet SA;

Satoshi Nakamura, MD (*Abstract Co-Author*) Nothing to Disclose
Yutaka Toyomasu, MD (*Abstract Co-Author*) Nothing to Disclose
Yasutaka Ichikawa, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the utility of automatic deep learning (DL)-based lung CT analysis in predicting the occurrence of symptomatic radiation pneumonitis (RP) after stereotactic body radiotherapy (SBRT) for lung malignancies.

**METHODS AND MATERIALS**

One hundred three patients who underwent SBRT for lung malignancies and had chest CT performed prior to SBRT were studied. The pre-SBRT chest CT was evaluated using an automatic DL-based lung CT analysis (QZIP-ILD). The analysis system can segment the lung on CT into the following nine regions and calculate the volume of each: normal (N), airspace/hyperinflationary region (A), emphysema (E), ground glass opacity (G), consolidation (C), traction bronchiectasis (T), reticulation (R), honeycombing (H), and fibrosis (F). The relation between the volume of each lung region and the occurrence of symptomatic RP (grade =2) was evaluated. RP was defined per multidisciplinary clinician consensus using CTCAE v5.0.

**RESULTS**

Eleven (11%) of the subjects developed symptomatic RP. Symptomatic RPs had significantly lower N volume (median 3111.8cc, interquartile range (IQR) 2367.7-3617.5cc) and A+N volume (median 3148.4cc, IQR 2381.8-3663.9cc) compared to asymptomatic RPs (N: median 3827.6cc, IQR 3086.2-4493.5cc, p=0.022; A+N, median 4074.5, IQR 3344.6-4756.7cc, p=0.0015) (Figure 1), while no significant differences in other indices (E, G, C, T, R, H, F or their combinations) were found between symptomatic and asymptomatic RPs. Receiver operating characteristic (ROC) analysis for predicting symptomatic RP showed that the area under the curve were 0.71 (95%CI 0.66-0.91) for N and 0.79 (95%CI 0.57-0.85) for A+N. With the cutoff values (N, 3719.2 cc; A+N, 3741.1 cc) obtained from the ROC analysis, a high sensitivity (N, 82%; A+N, 82%) and negative predictive value (N, 96%; A+N, 97%) for predicting symptomatic RP were observed.

**CONCLUSION**

The volumes of normal lung and normal lung + airspace/hyperinflation region identified by automatic DL-based lung CT analysis are significantly associated with symptomatic RP caused by SBRT and are useful indices to predict symptomatic RP with high sensitivity and negative predictive value.

**CLINICAL RELEVANCE/APPLICATION**

Automatic DL-based lung CT analysis provides a useful objective measure for predicting the occurrence of symptomatic RP after SBRT for lung malignancies.

## W7-SSCH07-6 SHORT-TERM TEMPORAL ANALYSIS OF INTRA- AND PERI-TUMORAL CT RADIOMICS FOR PREDICTING MAJOR PATHOLOGICAL RESPONSE TO NEOADJUVANT CHEMOIMMUNOTHERAPY IN NON-SMALL CELL LUNG CANCER

Yajia Gu (*Abstract Co-Author*) Nothing to Disclose
Jing Gong, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Neoadjuvant chemoimmunotherapy holds promise for improving outcomes in non-small cell lung cancer (NSCLC) treatment, yet accurately predicting patient response remains a clinical challenge. This study aims to develop a short-term temporal CT radiomics model to predict the major pathological response (MPR) to neoadjuvant chemoimmunotherapy (NCI) in NSCLC by decoding the intra- and peri-tumoral imaging phenotypes.

**METHODS AND MATERIALS**

We enrolled 352 patients undergoing curative surgery after NCI for IB-III NSCLC at two centers to establish a training cohort (n=186), an internal validation cohort (n=80), and an external validation cohort (n=86). We first segmented the primary tumor on pre- and after-NCI CT images manually. Then, we computed the intra- and peri-tumoral CT radiomics to reveal the imaging phenotypes of tumor microenvironment. After feature standardization with z-score method, we employed a two-step feature selection process to reduce the redundant features, which included an ANOVA F-value based feature selection and a recursive feature elimination configuring with least absolute shrinkage and selection operator. To balance the training dataset, we used a synthetic minority over-sampling technique to resample the dataset. Finally, we used a support machine vector classifier to build the short-term temporal model by computing the changes in radiomics features.

**RESULTS**

Short-term temporal predictive model incorporating intra- and peri-tumoral radiomic features achieved AUC values of 0.88, 0.76 and 0.74 in three datasets, which was significantly higher than that of RECIST model and pre-treatment model.

**CONCLUSION**

The results demonstrated that short-term temporal analysis of intra- and peri-tumoral CT radiomics holds promise for predicting MPR to neoadjuvant chemoimmunotherapy in NSCLC.

**CLINICAL RELEVANCE/APPLICATION**

These findings highlight the potential of radiomics as a non-invasive tool for treatment response assessment and personalized therapy selection in NSCLC patients.

## W7-SSCH08-1 ENHANCING PULMONARY EMBOLISM MANAGEMENT: THE IMPACT OF AI-BASED TRIAGE AND PRIORITIZATION ON DIAGNOSTIC TIMELINESS AND TREATMENT INITIATION

Ian Holland, MD (*Abstract Co-Author*) Nothing to Disclose
Zahra Chakeri, MD (*Abstract Co-Author*) Nothing to Disclose
Ariana Garabedian (*Abstract Co-Author*) Nothing to Disclose
Hamid Chalian, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Diaz, MD (*Abstract Co-Author*) Nothing to Disclose
Mehrzad Shafiei, MD (*Abstract Co-Author*) Nothing to Disclose
Seyedali Nabipoorashrafi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

AI-based triage and prioritization systems have improved the management of patients with pulmonary embolism (PE) by providing quicker and more accurate assessments. These systems utilize machine learning algorithms to analyze CT chest pulmonary angiography (CTPA) images for the rapid detection of PE, which can help reduce the time to inform ordering clinicians and ultimately begin treatment. This improvement in process efficiency can enhance patient outcomes by allowing for timely treatment and better use of healthcare resources, thereby supporting more effective care delivery for PE patients.

### METHODS AND MATERIALS

A retrospective analysis was conducted encompassing patients who underwent CTPA for PE detection, between September 2023 and March 2024 of an AI-based triage and prioritization software. Data regarding the time interval between the finalization of CTPA scans and communication with clinical teams (notification time, NT), as well as the time taken to initiate anticoagulation treatment (time to anticoagulation, TTA), were collected through a review of radiology reports and patient charts. Exclusion criteria comprised cases of chronic PE without new embolism. Statistical analysis employed the Mann-Whitney U test due to the skewed distribution of data.

### RESULTS

The pre-AI group consisted of 325 patients, while the post-AI group comprised 157 patients. Analysis revealed a statistically significant decrease (p-value $< 0.05$) in NT in the post-AI group (mean=33.54 min, IQR=25 min) compared to the pre-AI group (mean=64.41 min, IQR=28 min). Similarly, TTA was significantly reduced (p-value $< 0.05$) in the post-AI group (mean=149.22, IQR=93.75 min) compared to the pre-AI group (mean=248, IQR=197 min).

### CONCLUSION

The introduction of an AI-based triage and prioritization system for detecting pulmonary embolism at our large tertiary care center has significantly shortened the time to notify clinicians and initiate anticoagulation treatment. These findings highlight the potential of AI to streamline diagnostic processes and expedite clinical responses, contributing to improved patient management and outcomes.

### CLINICAL RELEVANCE/APPLICATION

The integration of an AI-based triage and prioritization solution into the conventional diagnosis of acute PE holds promise for enhancing patient care by expediting notification to clinicians and initiating timely treatment, thereby potentially improving outcomes in patients with acute PE.

## W7-SSCH08-2 INDICATORS FOR HOSPITALIZATION IN ACUTE PULMONARY EMBOLISM: UNCOVER THE ASSOCIATION BETWEEN D-DIMER LEVELS, THROMBUS VOLUME AND RADIOMICS

Thomas J. Vogl, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ibrahim Yel, MD (*Abstract Co-Author*) Nothing to Disclose
Leon D. Gruenewald, MD (*Abstract Co-Author*) Nothing to Disclose

Renate M. Hammerstingl, MD (*Abstract Co-Author*) Nothing to Disclose
Simon S. Martin, MD (*Abstract Co-Author*) Nothing to Disclose
Scherwin Mahmoudi, MD (*Abstract Co-Author*) Nothing to Disclose
Vitali Koch, MD (*Abstract Co-Author*) Nothing to Disclose

Christian Booz, MD (*Abstract Co-Author*) Speaker, Siemens AG
Jennifer Gotta (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to examine the correlation between D-dimer levels and thrombus size in acute pulmonary embolism (PE) combining dual-energy CT (DECT) and radiomics and to investigate the diagnostic utility of a machine learning classifier based on dual-energy computed tomography (DECT) radiomics for identifying patients with a complicated course, defined as at least hospitalization at IMC.

**METHODS AND MATERIALS**

The study was conducted including 136 participants who underwent pulmonary artery CT angiography from January 2015 to March 2022. Based on DECT imaging, 107 radiomic features were extracted for each patient using standardized image processing. After dividing the dataset into training and test sets, stepwise feature reduction based on reproducibility, variable importance and correlation analyses were performed to select the most relevant features; these were used to train and validate the gradient-boosted tree models.Receiver operating characteristics (ROC) analysis was utilized to evaluate the association between volumetric, laboratory data and adverse outcomes.

**RESULTS**

In the central PE group, we observed a significant correlation between thrombus volumetrics and D-dimer levels ($p = 0.0037$), as well as between thrombus volumetrics and hospitalization at the Intermediate Care Unit (IMC) ($p = 0.0001$). In contrast, no statistically significant differences were identified in thrombus sizes between patients who experienced complications and those who had a favorable course ($p = 0.3162$). The trained machine learning classifier achieved an accuracy of 61% and 55% in identifying patients with a complicated course, as indicated by an area under the ROC curve of 0.63 and 0.58.

**CONCLUSION**

In conclusion, our findings indicate a positive correlation between D-dimer levels and central PE's pulmonary embolic burden. Thrombus volumetrics may serve as an indicator for complications and outcomes in acute PE patients. Thus, thrombus volumetrics, as opposed to D-dimers, could be an additional marker for evaluating embolic disease severity. Moreover, DECT-derived radiomic feature models show promise in identifying patients with a complicated course, such as hospitalization at IMC.

**CLINICAL RELEVANCE/APPLICATION**

The association between thrombus volumetrics and potential complications in acute PE patients highlights its importance as a predictive marker for assessing disease severity and prognosis. Thus, thrombus volumetrics may offer valuable insights beyond D-dimer levels, enhancing our ability to manage and prognosticate acute embolic events more effectively.

## W7-SSCH08-3 UTILITY OF MACHINE LEARNING FOR PREDICTING SEVERE CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION BASED ON CT METRICS IN A SURGICAL COHORT

John T. Granton, MD (*Abstract Co-Author*) Nothing to Disclose
Sangwook Kim (*Abstract Co-Author*) Nothing to Disclose
Marc Deperrot, MD (*Abstract Co-Author*) Nothing to Disclose
Micheal McInnis, MD (*Abstract Co-Author*) Speakers Bureau, Boehringer Ingelheim GmbH;Speakers Bureau, Bayer AG
Gauri R. Karur, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Chris McIntosh (*Abstract Co-Author*) Nothing to Disclose
Micah Grubert Van Iderstine, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

The right to left ventricle (RV/LV) ratio is a validated predictor of outcome in acute pulmonary embolism (PE), independent of clot burden scores. In chronic thromboembolic pulmonary hypertension (CTEPH), the interplay between RV/LV ratio, clot burden on CT, and pulmonary hypertension has not been fully explored. The aim of this study was to evaluate RV/LV ratio as a predictor of severe pulmonary hypertension (PH) and to develop machine learning (ML) models to identify additional radiologic features associated with severe PH in surgical CTEPH.

**METHODS AND MATERIALS**

Patients were included after multidisciplinary review if they had a diagnosis of CTEPH according to 2022 European Society of Cardiology guidelines, a preoperative CT pulmonary angiogram, and pulmonary endarterectomy between 01/2017 and 06/2022. A mean pulmonary artery pressure of >50 mmHg was classified as severe on pre-operative right heart catheter. CTs were scored by a masked thoracic radiologist who classified each of the 32 pulmonary artery (PA) vessels as containing a web, eccentric thickening, an occlusion, or subsegmental disease. The RV, LV, main PA, and ascending aorta (Ao) diameters were measured in short axis. XGBoost models were developed to predict CTEPH feature importance and the models were compared to a logistic regression model using an RV/LV ratio input. 200-fold random shuffled stratified sampling with synthetic minority oversampling and a 20% test sample was employed. Model performance was evaluated based on sensitivity, specificity, receiver operating curve analysis, and F1 score.

**RESULTS**

There were 184 patients included. Similar to acute PE, clot burden was not helpful in identifying severe PH. The RV/LV ratio logistic regression model performed well (AUC 0.76) with a cut-off of 1.4 having a sensitivity of 71% and specificity of 56%. A baseline ML model (RLV0) including only the RV, LV, Pa, and Ao measures and their ratios yielded an average AUC of 0.66 +/- 0.10. When the 32 raw vessel scores were added, the average AUC was 0.72 +/- 0.08. The addition of demographics and statistics summarizing the CT findings raised the AUC to 0.75 +/- 0.08 (F1 score 0.41). The most impactful variables by Shapley values were RV/LV and PA/Ao metrics, patient gender, individual segmental CT scores and total number of webs.

**CONCLUSION**

While measures of clot burden had little bearing on PH severity independently, incorporation of clot burden and patient demographics improves performance of machine learning models. Future work will employ similar imaging-based models to predict clinically meaningful patient outcomes in CTEPH.

**CLINICAL RELEVANCE/APPLICATION**

Radiologists can identify patients with severe PH through measuring the RV/LV ratio in CTEPH with an optimal cut-off of 1.4.

## W7-SSCH08-4 CHRONIC PULMONARY EMBOLISM QUANTIFICATION DISTINGUISHES BETWEEN CHRONIC THROMBOEMBOLIC PULMONARY DISEASE (CTEPD) WITHOUT AND WITH PULMONARY HYPERTENSION (CTEPH) WITH HIGH ACCURACY

Micheal McInnis, MD (*Abstract Co-Author*) Speakers Bureau, Boehringer Ingelheim GmbH;Speakers Bureau, Bayer AG
Laura Donahoe (*Abstract Co-Author*) Nothing to Disclose
John T. Granton, MD (*Abstract Co-Author*) Nothing to Disclose
Marc Deperrot, MD (*Abstract Co-Author*) Nothing to Disclose
Dayana Davoudi (*Abstract Co-Author*) Nothing to Disclose
Katherine Lajkosz (*Abstract Co-Author*) Nothing to Disclose
Colin McQuade, MBBCh, FFR(RCSI) (*Presenter*) Nothing to Disclose

**PURPOSE**

Persistent perfusion defects are common after acute pulmonary embolism and, when symptomatic, the entity is termed CTEPD, and some develop CTEPH. Few studies show no or limited difference in clot burden between CTEPD and CTEPH but new clinical guidelines have since revised the mean pulmonary artery pressure threshold for a diagnosis of CTEPH from 25 mmHg to 20 mmHg. The purpose of this study was to evaluate difference in clot burden type and distribution in CTEPD versus CTEPH using new diagnostic criteria.

**METHODS AND MATERIALS**

This retrospective study evaluated patients with a multidisciplinary diagnosis of CTEPD or CTEPH in 2021or 2022 by right heart catheter using the ESC/ERS 2022 guidelines. Two CTEPH cases were randomly selected for each CTEPD case. CTPA studies were reviewed by a masked thoracic radiologist, scoring 32 vessels per case (main, interlobar, lobar, lingula, descending branches and segmental vessels) for chronic PE with the single most obstructive lesion recorded per vessel (occlusion, eccentric thickening, or web). Subsegmental disease was noted if present. Comparisons were made across clinical characteristics, clot distribution by most proximal lesion (UCSD level), Qanadli index, lesion number, type and location. Receiver operator characteristic (ROC) curve analysis was used to evaluate diagnostic performance of individual features.

**RESULTS**

There were 44 CTEPD and 88 CTEPH patients with no difference in mean age (58 yrs), BMI (29.8), and sex (50% female). Functional class was similar ($p=0.7$) but patients with CTEPH had measurably worse six-minute walk distance (379 vs 463 m, $p=0.001$), and right ventricular dilation ($p<0.001$) and dysfunction ($p<0.001$) by echocardiography. Co-morbidities were similar except a higher prevalence of deep vein thrombosis in CTEPD (52% vs 33%, $p=0.03$). CT identified more lesions in the CTEPH group (21.2 vs. 10.0 lesions/case, $p<0.001$) and it was a more diffuse process involving more lobes per case (mean 5 vs 3, $p<0.001$), though the right lower lobe was nearly always involved in both CTEPD (93%) and CTEPH (99%, $p=0.11$). The most proximal disease was more commonly main/lobar in CTEPH (UCSD level 1/2: 70% vs 36%, $p<0.001$). Qanadli index revealed 51% obstruction in CTEPH compared to 26% in CTEPD ($p<0.001$). ROC curve analysis demonstrated the total number of lesions to best discriminate between CTEPH and CTEPD with an AUC of 0.91 and an optimal cut-off of 16 lesions (sensitivity 90%, specificity 84%).

**CONCLUSION**

CTEPD and CTEPH are radiologically distinct with twice as much vascular obstruction seen in CTEPH.

**CLINICAL RELEVANCE/APPLICATION**

Both CTEPD and CTEPH patients can have significant functional impairment, but radiologists should suspect CTEPH when half of the vascular bed is involved on careful review.

## W7-SSCH08-6 HIGH-ACCURACY DEEP LEARNING-BASED CLASSIFICATION MODEL FOR AUTOMATIC AORTIC DISSECTION ON CHEST CT ANGIOGRAPHY

**PURPOSE**

To develop and evaluate the performance of a deep learning-based methodology for automatic identification of aortic dissection on chest CT angiography.

**METHODS AND MATERIALS**

This study included chest CT angiography of 1,373 patients with suspected acute aortic conditions, excluding those with a history of aortic surgery. The dataset is divided into training and testing sets, and further classified into three categories according to the Stanford classification system. The training set consists of 857 cases, including 84 Type A, 379 Type B, and 394 negative cases. The testing set comprises 516 cases, with 78 Type A, 121 Type B, and 317 negative cases. A two-stage deep learning algorithm based on V-Net was developed in this study, significantly enhancing the algorithm's capability to distinguish aortic dissection from similar conditions such as aortic intramural hematoma or penetrating aortic ulcer. The model performance was evaluated using sensitivity and specificity to measure its accuracy in diagnosing aortic dissection.

**RESULTS**

On the test cohort of 516 cases, the deep learning algorithm exhibited commendable capability in discerning aortic dissections. It achieved a sensitivity of 0.995 and specificity of 0.987, evidencing a high degree of accuracy in positive and negative case differentiation. With regard to the subtypes of aortic dissections, the model reached a sensitivity of 0.974 and a specificity of 0.984 for Stanford Type A, and for type B, the sensitivity was 0.950 with the specificity of 0.985.

**CONCLUSION**

Deep learning algorithms have demonstrated the capability for high-precision identification of aortic dissections on chest CT angiography, as well as high-accuracy classification of dissection subtypes.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning algorithms show good potential to facilitate reliable triage for patients with aortic dissection, helping enhancing clinical decision-making and expediting the workflow.

### PURPOSE

Obesity is a global health epidemic affecting ~42% of the US population, leading to metabolic complications including accumulation of ectopic fat in and around organs. Proton density fat fraction (PDFF) is a quantitative MRI biomarker for ectopic fat, traditionally used in the liver. Recently, investigators have used PDFF to evaluate other depots such as visceral and subcutaneous adipose tissue (VAT and SAT, respectively), finding that adipose tissue PDFF correlates positively with BMI and decreases with weight loss. The predictors that influence adipose tissue PDFF reduction during weight loss, however, remains a gap in knowledge. This study aims to identify the baseline predictors for VAT and SAT PDFF reduction after metabolic bariatric surgery (MBS).

### METHODS AND MATERIALS

Adults with obesity scheduled for MBS were prospectively recruited to an ongoing dual-center study which included collection of baseline clinical parameters (age, sex, BMI), fasting labs (glucose, HbA1c, insulin, lipid panel), and non-contrast MR exams (MRI-PDFF) on a clinical 3.0T MRI system (GE Signa Premier or GE Discovery MR750, GE Healthcare, Waukesha WI) at 2 timepoints (baseline and 12 months post-MBS). PDFF was measured in VAT and SAT by two study-trained analysts independently. Homeostatic model assessment for insulin resistance (HOMA-IR) was calculated from glucose and insulin. During MBS, participants underwent wedge biopsy of the left liver lobe for assessment of metabolic dysfunction-associated steatohepatitis (MASH). Bayesian Information Criterion based stepwise linear regression was used to identify baseline predictors of VAT and SAT PDFF change.

### RESULTS

51 adults with obesity (47 female, mean age 44.7 years, mean BMI 46.4 kg/m2, 24 sleeve gastrectomy [SG] and 27 Roux-en-Y gastric bypass [RYGB]) were recruited to date and included in this study. VAT and SAT PDFF had absolute changes of -5.8% and -4.3% after MBS ($p < 0.001$), respectively. For VAT PDFF change, the model selected surgery type and baseline HOMA-IR ($p < 0.001$, $r = 0.504$); RYGB and lower baseline HOMA-IR were significantly associated with greater VAT PDFF reduction. For SAT PDFF change, the model selected surgery type, MASH status, and baseline fasting glucose ($p < 0.001$, $r = 0.547$); RYGB, negative MASH status, and lower baseline glucose were significantly associated with greater SAT PDFF reduction.

### CONCLUSION

Participants with healthier metabolic profiles at baseline and those who underwent RYGB had greater reductions in VAT and SAT PDFF 12 months after MBS.

### CLINICAL RELEVANCE/APPLICATION

With further validation, adipose tissue PDFF could potentially be used to monitor metabolic health in patients with obesity and help inform management decisions including MBS procedure.

## W7-SSGI15-2 HEPATIC-ASSOCIATED VASCULAR MORPHOLOGICAL ASSESSMENT TO PREDICT OVERT HEPATIC ENCEPHALOPATHY BEFORE TIPS: A MULTICENTER STUDY

Chongyang Duan (*Abstract Co-Author*) Nothing to Disclose
Yujie Zhao (*Abstract Co-Author*) Nothing to Disclose
Zhaochen Liu (*Abstract Co-Author*) Nothing to Disclose
Jinqiang Chen (*Abstract Co-Author*) Nothing to Disclose
Xiaoqiong Chen (*Abstract Co-Author*) Nothing to Disclose
Sirui Fu, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To provide patients the chance of accepting curative transjugular intrahepatic portosystemic shunt (TIPS) rather than palliative treatments for portal hypertension-related variceal bleeding and ascites, we aimed to assess hepatic-associated vascular morphological change to improve the predictive accuracy of overt hepatic encephalopathy (HE) risks.

### METHODS AND MATERIALS

Patients who underwent TIPS between January 2012 and January 2022 were included in this multicenter retrospective study. 621 patients undergoing TIPS were subdivided into training (413 cases from three hospitals) and external validation datasets (208 cases from another three hospitals). Besides traditional clinical factors, we assessed hepatic-associated vascular morphological change by maximum diameter (including the absolute and ratio values). Three predictive models (clinical, hepatic-associated vascular, and combined) were constructed using logistic regression. Their discrimination and calibration were compared to test the necessity of hepatic-associated vascular assessment and identify the optimal model. Further, to verify the improved performance of ModelC-V, we compared it with four previous models, both in discrimination and calibration.

### RESULTS

621 patients were subdivided into training (413 cases: mean age, 52.0 years ± 11.4 [SD]; 95 women) and external validation (208 cases: mean age, 56.0 years ± 11.0 [SD]; 40 women) datasets. The combined model outperformed the clinical and hepatic-associated vascular models (training: 0.814, 0.754, 0.727; validation: 0.781, 0.679, 0.776; $P < 0.050$) and had the best calibration. Compared to previous models, ModelC-V showed superior performance in discrimination. The high-, middle-, and low-risk populations displayed significantly different overt HE incidence ($P < 0.001$). Particularly, despite the limited ability of pre-TIPS ammonia to predict overt HE risks, the combined model displayed a satisfactory ability for overt HE risks, both in low- and high-ammonia subgroups. Accordingly, an applet for ModelC-V was constructed.

### CONCLUSION

Hepatic-associated vascular assessment improved the predictive accuracy of overt HE, ensuring curative chances by TIPS for suitable patients and providing insights for cirrhosis-related studies.

### CLINICAL RELEVANCE/APPLICATION

We constructed a combined model that could predict post-TIPS overt HE based on the hepatic-associated vascular morphological assessment. Assisted by our model, patients with low risk may be able to accept alternative TIPS treatment.

## W7-SSGI15-3 DEVELOPMENT AND VALIDATION OF MRI PDFF CUT-OFFS FOR LIVING LIVER DONOR ELIGIBILITY ASSESSMENT

So Yeon Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Seung Soo Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Sun Kyung Jeon, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Hae Young Kim, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to derive MRI proton density fat fraction (PDFF) cut-offs for detecting various degrees of hepatic steatosis (HS) in potential living liver donors, using large droplet fat fraction as the histological reference standard.

### METHODS AND MATERIALS

This retrospective study included consecutive potential living liver donors who underwent MRI and liver biopsy between 2013 and 2023 at two tertiary institutions, each as development (n = 3062; 2015 men; median [interquartile range] age of 32 [25-38] years) and external validation (n = 472; 287 men; 35 [26-44] years) datasets. PDFF was measured using dedicated MRI sequences. Histologic HS defined as large droplet fat fraction was used as the reference standard. Dual PDFF cut-offs aimed at 95% sensitivity or 95% specificity, for diagnosing histologic HS of =10%, =20%, =30%, and =40%, were determined in the development dataset using ten-fold cross validation. The cut-offs were then validated in the external validation dataset. Equation for estimating histologic HS from PDFF was also derived using linear regression.

### RESULTS

The PDFF cut-offs for histologic HS of =10%, =20%, =30%, and =40%, targeting 95% sensitivity, were 3.7%, 5.5%, 8.0%, and 10.0%, respectively. External validation demonstrated high sensitivities = 97.9% with specificities ranging from 60.9% to 95.1%. The PDFF cut-offs targeting 95% specificity were 6.3%, 8.0%, 9.1%, and 10.1%, respectively. External validation rendered high specificities ranging from 88.5% to 95.3% with sensitivities ranging from 76.6% to 100%. For diagnosing histologic HS =30%, which is the most prevalently used threshold for living liver donor eligibility assessment, the PDFF cut-offs achieved sensitivities and specificities of both over 90%. The equation of (Histologic HS = -2.95 + 1.93 * PDFF) was derived.

### CONCLUSION

This study established and validated PDFF cut-off values for detecting HS in potential living liver donors. For diagnosis of hepatic steatosis =30%, which is the most widely used criterion in living liver donor evaluation, our PDFF cut-offs yielded sensitivities and specificities exceeding 90% in both internal and external validation.

### CLINICAL RELEVANCE/APPLICATION

This study was conducted using large droplet fat relevant to graft survival as the reference standard, as per Banff consensus recommendations. The dual cut-off values targeting high sensitivity or high specificity may facilitate donor evaluation by excluding potential donors with a high probability of

substantial steatosis from further work-up, or expediting the work-up for potential donors unlikely to have steatosis exceeding the eligibility limit.

## W7-SSGI15-4 BI-REGIONAL DYNAMIC CONTRAST-ENHANCED MRI FOR PREDICTION OF MICROVASCULAR INVASION IN SOLITARY BCLC STAGE A HEPATOCELLULAR CARCINOMA AND ITS SIGNIFICANCE FOR PROGNOSIS AND TREATMENT

Xinming Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Wei Cai (*Abstract Co-Author*) Nothing to Disclose
Yongjian Zhu, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Prediction of microvascular invasion (MVI) in hepatocellular carcinoma (HCC) preoperatively is challenging but essential for reducing tumor recurrence. We aimed to construct a nomogram based on bi-regional quantitative dynamic contrast-enhanced MRI (DCE-MRI), as well as and clinical-radiological (CR) features for predicting MVI, and to assess its ability for stratifying the risk of recurrence after hepatectomy.

### METHODS AND MATERIALS

Patients with solitary HCC less than 5.0 cm were prospective collected, and were randomly divided into a training (n = 93) and validation set (n = 40). Quantitative DCE-MRI parameters were obtained in both intra-tumoral region (ITR) and peritumoral region (PTR). Combined DCE perfusion parameters (CDCE) were constructed to predict MVI. MR imaging features were also evaluated. Nomogram incorporating CDCE and CR features was developed and evaluated. The prognostic significance of the nomogram and the survival benefits of hepatectomy approaches (anatomical resection [AR] or non-anatomical resection [NAR]) were also assessed.

### RESULTS

A total of 133 patients with MVI (n = 45) and without MVI (n = 88) were included. Total blood flow in ITR and arterial fraction in PTR exhibited the best predictive performance for MVI with areas under the curve (AUCs) of 0.790 and 0.792, respectively. CDCE demonstrated a predictive performance with AUCs of 0.868 and 0.857 in the training set and validation set, respectively. A combined nomogram integrated with the a-fetoprotein, corona enhancement, two-trait predictor of venous invasion, and CDCE showed effective discrimination in both the training and validation set (AUC = 0.966 and 0.937, respectively). Survival analysis demonstrated that the nomogram could stratify HCC patients in terms of recurrence-free survival (RFS). AR was associated with better RFS than NAR in the high-risk group ($P < 0.05$).No significant difference between AR and NAR was observed in low-risk group ($P > 0.05$).

### CONCLUSION

Quantitative DCE-MRI provides a promising tool for predicting MVI in HCC noninvasive and preoperatively. Additionally, the combined nomogram based on CR features and quantitative DCE-MRI parameters of ITR and PTR achieves excellent prediction performance. The predicted MVI risk classification can stratify the risk of recurrence after radical hepatectomy and aid in selection of optimal surgical approaches.

### CLINICAL RELEVANCE/APPLICATION

MVI is a significant predictor of prognosis in HCC. The combined model incorporating bi-regional DCE-MRI parameters and clinical-radiological CR features could predict MVI preoperatively, which could stratify the risk of recurrence and aid in in choosing appropriate treatment strategies.

### PURPOSE

Obesity is a critical public health concern due to its rising prevalence and morbidity. Patients with obesity have increased propensity to develop metabolic dysfunction-associated steatotic liver disease (MASLD) and its advanced form metabolic dysfunction-associated steatohepatitis (MASH). MASH is associated with increased systemic inflammation and insulin resistance, leading to difficulty with weight loss, however if this translates to dampened liver fat reduction during weight loss is unknown. We hypothesized that MASH would be associated with reduced liver fat reduction, independent of baseline liver fat content, in adults with obesity after metabolic bariatric surgery (MBS).

### METHODS AND MATERIALS

Adults with obesity scheduled for MBS were prospectively recruited to participate in an ongoing dual-center study with collection of baseline clinical parameters (age, sex, BMI), fasting labs (glucose, HbA1c, insulin, lipid panel, liver panel), and non-contrast MR examinations (MRI-PDFF) on a clinical 3.0T MRI system (GE Signa Premier or GE Discovery MR750, GE Healthcare, Waukesha WI) at 2 timepoints (baseline and 12 months post-MBS). During MBS, participants underwent wedge biopsy of the left liver lobe. Two pathologists in consensus scored the histology and classified participants as MASH or not. Mann-Whitney test was used for baseline differences between participants with and without MASH. Variables associated with MASH were used in multivariable linear regression to model changes in liver PDFF post-MBS. Bonferroni's correction for multiple comparisons was used for baseline ($a=0.005$) and multivariable analyses ($a=0.01$).

## RESULTS

52 adults with obesity (47 female, mean age 45.5 years, mean BMI 46.9 Kg/m2, 11 MASH) were recruited to date and included in this study. Participants with MASH had higher liver PDFF (20.9% v 6.7%, p<0.001), ALT (38 U/L v 23 U/L,p=0.003), triglycerides (180 mg/dL v 112 mg/dL, p<0.001), and insulin (24 mIU/L v 16 mIU/L, p<0.001). When controlling for baseline liver PDFF, MASH status (p=0.007, ß = -2.6%), ALT (p=0.005) and AST (p=0.004) were significant negative independent predictors of PDFF reduction after MBS, while triglyceride and insulin were not.

## CONCLUSION

Participants with MASH had 2.6 percentage points less reduction of liver PDFF after MBS, when controlling for baseline PDFF. Liver transaminases were also significant negative independent predictors of PDFF reduction while triglyceride and insulin were not, suggesting hepatic inflammation rather than hepatic insulin resistance may interfere with liver fat reduction.

## CLINICAL RELEVANCE/APPLICATION

For patients with obesity and MASH, adjuvant treatment may be needed to achieve the same goal reduction in liver fat as patients without MASH.

## W7-SSGI16-1 LI-RADS TREATMENT RESPONSE ALGORITHM VERSION 2024 VERSUS VERSION 2017: DIAGNOSTIC PERFORMANCE OF HEPATOCELLULAR CARCINOMA AFTER NONRADIATION-BASED LOCOREGIONAL TREATMENT

Yuan-Cheng Wang (*Abstract Co-Author*) Nothing to Disclose
Shuwei Zhou (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the performance of the Liver Imaging Reporting and Data System CT/MRI Nonradiation Treatment Response algorithm version 2024 (LR-TRA v2024) compared to LR-TRA v2017 and modified Response Evaluation Criteria in Solid Tumors (mRECIST) in detecting the pathologic viability of hepatocellular carcinomas (HCCs) treated with nonradiation-based local-regional therapies (LRT), and to evaluate whether incorporating ancillary features [LR-TRA v2024 (AFs)] improves diagnostic precision.

**METHODS AND MATERIALS**

This retrospective study included patients with HCCs who underwent nonradiation-based LRT followed by liver resection or transplantation between January 2017 and December 2022. Each treated lesion underwent categorization of treatment response criteria based on consensus readings by three radiologists, according to the LR-TRA v2024, LR-TRA v2017, and mRECIST criteria. The diagnostic performance of different TR criteria were compared intraindividually using the McNemar test, with pathologic tumor viability serving as the reference standard.

**RESULTS**

A total of 306 treated lesion (249 viable) in 269 patients (198 men; median age, 56 years) were evaluated. For predicting incomplete pathologic tumor necrosis, LR-TRA v2024-Viable and LR-TRA v2024 (AFs)-Viable exhibited sensitivities of 81.1% (202 of 249) and 85.9% (214 of 249), specificities of 75.4% (43 of 57) and 73.7% (42 of 57), and accuracy of 80.1% (245 of 306) and 83.7% (256 of 306). LR-TRA v2024 (AFs)-Viable exhibited an enhanced sensitivity (79.5%, 198 of 249) and accuracy (83.7%, 256 of 306) than LR-TRA v2017-Viable (both P = .006), as well as a marginally improved sensitivity and a significantly higher specificity than mRECIST-Viable (P = .016, P = .001, respectively). LR-TR-Equivocal was least assigned on LR-TRA v2024 (AFs) (4.9% [15 of 306]). For predicting complete pathologic tumor necrosis, LR-TRA v2024-Nonviable and LR-TRA v2017-Nonviable demonstrated the identical sensitivity, which was comparable to that of mRECIST-Nonviable (P = .108). Furthermore, they demonstrated significantly higher specificity and accuracy than mRECIST-Nonviable (P < .001, P = .047, respectively).

**CONCLUSION**

LR-TRA v2024 performs well in predicting pathologic tumor viability for HCCs treated with nonradiation-based LRT. Furthermore, LR-TRA v2024 (AFs)-Viable, utilizing ancillary features, reduced use of Equivocal category while significantly improving sensitivity and accuracy, without sacrificing specificity.

**CLINICAL RELEVANCE/APPLICATION**

A comprehensive understanding of the diagnostic performance of the newly published LR-TRA v2024, holds paramount importance in determining the efficacy of treatment for HCCs and guiding subsequent management decisions.

## W7-SSGI16-2 TUMOR VASCULAR SIGN IN THE RESPONSE ASSESSMENT OF GASTROINTESTINAL STROMAL TUMOR TREATED WITH RIPRETINIB: A MULTICENTER STUDY

Xiaoting Li (*Abstract Co-Author*) Nothing to Disclose
Sai Ge (*Abstract Co-Author*) Nothing to Disclose
Jian Li (*Abstract Co-Author*) Nothing to Disclose
Lin Shen (*Abstract Co-Author*) Nothing to Disclose
Zhilong Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Lei Tang, MD (*Abstract Co-Author*) Nothing to Disclose
Jia-Zheng Li (*Abstract Co-Author*) Nothing to Disclose
Yiyuan Wei (*Abstract Co-Author*) Nothing to Disclose
Meng He, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the occurrence and distribution of tumor vascular sign (TVS) in metastatic gastrointestinal stromal tumor (GIST), and the role of TVS in tumor response assessment in GIST with ripretinib treatment.

**METHODS AND MATERIALS**

This study followed a lesion-by-lesion-based design. 81 patients with advanced GIST in 8 medical centers were retrospectively and continuously included. All patients received ripretinib as later-line treatment after failure of imatinib, sunitinib or regorafenib. Abdominopelvic enhanced CT were analyzed at baseline and the first follow-up (2±1 months after treatment). All target lesions (the longest transverse diameter=10mm) were observed and recorded. Lesions were classified into poor-response group and good-response group based on size (RECIST) and density (Choi) changes at 6 months after treatment. TVS were categorized into intra-tumor vessel sign (iTVS) and peri-tumor vessel sign (pTVS). Multivariate logistic regression analysis was employed to identify the independent predictor of poor responder, and prediction models were established. The performance of the model was evaluated by calculating the area under the receiver operating characteristic (ROC) curve (AUC).

**RESULTS**

530 metastatic lesions were analyzed. Among the metastatic sites, hepatic metastases were prone to developing more iTVS than pTVS (P=0.139), while peritoneal metastases were more likely to exhibit pTVS (P=0.025). At baseline, the positive rate of iTVS was higher in poor-response group than that in good-response group (50.4% vs. 38.4%, P=0.016), however, the positive rate of pTVS did not show significant difference between the two groups (78.8% vs. 71.2%, P=0.093). Progressive iTVS was the independent risk factor of poor response. A combined model 1 was established using iTVS and size change (formula 1 = iTVS progression ×1.386+diameter progression × 2.169), which showed good efficacy in predicting progression at 6 months (AUC=0.78), superior to diameter alone (AUC=0.74,P=0.003) or iTVS alone (AUC=0.65,P<0.001). A joint model 2 was established using iTVS and density (formula 2 = iTVS progression × 1.117+ Choi progression × 2.612), presenting good efficacy in predicting 6-month progression (AUC=0.82), superior to Choi alone (AUC=0.79, P=0.006).

**CONCLUSION**

iTVS and pTVS were commonly observed in metastatic GIST. The presence of iTVS and its changes after ripretinib were associated with tumor response. The combination of iTVS with size or density may aid in the identification of progressive lesions.

**CLINICAL RELEVANCE/APPLICATION**

The TVSs and their changes monitored by enhanced CT scan may be a meaningful imaging sign that contributes to the early assessment of therapeutic response after ripretinib treatment for GIST.

## W7-SSGI16-3 ADDED VALUE OF HISTOGRAM ANALYSIS OF INTRAVOXEL INCOHERENT MOTION AND DIFFUSION KURTOSIS IMAGING FOR THE EVALUATION OF COMPLETE RESPONSE TO NEOADJUVANT THERAPY IN LOCALLY ADVANCED RECTAL CANCER

Peng Sun, MD,MD (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Yuan Liu (*Abstract Co-Author*) Nothing to Disclose
Si Xu (*Abstract Co-Author*) Nothing to Disclose
Lan Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Xin Li, MD,PhD (*Abstract Co-Author*) Nothing to Disclose

Fan Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Chuansheng Zheng, MD (*Abstract Co-Author*) Nothing to Disclose
Ziwei Jin (*Presenter*) Nothing to Disclose

**PURPOSE**

Standard methods for assessing complete response (CR) in locally advanced rectal cancer (LARC) include digital rectal examination (DRE), endoscopy, and MRI. However, DRE and endoscopy provide limited visualization, often failing to detect residual tumors within or around the rectal wall. The diagnostic efficacy of conventional MRI falls short of clinical demand.As advanced diffusion models, diffusion kurtosis imaging (DKI) provides insights into tissue structural connectivity, while intravoxel incoherent motion (IVIM) offers information on microvascular perfusion and diffusion of water molecules within living tissues.This study aims to evaluate how IVIM and DKI histogram analysis contribute to assessing CR to neoadjuvant therapy (NAT) in LARC.

**METHODS AND MATERIALS**

In this prospective study, fifty-nine participants with LARC (T3-4N0M0 or T1-4N+M0), who underwent NAT and subsequent surgery, with adequate MR image quality, were enrolled from November 2021 to March 2023. Conventional MRI (T2WI and DWI), IVIM, and DKI were performed before NAT (pre-NAT) and within two weeks before surgery (post-NAT). Image evaluation and analysis were independently performed by two experienced radiologists. Pathologic complete response (pCR) was used as the reference standard. An IVIM-DKI-added model (combination of IVIM and DKI histogram parameters with T2WI and DWI) was constructed. Receiver operating characteristic (ROC) curves were generated to evaluate the diagnostic performance of conventional MRI and the IVIM-DKI-added model.

**RESULTS**

A total of 59 participants (median age: 58.00 years [IQR 52.00, 62.00]; 38 [64%] men) were evaluated, including 21 pCR and 38 non-pCR cases. The histogram parameters of DKI, including skewness of kurtosis post-NAT (Post-K Skewness) and root mean squared of change ratio of diffusivity (?%D DKI-Root Mean Squared), were entered into the IVIM-DKI-added model. The area under the ROC curve (AUC) of the IVIM-DKI-added model for assessing CR to NAT was found to be significantly higher than that of conventional MRI (0.855 [95% CI: 0.749, 0.960] vs 0.685 [95% CI: 0.565, 0.806], P < 0.001).

**CONCLUSION**

IVIM and DKI provide added value to conventional MRI in the evaluation of complete response to neoadjuvant therapy in locally advanced rectal cancer.

**CLINICAL RELEVANCE/APPLICATION**

Leveraging the noninvasive nature of IVIM and DKI can help mitigate uncertainty in diagnosing CR to NAT using conventional MRI.

## W7-SSGI16-4 ESPRESSO BREAK (+/- 15 SEC) STUDY FOR TEST-RETEST REPRODUCIBILITY OF COLORECTAL LIVER METASTASES VOLUMES: POTENTIAL IMPLICATIONS FOR RECIST

**PURPOSE**

The effect of contrast injection timing on tumor volume and diameter measurements on portal venous phase contrast-enhanced (CE)CT is not established. This study aims to investigate the reproducibility of volume and diameter measurements in the setting of variable contrast timing. Patients with colorectal liver metastases (CRLM) were imaged with consecutive CECTs within ±15 sec.

**METHODS AND MATERIALS**

Patients with CRLM at two institutions consented for this IRB-approved prospective study to undergo a clinical CECT with fixed contrast timing (80 second) and an additional research CECT with one of the following time gap: ±5, ±10, or ±15 second. Ground truth segmentations were generated for the clinical CECT by a board-certified radiologist. An nnUNET segmentation model was trained with the clinical CECT and then used to obtain total tumor volume (TTV), largest tumor volume (LTV), largest tumor diameter (LTD) on the research CECT. Concordance correlation coefficients (CCC) were used to measure reproducibility for TTV, LTV, and LTD between clinical and research CECTs.

**RESULTS**

95 patients to date were analyzed. 31, 34, and 30 patients underwent 2 CECTs with ±5, 10, and 15 second gap, respectively. LTD mean was 43.5 mm (range 8.5 to 148.3 mm). CCCs were nearly perfect for TTV (0.9992), LTV (0.9988), and LTD (0.9916). Differences for TTV between clinical and research CECT increased with larger time gaps, with mean difference of 4.9%/6.6%/8.1% at 5/10/15 second gaps respectively. LTD difference over 20% were found in 0/31, 2/34, and 1/30 patients for the 5, 10, and 15 second time gap cohorts.

**CONCLUSION**

CRLM volume and diameter vary with the timing of a portal venous phase CECT, with larger differences observed for larger time gaps in a prospective test-retest setting. In some cases, the impact on the largest tumor volume exceeds 20%, which would have a significant impact on RECIST category.

**CLINICAL RELEVANCE/APPLICATION**

This prospective study offers a unique cohort to evaluate test-retest reproducibility of liver tumor volumetrics. Future studies on radiomics reproducibility are planned.

## W7-SSGI16-5 RESPONSE EVALUATION CRITERIA FOR PORTAL VEIN TUMOR THROMBUS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA POST TARGETED RADIATION BASED TREATMENTS

Amit Mehndiratta (*Abstract Co-Author*) Nothing to Disclose
Sonal Krishan, MD (*Abstract Co-Author*) Nothing to Disclose
Advitya Kaushik (*Abstract Co-Author*) Nothing to Disclose
Debolina Kabiraj, MBBS (*Presenter*) Nothing to Disclose

**PURPOSE**

Hepatocellular carcinoma (HCC) associated with portal vein tumor thrombosis (PVTT) has a grim prognosis. Despite Milan's criteria contraindicating curative interventions, some centers, including ours, have shown promising outcomes with locoregional therapies (LRTs) such as stereotactic-body-radiotherapy (SBRT) and transarterial-radioembolization (TARE). These therapies not only improve outcomes but also facilitate liver resection by downstaging or as a bridge to liver transplantation (LT). However, a standard criterion for response evaluation of PVTT is currently lacking. This study aims to develop an objective semiquantitative criterion for assessing PVTT response post-SBRT and/or TARE.

**METHODS AND MATERIALS**

This observational study involved 45 patients diagnosed with HCC and PVTT who underwent SBRT and/or TARE as bridging treatment to LT. Multiphasic CT performed and post-processing done by generating quantitative color arterial, portal and venous enhancement fraction maps. PVTT volume and percentage change in differential enhancement fraction calculated. Radiologists' assessment using the LI-RADS criteria recorded, and post-LT pathological correlation done. Non-parametric statistical analysis (Mann Whitney test) and receiver operator characteristic curve analysis used to identify responders (R) and non-responders (NR) based on differential arterial, portal, and venous enhancement parameters (DAE, DPE, and DVE), with statistical significance ($p<0.05$). Accuracy of the test cohort data assessed in the validation cohort.

**RESULTS**

Comparison of radiologist assessment with histopathology revealed a sensitivity and specificity of 86.2% and 64.4%, with accuracy of 64.4%. Statistically significant differences were observed between R and NR in terms of DAE ($p=0.001$) and DVE ($p=0.024$) and used to predict response status in the validation cohort. DAE threshold obtained from test patient data was 24.8%. A reduction of 24.8% or more in volumetric arterial enhancement fraction in PVTT post-treatment demonstrated sensitivity, specificity, and accuracy of 73.3%, 60%, and 70%, respectively in the validation group. Combining subjective and semiquantitative assessment, the accuracy was as high as 87%.

**CONCLUSION**

The volumetric differential change in enhancement fraction of PVTT, particularly DAE, demonstrates higher specificity and accuracy in identifying R and NR. Thus, it could serve as a semiquantitative objective criterion to assess PVTT response post SBRT and/or TARE.

**CLINICAL RELEVANCE/APPLICATION**

Integrating the above criterion as an adjunct to the current clinical scoring mechanism holds immense promise for enhancing radiologists' confidence in reporting PVTT treatment response and standardizing the process.

## W7-SSGI16-6 MR MORPHOMETRIC ASSESSMENT TO PREDICT CHEMOTHERAPY RESPONSE IN COLORECTAL LIVER METASTASIS: A PROSPECTIVE COMPARISON WITH DCE FUNCTIONAL PARAMETERS

Tong Tong, PHD (*Abstract Co-Author*) Nothing to Disclose
HUAN ZHANG (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the predictive significance of MR morphological features in assessing chemotherapy response among patients with colorectal liver metastasis (CRLM) and to compare its predictive power with dynamic contrast-enhanced (DCE) functional parameters.

## METHODS AND MATERIALS

Between August 2016 and July 2022, 161 patients with CRLM receiving standard first-line chemotherapy were prospectively enrolled. DCE-MR imaging was performed prior to treatment and after one cycle of chemotherapy using a MAGNETOM Skyra 3T scanner. A comprehensive analysis was conducted on baseline and early post-treatment morphological MR features, along with DCE functional parameters. Responses were evaluated according to RECIST criteria. A total of 18 morphological features and 90 DCE functional parameters were screened using lasso and logistic regression to identify significant predictors. Predictive models were subsequently developed and internally validated through bootstrap resampling to assess their prediction performance.

## RESULTS

Among the 161 patients, 77 were classified as responders and 84 as non-responders. Four morphological characteristics, including nonsmooth tumor margin ($p=0.002$), diameter increase ($p=0.001$), target sign ($p=0.018$), and tumor shrinkage ratio at early post-treatment ($p<0.001$), as well as two functional metrics, specifically the AT ratio between the interface and liver ($p=0.002$), and the difference in AT ratios between the peripheral tumor and liver before and after treatment ($p=0.017$), emerged as independent predictors. The morphological model offered superior predictive effectiveness compared to the functional one. Notably, the inclusion of functional and clinical factors did not significantly enhance the predictive power of the morphological model. The AUC of Internal validation through bootstrap resampling reached 0.939(95% CI: 0.902-0.977) with a high consistency with the training set(kappa=0.709). The accuracy, sensitivity and specificity were 85.5%, 87.2% and 84.1%, respectively.

## CONCLUSION

This study underscores the potential role of morphological criteria in predicting chemotherapy response in CRLM. A clinically relevant and straightforward predictive model based on morphological features has been developed, offering potential for widespread application in clinical practice.

## CLINICAL RELEVANCE/APPLICATION

Given the potential toxicities associated with chemotherapy, it is crucial to identify effective imaging features that can predict treatment response. The proposed morphological model offers clinicians a valuable tool for predicting chemotherapy response probabilities early in the treatment course and enabling personalized treatment planning.

Vanessa Twardy (*Abstract Co-Author*) Nothing to Disclose
Ingo Banke (*Abstract Co-Author*) Nothing to Disclose
Alexander W. Marka, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic performance of high-resolution deep learning-based hip MRI sequences compared to standard-resolution compressed sense (CS) sequences for detecting labral and cartilage lesions in femoroacetabular impingement syndrome (FAIS) using hip arthroscopy as reference.

### METHODS AND MATERIALS

Thirty-two patients suffering from FAIS underwent hip MR imaging at 3T. Coronal and sagittal intermediate-weighted scans with fat saturation were acquired using both standard-resolution CS and high-resolution Compressed Sense Artificial Intelligence (CSAI) sequences. MR scans were assessed by a radiology resident, a musculoskeletal (MSK) fellow, a fellowship-trained MSK radiologist, and a hip arthroscopy surgeon. Images were assessed for presence or absence of labral abnormalities and cartilage defects in five separate cartilage zones of the femur and the acetabulum. All patients underwent highest resolution 4K hip arthroscopy for FAIS. Sensitivity, specificity, and accuracy were calculated, using arthroscopy as standard of reference.

### RESULTS

Excellent sensitivity and specificity was found for the detection of labral abnormalities with a sensitivity ranging from 97-100% in both CSAI and CS sequences for radiology readers and between 81% (CS) to 91% (CSAI) for the hip surgeon. The specificity for the detection of labral abnormalities was 100% for all readers. Overall sensitivity for all readers for the detecting cartilage lesions was relatively low in CS (37%) with only moderate improvement in high-resolution CSAI sequences (42%). Sensitivity for radiology readers (CS: 37-45%; CSAI: 45%) and slightly lower for the hip surgeon (CS: 27%, CSAI: 32%). The highest overall sensitivity assessed for all readers was found in the acetabular weight-bearing zone (superolateral; CS: 81%, CSAI: 88%). The overall specificity was similar between CS and CSAI (CS: 81%, CSAI: 79%). The femoral weight-bearing zone (superolateral) showed the lowest overall specificity (CS: 47%, CSAI: 37%).

### CONCLUSION

Performance of non-arthrographic hip MRI showed excellent results for diagnosing labral abnormalities. While CSAI sequences improved the detection of cartilage abnormalities compared to CS, the overall diagnostic performance was low. These results underline the limitations of non-arthrographic MRI for detecting cartilage abnormalities, even with high-resolution MR sequences.

### CLINICAL RELEVANCE/APPLICATION

MRI is an important tool for diagnosing hip joint pathologies, but limitations for detecting abnormalities of the acetabular and femoral cartilage should be noted. Integrating CSAI may improve diagnostic accuracy. Further technical developments and investigations are needed to improve non-arthrographic hip MRI performance.

## W7-SSMK09-2 OPPORTUNISTIC SCREENING FOR OSTEOPOROSIS IN THE LUMBAR VERTEBRA AND PROXIMAL FEMUR OF PATIENTS UNDERGOING ABDOMINAL CT SCANS IN A BRITISH POPULATION

Nikolaos Papadakos (*Abstract Co-Author*) Advisory Board, Pfizer Inc
Muskan Nafis (*Abstract Co-Author*) Nothing to Disclose
Katie Moss (*Abstract Co-Author*) Nothing to Disclose

Manjiri Joshi, MBChB (*Abstract Co-Author*) Nothing to Disclose
Pardis Zalmay, FRCR (*Presenter*) Nothing to Disclose

**PURPOSE**

Osteoporosis is an underdiagnosed and undertreated condition predisposing people to debilitating fragility fractures. While CT scans have been explored for lumbar spine osteoporosis screening, research on their use in diagnosing hip osteoporosis is scarce. In this work-in-progress report, we examine the potential of CT in opportunistically detecting osteoporosis in both lumbar vertebra and the proximal femur, a novel approach in a British population.

**METHODS AND MATERIALS**

Retrospective analysis of CT and DEXA scans obtained within a 12-month interval from the same adult cohort was performed. BMD and T-scores from DEXA were compared with Hounsfield unit (HU) values from CT scans of the abdomen and pelvis. Various HU measurements were tested at the proximal femur in order to find a measurement technique that was most useful. CT scans obtained with intravenous contrast and on a Siemens Definition Dual-Drive machine (tube voltages 80-110 kVP).

**RESULTS**

Analysis of 118 patients revealed weak positive correlations between vertebral HU values and BMD, the strongest being 0.448 at L1. Stronger positive correlations were found for proximal femoral measurements, especially at the axial femoral neck (0.697). ROC curves at the lumbar levels demonstrated poor diagnostic performance but at the proximal femur showed promising diagnostic potential, particularly with an HU threshold of 82 at the axial femoral neck (78% sensitivity and 75% specificity).

**CONCLUSION**

While CT values correlated positively with lumbar and hip BMD, lumbar osteoporosis diagnosis via CT was less effective than previously reported. A proposed explanation for this is the utilisation of automated tube voltage selection (ATVS) in the CT scanner used for this study. ATVS tailors the tube voltage to the patient being scanned in order to reduce radiation dose. Altering tube voltage in turn significantly alters HU measurement. Previous studies have either used the same tube voltage (120 kVP) or not reported tube voltage. Despite this, CT measurement at the axial femoral neck showed promise for osteoporosis detection.

**CLINICAL RELEVANCE/APPLICATION**

Contrary to prior research based on older CT scan technology, caution is warranted in interpreting lumbar HU values due to the influence of modern dose-reduction technologies which are becoming increasingly common. Nonetheless, opportunistic assessment of the proximal femur on CT holds potential for osteoporosis detection and warrants further investigation. This study is a work-in-progress. Going ahead we aim to include CT scans performed on the other scanners in our centre, as well as scans performed without intravenous contrast.

## W7-SSMK09-4 INCIDENCE OF NON-TRAUMATIC OSTEONECROSIS OF THE FEMORAL HEAD (ONFH) ON SCREENING HIP MRI: A POSSIBLE LONG-TERM MANIFESTATION IN PATIENTS SURVIVED TO SEVERE COVID-19 IN THE FIRST PANDEMIC PEAK

Sandro Sironi, MD (*Abstract Co-Author*) Nothing to Disclose
Nicola Guindani (*Abstract Co-Author*) Nothing to Disclose
Mario Gaffuri (*Abstract Co-Author*) Nothing to Disclose
Federico Chiodini (*Abstract Co-Author*) Nothing to Disclose
Clarissa Valle, MD (*Abstract Co-Author*) Nothing to Disclose
Claudio Carlo Castelli (*Abstract Co-Author*) Nothing to Disclose
Pietro A. Bonaffini, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the incidence and the clinical profile of non-traumatic osteonecrosis of the femoral head (ONFH) in patients survived to severe COVID-19 during the first pandemic peak, treated with steroids, and scanned for screening with hip MRI.

**METHODS AND MATERIALS**

We prospectively enrolled adult patients (<60 years): a) survived to severe first peak COVID-19 (February-May 2020); b) hospitalised in ICU >25 days; c) treated with steroids (total cumulative dose >2g). Two years after disease onset. all patients underwent hip MRI (coronal-axial SE-T1 and STIR) for screening purposes: ONFH presence/absence, unilateral/bilateral involvement, and eventual femoral head(s) collapse were recorded. Among clinical data, the following parameters were collected: total corticosteroid therapy, symptoms (hip pain) presence/absence, quality of life ( EQ-5L score), the Oxford Hip Score (OHS) and presence of thrombosis or sepsis during ICU hospitalisation.

**RESULTS**

Twenty-five patients (mean age at ICU admission 54 years, range 42-60.75; mean age at time of MRI 56.4 years, range 44-63) were included. MRI demonstrated ONFH in 4/25 (16%) cases: 2 with bilateral involvement and no collapse, and 2 with unilateral involvement (1 collapse). Symptoms at time of MRI were present in 10/25 (40%) cases: in 3/10 ONFH was present, 3/10 MRI were completely normal and in 4/10 MRI was negative for ONFH but presumable alternative causes explaining hip symptoms were highlighted (right psoas bursitis 1, coxarthrosis 3). The mean EQ-5L score was 72.42 (range 45-100) and the mean Oxford Hip Score 47.46 (range 32-72) but no significant correlation with ONFH presence was found. The mean cumulative dose of steroids was: 6.3 g (range 2-16) for all patients, 9.6 g (range 5.6-16) for 4/25 with ONFH and 5.6 g (range 2-13.9) for 21/25 without ONFH. During ICU hospitalization 15/25 patients (60%) developed sepsis (4), thrombosis (6) or both (5). However, a past history of ICU sepsis was present only in 2 symptomatic patients with ONFH.

**CONCLUSION**

Patients survived to severe COVID-19 and treated with steroids demonstrated, 2 years after infection onset, about 15% incidence of ONFH; this seems correlated with a higher cumulative dose of steroids but not with thrombosis during ICU hospitalization. No correlation was found with symptoms, EQ-5L and Oxford Hip Score.

**CLINICAL RELEVANCE/APPLICATION**

ONFH in patients who survived severe COVID-19 during the first peak represent a possible but not frequent long-COVID manifestation (2 years) and may be more related to higher cumulative steroids dose rather than microvascular damage. This may suggest, in these categories of patients, the rationale of hip MRI screening.

## W7-SSMK09-5 A MULTI-MODAL PIPELINE FOR BUILDING LARGE-SCALE NORMATIVE DATABASE TO ASSIST WITH PERSONALIZED CARE OF HIP DISORDERS

Mohammadreza Movahhedi, PhD (*Abstract Co-Author*) Nothing to Disclose
Sarah D. Bixby, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Young-Jo Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Eduardo Novais (*Abstract Co-Author*) Nothing to Disclose
Nazgol Tavabi, PhD (*Abstract Co-Author*) Nothing to Disclose
Ata Kiapour, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and leverage a robust multi-modal fully automated pipeline to generate a large-scale registry of normal hip 3D morphological features from clinically available hip and pelvic CT scans to study normal development of hip the joint.

**METHODS AND MATERIALS**

Following IRB approval, a multi-modal pipeline was developed to generate a comprehensive registry of normal hip morphology during skeletal growth. The pipeline included natural language processing (NLP) module to process the clinical and radiology notes to identify any documented musculoskeletal pathology related to the hip joint pathology in patients with available pelvis CT scans at our hospital (2012-2022). The selected "normal" hip CT scans were then segmented into 3D models using a UNet-based deep learning module. A comprehensive rule-based pipeline was then used to measure 40+ hip anatomical features in 3D including femoral measurements, acetabular measurements and hip coverage.

**RESULTS**

The NLP pipeline achieved an accuracy of 0.98 in identify hip pathology from radiology reports. The 3D reconstruction and landmark detection pipeline resulted in average Dice coefficient of 0.98±0.03 and average surface error of <1 mm. The morphology measurement pipeline resulted in an average error of <2 mm and <6 degrees. From a total of 52,360 CT scans, we identified and analyzed 9,721 "good quality" normal CT scans (49.3% Females; Age: 7 to 25 years, average: 14±4 years; 19,442 hips). On average, females had smaller femoral heads, epiphyseal tubercle, femoral necks, acetabulum, and alpha angles along with greater peripheral cupping, coronal head-neck tilt, femoral head-neck offset, overall femoral head coverage, acetabular anteversion, and posterior-superior center-edge angles (P<0.001). There were no clinically meaningful sex-differences in anterior-superior center-edge angles and sacro-pelvic sagittal alignments.

**CONCLUSION**

Leveraging existing multi-modal medical data, we developed a fully automated pipeline that extracts anatomical features from the hip joint in 3D, specify the measurements that fall outside of the normal range compared to its population (same age, same sex), and precisely reveal the abnormalities. This rich database is currently being used to develop normative growth charts for detailed anatomical features of the hip throughout the skeletal growth and maturation. We are planning to publicly release this data to assist with personalized assessment of hip dysmorphology.

**CLINICAL RELEVANCE/APPLICATION**

The current project highlights the feasibility of multi-modal approaches to process existing clinical data to generate large-scale registries, which can then be used to improve care through evidence-based personalized diagnosis and treatment planning.

## W7-SSMK09-6 ACCELERATED 3D MRI OF THE HIP. QUALITY AND EFFICIENCY OF DEEP LEARNING-BASED COMPRESSED SENSING

Zhenlin Li (*Abstract Co-Author*) Nothing to Disclose
Chunchao Xia (*Abstract Co-Author*) Nothing to Disclose
Xu Xu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purposes of the present study were to explore the feasibility of the DL-based 3D CS proton density weighted image in hip MRI, and compare the image quality and diagnosis performance with conventional sense and CS sequences.

**METHODS AND MATERIALS**

The consecutive 70 patients (75 hips) who underwent the hip MRI from February 2023 to April 2023 were included in this study. All images were acquired on a 3T MR system using 16-channel elbow coil (Elition, Philips Healthcare). Objective image quality was assessed by signal-to-noise ratios (SNRs) of bone and muscle and contrast to noise ratios (CNRs). Delineative imaging quality, diagnostic certainty and artifacts were assessed on a five-point-scale.

**RESULTS**

Scan time decreased with increasing CS factor (sense4, CS4, DL-CS4: 5min34s; DL-CS8:2min56s). DL-CS4 showed the highest SNRs ($p < 0.01$) and CNR, while the SENSE 4 had significantly lower SNRs and CNR values (all $p < 0.05$). We found no evidence of differences between DL-CS4 and DL-CS8 for SNRs. For diagnostic certainty and artifacts, no overt differences were found between SENSE4 and CS4, DL-CS4 and DL-CS8. For delineative imaging quality, there were no differences between SENSE 4 and CS4. Meanwhile, we found no difference between DL-CS4 and DL-CS8 in evaluation of labrum and cartilage (all $p>0.05$) although DL-CS4 yielded slightly higher image scores. However, DL-CS8 yielded lower image scores than CS4 ($p=0.02$) and DL-CS4 ($p<0.05$) in evaluation of bony trabecula. Moreover, the inter-method agreements among patient group sequences were good or excellent.

**CONCLUSION**

DL-CS4 improves image quality with approximately the same scanning time as conventional PI and CS for 3D STIR TSE in the hip, and DL-CS8 reduces scanning time compared with conventional PI and CS while maintaining comparable image quality.

**CLINICAL RELEVANCE/APPLICATION**

In this study, DL-CS4 and DL-CS8 showed higher SNRs and CNRs than the other sequences. This demonstrated the feasibility of DL-CS in reducing noise with preserved contrast. Therefore, DL-CS8 has the potential to make 3D scans faster to increase the comfort and compliance of patients and to improve the workflow of hip MRI.

## W7-SSMK10-1 SHOULDER MR ARTHROGRAPHY USING AN IRON-BASED POSITIVE T1 CONTRAST AGENT (NEMO-103): COMPARISON WITH GADOLINIUM-BASED CONTRAST

Hong Seon Lee, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To demonstrate that in shoulder MR arthrography, NEMO-103 is interchangeable with gadolinium-based contrast agents (GBCAs) and exhibits superior diagnostic efficiency during the delayed phase (attributed to the longer joint-cavity residence times).

### METHODS AND MATERIALS

We retrospectively evaluated NEMO-103-based shoulder MR arthrography in phases I (30 minutes) and II (60 minutes) in eight patients (3 females [37.5%], age [mean±standard deviation]: 38.0±7.8 years; Comparison 1); and 31 NEMO-based (11 females [35.5%], age: 40.0±13.0 years) and 38 GBCA-based phase I MRIs (14 females [36.8%]; age: 49.4±18.7 years; Comparison 2). In Comparison 3, the eight aforementioned NEMO-103-based and 12 GBCA-based phase II MRIs (5 females [41.7%], age: 56.2±15.7 years) were compared. The study included demographic details and assessed the contrast-to-noise ratio (CNR), joint distension, and subjective image quality. Visual Turing tests were conducted on axial-plane MR images for Comparisons 1 and 2. NEMO-103 MRI scans were obtained from previous clinical phase 1/2a trials.

### RESULTS

Comparison 1 revealed no significant differences in image quality between the NEMO-103-based MR shoulder arthrography images in phases I and II. In Comparison 2, NEMO-103-based images showed no CNR difference but had improved distension, resulting in higher overall image quality scores than GBCA-based images (4.7±0.5 vs. 4.4±0.5; p=0.034). Comparison 3 favored NEMO-103-based arthrography, showing a higher CNR (92.9±26.7 vs. 61.5±29.7; p=0.027), more pronounced joint distension, and superior overall image quality scores (4.9±0.2 vs. 4.2±0.9; p=0.020) compared with GBCA-based images. In the two-step visual Turing tests, were 46.8% and 53.3%, respectively; this was not significantly different from random guessing (50.0%).

### CONCLUSION

NEMO-103-based and GBCA-based shoulder MR arthrography were interchangeable regarding CNR, joint distension, subjective image quality, and visual Turing test results. Additionally, NEMO-103 exhibited enhanced resistance to contrast resorption over time, suggesting its potential to extend the imaging window.

### CLINICAL RELEVANCE/APPLICATION

NEMO-103-based shoulder MR arthrography is interchangeable with gadolinium-based arthrography, with enhanced resistance to contrast resorption in the delayed phase, suggesting the potential for extended imaging windows.

## W7-SSMK10-2 CLINICAL IMPLEMENTATION OF 6-MINUTE DEEP LEARNING SUPER RESOLUTION MRI OF THE SHOULDER: ARTHROSCOPY-VALIDATED ASSESSMENT OF DIAGNOSTIC PERFORMANCE

Yannik Leonhardt (*Abstract Co-Author*) Nothing to Disclose
Shana G. Neumann, MD (*Abstract Co-Author*) Nothing to Disclose
Jan Vosshenrich, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the diagnostic performance of DL-augmented 6-minute 3-fold parallel imaging (PI) accelerated super-resolution MRI of the shoulder.

### METHODS AND MATERIALS

Patients who underwent 3-fold PI-accelerated 3T shoulder MRI between March 2023 and November 2023 and had arthroscopic shoulder surgery within 90 days were included. MRI studies were independently reviewed by seven musculoskeletal radiologists for image quality using 5-point Likert scales (1 = lowest score to 5 = highest score) and the presence of rotator cuff tendon tears, superior and anterior labral tears, biceps tendon tears, cartilage defects, Hill-Sachs lesions, Bankart fractures, subacromial-subdeltoid bursitis and AC-joint degeneration. Rotator cuff tears and cartilage lesions were divided into partial- and full-thickness defects. Statistical computations included kappa-based interreader agreements and diagnostic performance measures (significance level p<.05).

### RESULTS

121 adults (mean age: 55±14 years; 75 men) who underwent arthroscopy within a median of 39 days (range: 1-90) were evaluated. Image quality was rated good (median: 4 [IQR: 4,4]) with minimal motion artifacts (median: 4 [4;4]). Interreader agreement for detecting arthroscopy-confirmed abnormalities was good to very good (? = 0.68-0.94). Diagnostic performance testing indicated good to excellent performance for most intra- and periarticular abnormalities (AUCs = 0.67-1.00). Consensus sensitivities/specificities/accuracies were 89%/90%/89% for supraspinatus-infraspinatus tendon tears (n=102), 82%/63%/68% for subscapularis tendon tears (n=31), 93%/73%/86% for superior labral tears (n=81), 100%/100%/100% for anterior labral tears (n=16), 68%/90%/82% for biceps tendon tears (n=48), 42%/93%/81% for cartilage defects (n=65), 93%/99%/98% for Hill-Sachs deformities (n=14), 100%/99%/99% for bony Bankart lesions (n=4), 97%/63%/92% for subacromial-subdeltoid bursitis (n=102), and 98%/70%/93% for AC-joint degeneration (n=101).

### CONCLUSION

DL-augmented 3-fold PI-accelerated 6-minute super-resolution shoulder MRI has good to excellent diagnostic performance for diagnosing tendinous, labral, and osteocartilaginous abnormalities.

### CLINICAL RELEVANCE/APPLICATION

Deep learning-augmented fast shoulder MRI maximizes scan efficiency while maintaining high image quality and diagnostic accuracy.

## W7-SSMK10-3 DIAGNOSTIC VALUE OF DUAL-ENERGY CT MONOCHROMATIC IMAGING FOR ROTATOR CUFF INJURY: A COMPARISON WITH STANDARD CT

Suwei Liu (*Presenter*) Nothing to Disclose

### PURPOSE

This study evaluates the diagnostic value of dual-energy CT (DECT) monochromatic imaging compared to standard Computed Tomography (SCT) in assessing rotator cuff injury.

### METHODS AND MATERIALS

This retrospective study included patients who underwent GE Revolution ES CT and 3.0T MRI scans and arthroscopic surgery within 7 days from December 2023 to May 2024. Three radiologists independently assessed SCT, mono+50keV, mono+90keV, and MRI images for the visualization of supraspinatus tendon injury and recorded their diagnostic confidence. Reference standards were established using MRI diagnoses, and regions of interest (ROI) were delineated to measure CT values at tear, degeneration areas, and normal tendon areas on SCT, mono+50keV, and mono+90keV images to quantitatively evaluate the differences between tear and degeneration areas, between degeneration and normal tendon areas.

### RESULTS

The study included 100 patients with supraspinatus tendon injuries (mean age 55.9 ± 12.2 years; 46 males). CT values at the tear sites on SCT, mono+50keV, and mono+90keV images were significantly lower than those in degeneration areas ($p < 0.001$), with optimal cutoff values of 17.4 HU, 28.0HU, and 14.2HU, respectively, and AUCs of 0.920, 0.978, and 0.938. CT values in degeneration areas were significantly lower than in normal tendon areas ($p < 0.001$), with optimal cutoff values of 23.8HU, 36.1HU, and 19.6HU, respectively, and AUCs of 0.967, 0.970, and 0.946. There was no significant statistical difference in the diagnostic performance of MRI and DECT for supraspinatus tendon injuries ($p = 0.66$).

### CONCLUSION

DECT demonstrates high diagnostic accuracy and reliability in both qualitative and quantitative assessments of rotator cuff injury.

### CLINICAL RELEVANCE/APPLICATION

DECT offers an effective and reliable alternative to MRI for diagnosing rotator cuff injury, potentially serving as an alternative method for evaluating tendon integrity and detecting incidental rotator cuff injury.

## W7-SSMK10-4 ENHANCING ROTATOR CUFF TEAR DETECTION AND CLASSIFICATION: VALIDATION OF A DEEP LEARNING MODEL

Judith Herrmann, MD (*Abstract Co-Author*) Nothing to Disclose
Reza Dehdab, MD (*Abstract Co-Author*) Nothing to Disclose
Saif Afat, MD (*Abstract Co-Author*) Nothing to Disclose
Sebastian Gassenmaier, MD (*Abstract Co-Author*) Nothing to Disclose
Haidara Al Mansour, MD, MEng (*Abstract Co-Author*) Nothing to Disclose
Sebastian Werner, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To validate a prototype deep-learning (DL) model capable of detecting and classifying rotator cuff tears in shoulder magnetic resonance imaging (MRI).

### METHODS AND MATERIALS

Shoulder MRI scans from 103 patients from one institution were retrospectively analyzed. A DL algorithm processed proton-density weighted fat-suppressed sequences in three planes from each scan. The algorithm detects and classifies rotator cuff tears of the supraspinatus, infraspinatus and subscapularis muscles. Classification distinguishes between no tear, partial tear (low grade or high grade), and full-thickness tear. The reference standard was set by experienced musculoskeletal radiologists' readings.

### RESULTS

In the muscle-based analysis, the algorithm achieved an overall diagnostic accuracy for detecting any type of tear of 80% (70% sensitivity, 83% specificity). In the patient-based analysis for each single muscle, the accuracy was highest for the supraspinatus at 85% (74% sensitivity, 93%

specificity), followed by the infraspinatus at 77% (93% sensitivity, 74% specificity) and subscapularis at 77% (41% sensitivity, 86% specificity). Regarding different grades of tears, there were no statistically significant differences between the model and radiologists with accuracies for full, partial, low-grade and high-grade partial tears at 96% (82% sensitivity, 97% specificity), 77% (42% sensitivity, 86% specificity), 83% (29% sensitivity, 92% specificity) and 88% (21% sensitivity, 94% specificity), respectively.

**CONCLUSION**

The application of deep learning to diagnose rotator cuff tears worked best in diagnosing supraspinatus tears and full-thickness tears. For the diagnosis of infraspinatus, subscapularis, and partial-thickness tears, specificity was markedly higher than sensitivity, suggesting it rather as a tool of exclusion.

**CLINICAL RELEVANCE/APPLICATION**

The DL-based software can support the diagnosis of full-thickness supraspinatus tears and the exclusion of infraspinatus and subscapularis tears. The model's diagnostic performance does not reach that of experienced musculoskeletal radiologists, but it could be helpful for less experienced or non-expert radiologists.

## W7-SSMK10-5 OSTEOLYSIS: NOT JUST THE DISTAL CLAVICLE

Jeffrey A. Belair, MD (*Abstract Co-Author*) Nothing to Disclose
Blaire Adler (*Abstract Co-Author*) Nothing to Disclose
Aishwarya Gulati, MD, MBBS (*Presenter*) Nothing to Disclose

**PURPOSE**

Distal clavicular osteolysis (DCO) is a commonly encountered cause of shoulder pain, particularly in young males, and may result from repetitive overuse or antecedent trauma. We propose a variant of DCO in which subchondral resorptive changes span the acromioclavicular joint (ACJ), involving both the distal clavicle and the anterior acromion.

**METHODS AND MATERIALS**

A retrospective PACS query identified patients scanned in 2023 with reported DCO on shoulder MRIs performed on at least 1.5 T scanners using a dedicated shoulder protocol. Those with underlying ACJ osteoarthritis were excluded. Demographics and pre-MRI patient questionnaires were reviewed. Each case was re-reviewed to identify cases with additional resorptive changes involving the anterior acromion. The demographics of each patient population and any significant difference were then analyzed by binomial regression using SPSS.

**RESULTS**

128 cases (127 patients) meeting inclusion criteria were identified (93 males). Mean age was 39.5 years (SD 11.3). Average symptom duration before MRI was 408.6 days (13.4 months) (n=110). 45.3% had a history of antecedent trauma, 62.5% reported lifting weights, 38.2% reported overhead activities/sports, and 32% reported other repetitive movements. Of the 128 cases, 42 had subchondral edema and resorption in the acromion in addition to the clavicle. Maximum weight bench pressed was the only statistically significant factor associated with acromial involvement (p=0.02). There was no statistically significant difference between patient groups with respect to sex, trauma, weightlifting, overhead activities, repetitive motion, or duration of symptoms.

**CONCLUSION**

DCO is described as painful bone resorption with subchondral cyst formation, loss of cortical contour, and erosion of the distal clavicle. DCO may result from antecedent trauma or due to repetitive microtrauma, classically described in weightlifters. We identified a variant of DCO with resorptive changes on both sides of the ACJ. Maximum bench press weight was the only clinically significant factor associated with acromial involvement. This suggests that increased load-bearing may result in more extensive involvement of the ACJ. A larger patient population is needed to further elucidate any other associations.

**CLINICAL RELEVANCE/APPLICATION**

Patients with DCO may demonstrate resorptive changes on both sides of the ACJ, which should be recognized as a forme fruste of mechanical osteolysis. This should not be confused with ACJ arthropathy or an underlying inflammatory process, as patients may be amenable to conservative treatment with activity modification.

## W7-SSMK10-6 EFFECTIVE CROSS-SECTIONAL AREA OF ROTATOR CUFF MUSCLE USING MRI DIXON SEQUENCE AFFECT ON BIODEX ISOKINETIC TEST FOR THE SHOULDER

Woong-Kyo Jeong, MD (*Abstract Co-Author*) Nothing to Disclose
Chang Ho Kang, MD (*Abstract Co-Author*) Nothing to Disclose
Kyung-Sik Ahn, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Woo Young Kang, MD (*Abstract Co-Author*) Nothing to Disclose
Hee-Gone Lee (*Abstract Co-Author*) Nothing to Disclose
Baek Hyun Kim, MD (*Abstract Co-Author*) Nothing to Disclose
Euddeum Shim (*Abstract Co-Author*) Nothing to Disclose
Kyu-Chong Lee, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the correlation between the effective cross-sectional area (eCSA) of the rotator cuff muscle using the Dixon MRI sequence and the Biodex isokinetic test for the shoulder.

**METHODS AND MATERIALS**

A total of 87 patients who underwent both shoulder MRI and isokinetic strength test were enrolled. One radiologist drew the cross-sectional area (CSA) of the subscapularis (SSc), supraspinatus (SST), and infraspinatus+teres minor (ISTM) on the sagittal Y-view. The eCSA was calculated by multiplying the CSA and fat fraction based on the Dixon sequence. Eight shoulder movements (FL60, EX60, FL180, EX180, ER60, IR60, ER180, and IR180) each with four parameters (peak torque, peak torque/body weight [BW], torque at 30° [TQ30], and total work [TW]) were recorded in an isokinetic strength test. A multivariate general linear model was used to identify the correlation between eCSA and 32 Biodex parameters. Sex, body mass index (BMI), rotator cuff tear, long head of biceps tendon (LHBT) tear, and lifestyle habits were adjusted according to Wilk's lambda.

**RESULTS**

All shoulder Biodex parameters were adjusted with sex and BMI. ER180 was associated with IST and SSc tendon tear. IR180 was associated with SSc and LHBT tears. The eCSA of SSc was significantly correlated with TQ30 at FL60 and IR180 (p=0.009 and 0.025, respectively). The eCSA of SST and ISTM

was correlated with multiple Biodex parameters. TW showed the highest ß-coefficient among the four parameters, while BW showed no correlation with eCSA. TW at FL60, EX180, ER60, IR60, and ER180 was correlated with eCSA of both SST and ISTM. However, TW at EX60 was correlated with SST and TW at FL180 was correlated with ISTM (p=0.001 and 0.006, respectively).

**CONCLUSION**

A notable relationship was observed between the eCSA of the rotator cuff muscle using Dixon sequence and the Biodex test results. Furthermore, SSc tendon, IST tendon, and LHBT tears, as well as lifestyle habits, were also found to affect the outcomes of the Biodex test.

**CLINICAL RELEVANCE/APPLICATION**

Three specific Biodex parameters, namely TQ30 at IR180, TW at EX60, and TW at FL180, showed potential as valuable markers for SSc, SST, and IST muscle functions, respectively.

## W7-SSNR12-1 OXYGEN METABOLIC AND NEOVASCULARIZATION TUMOR MICROENVIRONMENT MAPPING FOR DIFFERENTIATION BETWEEN GLIOBLASTOMAS AND SOLITARY BRAIN METASTASES

Gui-Hua Jiang (*Abstract Co-Author*) Nothing to Disclose
Ouyang Qunhui (*Abstract Co-Author*) Nothing to Disclose
Wan-Yi Zheng, MD (*Abstract Co-Author*) Nothing to Disclose
Ping Liu, MD, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Glioblastomas (GB) and solitary brain metastases (BM) are the most common brain tumors in adults. Their management strategies, however, are quite different with significant consequences on clinical outcome. The aim of this study was to differentiate GB from BM employing MRI-derived neovascularization and oxygen metabolism tumor microenvironment (TME) mapping.

### METHODS AND MATERIALS

Thirty-seven patients with newly diagnosed, untreated, and histopathologically confirmed GB or BM preoperatively undergo the MRI including quantitative blood-oxygen-level-dependent (qBOLD) imaging and vascular architecture mapping (VAM). Imaging biomarker about oxygen metabolism and neovascularization were fused for classification different TMEs: necrosis, hypoxia with/without neovascularization, oxidative phosphorylation (OxPhos), and glycolysis with/without neovascularization. Different TME volume fractions and the oxygen metabolism - neovascularization parameters in different subregions were compared. The receiver operator characteristic curve analysis was performed for differentiation.

### RESULTS

For the distribution of the TME compartments, GBM showed lower hypoxia without neovascularization and total hypoxia (p=0.004 and 0.001, respectively), whereas, exhibited higher aerobic glycolysis and vital tumor (p = 0.001, respectively). The vital tumor had the highest diagnostic performance (AUC,0.906)for differentiation GBM and BM. For oxygen metabolism - neovascularization biomarkers, necrosis displayed higher tissue oxygen tension (PO2, p = 0.047) in GB. The GBM showed apparently higher volume ratio of viable tumor parts (31%, p = 0.036), along with lower OEF (19%, p = 0.019),higher tissue oxygen tension (PO2, p = 0.004) and higher microvessel density (MVD, p = 0.004). Of which, the OEF in the edema region showed best differentiate performance with the AUC of 0.911.

### CONCLUSION

MRI-derived oxygen metabolic and neovascularization TME characterization may be helpful to noninvasively distinguish GB and BM based on pathophysiological differences.

### CLINICAL RELEVANCE/APPLICATION

Combination of the MRI-derived oxygen metabolism and neovascularization provides insights into the complexity and heterogeneity TME of the solitary brain tumor in clinical routine. Which have the potential for more precise noninvasive determine the tumor pathophysiology, and further facilitating to improve the glioma management.

## W7-SSNR12-2 MRI DEFINES CSF2RA'S GENETIC COMMUNITY AS REGULATOR OF HYPOXIA RESPONSE AND PROGRESSION IN THE INVASIVE NON-ENHANCING RIM OF HIGH GRADE GLIOMA

Leland S. Hu, MD (*Abstract Co-Author*) Nothing to Disclose
Matthew Flick (*Abstract Co-Author*) Nothing to Disclose
Ramon F. Barajas JR, MD (*Presenter*) Nothing to Disclose

### PURPOSE

High-grade glioma (HGG) is the most common and aggressive form of primary brain cancer with poor prognosis. Standard of care surgery employs Magnetic Resonance Imaging to identify the contrast enhancing (CE) core for resection, leaving behind a non-enhancing (NE) invasive rim of tumor which invariably contributes to recurrence. The hypoxic tumor microenvironment is thought to drive invasion into healthy brain tissue, and understanding cellular responses to hypoxia may provide key insight into combatting recurrence. Here, we employ graph network analyses on a unique dataset of multi-regional spatially-localized CE and NE biopsies from a large cohort of patients with HGG to identify gene networks influencing hypoxia response and invasion.

**METHODS AND MATERIALS**

159 IDH-wildtype tumor biopsy samples from NE and CE regions of 74 glioma patients were profiled by RNA sequencing. 1159 differentially expressed genes (DEG) (EdgeR) were represented as nodes in a Neo4j graph network. Modularity optimization identified communities of densely connected nodes. Genes exclusively in NE communities were localized by cell type using single-cell RNAseq datasets and identified as source node candidates for NE network random walks. CSF2RA was selected as a source (walk length = 5; 10,000 walks/source node). Random walks traversing samples with significantly elevated CSF2RA expression (one-tailed test) were kept for analysis. Genes occurring at high frequency (one-tailed test) on random walks were ranked by correlation with CSF2RA expression in NE samples and analyzed by gene set enrichment analysis (GSEA) using clusterProfiler. Pearson's correlation of expression for hypoxia response genes with CSF2RA used Bonferroni correction for multiple testing.

**RESULTS**

CSF2RA, an immune signaling receptor gene, was upregulated (logFC = 0.789) in NE samples and uniquely occurred within NE communities. We confirm its enrichment in myeloid populations in single cell HGG datasets and the Glycolytic/Plurimetabolic glioma subtype. NE network random walks identified 46 DEGs associated with CSF2RA. GSEA revealed upregulation of proliferative and metabolic signatures and downregulation of signaling pathways within CSF2RA's network. CSF2RA correlated negatively with all hypoxia response genes across all samples and NE/CE separately.

**CONCLUSION**

CSF2RA's network in NE tumor reveals a possible mechanism for priming glioma progression through altered hypoxic response.

**CLINICAL RELEVANCE/APPLICATION**

As CSF2 ligand is expressed by glioma cells and has a role in myeloid recruitment during tumor progression, modulating the CSF2RA gene network is a promising direction for target signaling and microenvironmental features critical in glioma invasion.

## W7-SSNR12-4 MRI HISTOGRAM AND VISUALLY ACCESABLE REMBRANDT IMAGES FEATURES NOMOGRAM TO PREDICT PD-L1 LEVELS IN GLIOBLASTOMA

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Bin Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

To delineate the prognostic impact of the programmed death-ligand 1 (PD-L1) expression level in glioblastoma (GBM) patients and investigate the value of using magnetic resonance imaging (MRI) histograms, and Visually Accessible Rembrandt Images (VASARI) features to preoperatively predict the expression level of PD-L1 in GBM.

**METHODS AND MATERIALS**

The clinical and MRI data of 124 patients with GBM at our institution between November 2018 and April 2023 were retrospectively analyzed. The PD-L1 expression level in tumor tissue samples obtained from patients were quantified using immunohistochemical staining. The optimal cutoff PD-L1 level was determined using the X-tile program by Kaplan-Meier survival analysis and log-rank test, and categorized into PD-L1 low and PD-L1 high groups. The MRI histogram and VASARI features of the patients in the high and low PD-L1 expression groups were recorded. Manually traced the volumes of interest in all GBMs margin along the axial T1-weighted contrast-enhanced (T1C) images to encompass the entirety of the tumor, then the Firevoxel software automatically generated a grayscale histogram contains 18 histogram parameters. The VASARI features set contains 25 visual description features of images based on different MRI sequences and 2 measured numerical variables. The predictive models for PD-L1 expression level were constructed using logistic regression, and a nomogram was generated.

**RESULTS**

The GBM patients with high PD-L1 expression had an unfavorable overall survival. The T1C histogram features mean, 1st, 5th, 10th, 25th, 50th, and 75th percentiles and the VASARI feature F5 proportion enhancing were statistically significantly different between groups (all $p<0.05$). Multivariate logistic regression analysis showed that mean, 5th, 10th, and 50th percentiles, and F5 proportion enhancing were independent risk factors for predicting PD-L1 expression in GBM patients. The logistic regression model based on these 5 features showed a better predictive performance, and the area under the curve, accuracy, sensitivity, specificity were 0.795, 0.726, 0.887, and 0.621, respectively.

**CONCLUSION**

The nomogram based on MRI histogram and VASARI features can show promise to non-invasively predict the level of PD-L1 expression in GBM and could be helpful in guiding immune checkpoint inhibitors therapy and predicting patient prognosis.

**CLINICAL RELEVANCE/APPLICATION**

PD-L1 expression level may serve as a potential companion biomarker to trigger the use of immune checkpoint inhibitors therapy in GBM. The nomogram based on MRI histogram and VASARI features was a reliable tool for non-invasively predict the level of PD-L1 expression in GBM and could be helpful in guiding ICI therapy and predicting patient prognosis.

## W7-SSNR12-5 5.0 T MRI T1RHO MAPPING FOR GRADING GLIOMA AND CORRELATING IDH MUTATION STATUS: ADDED VALUE TO AMIDE PROTON TRANSFER-WEIGHTED IMAGING

Lijun Dong (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance of the longitudinal relaxation time in the rotating frame (T1rho) mapping and amide proton transfer (APT)-weighted imaging alone and in combination in grading gliomas and correlating isocitrate dehydrogenase (IDH) mutation status by using 5.0 T ultrahigh-field MRI.

**METHODS AND MATERIALS**

Forty-one consecutive patients with histopathologically confirmed glioma were evaluated by 5.0 T MRI examinations. Including T2-weighted imaging, T1-weighted imaging (T1WI), fluid-attenuated inversion recovery imaging, T1rho-weighted imaging, APT-weighted imaging, and contrast-enhanced T1WI. For each patient, regions of interest were marked accurately in the solid portion of tumor, peritumoral edema, and contralateral normal-appearing white matter, respectively on anatomic images. Differences between the low-grade glioma (LGG) versus high-grade glioma (HGG) groups and between the IDH mutant-type versus IDH wild-type groups were evaluated for all parameters using independent- and paired-samples t tests. receiver operating characteristics (ROC) analyses were performed to assess the diagnostic performance of each parameter and the combination of the T1rho values and APT signals.

**RESULTS**

Patients with HGG showed significantly higher T1rho values and APT signals in both the solid portion and peritumoral edema areas compared with LGG ($P<0.05$). The ROC analyses showed that the T1rho values in peritumoral edema areas achieved the highest area under the curve (AUC, 0.791) for glioma grading. By adding the T1rho values to the APT signals, the diagnostic ability of the combined parameters improved from 0.791 to 0.812. The T1rho values in solid portion of tumor achieved the highest AUC (0.763) in correlating the IDH mutation status, and the diagnostic ability improved to 0.790 by adding it to the APT signals.

**CONCLUSION**

Both T1rho mapping and APT-weighted imaging could be used to grade glioma and correlate IDH mutation status, and the diagnostic performance could be improved by combining the two techniques.

**CLINICAL RELEVANCE/APPLICATION**

It is possible to applying the combination of T1rho mapping and APT-weighted imaging in assessing the histologic grade and IDH mutation status of gliomas. And it should be considered for implementation in the routine workup of glioma patients.

## W7-SSNR12-6 DEVELOPMENT AND VALIDATION OF MRI-BASED ON DEEP LEARNING RADIOMICS SIGNATURES TO PREDICT EIGHT CORE MOLECULAR BIOMAKERS IN ADULT DIFFUSE GLIOMA: A MULTICOHORT STUDY

Junjie Li (*Abstract Co-Author*) Nothing to Disclose
Yaou Liu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhizheng Zhuo (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to develop a Deep Learning and Radiomics signature (DLR) model and a combined DLRC (Deep Learning and Radiomics with Clinical signature) model using MRI to predict eight core molecular pathological biomakers for adult diffuse glioma.

**METHODS AND MATERIALS**

A retrospective study was conducted on 1151 adult diffuse glioma patients in our hospital. Multi-parameter MRI images (T2 and T1C) and pathological information, including IDH mutation, 1p/19q co-deletion, MGMT methylation, TERT mutation, EGFR amplification, +7/-10, and KI67 expression were collected. Patients were randomly divided into a training set (n=805) and an internal test set (n=346). Subsequently, 3562 radiomics features and 4096 DL features were extracted. After feature reduction and selection, the MLP was used to build radiomics and DL model. The DLR model base on radiomics and DL results from MLP. Finally, logistic regression was used to integrate the DLR and clinical prediction model to build the DLRC prediction model. The DLR model and DLRC models were tested in external test sets from JL Hospital (n=118), TCGA (n=237), and UCSF (n=477).

**RESULTS**

The DLR model showed AUCs of 0.829 to 0.927 for predicting IDH mutation in internal, JL, TCGA, and UCSF test sets, AUCs of 0.805 to 0.880 for predicting 1p/19q co-deletion, AUCs of 0.531 to 0.714 for predicting MGMT methylation, and AUCs of 0.725 to 0.761 for predicting TERT mutation. In the internal test set, the DLR model showed an AUC of 0.753 for predicting EGFR amplification, an AUC of 0.832 for predicting +7/-10, an AUC of 0.792 for predicting CDKN2A/B co-deletion, and an AUC of 0.883 for predicting KI67 expression. In the internal, JL, TCGA, and UCSF test sets, the DLRC model showed AUCs of 0.899 to 0.966 for predicting IDH mutation, AUCs of 0.825 to 0.896 for predicting 1p/19q co-deletion, AUCs of 0.530 to 0.716 for predicting MGMT methylation, and AUCs of 0.620 to 0.844 for predicting TERT mutation. In the internal test set, the DLRC model showed an AUC of 0.775 for predicting EGFR amplification, an AUC of 0.849 for predicting +7/-10, an AUC of 0.815 for predicting CDKN2A/B co-deletion, and an AUC of 0.890 for predicting KI67 expression.

**CONCLUSION**

The DLR and DLRC models based on MRI make it possible to non-invasively predict eight core molecular pathological biomakers of adult diffuse glioma.

**CLINICAL RELEVANCE/APPLICATION**

The study verified the DLR and DLRC demonstrated high diagnostic performance in identifying eight molecular biomakers with adult diffuse glioma patients at MRI. Our approach has the potential to facilitate timely diagnoses and management of adult diffuse glioma patients encountered in routine clinical practice.

Edwina M Chang (*Abstract Co-Author*) Nothing to Disclose
Zahra Shokri Varniab, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Glioblastoma (GBM) therapy remains challenging because the blood-brain barrier (BBB) prevents tumor-delivery of therapeutic drugs and GBM give rise to tumor recurrences. Matrix Metalloproteinases-14 (MMP-14) and Cathepsin-B (Cat-B) are overexpressed in GBM, making them attractive targets for prodrug activation strategies. We developed two distinct tumor-enzyme activatable theranostic nanoprobes (TNP): TNP-MMP-14 is activated by MMP-14 and opens the BBB, TNP-Cat-B is activated by Cat-B and targets GBM cells. We hypothesized that opening the BBB first with TNP-MMP-14 will maximize the efficacy of TNP-Cat-B.

### METHODS AND MATERIALS

We synthesized (1) ferumoxytol nanoparticles conjugated with the vascular disrupting agent azademethylcolchicine through an MMP-14-cleavable linker and (2) ferumoxytol conjugated with the tubulin inhibitor monomethyl auristatin-E through a cathepsin-B-cleavable linker. Thirty-six NSG mice with stereotactically implanted luciferase-expressing GBM39 were treated with TNP-MMP-14 and TNP-Cat-B (group 1), TNP-Cat-B only (group 2) or saline sham therapy (group 3). All mice underwent pre- and post-treatment MRI and bioluminescence imaging (BLI). Tumor T2* relaxation times and BLI flux data were compared before and after treatment using Wilcoxon Matched-Pairs Signed-Rank Test and $p<0.05$.

### RESULTS

Group 1 tumors demonstrated a significantly stronger reduction in T2* relaxation times (pre-treatment 24.32±2.57ms, post-treatment 13.42±4.22ms; $p=0.0003$), compared to group 2 tumors (pre-treatment 25.16 ± 3.07ms, post-treatment 21.09 ±4.51ms; $p=0.02$). Group 3 tumors did not show significant changes in T2* signal. At ten days post-treatment, BLI flux was significantly reduced in group 1 tumors (pre-treatment 5.26E+09, post-treatment 3.91E+08; $p<0.05$), stable in group 2 tumors (pre-treatment 2.7E+9; post-treatment 3.38E+9; $p=0.50$) and and increased in group 3 tumors (base of 2.99E+9; post-treatment 1.99E+10; $p=0.03$). Histopathological correlations demonstrated significantly higher caspase-3 expression in group 1 compared to group 2 ($p=0.002$) and group 3 ($p=0.002$).

### CONCLUSION

MRI showed significantly improved drug delivery for GBM treated with combined vascular disrupting TNP and tumor cell targeted TNP compared to monotherapy.

### CLINICAL RELEVANCE/APPLICATION

MRI can be a valuable tool for evaluating the effectiveness of nanocarrier-based combination therapies for GBM. Our study also introduces a new approach using two different TNP to treat GBM.

## W7-SSNR13-2 HIERARCHICAL MULTI-TASK TRANSFORMER FOR TUMOR SEGMENTATION AND RESPONSE ASSESSMENT IN PATIENTS WITH MALIGNANT GLIOMAS VIA STRUCTURAL AND AMIDE PROTON TRANSFER-WEIGHTED MRI

Qianqi Huang (*Abstract Co-Author*) Nothing to Disclose
Jingpu Wu (*Abstract Co-Author*) Nothing to Disclose
Jinyuan Zhou, PhD (*Abstract Co-Author*) Inventor, Koninklijke Philips NV;Institutional license agreement, Koninklijke Philips NV;Speaker, Koninklijke Philips NV
Shanshan Jiang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Puyang Wang, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Amide protein transfer weighted (APTw) MRI has been validated to accurately detect recurrent malignant gliomas across different studies. However, APTw image interpretation is time consuming and requires professional knowledge. Our goal was to develop a reliable, automated imaging diagnostic tool to assess malignant glioma response to therapies are urgently needed.

**METHODS AND MATERIALS**

We proposed Hierarchical Multi-task Transformer framework to address both tumor segmentation and response assessment in patients with malignant gliomas. 3 key components of proposed framework are as follows: (1) Pixel branch to provide anchor queries to the lesion branch for initial pixel-wise segmentation. (2) Lesion branch composed of the transformer decoder in Mask2Former with improved segmentation loss to enhance recall of small enhancing tumor (ET) regions. (3) Patient branch to make dedicated scan-level predictions with a lesion-patient consistency loss. Pixel and lesion branches are designed to output the progression-aware segmentation map that further divide ET and non-enhancing tumor region (NER) into stable, improved or increasing regions. A total of 126 MRI scans (T1w, T2w, FLAIR, APTw, and contrast enhanced T1w) from 83 patients post-treated malignant gliomas were reassessed. Each scan was annotated as "response" to treatment or "progressive disease" according to the RANO criteria and pixel-wise annotated following the protocol in BraTs Challenge with ET, NER and the peritumoral edematous tissue. 5-fold cross-validation with random patient-level 80%/20% splits of imaging dataset was performed to evaluate the performance of tumor recurrence classification and volumetric and distance metrics of tumor sub-region segmentation.

**RESULTS**

For the response assessment, the proposed model without APTw images as input achieved an AUC of 0.84 (sensitivity, 0.91; specificity, 0.84). By adding the APTw images to the input, the classification result improved to AUC 0.87 (sensitivity, 0.86; specificity, 0.92). For brain tumor segmentation, by adding APTw images to the input, the Dice coefficient increased the most for the enhancing tumor core region from 0.64 to 0.76, suggesting that APTw imaging can help to distinguish tumor boundary.

**CONCLUSION**

The proposed framework utilizing multi-parametric MRIs with both structural and APTw images showed promising results in brain tumor segmentation and distinguishing between tumor progression and response post-treatment.

**CLINICAL RELEVANCE/APPLICATION**

The proposed framework could be a highly efficient solution for clinical experts to make precise diagnoses for patients with post-treatment malignant gliomas and further prognosis analysis.

## W7-SSNR13-3 ASSESSMENT OF HYPOXIA AND ITS DYNAMIC EVOLUTION IN GLIOBLASTOMA VIA QBOLD MRI

Bo Yin (*Abstract Co-Author*) Nothing to Disclose
Yiping Lu (*Abstract Co-Author*) Nothing to Disclose
Dong Dong Wang (*Abstract Co-Author*) Nothing to Disclose
Xuanxuan Li (*Abstract Co-Author*) Nothing to Disclose
Yinwei Ying (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the accuracy of quantitative blood oxygen level-dependent (qBOLD) imaging in detecting hypoxia in malignant glioma based on pathological findings, and explore the dynamic changes in tumor oxygenation status of glioma with and without the administration of metformin, a potential anti-hypoxia drug.

**METHODS AND MATERIALS**

Three healthy rats and seven C6-bearing rats were scanned with qBOLD imaging after anesthesia by 7.0T MRI. The qBOLD data were post-processed to generate parameters including Oxygen Extraction Fraction (OEF) and Cerebral Metabolism Rate of O2 (CMRO2). After the scan, the tumor tissues were stained by HIF-1a and pimonidazole for hypoxia detection and the results were analyzed by HALO software. The correlation between the expression of hypoxia markers and the corresponding qBOLD-related parameters were analyzed. Another six C6-bearing rats were randomly divided into metformin-treated and control group equally for dynamic qBOLD observation. The rats in treatment group were injected with metformin intraperitoneally daily from the 12th day after tumor implantation. Rats in both groups received qBOLD scans on the 12th, 15th and 18th day respectively after the tumor implantation.

**RESULTS**

In healthy rats, higher T2, T2*, CBV, CBF and CMRO2 values were detected in grey matter compared with the white matter, while the OEF the opposite ($p<0.05$). Compared with contralateral normal-appearing white matter, the mean values of T2, T2*, CBV and CBF are notably higher in tumor, but decreased values in OEF and CMRO2 were detected ($p<0.05$). Tumor tissue achieved remarkable high staining scores in both HIF-1a and pimonidazole, however, no significant correlation was detected in corresponding regions($p=0.11$). T2* ($r=0.44$, $p=0.014$) and T2 ($r=0.43$, $p=0.017$) values demonstrated significantly negative relationships with the expression score of pimonidazole in tumor regions. OEF values in tumor tissue increased with larger variations as tumor progressed, while CMRO2 declined. In metformin-treated group, delayed decreases of T2 and T2* values were observed on Day 15th. After metformin delivery, OEF in tumor stayed low and CMRO2 gradually declined, differing significantly from the control group on Day 18th (OEF: 12.87 ± 3.74% vs 26.73 ± 7.62, $p<0.001$; CMRO2: 0.72 ± 0.17 vs 1.25 ± 0.31umol/min/100g, $p<0.001$).

**CONCLUSION**

T2* and T2 value was related to hypoxia status of glioma in C6-bearing rats, while other qBOLD-derived parameters were not. Via qBOLD dynamic observation, the administration of metformin has the potential to change the oxygen metabolism status of glioma and delay the process of hypoxia in glioma.

**CLINICAL RELEVANCE/APPLICATION**

The findings could help pinpoint the ideal patient group for metformin therapy.

## W7-SSNR13-4 MAPPING TUMOR HABITATS IN IDH-WILD TYPE GLIOBLASTOMA: INTEGRATING MR IMAGING, PATHOLOGIC, AND RNA DATA FROM IVY GLIOBLASTOMA ATLAS PROJECT

Ho Sung Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ha-Kyung Jung, MD (*Abstract Co-Author*) Nothing to Disclose
DONGJUN LEE, MD (*Abstract Co-Author*) Nothing to Disclose

Nakyoung Kim (*Abstract Co-Author*) Nothing to Disclose
Ji Eun Park, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To spatially validate intratumoral subregions (tumor habitat) using physiologic MRI on pathology of the isocitrate dehydrogenase (IDH)-wildtype whole-glioblastoma sample.

**METHODS AND MATERIALS**

Data of 20 patients (168 slides) were obtained from the Ivy Glioblastoma Atlas Project. On MRI, tumor habitats were defined using voxel-wise clustering of apparent diffusion coefficient (ADC) and cerebral blood volume (CBV) maps for contrast-enhancing lesion (CEL) and non-enhancing lesion (NEL). On pathology slides, normalized areas of leading edge (LE), infiltrating tumor (IT), cellular tumor (CT), hypervascular lesion (CThypervascular), and perinecrotic lesion (CTperinecrotic) were obtained. Gross specimen was co-registered on MRI and correlation between pathology-MRI habitats was calculated. RNA sequencing of 67 samples was assessed using 4 Neftel subtypes and further correlated with pathology.

**RESULTS**

Six tumor habitats were identified: hypervascular, hypovascular cellular, and hypovascular hypocellular habitats for CEL and NEL. CT was correlated with hypovascular cellular habitat in CEL ($r= 0.238$, $p =.005$). IT was correlated with hypovascular cellular habitat in NEL ($r= 0.294$, $p =.017$). CThypervascular was correlated with hypervascular habitat in NEL ($r= 0.195$, $p = .023$). CTperinecrotic was correlated with imaging necrosis ($r= 0.199$, $p =.005$). Astrocyte-like subtypes were correlated with IT ($r= 0.256$, $p <.001$), while mesenchymal-like subtypes were correlated with CTperinecrotic area ($r= 0.246$, $p <.001$).

**CONCLUSION**

Pathologically matched tumor subregions were cellular tumor with hypovascular cellular habitat in CEL and infiltrative tumor with hypovascular cellular habitat in NEL. Identification of the most aggressive as well as infiltrative tumor portion can be achieved using non-invasive MRI tumor habitats.

**CLINICAL RELEVANCE/APPLICATION**

The biologic validation of tumor subregions in glioblastoma, IDH-wild type, is important in tumor imaging; however, it has been limited due to lack of complete dataset of imaging and pathology. We utilized IvyGAP data to facilitate spatially validated MRI-based tumor subregions and pathologic slides with full physiologic MRI, pathology, and RNA sequencing data. Topological biologic validation showed a positive correlation between hypovascular cellular habitat in CEL and cellular tumor, as well as hypocellular habitat in NEL and infiltrative tumor. Based on noninvasive identification of the most aggressive cellular tumor portion and infiltrative tumor portion based on topological biologic validation with pathologic slides, our spatial MRI tumor habitat analysis enables accurate treatment monitoring and can potentially guide local therapy.

## W7-SSNR13-5 CEST MRI UNVEIL OF THE DISTINGUISHED TREATMENT DRIVEN PERITUMORAL REGIONS PATTERN IN NEWLY DIAGNOSED MALIGNANT GLIOMA

Qianqi Huang (*Abstract Co-Author*) Nothing to Disclose
Jingpu Wu (*Abstract Co-Author*) Nothing to Disclose
Shanshan Jiang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jinyuan Zhou, PhD (*Abstract Co-Author*) Inventor, Koninklijke Philips NV;Institutional license agreement, Koninklijke Philips NV;Speaker, Koninklijke Philips NV
Puyang Wang, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Our objective is to investigate whether CEST MRI is capable to provide any distinguishable patterns regarding tumor recurrence vs. treatment effect, and to unveil the underline potential mechanism of maliciously invasive behavior of high grade gliomas.

**METHODS AND MATERIALS**

Patient enrollment The study included a dataset comprising 48 scans collected from a total of 46 patients. Each patient had all study-related MRI data after their standard chemoradiation regimen completion. MRI protocol The sequences performed on Philips 3T included T1 mapping; T2 mapping; FLAIR; and Gd-T1w. A 3D imaging acquisition scheme was used for volumetric APTw imaging (saturation power = 2 μT; saturation time = 2s). Data postprocessing T1 and T2 maps, APTw and CEST@2ppm MRI data were uniformly rescaled and aligned through a co-registration process. A researcher manually annotated the peritumoral zones characterized by abnormal FLAIR/T2-weighted signal intensities surrounding gadolinium enhanced tumor core. Statistical analysis The histogram method was utilized to derive features from the ROI. MRI Parameters that achieved statistical significance ($P<0.05$) were selected by the U test and receiver operating characteristic (ROC) analysis then used to construct and train multivariate logistic regression models. 5-folds evaluation method was used with the aim of assessing the efficacy of combined MR images.

**RESULTS**

20 scans were confirmed as treatment effects from 19 patients, and 28 scans were tumor recurrence from 27 patients. The Z-spectra and MTRasym spectra exhibit treatment effects with higher Z-spectra and tumor recurrence with higher MTRasym values across chemical shift offsets. Some histogram parameters from T1, T2, CEST@2ppm and APTw shows significant difference between two groups especially mode value in CEST@2ppm, Kurtosis in T1, 25th percentile in APTw. The combination of APTw, T1 map, T2 map, and CEST@2ppm yields the highest differentiating performance with a mean AUC of $0.85 \pm 0.07$, indicating a strong predictive capability.

**CONCLUSION**

Our study found APTw and CEST@2ppm MRI show that PER had higher CEST signal intensities in tumor recurrence than treatment treatments. It might be associated with higher protein concentrations from local invasive tumor cells and creatine which promote invasion in the PER.

**CLINICAL RELEVANCE/APPLICATION**

The different progressive patterns in peritumoral regions between treatment effects and tumor recurrence are assessable by CEST MRI. It provide a potential imaging maker matrix to unveil the mechanism of invasive behavior of malignant gliomas.

## W7-SSNR13-6 FRACTAL DIMENSION ANALYSIS FOR IDH-1 WILD-TYPE HIGH-GRADE GLIOMA: TOWARDS A SURVIVAL MATHEMATICAL PREDICTION MODEL MATHEMATICAL PREDICTION MODEL

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Xi Huaze, MMedSc, BMBCh (*Presenter*) Nothing to Disclose

## PURPOSE

This study investigates the utility of fractal dimension (FD) in assessing the mutation status of the isocitrate dehydrogenase 1 (IDH-1) gene and the proliferation activity of tumor cells in high-grade glioblastoma (HGG). Additionally, the study aims to construct a mathematical model for predicting the survival of patients with IDH-1 wild-type HGG.

## METHODS AND MATERIALS

A total of 75 patients with HGG confirmed by pathology and IDH-1 mutation status and Ki-67 index were collected, including 52 cases of IDH-1 wild type and 23 cases of IDH-1 mutant. The tumor boundary and peritumoral edema range were automatically delineated on the maximum level of T1WI, T2WI, and DWI images and the two levels above and below. The FD value of the outer edge was measured, and the average value of the three levels was used as the measured value. Postoperative recovery and survival of patients were followed up, and the difference in FD values between IDH-1 mutant and wild-type groups was compared. The receiver operating characteristic (ROC) curve was used to analyze the efficacy of different FD values for predicting IDH-1 mutation. Logistic regression analysis was used to evaluate the independent risk factors related to death in IDH-1 wild-type patients, and a mathematical model for predicting the survival of patients was constructed based on these parameters.

## RESULTS

The T1 (tumor) -FD, T2 (tumor) -FD, T2 (edema) -FD, and DWI (tumor) -FD of IDH-1 wild type were higher than those of IDH-1 mutant type (all $P<0.05$). The FD value on DWI had the highest diagnostic efficiency, with an AUC of 0.868, a specificity of 0.696, and a sensitivity of 0.923. All FD values were positively correlated with the Ki-67 index, and T2 (tumor) -FD had the highest correlation with the Ki-67 index ($r=0.4853$, $P<0.0001$). DWI (tumor) -FD, Ki67 index, age, [1] and maximum tumor cross-sectional perimeter are independent risk factors for predicting the survival of IDH-1 wild-type HGG patients, and BMI is a protective factor for poor prognosis of patients.A, B, and C

## CONCLUSION

FD can evaluate the IDH-1 gene mutation status of patients, and it is positively correlated with Ki-67 index. The mathematical model based on FD and other multi-parameters can predict death events in patients.

## CLINICAL RELEVANCE/APPLICATION

FD is a parameter that describes the complexity of morphology. Different from the analysis of the internal gray level and texture of the image in radiomics, FD can quantitatively describe the abstract morphology of tumor growth, which is a relatively new morphological parameter. Therefore, preoperative evaluation of IDH-1 mutation status and Ki-67 index is of great significance for the selection of treatment options. The mathematical model based on FD can predict the probability of death of patients.

### PURPOSE

To evaluate cholecystocholangiographic (CCG) patterns in infants with suspected biliary atresia (BA).

### METHODS AND MATERIALS

IRB-approved retrospective review of imaging and clinical records of infants with suspected BA between September 2012 and April 2024 was performed. CCGs were interpreted independently by two study authors. Biopsy at portoenterostomy was used as the reference standard for a diagnosis of BA; other diagnoses were established through appropriate testing and clinical follow up.

### RESULTS

96 infants (46 female; mean age 65 ± 31 days, range: 9-201 d) with suspected BA underwent 100 CCG. 81 CCG were performed by general surgeons (GS) after laparotomy, and 19 were performed percutaneously by interventional radiologists (IR); four IR CCG were repeated intraoperatively.Abnormal CCG patterns were: A, failed opacification, consistent with Kasai Types IIb or III BA (n=20); B, gallbladder with or without a cystic duct, consistent with Kasai Types IIb or III BA (n=16); C, gallbladder with common bile duct only, consistent with Kasai Type IIa BA (n=22); D, gallbladder with common hepatic duct and wispy intrahepatic ducts, consistent with Kasai Type I BA (n=9); and E, gallbladder with common bile duct and common hepatic duct but with wispy intrahepatic ducts (n=4).Fifteen of 19 infants (corresponding to 16/20 CCG, 80%) with pattern A CCG had BA; of the other four, three infants had hepatitis and one had CF and TPN cholestasis. Fifteen of 16 infants (15/16 CCG, 94%) with pattern B CCG had BA; the other had CF and TPN cholestasis. All 20 infants (21/21 CCG, 100%) with pattern C CCG had BA. All nine infants (9/9 CCG, 100%) with pattern D CCG had BA. Two of five infants (2/5 CCG, 40%) with pattern E CCG had BA, although one also had a-1-antitrypsin deficiency (a1ATD); of the other three, one had hepatitis, one had a1ATD alone and one had an Alagille-like syndrome.Normal CCG was observed in 29 infants, and none (0/29 CCG, 0%) had BA. The most common diagnoses were hepatitis and TPN cholestasis. 12 normal CCG were performed percutaneously by IR, thus avoiding laparotomy.Two infants with IR CCG repeated by GS had pattern A IR CCG but pattern B or normal GS CCG, accounting for some apparent repetition and discrepancy in numbers of infants and CCG by pattern.

### CONCLUSION

In this large series evaluating CCG patterns in patients with suspected BA, normal CCG was highly prevalent and had high negative predictive value. Percutaneous technique may obviate the need for laparotomy. Patterns B, C and D were reliably diagnostic of BA.

### CLINICAL RELEVANCE/APPLICATION

Better understanding of CCG patterns may speed a diagnosis of BA and further establish the role of CCG in the work-up of BA, minimizing laparotomy. BA CCG classification could later inform type-specific surgical outcomes analysis.

## W7-SSPD04-2 PERCUTANEOUS PORTAL VEIN RECANALIZATION IN PEDIATRIC PATIENTS WITH EXTRAHEPATIC PORTAL VEIN OBSTRUCTION

Francesco S. Carbone, MD (*Abstract Co-Author*) Nothing to Disclose
Ludovico Dulcetta, MD (*Abstract Co-Author*) Nothing to Disclose
Sandro Sironi, MD (*Abstract Co-Author*) Nothing to Disclose
Pietro A. Bonaffini, MD (*Abstract Co-Author*) Nothing to Disclose
Riccardo Muglia (*Abstract Co-Author*) Nothing to Disclose
Paolo Marra, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Portal hypertension resulting from extrahepatic portal vein obstruction (EHPVO) in children has been managed primarily through surgical intervention involving Meso-Rex shunt creation, but only 30-50% of patients have a viable Rex vein, which is required by surgery. The aim of the study is to report a preliminary series of patients who underwent interventional radiology attempts at portal vein recanalization (PVR) prior to consider any type of other intervention.

**METHODS AND MATERIALS**

A cohort of consecutive patients presenting with EHPVO at our institution from 2021-2024 was retrospectively collected. After a preliminary transjugular wedge hepatic venography to evaluate the patency of the native intrahepatic portal system, or in the same session, a percutaneous transhepatic and transplenic portal venography was carried out to recanalize the native portal vein. Patients who failed recanalization were listed for meso-portal bypass, if feasible, or considered for other shunts including TIPS. Clinical and procedural data, technical and clinical success, complications and follow up data were recorded. Technical success was considered at least the partial revascularization of the native portal system.

**RESULTS**

Twelve patients (7 males; median age 8 years) with severe portal hypertension due to EHPVO underwent 16 percutaneous transhepatic (n=1), transplenic (n=12) or simultaneous transhepatic/transplenic (n=3) attempts at portal vein recanalization. Rex vein was patent in 4/12 (33%). Successful recanalization was achieved in 6/12 patients (50%), 2/6 with obliterated Rex vein. No major adverse events were observed. After successful angioplasty, 5/6 patients required metal stenting to obtain sustained patency. None of the failed patients was considered suitable for Meso-Rex shunt creation and underwent TIPS (n=2), splenectomy (n=1), surgical shunt (n=1). Two patients were followed-up without further interventions. After a median follow-up of 4.5 months patency of the main portal vein was demonstrated for all the patients who achieved PVR, without clinical and laboratory improvement of portal hypertension.

**CONCLUSION**

Our preliminary experience suggests that 50% of children with EHPVO can restore the portal flow by endovascular treatment, even when the Rex vein is obliterated and Meso-Rex surgery unfeasible. In EHPVO, thanks to its low invasiveness, percutaneous recanalization of the portal vein may be regarded as the primary intervention, before considering the meso-portal bypass.

**CLINICAL RELEVANCE/APPLICATION**

Innovative percutaneous procedures may have a revolutionary impact and overcome the conventional surgical approach in the management of EHPVO and its complications in children.

## W7-SSPD04-3 PEDIATRIC INTERVENTIONAL RADIOLOGY EXPERIENCE IN THE TREATMENT OF MOREL-LAVALLEE LESIONS: TREATMENT VARIABILITY AND OUTCOMES

Anne Marie Cahill, MBBCh (*Abstract Co-Author*) Advisory Committee, Siemens AG;Speakers Bureau, Avanos Medical, Inc
Ganesh Krishnamurthy, MBBS (*Abstract Co-Author*) Nothing to Disclose
Abhay S. Srinivasan, MD (*Abstract Co-Author*) Nothing to Disclose

Fernando A. Escobar, MD (*Abstract Co-Author*) Nothing to Disclose
Michael R. Acord, MD (*Abstract Co-Author*) Nothing to Disclose
Stephanie C. Cajigas-Loyola, MD (*Abstract Co-Author*) Nothing to Disclose
Sean Schoeman, MBChB (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate our experience and outcomes in treating Morel-Lavallée lesions over the last 6 years.

**METHODS AND MATERIALS**

Patients from a single institution who underwent sclerotherapy in interventional radiology (IR) were retrospectively reviewed following IRB exemption. Imaging and medical records were reviewed for indications, procedure details and outcomes.

**RESULTS**

Nine patients [5 female, median age 15.9 years (IQR: 15.4 - 17.7 years) and median weight 55 kg (IQR: 50 - 70 kg)] were included. A total of 9 lower limb lesions, secondary to trauma, were treated: thigh (2), hip (1), shin (1), calf (2), and knee (3). Preprocedural imaging included ultrasound (100%), X-ray (78%), MRI (44%) and CT (22%). Median interval from injury to IR treatment was 112 days (IQR: 20 - 177 days). Prior to IR referral, management was variable. 4 patients' lesions had no or conservative management. Five patients had either aspiration or incision and drainage by surgery. There were 18 IR treatment cycles performed in the 9 patients: 5 therapies (1), 3 therapies (1), 2 therapies (3), and monotherapy (4). Aspiration was followed by sclerosant administration in 94% (n=17) using Doxycycline (100%), ethanol (35%), sodium tetradecyl sulphate (29%), and betadine (12%). Multiple sclerosant agents were used in 41% (n=7) of cases. In 61% (n = 11) of procedures a drain was placed and 56% (n = 10) included multiday treatment with repeat doxycycline injection. A cytology brush was used to disrupt the lesion capsule in 4 procedures. Clinical success with lesion resolution occurred in 6/9 patients (67%), after 5 treatment episodes in 1 patient, 2 treatment episodes in 3 patients and a single treatment episode in 2 patients. All the successfully treated lesions occurred at the level of the knee or below. In 4/6 patients there was a multi-day component to the treatment protocol. Three patients with lesions involving the thigh (2) and hip (1) required surgical excision after recurrence following 1-3 treatment episodes.

**CONCLUSION**

Based on our small cohort, injury at or below the level of the knee had the highest response rates to percutaneous sclerotherapy. Further research, after protocol standardization, will be critical for establishing optimal patient selection, sclerosant type, frequency, and post intervention management.

**CLINICAL RELEVANCE/APPLICATION**

Although there is no established treatment algorithm for the management of post-traumatic Morel-Lavallée lesions in the pediatric population, we have defined a group that may be responsive to percutaneous therapy. Further research will be required to describe a suitable algorithm.

## W7-SSPD04-4 STANDARDIZED UPTAKE VALUES AND APPARENT DIFFUSION COEFFICIENT AS PREDICTIVE BIOMARKERS FOR TREATMENT RESPONSE IN METASTATIC PEDIATRIC EWING SARCOMA: A MULTICENTER PROSPECTIVE STUDY

Shashi Singh, MBBS (*Abstract Co-Author*) Nothing to Disclose
Heike E. Daldrup-Link, MD (*Abstract Co-Author*) Managing director, Monasteria Press LLC Research Grant, MegaPro Inc

Lisa C. Adams, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ricarda V. von Kruchten, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate correlations of tumor metabolism and tumor cell diffusion (an indirect measure of tumor cell density) in metastatic Ewing Sarcoma at baseline and after induction chemotherapy. Additionally, potential correlations with overall survival in children and adolescents were explored.

**METHODS AND MATERIALS**

We performed a secondary review of patients with metastatic Ewing sarcoma who were enrolled in the prospective, multicenter phase III Children's Oncology Group trial AEWS1221. A subgroup of 21 patients (12 females and 9 males, mean age 14.10 ± 4.67 years) underwent MRI and 18F-FDG PET-CT scans at baseline and post-induction chemotherapy. We measured the standardized maximum uptake values (SUVmax) and the mean and minimum apparent diffusion coefficient (ADCmean and ADCmin) of the whole primary tumor and the viable tumor, excluding central necrosis. For each modality, we compared measurements of the whole tumor and viable tumor with paired t-tests. We calculated Pearson's correlation coefficients to assess a correlation between SUVmax and ADCmin as well as imaging measures and progression-free survival (PFS).

**RESULTS**

At baseline, whole tumor SUVmax did not correlate with whole tumor ADCmin, but viable tumor SUVmax correlated inversely with viable tumor ADCmean ($R = -0.51$, $p = 0.022$). This was due to differences in ADC since whole tumor SUVmax and viable tumor SUVmax were not significantly different, while whole tumor ADCmin and viable tumor ADCmean differed significantly. After induction therapy, whole tumor SUVmax correlated with whole tumor ADCmin ($R = -0.59$; $p = 0.028$), and viable tumor SUVmax did not correlate with viable tumor ADCmean ($R = -0.15$; $p = 0.62$). Pre-minus-posttreatment change in tumor volume correlated with both whole tumor ADCmin ($R = -1.07$; $p = 0.01$), as well as viable tumor ADCmean ($R = -0.02$; $p = 0.21$). However, none of the measurements correlated with PFS.

**CONCLUSION**

At baseline, SUVmax and ADCmean of the viable tumor only, excluding necrosis, are promising biomarkers for local tumor response. Post-induction therapy, SUVmax, and ADCmin across the entire tumor, including necrotic portions, indicate treatment-related changes. If differences between pretreatment and post-treatment measures are calculated, then both whole tumor ADCmin and viable tumor ADCmean can be used as biomarkers for changes in tumor volume.

**CLINICAL RELEVANCE/APPLICATION**

A more nuanced approach to tumor ADC measurements can improve therapy response predictions, and thereby, help guide treatment decisions and potentially tailor therapy intensity based on the predicted tumor behavior.

## W7-SSPD04-5 INTEGRATED METABOLIC AND FUNCTIONAL IMAGING THROUGH PET/MRI FOR PEDIATRIC HODGKIN LYMPHOMA: EXPLORING THE COMPLEMENTARY ROLE OF 18F-FDG UPTAKE AND DIFFUSION RESTRICTION

Ilias Tsiflikas, MD (*Abstract Co-Author*) Nothing to Disclose
Sergios Gatidis, MD (*Abstract Co-Author*) Nothing to Disclose
Josephine Berger (*Presenter*) Nothing to Disclose

**PURPOSE**

In an effort to address the challenges of assessing tumor heterogeneity and therapeutic response in pediatric classic Hodgkin lymphoma (cHL) we explored the complimentary roles of 18F-FDG uptake and diffusion restriction with an integrated PET/MRI system. We propose that tumor dynamics are too complex to be expressed by a single marker; thus, a complementary approach is needed rather than merely comparing two methods.

**METHODS AND MATERIALS**

A cohort of twenty-five patients (mean age 15 ± 2.5y, 15 female) from our prospective PET/MRI study underwent baseline and ERA imaging on an integrated clinical PET/MRI system. Using dedicated software (Multiparametric Analysis, Siemens Healthcare), we performed a voxel-by-voxel analysis of fused ADC, PET, and T2-weighted images. The volume of interest (VOI) was covering the whole lesion. Data were exported to statistical software for Gaussian mixture model (GMM) clustering and contingency analysis.

**RESULTS**

At baseline, 156 lesions and after two cycles of chemotherapy, 48 lesions were analyzed. Lesions were excluded due to complete remission or technical issues. We identified three clusters (C1, C2, C3) with a significant negative correlation between ADC and SUV in C1 and a weak positive correlation in C2 and C3 (all $p < 0.001$), which increased after treatment. The results of Wilcoxon signed-rank test showed that nodular sclerosis type of cHL had a significantly different distribution of voxels in C2 and C3 than lymphocyte-rich and mixed cellularity cHL ($p < 0,05$). For ERA, this difference among cHL types is only significant in C3 ($p < 0,05$). There was also a substantial difference in the distribution of C3 lesions at ERA in patients with relapse compared to patients without relapse ($p=0.001$).

**CONCLUSION**

Our voxel-wise analysis identified specific subvolumes within cHL lesions that responded differently to chemotherapy, highlighting tumor complexity and heterogeneity. Specifically, parts of tumors lacking the expected negative correlation between SUV and ADC differed histologically and could have prognostic implications. The study's limitations include its small sample size from a single center and uneven distribution of histological subtypes within cHL.

**CLINICAL RELEVANCE/APPLICATION**

By incorporating more imaging and clinical variables in larger cohorts with cHL and other cancers and employing advanced methods such as hyperpolarized 13C-MRI, we could offer an even more comprehensive view of tumor metabolism, potentially leading to improved diagnostics and personalized treatment strategies.

Bernhard Schmidt, PhD (*Presenter*) Employee, Siemens AG

### PURPOSE

Phantoms are important tools for the assessment and performance verification process in computed tomography (CT). Modern CT system increasingly incorporate algorithms, which rely on a realistic depiction of human anatomy.This study utilizes a 3D-printing solution used to create patient-realistic CT phantoms in combination with the PolyJet multi-material photopolymer 3D printing technology (VoxelPrint, StrataSys Ltd.).

### METHODS AND MATERIALS

A dedicated software prototype was developed for the pixel-to-pixel based mapping process between clinical CT images and three polymer materials which exhibit different CT designed radiopacities (RadioMatrix™, StrataSys Ltd.). These three materials realize support points with a fixed Hounsfield value for a given x-ray spectra in the resulting phantom derived images. All intermediate Hounsfield values are generated by mixture of these materials in relative fractions by a separately determined calibration table. (Siemens Healthineers).A high-resolution head CT angiography spiral data set acquired with a first-generation dual source photon counting scanner (NAEOTOM Alpha, Siemens Healthineers) is used as input. The printed phantom was identical in its size as the original data with an in-plane diameter of around 160 mm and coverage of 140 mm starting at the cerebellar fossa. It was evaluated in terms of realized contrast, noise texture and resolution at different image quality levels and compared to the original clinical data set by repeated acquisitions.

### RESULTS

Qualitatively, CT images of the patient-based phantom closely resemble the original CT images, both in texture and contrast levels with clearly visible vascular vessel, soft tissue and fat structure. Density and geometrical accuracies between phantom and patient images were evaluated for the Circle of Willis vasculature. Regions-of-interest (ROIs) comparing Hounsfield values demonstrated differences below 10 HU for the iodine enhanced vessels (e.g. basilar artery) and soft tissue structures. An increase in contrast in the vessels was observed for 90kV tube voltage mimicking the behavior of iodine observed in clinical angiography data. Repeating a visual assessment at different reconstruction sharpness levels revealed a loss only for the reconstruction close to the sharpness of the original input images, while no artefacts or structures associated to printer resolution effects were observed.

### CONCLUSION

Our study demonstrates the feasibility of a 3D-printed patient-realistic head CT angiography phantom with accurate geometry, texture, and contrast reproduction that should enable protocol optimization, CT research and development.

### CLINICAL RELEVANCE/APPLICATION

quality control, protocol optimization, CT research

## W7-SSPH11-2 LOW-CONTRAST DETECTABILITY OF PHOTON-COUNTING-DETECTOR CT AT STANDARD AND ULTRA-HIGH-RESOLUTION MODES COMPARED TO ENERGY-INTEGRATING-DETECTOR CT

Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Lifeng Yu, PhD (*Abstract Co-Author*) Nothing to Disclose
Jarod Wellinghoff (*Abstract Co-Author*) Nothing to Disclose
Michael R. Bruesewitz, RT (*Abstract Co-Author*) Nothing to Disclose
Zhongxing Zhou, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon-counting-detector (PCD) CT has demonstrated advantages over energy-integrating-detector (EID) CT with its improved spatial resolution, enhanced iodine contrast-to-noise ratio, and reduced electronic noise. However, the low-contrast detection performance of PCD-CT in comparison with EID-CT remains unclear. The purpose of this work is to compare the low-contrast detectability of PCD-CT and EID-CT across different scan modes and kernels using a channelized Hotelling observer (CHO).

**METHODS AND MATERIALS**

A custom-designed phantom with objects of different contrasts (6, 10, 20, 30 HU) and sizes (3,6,9,12 mm) was scanned on a PCD-CT scanner (NAEOTOM Alpha, Siemens) using two modes: standard resolution (SR) (detector configuration: 144x0.4 mm) and ultra-high-resolution (UHR) (120x0.2 mm), and an EID scanner (Siemens SOMATOM Force), each at 3 dose levels (CTDIvol = 6, 12, and 24 mGy). The low-energy threshold ("T3D") image was used for PCD-CT. Each dose level was scanned 3 times at 120 kV. Images were reconstructed using both filtered-back-projection (FBP) and iterative reconstruction (IR) with a slice thickness of 3 mm and closely matched smooth (Br40), medium-sharp (Br56/Br54), and sharp (Br68/Br69) kernels. A previously optimized CHO method (3 repeated scans, 2 sets of background regions, and 4-channel Gabor filter) was used to calculate the low-contrast detectability (d') for each of the 12 objects, 3 dose levels, 2 scan modes, and 2 reconstruction conditions. A weighted average of d' over all lesion and dose conditions (12x3) was calculated for each scan mode and reconstruction condition, which was used as a summary metric to compare between PCD-CT and EID-CT.

**RESULTS**

For smooth kernel and FBP, significant differences in d' were found between and EID: EID>PCD-UHR>PCD-SR ($p<0.01$). For smooth kernel and IR, PCD-UHR had a higher d' over EID ($p<0.01$), but no significant difference was found between PCD-UHR and PCD-SR, or PCD-SR and EID. For medium-sharp kernel and FBP, EID had a higher d' than PCD-SR ($P<0.01$), but no significant differences were found between EID and PCD-UHR, or between PCD-UHR and PCD-SR. For medium-sharp kernel and IR, PCD-UHR gained higher d' than PCD-SR ($p<0.05$) and EID ($p<0.01$), but there was no significant difference between PCD-SR and EID. For sharp kernel, PCD-UHR and PCD-SR were both superior to EID for both FBP and IR ($p<0.01$).

**CONCLUSION**

PCD-CT demonstrated non-superiority with FBP and non-inferiority with IR in terms of d' compared to EID-CT for smooth kernel reconstructions. With increased sharpness, PCD-CT tends to show greater advantages in low-contrast detectability over EID-CT.

**CLINICAL RELEVANCE/APPLICATION**

PCD-CT significantly improves low-contrast detectability over EID-CT when a sharper kernel is used.

## W7-SSPH11-3 3D-PRINTED DEFORMABLE LUNG PHANTOM FOR RESPIRATORY MOTION APPLICATIONS IN CT

Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation

Sven Kabus, PhD (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Neghemi Micah (*Abstract Co-Author*) Nothing to Disclose
Kai Mei, PhD (*Abstract Co-Author*) Nothing to Disclose
Amy Perkins (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Jessica Im, BEng (*Presenter*) Nothing to Disclose

**PURPOSE**

Respiratory motion in 4-dimensional computed tomography (4DCT) reduces image quality and tumor tracking accuracy. Addressing these challenges requires advancements in technologies like respiratory gating and tumor tracking, necessitating more realistic respiratory motion phantoms (RMPs). Current lung RMPs are too simplistic and rigid, failing to replicate complex lung motion. This study introduces a lifelike, deformable lung phantom that accurately mimics lung deformations on CT.

**METHODS AND MATERIALS**

The lung phantom in this study was fabricated based on the end inhalation image of a patient 4DCT. The PixelPrint method was used to convert the image of the right lung to 3D-printer instructions, where density of printed material is continuously modulated to match the patient attenuation profile. This phantom was 3D-printed using a flexible thermoplastic polyurethane (TPU) material. A CT scan of the phantom was acquired, and its attenuation profile was compared to the patient. To assess the phantom's deformation characteristics, a simple linear compression device was designed. The phantom was compressed by various amounts between 0 - 14.8 mm in the superior/inferior (SI) direction, such that the displacements of the phantom's base matched the patient diaphragm displacements on 4DCT. The phantom was scanned at each compression level, and deformable image registration was used to quantify the displacements of structures in the phantom and patient.

**RESULTS**

The lung phantom exhibits realistic anatomic structures on CT imaging including the tumor, vessels, bronchi, and lung fissures. The attenuation profile measured across an axial slice of the phantom had a mean difference of 18 Hounsfield Units (HU) compared to the patient. Furthermore, displacements of several structures in the lung demonstrated mean errors of 0.5, 0.7, and 1.3 mm in the SI, right/left, and anterior/posterior directions compared to the patient. These fall within the size of about one voxel on the patient image, suggesting high accuracy in the phantom's ability to mimic lung deformations, especially in the SI direction.

**CONCLUSION**

This lung phantom has the potential to provide a more realistic testing environment for technologies addressing respiratory motion. Furthermore, the 3D-printing approach outlined in this study is highly customizable, which enables incorporation into different motion actuation systems, as well as development of patient-specific RMPs for personalized treatment planning.

**CLINICAL RELEVANCE/APPLICATION**

The introduction of this realistic, deformable lung phantom will enable more precise initial testing of technologies designed to address respiratory motion. This will speed up and improve the transfer of research findings to clinical settings.

## W7-SSPH11-4 IMAGE NOISE ANALYSIS OF TIN FILTERED-BASED SPECTRAL CT TECHNIQUE: A PHANTOM STUDY EVALUATING THE SIZE AND RADIATION DOSE DEPENDENCY

Colin Shan (*Abstract Co-Author*) Nothing to Disclose
Xinhui Duan, PhD (*Abstract Co-Author*) Nothing to Disclose

Liqiang Ren, PhD (*Abstract Co-Author*) Nothing to Disclose
Yue Zhang, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the dependency of phantom size and radiation dose of a tin-filtered spectral shaping CT technique on image noise.

**METHODS AND MATERIALS**

ACR CT accreditation phantom (20cmX20cm) and two body rings (33cmX26cm and 40cmX30cm) were arranged to simulate three patient sizes from small to large, and scanned on a dual-source dual-energy CT (SOMATOM Force, Siemens) in single-energy mode at 120kV, Sn100 kV and Sn150 kV (Sn: tin; thickness: 0.6mm). The initial radiation dose levels (CTDIvol) were determined as 3, 8, and 12 mGy for the three phantoms, respectively, and matched for the three kVs. Except that Sn100 kV was not able to reach 12 mGy. So for 40cm phantom, 6 and 3 mGy were used with Sn100 kV. All scans were repeated at 50% and 25% of the initial dose levels, namely 1.5 and 0.75 mGy, 4 and 2 mGy, and 6 and 3 mGy for small, medium, and large phantoms, respectively. All images were reconstructed using an iterative reconstruction algorithm (ADMIRE-3), a regular body kernel (Br44) at slice thickness/increment of 1mm x 0.5mm, and a fixed filed-of-view of 210mm. The reconstructed CT images were uploaded to CTPro (ctpro.net; a web-based software platform for CT image quality evaluation and radiation dose optimization). The uniformity module of ACR CT phantom was selected for noise evaluations including noise magnitude and two-dimensional noise power spectrum (NPS) using the NPS software tool in CTPro. For each measurement, 12 square region-of-interests (ROIs) were placed on each slice and repeated for the central 50 consecutive slices.

**RESULTS**

For both small and medium phantoms, NPS curves demonstrated that Sn100 and Sn150 kV decreased the noise level at all spatial frequencies compared to 120 kV scans at all matched dose levels. For 40 cm phantom, NPS curves showed that, at the same dose level, Sn150 kV had a decreased noise level at lower spatial frequencies, while increased at higher spatial frequencies. Compared to 120 kV, Sn100 kV decreased the overall noise levels by 10-18%, 23-34%, 16-25% for small, medium, and large phantoms, whereas Sn150 kV decreased by 3-6% and 11-12% for small and medium phantoms. Sn150 kV decreased the noise by 4% and 5% for 12 mGy and 3 mGy, but increased by 6% for 6 mGy of the large phantom.

**CONCLUSION**

The noise reduction performance of the tin-filtered spectral shaping CT technique is size and dose dependent, and Sn150 kV can potentially increase the noise for large sizes.

**CLINICAL RELEVANCE/APPLICATION**

The use of the additional filter can achieve more noise reduction with a lower tube potential (e.g., 100 kV versus 150 kV) and the Sn150 kV may be dose inefficient when it is used for larger patients.

Joshua Levy (*Presenter*) Stockholder, The Phantom Laboratory;President, The Phantom Laboratory ;Stockholder, Image Owl, Inc;CEO, Image Owl, Inc;

**PURPOSE**

To evaluate the reproducibility of CT texture analysis (CTTA) metrics extracted from CT images of a 3D printed phantom with varying textural heterogeneity placed within an anthropomorphic liver phantom (Phantom Laboratory, NY) and imaged across two different CT vendors.

**METHODS AND MATERIALS**

Scans were acquired on a Siemens Somatom Definition Flash CT scanner (conventional bore) and a 16 cm detector GE Revolution Apex Edition CT scanner, respectively, with variations across slice thicknesses (0.6mm, 1.5mm, 3mm), dose levels (CTDIvol of 13.86 mGy standard, 40% reduction and 60% reduction), tube voltages (100 kVp and 120 kVp), and reconstruction methods (filtered back projection and iterative method). By varying these parameters, 18 distinct volumetric CT images were acquired. Manual segmentation was performed to identify 7 circular volumes of interest (VOIs)—in the liver phantom, these were contoured around the seven 3D-printed texture inserts. Feature extraction was performed using Pyradiomics' open-source software to obtain 57 features belonging to 6 subgroups of texture extraction methods. The intra-class correlation coefficient (ICC) of 2-way random/mixed* model was used to assess the consistency between the CTTA values acquired across the two CT vendors and imaging/ reconstruction protocols. A heat map was constructed to identify reproducible radiomic metrics across the various settings.

**RESULTS**

While a total of 34.34% features showed good reproducibility (ICC3.1 = 0.6), only 5.64% features showed an ICC3.1= 0.8. Of the six texture subgroups, first-order metrics such as intensity and histogram showed better reproducibility than others. Of the neighborhood-based texture subgroups, graylevel co-occurrence matrix approach showed better reproducibility than the other approaches. Among imaging variables, changes in slice thickness affected all metrics more intensely compared to other imaging variables in reducing the ICC3.1.

**CONCLUSION**

CT vendor/protocols impact different CT texture metrics differently. For example, some CTTA metrics, especially those from neighboring gray tone difference matrix (NGTDM) family, lack reproducibility across CT vendors.

**CLINICAL RELEVANCE/APPLICATION**

Identifying reproducible CTTA metrics from the large radiomic feature set reduces feature dimensionality errors, mitigates overfitting, and reduces the chances of erroneous conclusions in multisite radiomic studies.

## W7-SSPH11-6 THE COLOR OF CLARITY: X-RAY ENERGY AND ITS IMPACT ON SPATIAL RESOLUTION IN PHOTON COUNTING CT

Ke Li, PhD (*Abstract Co-Author*) Research Consultant, Pulmera Inc.
Guang-Hong Chen, PhD (*Abstract Co-Author*) Nothing to Disclose
Linying Zhan, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon counting detector CT (PCD-CT) is widely acclaimed for its superb spatial resolution. This study extends beyond traditional comparisons with energy integrating detector CT (EID-CT) to examine a novel aspect of PCD-CT: the significant influence of x-ray energy on spatial resolution. This parameter can be analogously described as the 'color' of x-rays, introducing a color dimension to spatial resolution analysis. The study also aims to pinpoint whether the noted improvements in resolution with PCD-CT are predominantly attributable to the photon counting mechanism or to a sophisticated interaction with the spectral characteristics of x-ray energy.

**METHODS AND MATERIALS**

Pre-sampling MTF of a CdTe-based direct conversion PCD (0.1 mm pixel pitch) were experimentally measured at 13 different energy thresholds ranging from 5 to 60 keV. At each threshold, the measurement was repeated 1000 times to establish uncertainty range. The obtained experimental data served as validation for a detector model capable of estimating MTF across arbitrary energy thresholds. By eliminating low energy thresholding and applying photon energy-based weighting, the detector model effectively simulates the transformation of the PCD into a direct conversion EID with matching sensor thickness, bias voltage, and pixel pitch. Subsequently, we measured the MTF of this EID and compared it against the MTF of the original PCD.

**RESULTS**

The spatial resolution of the PCD consistently improves as the energy threshold level increases, particularly when set above 25 keV to reject reabsorbed K-fluorescence photon signals. Across energy threshold levels of 5, 15, 25, 40, and 60 keV, the measured MTF50 values for the PCD are 3.1±0.04, 3.2±0.02, 3.3±0.02, 4.0±0.08, and 4.4±0.1 lp/mm, respectively; the MTF10 values are 6.3±0.04, 6.6±0.04, 6.8±0.07, 7.4±0.1, and 7.9±0.06 lp/mm, respectively. In comparison, utilizing the CdTe direct-conversion detector in EID mode yields an MTF50 of 3.1 lp/mm and an MTF10 of 6.2 lp/mm.

**CONCLUSION**

This study establishes that the spatial resolution of PCD-CT significantly improves with higher x-ray energy thresholds, highlighting the profound impact of x-ray 'color' on spatial resolution. The observed spatial resolution enhancements in MTF50 and MTF10 values confirm that PCD-CT's superior performance is intricately linked to both the photon counting mechanism and its interaction with x-ray spectral characteristics. This dual influence suggests promising avenues for advancing CT imaging through spectral optimization.

**CLINICAL RELEVANCE/APPLICATION**

This study elucidates the core advantages of using PCDs for high-resolution clinical CT imaging applications and suggests promising avenues for advancing CT imaging through spectral optimization.

## W7-SSPH12-1 EVALUATING SPATIAL-TEMPORAL IMAGE QUALITY AND DOSE IN ANGIOGRAPHY WITH MONTE CARLO SIMULATIONS: WOULD A NEW ANTISCATTER GRID PROTOTYPE WITH LARGE AIR GAP INCREASE STAFF AND PATIENT EFFECTIVE DOSES?

Hilde Bosmans, PhD (*Abstract Co-Author*) Stockholder, Qaelum NV;Research Grant, Siemens AG;Research Grant, General Electric Company
Nicholas Marshall (*Abstract Co-Author*) Nothing to Disclose
Rodrigo T. Massera, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

A new high-ratio antiscatter grid (ASG) for cardioangiography requires a source-to-detector distance (SID) of 120 cm. This increases geometric magnification and removes the image receptor from the patient exit plane, potentially impacting operator protection. This work studied the impact increased SID on staff effective dose and system performance using a task-based figure of merit.

### METHODS AND MATERIALS

A validated optimization framework for angiography procedures combining analytical calculations and Monte Carlo (MC) simulations (modified PENELOPE/penEasy) was implemented. Mathematical (ORNL) and voxelized (ICRP 110/male) anthropomorphic phantoms represented the patient and physician, respectively. Patient thorax thickness was 28 cm. The physician, protected with lead apron and glasses, ceiling shield and table shield, was positioned at the femoral artery access point. Image quality was quantified with a signal-to-noise ratio (SNR(u)) weighted by MTF-based factors to describe the effect of object size and geometric blurring from patient motion and focus size. The optimization was performed by maximizing a Figure of Merit (FOM) defined as SDNR(u)2/D where D was alternatively the patient incident air kerma, patient effective dose or operator effective dose. The x-ray beam was collimated at the chest of the patient, positioned at the isocenter, 75 cm from the source. Optimal x-ray technique factors (exposure time, tube current, kV and additional filtration) to reach a target $SDNR^2(u)$ value. Tube potential was varied from 40 to 120 kV, and spectral filtration from 0.0 to 0.9 mm Cu. Scenario A modelled standard current technique, with a 105 cm SID, field-of-view (FOV) of 22 cm and ASG of ratio (r) 15 and frequency (f) 80 cm-1, while scenario B modelled a 120 cm SID (airgap of 29 cm), 25 cm FOV and new ASG with r=29 and f=80 cm-1.

### RESULTS

For the same x-ray tube parameters (kV, filtration and mAs), scenario B resulted in a 2% higher staff effective dose, on average, than scenario A. However, when the x-ray tube parameters (considering its limitations) were optimized for incident air kerma and adjusted to provide the target image quality value, scenario B respectively reduced incident air kerma and staff doses up to 24% and 16%, respectively.

### CONCLUSION

Optimized exposure parameters for a new high-ratio antiscatter grid with a longer SID reduced patient and staff doses for the angiography application considered. The increased air gap between patient and detector used with the new grid did not result in higher patient or staff doses.

### CLINICAL RELEVANCE/APPLICATION

Lower staff and patient doses could be achieved for the same image quality if an optimized SID and antiscatter grid is used in angiography systems.

## W7-SSPH12-2 ORGAN-SPECIFIC COMPARISON OF IMAGING AND THERAPEUTIC DOSES FROM YTTRIUM-90 RADIOEMBOLIZATION

Stephanie Leon, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Oliver Paucar (*Abstract Co-Author*) Nothing to Disclose
Dante E. Roa, PhD (*Abstract Co-Author*) Nothing to Disclose
Edmond Olguin, PhD (*Abstract Co-Author*) Nothing to Disclose
Andres Gonzales Galvez (*Abstract Co-Author*) Nothing to Disclose
Terrance Moretti, PhD, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Patients receiving Yttrium-90 Transarterial Radioembolization (TARE) undergo at least two interventional imaging procedures, the first for treatment planning and the second for administration of the microspheres. These procedures may exceed multiple Gy in dose to the reference point, but are not

typically considered in treatment planning. Dose concerns are elevated for patients who receive multiple Y90 treatments, which further increases the cumulative imaging dose, potentially pushing certain doses above thresholds for deterministic effects. This work evaluates the organ doses from the imaging and therapeutic components of TARE and compares their magnitudes.

**METHODS AND MATERIALS**

With IRB approval, ten TARE patients treated for hepatocellular carcinoma were selected for retrospective image-based dosimetry. All patients had received imaging in one interventional suite for which a previously-validated Monte Carlo (MC) model existed. Voxelized models of these patients were subjected to simulated irradiation conditions which matched those recorded in the radiation dose structured reports for both imaging procedures for one Y90 treatment. The pre-treatment planning SPECT/CT was used as the Y90 source model. All doses were summed on a per-voxel level. Doses were assessed by imaging acquisition mode (fluoroscopy, DSA, or CBCT) and percentage of total from Y90. Relative contributions were broken down for several potential organs-at-risk.

**RESULTS**

Within the liver, more than 95% of the dose came from Y90 on average across all patients. Outside of the liver, the mean percentage contribution of Y90 to total dose ranged from 26% to 94%. Lung dose was much more dependent on relative position of the tumor than the dose calculated during treatment planning. The largest imaging dose contribution overall was from DSA (14.7%), followed by fluoroscopy (9.3%), and CBCT (7.4%).

**CONCLUSION**

For a single administration of Y90, no patient received a lung dose from imaging which would cause a TARE dose threshold to be reached or exceeded, but for patients receiving multiple administrations, these thresholds may be crossed. Imaging dose to other structures was not at levels warranting concern for a single TARE treatment, but patients receiving multiple TARE treatments should be given extra consideration, particularly if the doses to these other structures are high from the microsphere treatment.

**CLINICAL RELEVANCE/APPLICATION**

The addition of imaging dose to the therapeutic dose from TARE may explain clinical cases of radiation pneumonitis in patients near the threshold for deterministic effects calculated from the microspheres. Understanding the largest contributions to imaging doses can help interventionalists apply dose-saving measures more effectively.

## W7-SSPH12-3 COMPARISON OF STANDARD BREAST DOSIMETRY PROTOCOL WITH NEW APPM-TG282 METHODOLOGY BY USING BREAST COMPOSITION DATA FOR A SCREENING POPULATION

Ioannis Delakis, MSc, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the new breast dosimetry methodology presented by the American Association of Physicists in Medicine (AAPM) Task Group (TG) 282 with the standard breast dosimetry protocol, by using breast composition information derived from digital mammography screening exams.

**METHODS AND MATERIALS**

The study included over 20,000 mammography exams performed at breast screening clinics equipped with Full-Field Digital Mammography (FFDM) systems of two different vendors at each site. All images were analyzed using the Volpara software to determine breast glandularity. The Average Glandular Dose (AGD) for each exposure was calculated using client-specific volumetric breast density and applying the standard breast dosimetry protocol (Dance model) and the new dosimetry methodology presented by AAPM TG282. This provided individualized AGD values for each dataset, one for each methodology. The calculation was repeated without using client-specific breast glandularity information but instead using the median breast density assumed by each dosimetry methodology for the screened individual's age and breast thickness. This provided conventional AGD values for standard and AAPM TG282 methodologies.

**RESULTS**

The ratio of conventional-to-individualised AGD values calculated using the standard breast dosimetry protocol showed positive correlation with breast thickness (Pearson Correlation Coefficient: 0.55-0.65) indicating that individualised AGD is higher than conventional AGD in smaller breasts with the effect reversed above approximately 80mm breast thickness. On the other hand, the ratio of conventional-to-individualised AGD using the AAPM TG282 model showed no dependence on breast thickness (Pearson Correlation Coefficient: <0.1). These results, which were independent of the FFDM vendor and were consistent across sites, can be explained by the different breast glandularity assumptions in each method, with the AAPM TG282 providing a closer approximation of the breast density distribution seen in our screening population than the standard breast dosimetry protocol.

**CONCLUSION**

Individualised AGD calculations for our breast screening population demonstrated that the AAPM TG282 breast dosimetry methodology can provide a better estimation of AGD than the standard breast dosimetry protocol. Using client-specific volumetric breast density can also be a useful tool to further tailor AGD calculations, albeit with the limitation of not considering glandular tissue spatial distribution.

**CLINICAL RELEVANCE/APPLICATION**

The choice of AGD calculation method for breast exams can result in differences due to the different breast density models used. This is critical in risk-benefit analysis and radiation dose optimization for breast exams.

## W7-SSPH12-4 PEAK SKIN DOSE CALCULATOR FOR PATIENTS UNDERGOING RADIOGRAPHY AND FLUOROSCOPY

Choonsik Lee, PhD (*Abstract Co-Author*) Nothing to Disclose
Haegin Han, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The NCIRF software, developed by the National Cancer Institute, provides a user-friendly tool for assessing organ and effective doses for patients undergoing radiography and fluoroscopy. The software performs Monte-Carlo particle transport simulations, considering the X-ray spectrum, C-arm position, and patient-specific characteristics, such as age and sex, to deliver accurate dose calculations. However, it lacks the ability to evaluate peak skin dose (PSD) and skin dose distribution, which are of crucial interest. This study aimed to develop and integrate a module for evaluating PSD and skin dose distribution into the NCIRF software.

**METHODS AND MATERIALS**

For calculating skin dose distribution, voxel-wise radiation doses for skin voxels were computed by incorporating NCIRF phantoms into the Geant4 simulation toolkit. To avoid overestimating PSD due to high uncertainty in individual voxel measurements, in the present study, a dedicated algorithm was

developed. A 2D heat map of skin dose distribution for the front and back sides of the phantom was generated and processed using an iterative procedure that employed image smoothing and noise assessment techniques. That is, the heat map was smoothened until the noise level reaches the empirically decided value. Then, the highest dose on the heat map was identified and selected to represent the PSD.

**RESULTS**

The methodology was applied to four cases varying in peak voltage, phantom ages, and exposure levels. It successfully mapped skin dose distributions and yielded PSD estimates that aligned with those from large particle number (1010) simulations with the error of the highest voxel-wise dose lower than 1%: for the simulation with the particle number of 105 and 106, the differences were at most 9% and 1%, respectively. Note that when Tested on a MacBook M2, simulation times for the particle number of 106 were less than 10 seconds.

**CONCLUSION**

The new NCIRF module offers PSD calculation via Monte-Carlo simulation, providing a precise and accessible measurement method. The module's user-friendly interface and capability to consider specific dose calculation conditions allow users of all expertise levels to estimate PSD and skin dose distributions under varied exposure scenarios. This aids large-scale epidemiological research and offers a valuable resource for investigating PSD-related skin injuries in fluoroscopic procedures.

**CLINICAL RELEVANCE/APPLICATION**

The integration of Monte-Carlo simulations with NCIRF provides an accurate and time-efficient approach for estimating PSD and skin dose distribution in fluoroscopic procedures, assisting clinicians and researchers in assessing potential radiation-induced skin injuries and enabling better patient care.

## W7-SSPH12-5 TYPICAL DOSE VALUES FOR PRE-Y90 HEPATIC ARTERIAL MAPPING PROCEDURES PERFORMED IN A HYBRID CT-ANGIO SUITE

Manuel M. Arreola, PhD (*Abstract Co-Author*) Nothing to Disclose
Bryan C. Schwarz, PhD (*Abstract Co-Author*) Nothing to Disclose
Emily Marshall, PhD (*Abstract Co-Author*) Scientific Advisory Board, Bayer AG;Consultant, Bayer AG;Scientific Advisory Board, Radimetrics Dosimetry Services;Consultant, Radimetrics Dosimetry Services
Megan Glassell, PhD (*Abstract Co-Author*) Nothing to Disclose
Daniella Fabri, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Integration of hybrid imaging modalities, such as CT and fluoroscopy, has become increasingly prevalent in clinical practice. Understanding the typical dose values (TD) and procedure details for these hybrid procedures is essential for optimizing patient safety, ensuring efficient workflow, and maintaining diagnostic and treatment accuracy.

**METHODS AND MATERIALS**

A retrospective analysis was conducted, 629 cases from a CT-Angio suite from 01/2023 to 09/2023. The most frequently hybrid performed procedure (i.e. cases utilizing Angio and CT during the procedure) in this suite, were pre-Y90 hepatic arterial mappings, thus a sub-analysis was performed on this procedure type. Dose and procedural data were retrieved utilizing the institutional dose management system, supplemented by information from PACS where necessary. With case-specific information, an estimate of pre-Y90 hepatic arterial mapping TD values were made. The ICRP's TD corresponds to the median value of a dose parameters distribution. TD values include CTDIvol, DLP, DAP, cumulative air kerma (CAK), fluoroscopy peak skin dose (PSD), CT PSD, and an estimation of the cumulative PSD. CT PSD was estimated using a previously validated relationship between CTDIvol and entrance skin dose from CT.

**RESULTS**

A total of 86 cases of pre y-90 mappings were included (8 of them PSD information was missing), corresponding to 14% of total cases and 53% of hybrid cases . A median of 78.5 irradiation events (32 to 228) were performed in the included cases and 9 CT (2-22) acquisitions. These cases had a TD CTDIvol of 93 mGy (23.4mGy - 250.3mGy), DLP of 1657 mGycm (375 mGycm-8668 mGycm), DAP of 1142.84 mGycm2 (547.92 mGycm2 - 9422.8mGycm2), and CAK of 1142.8 mGy (275.2 mGy - 4946.5 mGy). The typical fluoroscopy PSD was 1030 mGy (170 mGy - 4320 mGy) and a CT PSD of 178.59 mGy (44.87 mGy -480.68 mGy). The typical cumulative PSD was 1240 mGy (270mGy - 4660) mGy.

**CONCLUSION**

We offer a comprehensive analysis of typical doses for pre-Y90 hepatic arterial mapping in a hybrid CT-Angio suite. By examining a case dataset, we clarified fluoroscopic irradiation and CT acquisitions, contributing to efforts in comparing imaging outcomes and enhancing patient safety in hybrid imaging.

**CLINICAL RELEVANCE/APPLICATION**

Integration of hybrid imaging has transformed healthcare procedures. This study's insights into typical dose values for pre-Y90 hepatic arterial mapping in a hybrid CT-Angio suite are clinically significant, offering valuable guidance to healthcare practitioners. This information not only allows for the refinement of techniques and minimization of patient radiation exposure but also supports informed resource allocation to enhance procedures with clear added benefits of the angio-CT capabilities within the Hybrid room.

## W7-SSPH12-6 USEFULNESS OF DOSE REDUCTION AT HIGH-KVP TECHNIQUE ON CHEST X-RAY: COMPARISON OF 26 ORGANS BASED ON ICRP

Youngseok Ji, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Chest X-ray Radiography is a high proportion of overall radiography, and its high importance in diagnosis. Many studies, such as the use of additional filters, are being conducted to reduce the radiation dose, and the High-kVp Technique is actively used in clinical practice because it has the advantage of reducing the radiation dose by shortening the exposure time. Chest AP (Ch-AP) is generally adopted when Chest PA (Ch-PA) is not possible, however there has been no study analyzing the exact difference in dose from the perspective of radiation exposure dose for each organ of the human body. Therefore, this study aims to present quantitative results by comparatively analyzing the doses to 26 organs, focusing on Ch-PA (High-kVp) and Ch-AP (General kVp).

**METHODS AND MATERIALS**

Monte Carlo N-Particle Transport Code (MCNP6, Los Alamos National Security) was used to measure the dose for each organ (26 ea), and human phantom used a computational phantom (HDRK; High-Definition Reference Korean-Man) (Figure 1). For normalization of simulation and actual data, DAP

(Dose Area Product) value from stational X-ray (GC85A, Samsung Electronics) and Mobile X-ray (GM85, Samsung Electronics). Parameters were based on our institution that meet domestic and international Chest-DRLs. Ch-PA was 125 kVp / 2 mAs, SID (180 cm), and FOV (17x17 inch). Ch-AP was 75 kVp / 4 mAs, SID (110 cm), and FOV (17x17 inch). Human organs were comparatively analyzed based on 26 organs specified in ICRP Publication 103 (Table 1).

**RESULTS**

The total dose (26 organs) of Ch-PA and Ch-AP was calculated to be 0.18 mSv and 1.15 mSv, respectively. It was confirmed that the dose of Ch-PA applied High-kVp was 15.65% compared to Ch-AP. However, Certain organs of Ch-PA showed higher doses than Ch-AP; Lung (1.17 μSv, 1.6 times higher), Esophagus (0.25 μSv, 3.0 times higher), Thyroid (0.21 μSv, 4.4 times higher), Adrenal (0.18 μSv, 1.1 times higher), Kidney (0.34 μSv, 1.3 times higher). Brain and Thymus showed the same dose of 0.01 μSv, 0.03 μSv, respectively. In the other 19 organs, Ch-AP showed a high dose (Figure 2).

**CONCLUSION**

Ch-PA applied with High-kVp showed an 84.35% dose reduction from Ch-AP. However, since higher doses were confirmed in seven organs than Ch-AP, High-kVp Technique did not show a dose reduction in all organs.

**CLINICAL RELEVANCE/APPLICATION**

It is known that Monte-Carlo is the most realistic method to measure doses for each organ, and this study increased reliability by combining actual DAP data. In addition, this is the first study to model a realistic wall-bucky stand to reflect the clinical situation, thus organ dose also includes scattered X-ray from detector materials.

## W7-STCE1-1 IMPLEMENTATION, FEASIBILITY, AND POSSIBILITIES OF LOW-FIELD MAGNETIC RESONANCE IMAGING: EXPERIENCES FROM PAKISTAN

Latika Giri (*Abstract Co-Author*) Nothing to Disclose
Saroj Jha (*Abstract Co-Author*) Nothing to Disclose
Muhammad Umair, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the feasibility, implementation, and clinical relevance of low-field Magnetic Resonance Imaging (LF MRI) in Pakistan, focusing on its potential to improve healthcare accessibility and quality in resource-limited settings.

### METHODS AND MATERIALS

We analyzed cases performed at the low field MR systems (<=0.5 Tesla) in a multicentric imaging practice in Pakistan (a few case studies are included here for reference) from neurological, musculoskeletal, and abdominal imaging for the quality and clinical relevance. Data on scanner models, patient outcomes, and diagnostic accuracy were collected for the reported cases. Additionally, advancements in LF MRI technology and its application in cardiovascular magnetic resonance (CMR) imaging were reviewed from the existing literature.

### RESULTS

LF MRI demonstrated adaptability across various clinical scenarios, with acceptable imaging quality and diagnostic outcomes. Despite lower SNR, advanced image reconstruction techniques provided sufficient diagnostic quality. Key findings include:
- Neurological imaging Effective identification of structural abnormalities with reduced artifacts and improved patient comfort due to lower acoustic noise levels.
- Musculoskeletal Imaging Enhanced imaging of ligaments and cartilage, resulting in improved T2 contrast.
- Abdominal Imaging Adequate visualization of the abdominal organs, with optimized pulse sequences compensating for lower field strengths. LF MRI scanners, including Hitachi Airis II (0.3T), Hitachi Aperto (0.4T), Hitachi Aperto Inspire (0.4T) and GE Signa Profile (0.2T), provided diagnostic images of acceptable quality for clinical decision-making. Urban centers had better LF MRI coverage compared to rural areas, highlighting a disparity in access.

### CONCLUSION

LF MRI enhances diagnostic imaging in LMICs, addressing healthcare disparities caused by limited access to high-field MRI. Successful integration in Pakistan demonstrates its potential to provide cost-effective, reliable diagnostic imaging. Technological advancements, such as improved gradient systems and advanced reconstruction techniques, mitigate challenges associated with lower SNR and longer scan times.

### CLINICAL RELEVANCE/APPLICATION

LF MRI offers a practical and accessible imaging alternative for LMICs, delivering reliable diagnostic information at a lower cost and with fewer technical complexities. Its implementation in Pakistan highlights its potential to improve healthcare outcomes, particularly in underserved areas. This early investigation supports the broader adoption of LF MRI to bridge the healthcare gap in Pakistan's healthcare ecosystem and other resource-constrained regions, promoting equitable access to advanced diagnostic imaging.

## W7-STCE1-2 INITIAL STUDY FOR FEMALE PELVIC PHANTOM IN LOW-FIELD (60MT) MRI SYSTEM

Selin Chiragzada (*Abstract Co-Author*) Nothing to Disclose
Hiya Ghosh (*Abstract Co-Author*) Nothing to Disclose
Dinesh Kumar, PhD, MBA (*Abstract Co-Author*) Nothing to Disclose
Jae Eun Song, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Low-field MRIs are gaining popularity as they provide the added benefit of MR imaging with easy accessibility for patients and physicians. Promaxo MRI is a commercial interventional MR system for surgical localization of prostate cancer. This paper presents early phantom results using the Promaxo single-sided low-field MRI system for female pelvic imaging.

### METHODS AND MATERIALS

Phantom Experiments: The female pelvic phantom was developed using 3D printed structures derived from a high-resolution MRI of a 25-year-old cis-female woman using Avizo and Blender processing. The hollowed out structures corresponding to the anatomy were filled with five different materials based on the T2 contrast of the materials. Bladder, rectum, uterus, vagina, and coccyx were filled with filtered water, mineral oil, olive oil, silicone oil, and

10mM $CuSO_4$, respectively. Acquisition and Reconstruction: Promaxo's single-sided low-field (60mT) MRI system was used to image the phantoms and a standard 2-channel receive coil. The sequence has echo train length varying from 8 to 12 echoes, a TR = 1.45 sec, and with an echo spacing varying from 5.4 to 3.2 millisecs. Images were reconstructed with 1.5 mm x 1.5 mm in plane resolution, an effective field of view of 180 mm x 180 mm x 100 mm, and a slice thickness of 2.75 mm. The reconstruction was performed using an iterative, conjugate gradient least square (CGLS) method with Tikhonov regularization.

## RESULTS

The female pelvic phantom shows different T2 contrasts for different compartments. The dimensions of the bladder and uterus were measured from the 3D printed phantom and the low-field MR image. The low-field MR image was segmented using Slicer software. The error of the low-field MR image was less than 10% for both organs (5.5±3.5) with slice thickness, partial volume effect, and operator variability as potential sources of error.

## CONCLUSION

We present results for female pelvic imaging with a low-field MRI system using a phantom constructed based on real human data. For future work, we will extend imaging to female patients diagnosed with pelvic disease.

## CLINICAL RELEVANCE/APPLICATION

Our ability to visualize female pelvic organs is useful for the diagnosis of female pelvic conditions, such as pelvic organ prolapse (POP). POP often goes undiagnosed until symptoms begin to appear, and diagnosis usually involves a simple pelvic exam and an assessment of the patient's symptoms. While there are existing protocols for diagnosis and staging of POP using MRI, they are rarely used due to costs and inaccessibility to conventional MRIs. An office-based MRI system would allow patients to get scanned during a routine check-up and enable earlier diagnosis of POP.

## W7-STCE2-1 A NOVEL METHOD FOR SYNTHESIZING HIGH-RESOLUTION 3D FLAIR BRAIN MR IMAGES BASED ON CLINICAL LOW-RESOLUTION 2D IMAGES

Zechen Zhou (*Abstract Co-Author*) Nothing to Disclose
Zheng Zhang (*Abstract Co-Author*) Nothing to Disclose
Yuehua Li (*Abstract Co-Author*) Nothing to Disclose
Xin-Yu Song (*Abstract Co-Author*) Nothing to Disclose
Lei Xiang (*Abstract Co-Author*) Nothing to Disclose
Thomas C. Arnold, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

3D high-resolution (HR) MR imaging is a useful tool for lesion detection. However, routine clinical practice often favors the acquisition of low-resolution (LR) 2D images to minimize scanning time. This study proposes a deep learning network for synthesizing HR 3D fluid-attenuated inversion recovery (FLAIR) images from LR 2D acquisitions, and evaluates the image quality of the synthesized images.

### METHODS AND MATERIALS

This retrospective study included 60 patients who underwent multimodal 3T brain magnetic resonance imaging, dividing them into a training set of 50 patients and a test set of 10 patients. Utilizing our developed 2.5D-based Visual State Space (VSS) model depicted in Fig. A, we input 2D LR FLAIR sequences and 3D high-resolution time-of-flight magnetic resonance angiography images to synthesize HR FLAIR images. Quantitative metrics were used to evaluate the quality of the synthesized HR FLAIR images (Syn-HR FLAIR). Additionally, two experienced radiologists independently rated the visual quality of images in axial and coronal planes on a three-point scale (1 = poor; 2 = modest; 3 = good). The efficacy of Syn-HR FLAIR images was assessed by comparing the visual quality scores of gray-white matter interface and lesion resolution, as well as quantitative measurements of lesion volume, among LR FLAIR, Syn-HR FLAIR, and real HR FLAIR images.

### RESULTS

The Syn-HR FLAIR images accelerated the scan time by 12 fold (2D FLAIR:28s, 3D FLAIR:342s) on average and showed high similarity to real HR FLAIR images as shown in Fig. B (normalized mean absolute error, 0.013 for the test set; peak signal-to-noise ratio, 32.06 dB; structural similarity, 0.936). The visual score (VS) of Syn-HR FLAIR was comparable to real HR FLAIR in both planes (gray-white matter interface: $P > 0.99$ and $P > 0.99$, respectively; lesion resolution: $P = 0.10$ and $P = 0.06$) and significantly better than LR FLAIR ($P < 0.05$). Lesion volumes were smaller in LR images compared to Syn-HR images (Mean of differences = $2.5 \pm 1.8$; $P < 0.001$), with both being smaller than in HR images as shown in Fig. D and E.

### CONCLUSION

The proposed deep learning model can accurately synthesize 3D HR FLAIR images comparable to acquired 3D HR FLAIR images, providing an efficient method to obtain HR images for either prospective brain protocol acceleration or retrospective resolution enhancement.

### CLINICAL RELEVANCE/APPLICATION

The proposed image synthesis method allows reconstruction of 3D HR brain images from rapid 2D scans and supports downstream quantitative volumetric analysis for lesions, which largely improves the scan efficiency while maintaining the diagnostic quality.

## W7-STCE2-2 IMPROVING GENERALIST SCREENING MAMMOGRAM PERFORMANCE WITH SUSTAINABLE AI-DRIVEN TARGETED REVIEW

Bryan Haslam, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Jiye G. Kim, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Leeann Louis, BS, PhD (*Abstract Co-Author*) Researcher, RadNet, Inc
Edgar Wakelin (*Abstract Co-Author*) Nothing to Disclose
Matthew McCabe, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

A major challenge in screening mammography (MG) is variability in interpretation quality. Radiologists who specialize in breast imaging (Specialists) have higher cancer detection rates (CDRs) than other radiologists (Generalists). Generalists therefore represent a greater risk of missed cancer diagnosis. In order to sustainably mitigate this risk, we developed an AI-driven review workflow to efficiently allocate specialist resources to exams most at risk for cancer. We evaluated the ability of this workflow, termed “Safeguard Review” (SR), to improve performance statistics of Generalists and Specialists.

### METHODS AND MATERIALS

In the SR program, MGs were interpreted by a primary radiologist. An FDA-cleared breast cancer AI model also evaluated MGs and assigned a cancer suspicion score. If an exam was scored by the AI in the top 8% of cancer suspicion, but the primary radiologist did not recall the patient, the exam was routed to a Specialist for review. We evaluated the impact of this program on the performance of 10 radiologists (6 Specialists, 4 Generalists; "Specialist" defined as a Radiologist for whom >75% of their workload during the study period was breast imaging) who collectively read 36,444 screening MGs between July 2021 and May 2022. Performance was assessed using recall rate (RR), cancer detection rate (CDR), and positive predictive value of recalls (PPV1), and results were compared without and with SR. Statistical analysis was performed by bootstrap resampling exams.

### RESULTS

Out of 36,444 MGs, 2,208 went through SR (6%). There were 2,935 recalls (123 from SR; 4%) and 248 cancers (41 from SR; 17%). Without SR, Generalists were comparable to Specialists in RR (G: 7.12, S: 7.79, p=0.067), but significantly worse in CDR (G: 3.27, S: 5.98, p = 0.007) and PPV1 (G: 4.59, S: 7.67, p=0.016). We found that the relative impact of SR on CDR was significantly greater for Generalists (76% increase; 95% CI: 23-167%) than for Specialists (16.6% increase; 95% CI: 10.6-23.5%, p = 0.007). We similarly found that the relative impact of SR on PPV1 was significantly greater for Generalists (65% increase; 95% CI: 19.1-134.7%) than for Specialists (11.9% increase; 95% CI: 6.8-17.5%, p = 0.006). Further, we found the Generalists and Specialists with SR did not differ significantly on any metric (RR: G: 7.55, S: 8.12, p=0.093; CDR: G: 5.53, S: 6.96, p=0.135; PPV1: G: 7.33, S: 8.58, p=0.231).

### CONCLUSION

The SR program is a sustainable approach to improving radiologist performance in which generalist radiologists report the greatest improvement while only reviewing 6% of exams.

### CLINICAL RELEVANCE/APPLICATION

"Safeguard Review" sustainably improved Generalist radiologist performance to that of a Specialist.

## W7-STCE2-3 ENGAGING A MULTIDISCIPLINARY GREEN RADIOLOGY COMMITTEE IN ANNUAL GOAL PLANNING TO DRIVE ACTIONS FOR SUSTAINABLE AND IMPACTFUL CHANGE MANAGEMENT

Hayley Panet (*Abstract Co-Author*) Nothing to Disclose
Kate Hanneman, MD, MPH (*Abstract Co-Author*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Ania Kielar (*Presenter*) Nothing to Disclose

### PURPOSE

Health care contributes over 5% of total global greenhouse gas (GHG) emissions. Within the hospital setting, medical imaging departments are one of the largest contributors. An essential driver for change management is staff engagement. The role of an interdisciplinary Green Radiology program has been to set direction and influence collaboration to advance sustainability and impact. Therefore, we sought to develop targeted goals aimed to improve impact on GHG emissions and create sustainable change management strategies.

### METHODS AND MATERIALS

We engaged a multidisciplinary group of leaders, physicians, engineers and hospital administrators interested in promoting sustainability in medical imaging to form the Green Radiology committee. This leadership structure fostered collaboration and determined annual goals through a series of brainstorming sessions aimed to engage departmental members in authentic actions for sustainable change management. Subsequently, a dedicated implementation plan was established to further share accountability and engage staff in achieving green radiology goals. Quarterly status updates monitored outcomes and ensured progress was achieved.

### RESULTS

The development of a formal Green Radiology committee helped accelerate the engagement and foundational support to design and establish sustainability initiatives. The Green Radiology committee identified three goals to achieve within the year. The first priority identified was to commit to gathering energy and power data. This was achieved with the purchase and installation of new power meters supported by hospital electrician and biomedical engineering. The second priority was to develop a visual campaign of Top 10 ideas to share with frontline staff sharing ideas on changes that can have a positive impact on sustainability. Lastly, the team developed a baseline survey to assess current state practices and knowledge about green radiology and sustainability practices. Each of these goals have provided a foundational action plan for future improvements and next steps to guide the Green Radiology committee.

### CONCLUSION

By setting an annual action plan with targeted and realistic goals, the interdisciplinary Green Radiology Committee was able to establish accountability, achieve progress, and engage and promote sustainable changes.

### CLINICAL RELEVANCE/APPLICATION

All radiology medical imaging departments can form an interdisciplinary Green Radiology committee and establish meaningful actions to drive sustainable and impactful changes. In addition, these learnings can help other medical imaging and hospital departments establish and formulate Green Radiology programs that drives engagement and positive sustainable goals.

BREE

## Breast Imaging Education Exhibits

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Sub-Events**

### BREE-1 KEEPING UP WITH THE CUTTING EDGE: MULTIMODALITY REVIEW OF ONCOPLASTIC BREAST SURGERY

**Awards**
**Certificate of Merit**

Alexander Kuehne, MD (*Abstract Co-Author*) Nothing to Disclose
William J. Hoover, MD (*Abstract Co-Author*) Nothing to Disclose
John M. Lewin, MD (*Abstract Co-Author*) Officer, Novian Health Inc
Caroline Merriam, DO (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Surgical management of breast cancer continues to evolve as oncoplastic surgery (OPS) grows in popularity.
- OPS allows for tumor resection with lumpectomy or mastectomy, followed by breast reconstruction.
- To improve cosmetic outcomes after breast reconstruction, several plastic surgery techniques are utilized including volume replacement, volume rearragement, and volume displacement.
- This educational exhibit will provide a description and illustration of several common oncoplastic breast surgeries.
- For each procedure, we will review expected post-operative imaging features on mammogram, ultrasound, and breast MRI.
- The exhibit will conclude with a discussion of acute and long-term complications of OPS including breast abscess, fat necrosis, hematoma, flap necrosis, and breast cancer recurrence.

**TABLE OF CONTENTS/OUTLINE**

1. Brief history of oncoplastic breast surgery (OPS)2. Who is a candidate for OPS?3. Pictorial review of eight OPS techniques, including expected post-operative imaging findings for each technique:
- Reduction mammoplasty
- Nipple areolar complex centralization
- Latissimus dorsi flap
- Deep inferior epigastric perforator (DIEP) flap
- Transverse rectus abdominis myocutaneous (TRAM) flap
- Superior gluteal artery flap
- Autologous fat grafting
- Omental flap4. Case-based review of acute and long-term complications of OPS

### BREE-10 WHEN A MASS IS MELANOMA: VARIABLE IMAGING PRESENTATIONS OF A RARE BREAST DIAGNOSIS

Molly Hill, MD (*Abstract Co-Author*) Nothing to Disclose
Allison Aripoli, MD (*Abstract Co-Author*) Nothing to Disclose
Ashley I. Huppe, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica K. Peterson, MD (*Abstract Co-Author*) Nothing to Disclose
Camron B. Smith, DO (*Abstract Co-Author*) Nothing to Disclose
Onalisa D. Winblad, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela E. Wermuth, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Extramammary metastases to the breast are rare, with melanoma being the most common.2. Metastatic melanoma to the breast may be identified in symptomatic or asymptomatic patients with or without a known history of melanoma.3. Imaging features of melanoma metastases to the breast overlap with findings of primary breast malignancy.4. A thorough understanding of common and unusual imaging presentations of metastatic melanoma is key to maintaining a high clinical suspicion, with biopsy ultimately necessary for diagnosis.

**TABLE OF CONTENTS/OUTLINE**

1. Background: Review the prevalence of melanoma metastases (including those to the breast), mechanism of metastatic spread, timeline of presentation, and appropriate workup.2. Case-based imaging review: Multimodality examples of metastatic melanoma to the breast, emphasizing common and unique imaging presentations on:- Mammography- Ultrasound- MRI3. Clinical importance: Discuss the frequency of melanoma, importance of careful clinical history and accurate diagnosis, and general prognosis of melanoma metastases to the breast.

### BREE-100 THE RADIOLOGIST'S ROADMAP TO BREAST IMPLANT EVALUATION: A RESIDENT'S TUTORIAL

**Cum Laude**

Tatiana C. Tucunduva, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Abstract Co-Author*) Nothing to Disclose
Marcela P. Viana, MD (*Abstract Co-Author*) Nothing to Disclose
Jacqueline Herica Watanabe, MD (*Abstract Co-Author*) Nothing to Disclose
Aracava M. Marcia, MD (*Abstract Co-Author*) Nothing to Disclose
Luciano F. Chala, MD (*Abstract Co-Author*) Nothing to Disclose
Tomie H. Ichihara, MD (*Abstract Co-Author*) Nothing to Disclose
Giselle G. Mello, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Understanding Implant Types and Anatomy - Imaging Techniques for Implant Assessment - MRI Protocols and Implant Evaluation - Managing Complications and Reviewing Cases

**TABLE OF CONTENTS/OUTLINE**

Basic Principles of Breast Implant Evaluation: Understand implant types (saline vs. silicone, single vs. double lumen, expanders), relevant anatomy, and terminology. Imaging Methods for Implant Evaluation: Mammography: Use and limitations in implant evaluation; Ultrasound: Applicability in detecting ruptures and other changes; MRI Imaging: Exam protocols, essential sequences (T1, T2, STIR, fat-suppression sequences), and its importance in the comprehensive evaluation of implants and surrounding tissue. MRI Exam Protocols: Recommended sequences for a detailed evaluation; Location and positioning of the patient. Implant Evaluation: Identification and interpretation of normal findings (position, lumen integrity); Recognition of changes and complications: folds, axis rotation, ruptures (intracapsular and extracapsular), capsular contracture; Complications and Associated Pathologies: Granulomas: Identification and implications; Breast Implant-Associated Anaplastic Large Cell Lymphoma (BIA-ALCL): Signs, symptoms, and imaging diagnosis; Hemangioma: Imaging characteristics and relevance. Management of Complications: Strategies for early diagnosis of complications; Multidisciplinary approach in managing complications and pathologies associated with implants. Case Discussion and Literature Review: Analysis of case studies to illustrate the principles of evaluation and management; Updated literature review on the latest trends and findings related to breast implants.

## BREE-101 ASSOCIATION BETWEEN BREAST ARTERIAL CALCIFICATIONS AND INCREASED CARDIOVASCULAR RISK: REPORTING CONSIDERATIONS, CLINICAL IMPLICATIONS, AND ROLE IN PREVENTIVE CARE

Elsie Nguyen, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Kate Hanneman, MD, MPH (*Abstract Co-Author*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Jean M. Seely, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Charlotte J. Yong-Hing, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Roisin Heaney, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Hayley McKee, MSc, BSc (*Abstract Co-Author*) Nothing to Disclose
Kaitlin M. Zaki-Metias, MD, FRCPC (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purpose of this educational exhibit is to review the association of breast arterial calcifications (BAC) and cardiovascular disease (CVD), detection and reporting methods, and perceptions of radiologists, referring physicians, and patients. 1. BAC are associated with an increased risk of CVD, incident CVD events, and correlate with other methods of cardiovascular risk stratification. 2. BAC are positively correlated with multiparity, menopausal status, metabolic syndrome, hyperlipidemia, hypertension, diabetes, and chronic renal disease, among other comorbidities. 3. Several methods of BAC detection and reporting have been proposed, including binary assessment, subjective quantification or grading, digital measurement, and AI-based detection and reporting models. 4. Reporting of BAC on mammography may allow for supplementary screening for CVD on screening and diagnostic mammography, leading to earlier identification of asymptomatic individuals at high risk for adverse cardiac events and allowing for more targeted preventive care.

**TABLE OF CONTENTS/OUTLINE**

1. Understand the association between BAC on mammography and cardiovascular risk. 2. Review the various methods to identify, quantify, and grade BAC including visual binary assessment, subjective severity grading, digital measurement and quantification, and artificial intelligence-based models. 3. Discuss the awareness and attitudes surrounding BAC of radiologists, referring physicians, and patients over the past 5 years. 4. Describe the current gaps, next steps, and challenges in implementation of BAC reporting and clinical management guidelines, including the necessity of interdisciplinary collaboration.

## BREE-102 MULTIMODALITY DETECTION OF BREAST CANCER RECURRENCE

Jean M. Kunjummen, DO (*Abstract Co-Author*) Nothing to Disclose
Maria Piraner, MD (*Abstract Co-Author*) Nothing to Disclose
Rebecca L. Seidel, MD (*Abstract Co-Author*) Consultant, Therapixel SA;Consultant, Delphinus Medical Technologies, Inc
Nishitha Reddy, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Breast cancer is the most common cancer in the female population, for which oncologic and surgical treatment options continue to be developed. Breast cancer recurrence rates vary from 5-20% depending on the tumor subtype. Expected postoperative changes of the breast can be difficult to distinguish from tumor recurrence. Knowledge of multimodality appearances of the postsurgical breast is essential to detecting breast cancer recurrence. Understanding the role of multimodality breast cancer surveillance (ultrasound, mammography, MRI, PET/CT) allows for early detection of recurrent or new breast cancer.

**TABLE OF CONTENTS/OUTLINE**

Review the risk factors for breast cancer recurrence. Review current postsurgical breast screening recommendations. Evaluate the role of multimodality imaging, specifically pertaining to the postsurgical breast. Distinguish between expected postsurgical change versus features suspicious for breast cancer recurrence.

## BREE-103 POSTSURGICAL BREAST REDUCTION IMAGING

Laurie R. Margolies, MD (*Abstract Co-Author*) Stock options, Nuevozen Corporation Medical Advisory Board, Screenpoint Medical
Stephanie B. Shamir, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Reduction mammoplasty is a common surgery that results in predictable imaging patterns. 2. Reduction mammoplasty can result in imaging changes such as new asymmetries, calcifications, architectural distortion, and areas of enhancement that may appear suspicious, especially when a surgical history is not provided. 3. It is important to not dismiss potentially concerning asymmetries as part of post-surgical change unless they clearly follow the specific expected imaging patterns.

**TABLE OF CONTENTS/OUTLINE**

1. Background • Reduction mammoplasty is performed using classic surgical techniques involving removal and displacement of parenchymal tissue, particularly from the inferior breast • The procedure results in a predictable post-surgical appearance 2. Demonstrate normal post-reduction imaging features • Asymmetries, architectural distortions, fat necrosis and calcifications are expected • Scarring should typically stabilize or decrease with time, and calcifications should coarsen 3. Case Series • Cases of invasive cancer in the post-surgical breast that illustrate ways to recognize areas to be further queried 4. Considerations • Consideration of pre-operative mammogram to confirm the absence of pre-existing malignancy, and to establish a baseline imaging appearance prior to surgery 5. References

## BREE-104 IS IT A RECURRENCE OR NOT? MULTIMODALITY IMAGING OF BREAST CANCER RECURRENCE: LITERATURE REVIEW AND CASE BASED PRESENTATION

Inci Kizildag Yirgin (*Abstract Co-Author*) Nothing to Disclose
Mustafa Durmaz, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The timely and accurate follow-up of patients with a history of breast cancer is mandatory. Women with a personal history of breast cancer are at an increased risk of either a local recurrence or a new primary breast cancer. Local recurrence can increase the risk of distant metastasis or breast cancer-related deaths, and previous studies have shown that early detection of second breast cancers can decrease the mortality rates.Surveillance is essential for the detection of recurrent disease at the earliest possible stage, allowing for prompt treatment, and potentially improving overall survival. International guidelines recommend annual mammography as the only surveillance technique (ASCO, NCCN, ESMO), but a mammogram is less sensitive in the post-surgical period due to post-treatment changes (fat necrosis, surgical scars). Breast MRI is a highly sensitive imaging modality to detect local recurrence in certain patient groups. The purpose of this educational exhibit will be to learn the role of imaging methods and findings due to treatment and findings of recurrence in breast cancer surveillance patients.

**TABLE OF CONTENTS/OUTLINE**

Review of incidence, risk factors, diagnostic performance of multimodality surveillance, and presentation of breast cancer recurrence. Review of post-breast-conserving treatment imaging findings and their timing of evolution. Review of available guidelines for multimodality surveillance after curative treatment for locoregional breast cancer. To learn to deal with complex findings between different imaging methods to avoid unnecessary biopsies. To learn the importance of serial follow-up Imaging. Case-based review of different presentations of breast cancer recurrence.

## BREE-105 UNCOMMON BENIGN LESIONS THAT MIMIC BREAST CARCINOMA

Laura Escudero, MD (*Abstract Co-Author*) Nothing to Disclose
Carlota Garcia Baron (*Abstract Co-Author*) Nothing to Disclose
Maria J. Ciudad, MD (*Abstract Co-Author*) Nothing to Disclose
Myriam F. Montes, MD (*Abstract Co-Author*) Nothing to Disclose
Nancy Sanchez Rubio, MD (*Abstract Co-Author*) Nothing to Disclose
Beatriz Lannegrand Menendez (*Abstract Co-Author*) Nothing to Disclose
Virginia Luxmila Arias Torrealba, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The majority of brest lesions found in breast routine studies are benign and incidental findings. Most lesions have identifiable radiological characteristics suggesting benign findings without the need for additional tests. To a lesser extent, others require radiological followup tests, with diagnosis possibly achieved solely through imaging behavior. There is a group of uncommon benign lesions that, due to their imaging characteristics and clinical findings, may mimic a suspicious malignancy, requiring definitive diagnosis through a biopsy. The objective of this presentation is to provide a guide to the radiological characteristics of sarcoidosis, granulomatous mastitis, diabetic mastopathy, pseudoangiomatous stromal hyperplasia, and traumatic neuroma at the mastectomy site, in different imaging studies available to us today (mammography, ultrasound, and MRI), allowing for a more detailed characterization, as these particular lesions exhibit significant radiological similarity to malignant lesions. We will briefly describe their clinical, epidemiological, and pathological manifestations. Our description help broaden the diagnostic options when faced with a suspicious image of malignancy in patients presenting some of the clinical-radiological characteristics described here.

**TABLE OF CONTENTS/OUTLINE**

1. Sarcoidosis.2. Neutrophilic granulomatous mastitis.3. Diabetic mastopathy.4. Pseudoangiomatous stromal hyperplasia.5. Traumatic neuroma at the mastectomy site.

## BREE-106 THE MORE YOU KNOW: TEACHING POINTS OF DISCORDANT BREAST BIOPSIES

Ann L. Brown, MD (*Abstract Co-Author*) Consultant, Elucent Medical
Rifat A. Wahab, DO (*Abstract Co-Author*) Nothing to Disclose
Kyle M. Lewis, MD (*Abstract Co-Author*) Nothing to Disclose
Erich J. Boomgarden, MD (*Abstract Co-Author*) Nothing to Disclose
Charmi Vijapura, MD (*Abstract Co-Author*) Nothing to Disclose
Mary C. Mahoney, MD (*Abstract Co-Author*) Nothing to Disclose
Katherine Mulquin, DO, BS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Define radiology-pathology concordance as it pertains to breast imaging interventions.2) Detail scenarios in clinical practice that can contribute to biopsy discordance.3) Review clinical implications of discordant biopsies and management strategies including instituting breast radiology-pathology correlation conference.

**TABLE OF CONTENTS/OUTLINE**

1) Definitions of benign discordant and malignant discordant biopsies2) Specific and non-specific discordance3) Overview of 5 major categories that contribute to discordant biopsieso Technical Factors--Undersampling (small gauge needle, low number of samples)--Missing the targeted lesion (small

target, difficult location)o Complications (bleeding after first sample, vasovagal reaction)o Multiple suspicious lesionso Large or heterogenous finding--Cystic/Necrotic MassNew finding in region with extensive post-treatment changes4) Benefit of incorporating radiology-pathology correlation conference into breast practiceso Consensus management to maximize cancer detection, identify discordant cases in a timely fashion, and avoid unnecessary followup/surgeryCONCLUSIONS1. Discordant biopsies are uncommon, but they can result in delays of care or misdiagnosis when they occur.2. Identification of imaging and clinical features associated with discordant biopsies is important for timely and accurate diagnoses.

## BREE-107 FEELING GOOD AND FEELING NEW (BREAST MASSES) ON GLUCAGON-LIKE PEPTIDE-1 (GLP-1) AGONISTS

Bonmyong Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Sophia R. O'Brien, MD, MEd (*Abstract Co-Author*) Nothing to Disclose
Elizabeth S. McDonald, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Samantha P. Zuckerman, MD (*Abstract Co-Author*) Nothing to Disclose
Joseph J. Villavicencio, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Use of glucagon-like peptide-1 (GLP-1) agonists for weight loss is associated with both mammographic changes and clinical breast symptoms.2. Patients may present with symptoms (lumps, pain) following the use of GLP-1 agonists that warrant ultrasound evaluation. This may yield actionable findings that may have otherwise been occult on screening mammography. 3. Changes in density following the use of GLP-1 agonists may obfuscate previously identified findings; this may create a clinical dilemma in the setting of actionable BI-RADS findings. 4. Changes in density following the use of GLP-1 agonists may prompt more recommendations for supplemental screening. 5. There may be no discernible mammographic changes even in cases of significant weight loss while on GLP-1 agonists.

### TABLE OF CONTENTS/OUTLINE

Case 1: 41F, screening. Interval decrease in breast size and increased breast density following 50 lb weight loss on semaglutide. Case 2: 44F, screening. Interval decrease in breast size and increased breast density following 40 lb weight loss on semaglutide with obfuscation of a focal asymmetry.Case 3: 62F with a palpable right axillary lymph node following 50 lb weight loss on tirzepatide and semaglutide. Targeted ultrasound of the right axilla demonstrated an abnormal lymph node yielding metastatic breast cancer which was mammographically occult. Subsequent breast MR demonstrates a correlate for a primary malignancy in the right breast. Weight loss may have prompted a palpable finding.Case 4: 60F with new palpable areas of concern in the bilateral breasts which demonstrate benign findings on ultrasound evaluation. Case 5: 60F, screening. No significant change on mammography despite 50 lb weight loss.

## BREE-108 IS THERE ANY SECRET REGARDING TO IDIOPATHIC GRANULOMATOUS MASTITIS?

Leire Ormaetxe Albeniz, MD (*Abstract Co-Author*) Nothing to Disclose
Monica Santamaria, MD (*Abstract Co-Author*) Nothing to Disclose
Ruth Gonzalez Sanchez (*Abstract Co-Author*) Nothing to Disclose
Elena Cintora Leon (*Abstract Co-Author*) Nothing to Disclose

Ines Alonso Sanchez, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Udondo Gonzalez del Tanago, MD (*Abstract Co-Author*) Nothing to Disclose
Loreto De Llano (*Abstract Co-Author*) Nothing to Disclose
Olatz Gorrino Angulo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Review the clinical and radiological manifestations of Idiopathic Granulomatous Mastitis (IGM). Explain the diagnostic approach and appropriate management. Describe the main entities included in the differential diagnosis

### TABLE OF CONTENTS/OUTLINE

IGM is a rare chronic inflammatory disease that can mimic carcinoma. Typically affects young women with history of pregnancy and breastfeeding. IGM is usually presented as palpable painful breast lump with inflammatory skin changes. It can also associate fluid collections and sinus tracts. Radiological findings in the different imaging modalities are non-specific and a percutaneous biopsy is always needed for diagnosis. We will revise a series of cases diagnosed with IGM in the last eight years, to illustrate the most frequent radiological findings and go through the main steps we should take to achieve the final diagnosis. Depending on age, radiological studies started with ultrasound or a mammography, but all the patients underwent an us-guided biopsy to confirm the diagnosis. The most common us-findings in our cases were hypoechoic images of tubular and nodular morphology with a tendency to join, hypoechoic irregular masses and sinus tracts. Some patients also had fluid collections and axillary involvement. All the women in our series were treated conservatively with good results, except for two who needed surgery.

## BREE-109 WHAT CALCIFICATIONS? RADIOLOGIC PRESENTATIONS OF NONCALCIFIED DCIS WITH PATHOLOGIC CORRELATION

Vidushani S. Perera, MD (*Abstract Co-Author*) Nothing to Disclose
Ayah Ali (*Abstract Co-Author*) Nothing to Disclose
Amy Maduram, MD (*Abstract Co-Author*) Nothing to Disclose
Syeda R. Zaidi, MD (*Abstract Co-Author*) Nothing to Disclose
Michelle Kraay, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

(1) DCIS represents 20 to 25% of all breast cancer diagnoses in the United States and is considered to be a precursor of invasive breast cancer. Although the majority of DCIS (80-90%) presents as calcifications seen on mammography, 10-20% of DCIS diagnoses may present as noncalcified findings on mammography, ultrasound, and MRI. It is vital for radiologists to be aware of the different presentations of noncalcified DCIS, including as a palpable mass, bloody nipple discharge, noncalcified findings on mammography such as architectural distortion and focal asymmetry, and non-mass enhancement on MRI. (2) DCIS is a heterogeneous lesion with five major architectural patterns seen on pathology, including comedo, cribriform, micropapillary, papillary, and solid. The comedo type is most commonly associated with the formation of calcifications mammographically. (3) Noncalcified DCIS lesions may be larger at presentation than calcified DCIS due to the difficulty in mammographic detection and has a reported upgrade rate of 21.8% at a single institution. DCIS can be treated with a combination of surgery, radiation, and hormone therapy.

### TABLE OF CONTENTS/OUTLINE

(1) Overview of DCIS epidemiology and histopathology. (2) Common imaging presentation of DCIS as calcifications. (3) Noncalcified DCIS cases presenting as a palpable mass, focal asymmetry, architectural distortion, non-mass enhancement on MR with corresponding pathology. (4) Cases

presenting as symptoms including bloody nipple discharge, Paget's disease, and pregnancy-associated enlarging fibroadenoma. (5) Management of DCIS. (6) Self-assessment quiz.

## BREE-11 BEYOND CONVENTIONAL: ADVANCED T2 WEIGHTED IMAGING IN BREAST MRI - EMPOWERING EDUCATION AND DIAGNOSIS

Mami Iima, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kazushige Ichikawa (*Abstract Co-Author*) Nothing to Disclose
Shinji Naganawa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Satoko Ishigaki, MD (*Abstract Co-Author*) Nothing to Disclose
Yutaka Kato (*Abstract Co-Author*) Nothing to Disclose
Hiroko Satake, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Advanced T2-weighted imaging (T2WI) techniques, such as 3D T2WI and deep learning (DL) based T2WI, are explored in breast imaging. We start with an overview of conventional T2WI, discussing its fundamental role in diagnosing breast cancer. The focus then shifts to advanced methods that reduce scan times and improve image resolution, highlighting their benefits in educational settings. Detailed analyses illustrate how these advancements enhance the visualization of crucial T2WI findings like focal edema and intratumoral necrosis in breast cancer. Additionally, the educational value of these technologies in teaching radiologic-pathologic correlation through case studies is explored. The session also addresses the challenges and opportunities presented by cases with lymph node (LN) metastasis, proposing strategies to incorporate these insights to improve diagnostic skills in breast imaging.

### TABLE OF CONTENTS/OUTLINE

1. Imaging Sequence• Overview of conventional T2WI in breast MRI• Introduction to advanced T2WI such as 3D or DL-based T2WI, emphasizing the reduced acquisition time with high resolution2. Focal Edema and Intratumoral Necrosis in Breast Cancer• Detailed analysis of how advanced T2WI can improve the visualization• Discussion on the clinical relevance of these findings in diagnosis3. Radiologic-Pathologic Correlation• Exploration of morphology and signal intensity using advanced T2WI• Case studies highlighting the correlation between radiologic findings and pathologic results, demonstrating the educational value of breast imaging4. Challenges in the Diagnosis of LN Metastasis• Addressing the challenges and learning opportunities presented by cases with LN metastasis

## BREE-110 NEOADJUVANT ENDOCRINE THERAPY MONITORING OF PRIMARY BREAST CANCER: COMBINED ASSESSMENT USING FES-DEDICATED BREAST PET AND DYNAMIC CONTRAST-ENHANCED MRI

Jo Chien (*Abstract Co-Author*) Nothing to Disclose
Pouya Metanat, MD, MPH (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Learn the clinical and biological features of 18F-fluoroestradiol (FES), an estrogen receptor targeting PET tracer. • Learn characteristics of dedicated breast PET (dbPET) imaging in comparison with whole body PET imaging. • Learn differences and similarities between dynamic contrast enhanced (DCE) breast MRI and FES-dbPET imaging. • Learn potential clinical benefit of FES-dbPET when used in conjunction with DCE breast MRI for treatment response evaluation during neoadjuvant endocrine therapy (NET).

### TABLE OF CONTENTS/OUTLINE

1. 18F-fluoroestradiol (FES) - Biological characteristics of FES - Review of literature on whole-body PET with FES 2. Dedicated breast PET (dbPET) - dbPET scanner characteristics - Imaging protocol 3. Clinical workflow of FES-dbPET 4. Comparison of DCE breast MRI and FES-dbPET 5. Case presentation of FES-dbPET and DCE breast MRI during neoadjuvant endocrine therapy (NET) 6. Discussion of the imaging findings of the cases presented at #5 - mechanisms of underlying tumor depiction at FES-dbPET vs. DCE breast MRI - influence of menopausal status on FES-dbPET - influence of NET regimen on FES-dbPET findings 7. Future directions of dbPET application in breast cancer therapy 8. Summary of the educational points

## BREE-111 A SINISTER TREND: MORE YOUNG WOMEN ARE GETTING BREAST CANCER; WHO, WHY, AND WHAT DO WE KNOW?

**Awards**
**Certificate of Merit**

Jaimee E. Mannix, MD (*Abstract Co-Author*) Nothing to Disclose
Kate Walter (*Abstract Co-Author*) Nothing to Disclose
Nawar Aljundi (*Abstract Co-Author*) Nothing to Disclose
Gianmarco Calderara (*Abstract Co-Author*) Nothing to Disclose
Julia C. Kirsten, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Discuss increased incidence of breast cancer in women aged 20-49 over the past 20 years, with significant increase after 2016.2. Review differences in breast cancer incidence rates by age group, race, hormone receptor status, and stage.3. Discuss modifiable risk factors and social determinants of health which may play a role in increased incidence.

**TABLE OF CONTENTS/OUTLINE**

1) Clinical manifestations/pathology of breast cancer in young patients. Recommended diagnostic workup in young patients.2) Incidence of breast cancer is increasing over time in young women aged 20-49, especially after 2016.3) Differences in breast cancer incidence rates by age group, race, hormone receptor status, and stage.4) New data regarding trends and incidence in young women with breast cancer.(a) Increased incidence is due almost entirely to an increase in tumors which are estrogen-receptor positive. Higher rates of breast cancer are seen among Black women, especially among those ages 20 to 29.(b) An increase in diagnosis of stage 1 and 4 tumors in young women has been observed. Data suggests that when stage 1 tumors are missed in younger women, the tumors tend not to be found until they reach stage 4.5) Differences in overall survival and disease free survival rates in young patients vs those diagnosed when older.6) Identification of risk factors for breast cancer such as maternal parity, age of first birth, and family history as well as modifiable risk factors such as obesity, caloric intake, alcohol intake, smoking, chemical exposures, and exercise.7) Treatment differences in young women versus older women and evaluation of effect on quality of life, sexuality, and fertility.8) Role of support groups with age matched peers.9) Conclusion

## BREE-112 INCIDENTAL BREAST FINDINGS ON NON-BREAST IMAGING: A COMPREHENSIVE REVIEW FROM BENIGN TO ACTIONABLE

Fatima Salah, MD, FRCR (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

This educational exhibit aims to: 1. Present example cases and outcomes of incidental breast findings seen on non-breast imaging: both benign and malignant. 2. Review suspicious findings that warrant additional work-up with dedicated breast imaging. 3. Illustrate examples in which additional imaging could have been omitted. 4. Highlight value of accurate evaluation of incidental breast findings and their effect on subsequent patient management.

**TABLE OF CONTENTS/OUTLINE**

1. Define and introduce importance of incidental breast findings on non-breast cross sectional imaging. 2. Illustrate cases whereby breast findings were clearly negative or benign, BIRADS 1 or 2. 3. Present incidental breast findings in which additional dedicated breast imaging was warranted in both benign and malignant outcomes: a. BIRADS 4: Benign outcome after recommended biopsy. b. Malignant Outcome: Primary breast cancer and Metastasis.

## BREE-113 THE ARMPIT: A PLACE TO BE EXPLORED

Erica Endo, MD (*Abstract Co-Author*) Nothing to Disclose
Marco A. Costenaro, MD (*Abstract Co-Author*) Nothing to Disclose
Naomi Murakami SR, MBBS (*Abstract Co-Author*) Nothing to Disclose
Adriana Kumagai, MD (*Abstract Co-Author*) Nothing to Disclose
Patricia Rosseto Franco, MD (*Abstract Co-Author*) Nothing to Disclose
Vera Christina C. Ferreira, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Approaching axillary findings by ultrasound, mammography, CT scan and MRI. Differential diagnosis for axillary findings. Significance of accurate diagnosis in disease management

**TABLE OF CONTENTS/OUTLINE**

There are numerous diseases that can lead to axillary masses or lymphadenopathy, each requiring a specific approach. Some may benefit from percutaneous biopsies, others may need blood tests or specific diagnostic tools. Radiologists must be proficient in distinguishing axillary lesions originating from other sites to ensure optimal patient care. To comprehensively understand the patient's condition, it's crucial to study not only the lesion itself but also its location, associated findings, patient epidemiology and personal history.This study presents a series of cases involving axillary lesions caused by atypical conditions. It aims to familiarize radiologists with a wide range of non-breast lesions affecting axillary tissue, enabling them to provide accurate diagnoses.Axillary anatomySkin and appendages (Epidermoid cyst - Apocrine sweat gland adenocarcinoma)Fat and connective tissues (Axillary lipoma - Rhabdomyosarcoma - Hemangioma)Vascular abnormalities (Traumatic axillary artery pseudoaneurysm - Mondor disease)Lymph nodes metastasis (Ovarian cancer - Sarcoma -Thymus cancer)Reactive lymph nodes, systemic diseases (Cat scratch disease - Human Immunodeficiency Virus)Congenital anomalies (Fibroadenoma and cysts in axillary accessory breast)Axillary post-surgical complications (Lymphocele - Abscess)Musculoskeletal (Synovial cyst)

## BREE-114 HIGH-FREQUENCY ULTRASOUND FOR EVALUATING SKIN LESIONS ON THE BREAST SEEN ON MAGNETIC RESONANCE IMAGING (MRI)

Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Marina Morais (*Abstract Co-Author*) Nothing to Disclose
Ivana Gibbons (*Abstract Co-Author*) Nothing to Disclose
Candida Maria A. Soares, MD (*Abstract Co-Author*) Nothing to Disclose
Mariah C. Wanderley (*Abstract Co-Author*) Nothing to Disclose
Vinicius C. Felipe SR, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The objectives of this presentation are:1. To demonstrate through a case review the correlation of focal breast skin enhancements on MRI with high-frequency dermatological ultrasound.2. To correlate skin lesions observed during physical examination and dermatoscopy with high-frequency ultrasound.3. Radiologists who work with breast imaging should be aware of the typical findings of benign and malignant skin lesions to avoid unnecessary procedures and delays in diagnosing potential malignancies.

**TABLE OF CONTENTS/OUTLINE**

1. Cutaneous Hemangioma.a. Enhancement pattern seen on MRI.b. Representation in high-frequency ultrasound.c. Ectoscopic and dermatoscopic evaluation.2. Paget's Disease in a Breast Previously Subjected to Mastectomy for Neoplasia.a. Enhancement pattern seen on MRI.b. Representation in high-frequency ultrasound.c. Ectoscopic and dermatoscopic evaluation.3. Cutaneous Angiosarcoma.a. Enhancement pattern seen on MRI.b. Representation in high-frequency ultrasound.c. Ectoscopic evaluation and surgical specimen after mastectomy.4. Seborrheic Keratosis.a. Enhancement

pattern seen on MRI.b. Representation in high-frequency ultrasound.c. Ectoscopic and dermatoscopic evaluation.5. Hypertrophic Scar.a. Enhancement pattern seen on MRI.b. Representation in high-frequency ultrasound.c. Ectoscopic and dermatoscopic evaluation.

## BREE-115 BRCA1 AND 2 MUTATION- THE RADIOLOGIST'S PIVOTAL ROLE IN CHANGING PATIENT'S FATE

Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Aline D. Guimaraes, MD, MBA (*Presenter*) Nothing to Disclose

### TEACHING POINTS

BRCA 1 and 2 mutation carriers have an increased risk of developing breast cancer. They have 3% greater risk before 30 years and their lifetime risk increases 50 to 80% by the age of 70 years. The increased risk and the early onset of cancer implies a different screening strategy with guidelines around the world recommending to start breast cancer screening at an earlier age and to include MRI as an adjunct to mammography. Furthermore, there are differences between these two groups of high-risk patients regarding the age of appearance of breast cancer, the histologic and nuclear grades, molecular subtypes, lesion's location and imaging features at different breast imaging modalities. It is essential that the radiologists know the epidemiological aspects involved in BRCA1 and BRCA2 mutation carriers, as well as the imaging aspects most commonly found in these patients, specially because BRCA1 carriers tend to present lesions with benign morphological aspects, despite the aggressive pathological features, imposing increased caution on this group of patients. In this case based didactic exhibit, we will explore the clinical, pathological and imaging features in this two subgroups of patients, discuss the screening implications and demonstrate that the radiologist has a pivotal role in changing the fate of these mutation carriers.

### TABLE OF CONTENTS/OUTLINE

1) BRCA1 and 2 Epidemiology 2) Screening recommendation in BRCA1 and 2 mutation carriers 3) Differences between BRCA1 and 2 breast cancer 3.1) Clinical 3.2) Pathological 3.3) Imaging 3.3.1) Mammography, 3.3.2) Ultrasound 3.3.3) MRI 4) Multimodality case based review (BRCA1 and 2 breast cancers) 5) Implications of the knowledge acquired in the radiologist’s practice

## BREE-116 AUGMENTED BUT CHALLENGED - IMPLANT DIAGNOSTIC DILEMMAS

Dunya M. Imad, MD (*Abstract Co-Author*) Nothing to Disclose
Jenna Pellegrino, MD (*Abstract Co-Author*) Nothing to Disclose
Priscilla J. Slanetz, MD, MPH (*Presenter*) Royalties, Wolters Kluwer nv

### TEACHING POINTS

Introduced in the 1960’s, breast implant augmentation has become one of the most popular cosmetic procedures globally. As a result, there are a substantial number of women with implants that present for imaging, whether it be for cancer screening or for a symptom such as a lump or pain. In most cases, radiologists can readily determine if a breast implant is intact or if there is a rupture. However, the imaging evaluation can sometimes be more challenging as not all patients present with classic findings. Therefore, breast radiologists need to develop problem-solving skills to troubleshoot such cases so that any issue with an implant is quickly diagnosed and addressed.

### TABLE OF CONTENTS/OUTLINE

In this exhibit, we will provide a systematic approach to evaluating breast implants for rupture or other complications, such as implant-associated malignancy, capsular fat necrosis, implant infection, postoperative collections/hematomas, and alloderm grafting. We will then present examples of challenging cases where clinical history and multi-modality imaging allowed the radiologist to accurately characterize the implant complication.

## BREE-117 WHAT IS THAT ENHANCING ASYMMETRY? A SERIES OF MALIGNANT AND BENIGN CONTRAST ENHANCED MAMMOGRAPHY-GUIDED BREAST BIOPSIES

Ceren Yalniz, MD (*Abstract Co-Author*) Nothing to Disclose
Stefanie A. Woodard, DO (*Abstract Co-Author*) Investigator, Bracco Group Institutional research support, Bracco Group
Kathryn W. Zamora, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Stefanie B. Zalasin, MD (*Abstract Co-Author*) Nothing to Disclose
Stephanie D. Colvin, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Understand indications for contrast enhanced mammography-guided biopsies (CEM-Bx). Apply appropriate BI-RADS terminology to contrast enhanced mammography (CEM) findings. Review cases of CEM-Bx performed at our institution. Correlate radiology imaging findings and pathology results for malignant and benign cases.

### TABLE OF CONTENTS/OUTLINE

Background: CEM is an emerging technology with increasing popularity and utilization. Contrast enhanced imaging demonstrates a higher sensitivity for detection of breast cancer and detects abnormalities not identified on non-contrast examinations. CEM has many indications including screening of high-risk patients who cannot undergo magnetic resonance imaging (MRI). CEM-Bx enables sampling of enhancing lesions that are occult on other modalities including 2D/synthesized mammogram, tomosynthesis, and ultrasound. CEM-Bx also has potential to improve cancer detection in our most at-risk patient population that cannot be screened by MRI. Malignant cases: Present a series of at least 5 breast cancer cases diagnosed by CEM-Bx at our institution. Benign cases: Present a series of at least 5 benign cases diagnosed by CEM-Bx at our institution.

## BREE-118 BREAST IMAGING FINDINGS OF MESENCHYMAL MASSES WITH CLINICAL-RADIOLOGIC-PATHOLOGIC CORRELATION

**Awards**
**Certificate of Merit**

Ramapriya Ganti, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shanna Mayorov, BS, MS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

; Describe the constellation of imaging findings of breast masses of mesenchymal origin. ; Delineate classic mimickers of mesenchymal tumors. ; Familiarize readers with radiologic-histopathologic correlation. ; Discuss available management options for each entity.

**TABLE OF CONTENTS/OUTLINE**

1. Background : Mesenchymal masses pose a diagnostic challenge for the breast imager as this category of lesions encompasses both benign and malignant masses, demonstrates similar imaging appearances, and has varied pathologic and treatment related paradigms. Both groups typically manifest in the breast as a single mass that is often palpable. 2. Discussion: Pictorial review of approximately 12 breast masses of mesenchymal origin with emphasis on imaging findings, including benign lipoma, hamartoma, angiolipoma, hemangioma, pseudoangiomatous stromal hyperplasia, leiomyoma, phyllodes tumor, primary and secondary sarcoma, neurogenic tumors, granular cell tumors, myofibroblastoma, and desmoid tumors. Brief epidemiology, clinical symptoms if any, diagnostic assessment including imaging findings, the role of biopsy, histopathologic correlation including staining techniques and their role in identification, and treatment considerations will be described. 3. Conclusion: Knowledge of the imaging manifestations, histopathologic features, and management strategies of mesenchymal tumors allows breast radiologists to improve the identification of these lesions and direct appropriate work-up and management.

## BREE-119 BREAST IMAGING OF PATIENTS WITH LI-FRAUMENI SYNDROME WITH UPDATED REVIEW OF BREAST SCREENING GUIDELINES

**Awards**
**Magna Cum Laude**

Tanya W. Moseley, MD, PhD (*Abstract Co-Author*) Consultant, Hologic, Inc;Consultant, Merit Medical Systems, Inc;Owner, TW Moseley, LLC;CEO, TW Moseley, LLC
Emily S. Nia, MD (*Abstract Co-Author*) Nothing to Disclose

Mary S. Guirguis, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Understand the clinical implications of Li-Fraumeni Syndrome (LFS) in women • Review the current breast cancer screening guidelines for LFS in women • Review the appropriateness criteria of breast imaging modalities to screen women with LFS • Illustrate imaging findings of LFS in the breast

**TABLE OF CONTENTS/OUTLINE**

1. Review the biology and inheritance pattern of Li-Fraumeni Syndrome (LFS). 2. Review the tumors which patients with LFS are susceptible to, with a particular emphasis on the types of breast cancers associated with LFS. 3. Highlight the screening guidelines and appropriateness criteria in patients with LFS. 4. Showcase illustrative breast imaging cases in patients with LFS.

## BREE-12 "DO THEY MATCH?" HOW TO ACHIEVE AN ACCURATE SECOND LOOK ULTRASOUND FOR BREAST LESIONS IDENTIFIED AT MR IMAGING. PICTORIAL REVIEW FOR RADIOLOGISTS IN TRAINING

Maria P. Swiecicki, MD (*Abstract Co-Author*) Nothing to Disclose
Karina Pesce, PhD (*Abstract Co-Author*) Nothing to Disclose
Giannina M. Secco, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Jose Chico (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To help localize MRI detected lesions at second look ultrasound by giving imaging tips for the radiologist in training.2. To illustrate with clinical cases the correlation between both imaging techniques.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction.2. Technique for a good second look US using lesion morphology and localization within the breast.3. Anatomical details that can assist in proper lesion localization.4. Illustration with clinical cases to show how to achieve an adequate correlation between MRI and US images for an accurate lesion localization.5. Conclusions.In conclusion, this educational exhibit is intended to be a guide for radiologists in training that are beginning to perform second look US, describing the technique and illustrating parameters that can assist them in this task.

## BREE-120 ONE-STEP QUALITATIVE AND QUANTITATIVE EVALUATION OF AXILLARY LYMPH NODE METASTASIS IN BREAST CANCER USING DUAL-ENERGY SPECTRAL CT COMBINED WITH CONTRAST ENHANCED SPECTRAL MAMMOGRAPHY: THE EVIDENCE AND ITS LIMITS

Huizhi Cao (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Contrast-enhanced spectral mammography (CESM) and dual-energy spectral CT (DECT) are both exciting technology in potential clinical application. The focus of this presentation is: 1. To understand the concepts and imaging principles of contrast-enhanced mammography and spectral CT imaging technology.2. To learn about how CESM combined with CT spectral imaging technology can assess axillary lymph node metastasis in preoperative breast cancer. 3. To delve into qualitative and quantitative evaluation criteria derived from pathological results of axillary lymph node metastasis post-surgery. 4. To understanding the pros and cons of CESM and spectral CT imaging technology in axillary lymph node metastasis evaluation.

**TABLE OF CONTENTS/OUTLINE**

1. Background introduction to contrast-enhanced mammography and spectral CT Imaging technology, along with post-processing techniques such as monochromatic Images (keV) and material density images (iodine-based, calcium-based), and spectral Hounsfield unit curve analysis.2. Strategies for preoperative diagnosis of metastatic sentinel lymph nodes in breast cancer utilizing DECT and CESM.3. Clinical exemplification of CESM coupled with spectral CT imaging technology in evaluating axillary lymph node metastasis in preoperative breast cancer.4. Qualitative and quantitative evaluation methods for assessing breast cancer axillary lymph node metastasis using CESM and spectral CT technology.5. Examination of advantages and limitations of both technologies in axillary lymph node metastasis evaluation.

## BREE-121 MASTITIS UNMASKED: EXPECTED AND UNUSUAL FINDINGS

Danielle Teles Leal (*Abstract Co-Author*) Nothing to Disclose

Carla C. Tajima (*Abstract Co-Author*) Nothing to Disclose
Sofia B. Maksoud, MD (*Abstract Co-Author*) Nothing to Disclose
Carla C. Benetti, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Mastitis is an inflammation of the mammary gland that can affect different parts of the breast, such as the tissue, nipple, areola, ducts, and skin. It can occur with or without the presence of bacteria. There are various forms of mastitis, including those related to the neonatal and pubertal periods, as well as more common cases during the postpartum period. Additionally, there are less common specific inflammations, such as tuberculosis, syphilis, and actinomycosis. These inflammations can be classified as lactational (during breastfeeding) or non-lactational. Ultrasound is used as the initial method to evaluate women with acute mastitis, especially when abscesses are suspected. Ultrasound imaging findings include edema of the skin and subcutaneous tissue, areas with increased echogenicity permeated by parenchymal areas, loss of definition of the breast planes, hyperechogenicity of perilobular fat and axillary lymph nodes with cortical thickening. Mammography is recommended to rule out cancer and can be performed outside the peripartum period, especially for women over 30 years old. Magnetic resonance imaging (MRI) is not usually necessary and is reserved for atypical cases. The main differential diagnosis to consider is inflammatory carcinoma when a patient presents with redness and swelling in the breast, without evidence of abscess on ultrasound.

**TABLE OF CONTENTS/OUTLINE**

- Review clinical, pathophysiological, and imaging aspects of mastitis.- Illustrate common and uncommon findings of mastitis in a didactic manner.

## BREE-122 SEEING BEYOND MASSES: NON-MASS LESIONS PERSPECTIVES ON ULTRASOUND

Leticia T. Oliveira, MD (*Abstract Co-Author*) Nothing to Disclose

Carla C. Benetti, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The probable changes for the sixth edition of BI-RADS® (Breast Imaging Reporting and Data System) have already been made available, including the introduction of "non-mass lesion" in the ultrasound lexicon. It is defined as a discrete echotexture alteration area, distinct from the adjacent parenchyma, that does not meet the criteria for nodule, identifiable in at least two planes, but may be visualized in only one plane. In most cases, it has a benign etiology, but it can be the initial manifestation of breast cancer, most commonly in situ. It is cathegorized by terms of echogenicity, distribution and associated findings. Calcifications, architectural distortion, posterior acoustic shadowing, abnormal ductal extension or changes, echogenic halo and hypervascularity are examples of associated findings that suggest malignancy. In the face of a non-mass lesion finding on the ultrasound, it is important to correlate it with other imaging exams, as the identification in different methods can increase the degree of suspicion, as well as association with papillary flow or palpable alteration. Definitive diagnosis is made by tissue sampling, most commonly percutaneous core-needle biopsy.

**TABLE OF CONTENTS/OUTLINE**

- To be familiar with the likely changes in the next edition of BI-RADS®, in order to standardize its description.- Suggest the description of ultrasound, in accordance with the expectations of the lexicon changes of the new BI-RADS®, correlating with other imaging modalities.

## BREE-123 SO, YOU THINK YOU CAN IDENTIFY BREAST CANCER? UNCOMMON PRESENTATIONS OF THE MOST COMMON CANCER IN WOMEN

Himeghna Deepak (*Abstract Co-Author*) Nothing to Disclose
Milin Rana, MD (*Abstract Co-Author*) Nothing to Disclose
Rachel Klapper, MD (*Abstract Co-Author*) Nothing to Disclose
Nayanatara Swamy, MD, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1.Breast cancers exhibit a diverse array of imaging presentations, staying updated on these presentations will help us detect them early. 2.Fat containing masses in the breast are largely benign, except in those cases where the breast cancer has engulfed fat. 3.Although rare, interval breast cancers do occur. Therefore, it's crucial to educate women not to disregard a palpable lump, even if they had a benign screening mammogram within the past year. 4.Identifying suspicious asymmetries and focal asymmetries can be challenging on screening mammography. By learning from both positive and negative call-backs, we can set our threshold of suspicion optimally. 5.Maintaining high standards for image quality of screening mammograms will help ensure that the cancers located far posteriorly and anteriorly are identified. 6.Women who have undergone reduction mammoplasty have post-operative changes which make identification of breast cancers daunting. 7.Cross-sectional imaging can be a useful tool in identifying breast cancers in subsets of the population that do not yet undergo routine screening mammography.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Case-based review o The fat engulfing breast cancer o The interval breast cancer o The low density mass o The subtle asymmetry o The subtle focal asymmetry o The anteriorly located breast Cancer o The posteriorly located breast cancer - not one, but two masses!! o DCIS presenting as microcalcifications and a mass in same patient o DCIS detected by breast MRI (focal asymmetry on mammogram) o Breast cancers in two women with history of reduction mammoplasty o The Breast cancer initially detected by PET-CT o The breast cancer initially detected by CT 3. Conclusion

Ruth H. Bonini, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Foreign bodies in the breast topography are uncommon and exhibit a variable imaging spectrum, contingent upon the nature and location of the material. The most frequently encountered foreign bodies are those intentionally inserted by radiologists, such as metallic clips during or after biopsy procedures and pre-surgical localization wires or by breast surgeons in surgical interventions. Less frequently, metallic foreign bodies associated with trauma, such gunshot fragments or glass fragments related to car accidents may be encountered.Materials related to cosmetic procedures, and even implantable medical devices like pacemakers and catheters are other foreign bodies that can be present and sometimes interfere with mammography interpretation.Patients may either be asymptomatic or present with localized pain or abscess. A comprehensive clinical history linked with prior mammograms will often lead to a conclusive or presumptive diagnosis, without the need for additional diagnostic tests or unnecessary biopsies.

**TABLE OF CONTENTS/OUTLINE**

In a didactic manner several cases of breast or thoracic foreign bodies seen on mammograms, selected from the digital archives of our institutions, will be presented. Illustrate instances where foreign bodies within or next to the breast impede the thorough evaluation of examinations.

## BREE-125 EXTREME AGES IN BREAST CANCER: TWO SIDES OF THE SAME COIN

Maria P. Swiecicki, MD (*Abstract Co-Author*) Nothing to Disclose
Ana G. Luna (*Abstract Co-Author*) Nothing to Disclose
Maria Jose Chico (*Abstract Co-Author*) Nothing to Disclose
MONICA OTILIA MACHUCA CASTILLO (*Abstract Co-Author*) Nothing to Disclose
Karina Pesce, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1.To Understand the imaging features of breast cancer in young women (<40 years old) and elderly women (>80 years old).2.To Identify the challenges and limitations of different imaging modalities in diagnosing breast cancer at both ends of life.3.To Discuss the implications of age-related factors on breast cancer prognosis and treatment planning.

**TABLE OF CONTENTS/OUTLINE**

IntroductionBreast cancer manifests with distinct characteristics across different age groups, particularly in the extremes of life - the very young (<40 years old) and elderly women (>80 years old).Imaging Appearance of Cancer at Both Ends of Life.Clinical Case.Management.In conclusion, this abstract highlight the importance of recognizing age-specific variations in breast cancer characteristics and the pivotal role of imaging in facilitating early detection and personalized treatment strategies.

## BREE-128 ARTIFACTS IN BREAST MRI AND CHALLENGES IN THEIR INTERPRETATION

Karina Pesce, PhD (*Abstract Co-Author*) Nothing to Disclose
Maria Jose Chico (*Abstract Co-Author*) Nothing to Disclose
Griselda Choque Leniz, MEd,MEd (*Abstract Co-Author*) Nothing to Disclose
Fatima Quispe Villca SR, MMed (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Identify the different types of artifacts in breast magnetic resonance imaging. Several examples of technical and patient-related artifacts that one might encounter will be illustrated.

**TABLE OF CONTENTS/OUTLINE**

Breast magnetic resonance imaging has become an important tool for high risk screening, breast cancer staging, response to treatment, assessment of recurrence after treatment, and evaluation of breast implants. However, the challenge arises in identifying artifacts generated in breast magnetic resonance images that can degrade image quality and obscure important diagnostic findings. The present work aims to recognize the artifacts and understand how to address them and optimize breast magnetic resonance image quality and avoid interpretive errors.

## BREE-13 BEYOND THE SURFACE: A COMPREHENSIVE EXPLORATION OF BREAST LYMPHOMAS THROUGH MULTIMODALITY IMAGING AND HISTOPATHOLOGY

Mary C. Mahoney, MD (*Abstract Co-Author*) Nothing to Disclose
Mitva J. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Randy C. Miles, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Rifat A. Wahab, DO (*Abstract Co-Author*) Nothing to Disclose
Serine E. Baydoun, MD (*Abstract Co-Author*) Nothing to Disclose
Lauren E. Rosen, MD (*Abstract Co-Author*) Nothing to Disclose
Charmi Vijapura, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Describe typical and atypical multimodality imaging findings on mammogram, ultrasound, and MRI of breast lymphomas.2. Highlight clinical presentations seen with each breast lymphoma type in the radiology setting.3. Discuss current treatment and management recommendations of the various types of breast lymphomas.4. Review pathology and key immunohistochemistry profiles of these breast lymphomas.

**TABLE OF CONTENTS/OUTLINE**

1) Introduction to various types of breast lymphomas2) Review of B vs. T cell origin3) Incidence breakdown of each lymphoma type4) Comparison of primary verses secondary breast lymphomas5) Case-by-case review with imaging, key information, and management discussion--Diffuse large B-cell lymphoma--Extranodal marginal zone lymphoma (MALT lymphoma)--Follicular lymphoma--Burkitt lymphoma--B- and T-lymphoblastic lymphoma/leukemia (CLL/SLL)--Anaplastic large cell lymphoma with emphasis on breast-implant associated type6) Discussion of optimal biopsy and tissue collection techniques in breast imaging

## BREE-130 LYMPHOCYTES IN MY BREAST, WHAT DOES IT MEAN? LYMPHOMA, TILS (TUMOR INFILTRATING LYMPHOCYTES) AND BEYOND. A PICTORIAL REVIEW OF LYMPHOCYTE-CONTAINING BREAST LESIONS

Javier Azpeitia Arman, MD (*Abstract Co-Author*) Nothing to Disclose
Ana Ines Rubio Aguilera, MD (*Abstract Co-Author*) Nothing to Disclose

Soledad Alonso Garcia (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia-Hernandez, MD (*Abstract Co-Author*) Nothing to Disclose
Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-To review the different breast lesions containing lymphocytes. - To describe features of breast lymphomas. - To analyze the concept of TILS (tumor infiltrating lymphocytes) in breast tumors. - To illustrate imaging findings in different imaging modalities (CEM, US, MRI) with correlation with pathology. - To emphasize pitfalls, diagnostic difficulties, and differential diagnosis

**TABLE OF CONTENTS/OUTLINE**

Lesions containing different types of lymphocytic infiltration may appear within the breast. Understanding TILS concept and knowledge of lymphocyte containing lesions is essential for the radiologist.We present: - Lymphoid tissue in the breast. Anatomy and physiology. - Breast lymphoma. Images of primary and secondary breast lymphomas from our series will be presented. Usually, non-specific, most frequently enlarging masses. -Medullary carcinoma. A circumscribed mass in which lymphocytic infiltrate is a key diagnostic criterion. -Lymphocytic mastitis/diabetic mastopathy. Lymphocytes may also appear in inflammatory lesions. Lymphocytic mastitis is unusual and probably immune-mediated. If associated with diabetes called Diabetic mastopathy, with lobular atrophy and sclerosis called Sclerosing type. Usually, non-circumscribed masses or focal asymmetry. -TILS are clinically relevant regarding implications on response to treatment and prognosis. This lymphocytic infiltrate might represent a form of host resistance to the tumor. TILS are most frequently found in triple negative breast cancer, followed by HER2 positive and less frequently in luminal breast cancer.

## BREE-131 ENHANCING DIAGNOSTIC VALUE WITH CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY THROUGH QUANTITATIVE ENHANCEMENT ANALYSIS

Huizhi Cao (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To understand the mechanism and clinical utility of contrast-enhanced spectral mammography (CESM) in breast cancer screening, staging, and treatment monitoring. 2. To demonstrate quantitative variables and kinetic enhancement patterns of breast lesions on CESM in enhancing diagnostic accuracy and differential diagnosis. 3. To discuss the diagnostic performance of radiomics in combination with CESM for suspicious malignant lesions characterization. 4. To present case studies with the integration of history, imaging findings, and tissue diagnosis for utilizing quantitative CESM characteristics in challenging or equivocal mammographic abnormalities.

**TABLE OF CONTENTS/OUTLINE**

1. To introduce the principle of CESM, contrast protocol, abnormal enhancing characteristics and illustrative cases in demonstrating CESM's role in BIRADS assessment and management of equivocal mammographic lesions. 2. To demonstrate quantitative analysis of kinetic enhancement patterns on CESM in distinguishing benign from malignant breast lesions. 3. To understand the concept of radiomics and its integration with CESM in identifying suspicious malignant microcalcifications (BIRADS 4). 4. To discuss strategies for appropriately utilizing quantitative CESM characteristics in complex or ambiguous mammographic abnormalities.

## BREE-132 ENHANCING PREDICTIVE POWER OF CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY (CESM) IN ASSESSING RESPONSE TO NEO-ADJUVANT CHEMOTHERAPY

Huizhi Cao (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To grasp the technical foundations of contrast-enhanced spectral mammography (CESM) and its Operationalization. 2. To identify lesion types amenable to evaluation via CESM. 3. To unveil CESM's capacity for accurate assessment of tumor response post Neo-adjuvant chemotherapy (NAC), comparable to MRI. 4. To employe quantitative objective measures in predicting response to NAC through RECIST 1.1 and combined evaluation approaches. 5. To appreciate the scope and nuances of CESM's utility in treatment monitoring.

**TABLE OF CONTENTS/OUTLINE**

1. Unveiling the underlying principles and physics of contrast-enhanced spectral mammography. 2. Exploring CESM's clinical application as a promising follow-up modality post-NAC. 3. Understanding the variables influencing tumor shrinkage and assessment during NAC, including primary tumor Size, edema, or necrosis. 4. Qualitative and quantitative assessment of CESM in predicting response to NAC. 5. Weighing the advantages and constraints of CESM.

## BREE-134 AXILLARY IMAGING: PEARLS AND PITFALLS

Caroline Merriam, DO (*Abstract Co-Author*) Nothing to Disclose
Liva Andrejeva-Wright, MD (*Abstract Co-Author*) Nothing to Disclose
Manroop Kaur, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. The axilla is normally comprised of lymph nodes, axillary neurovascular bundles, and adipose tissue.2. Accessory breast tissue is categorized into classes, and the axilla is the most common location for fibroglandular accessory breast tissue (Class IV).3. Recognizing abnormalities in ectopic breast tissue is important as malignancies may arise at an earlier age in aberrant tissue.4. The purpose of the exhibit is to review benign and malignant pathologies in the axilla through a multi-modality case-based presentation.5. Benign features of axillary lesions include well-circumscribed margins in parallel orientation with posterior acoustic enhancement and absence of early enhancement. 6. Malignant features of axillary lesions include spiculated/angulated margins in taller than wide orientation, posterior acoustic shadowing, and early enhancement characteristics.

**TABLE OF CONTENTS/OUTLINE**

1. Normal anatomical structure of the breast and axilla.2. Imaging characteristics of normal axillary tissue versus accessory breast tissue.3. Multi-modality case-based review of benign pathologies in the axilla: accessory breast tissue, fibroadenoma, sebaceous cyst, Hidranitis suppurativa, reactive lymph nodes, lymphatic malformation, capillary hemangioma 4. Multi-modality case-based (US, Mammography, MRI) review of malignant pathologies in the axilla: primary breast cancer (DCIS/LCIS), metastatic lymph nodes from breast-primary cancer, metastatic lymph nodes from non-breast primary cancer. 5. BI-RADS application for lesions in the axilla and next steps for follow-up.

## BREE-135 MAXIMIZING SENSITIVITY: THE ART OF MAMMOGRAPHY POSITIONING AND ITS IMPACT ON EARLY DETECTION OF BREAST CANCER

Aline C. Oliveira (*Abstract Co-Author*) Nothing to Disclose
Livia P. Souza, MD (*Abstract Co-Author*) Nothing to Disclose
Gabriela Lauar, MD (*Abstract Co-Author*) Nothing to Disclose
Carla C. Tajima (*Abstract Co-Author*) Nothing to Disclose

Sofia B. Maksoud, MD (*Abstract Co-Author*) Nothing to Disclose
Mateus Oliveira Gloria, MD (*Abstract Co-Author*) Nothing to Disclose
Carla C. Benetti, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Mammography assumes a pivotal role in breast cancer screening, renowned for its efficacy in early disease detection and subsequent reduction in mortality rates. Nevertheless, the efficacy of mammography is contingent upon various factors, encompassing the proficiency of mammography technologists, accurate calibration of equipment parameters, and the unique anatomical features of each patient. These multifaceted considerations can attenuate the sensitivity of the modality. Among the manifold factors influencing the interpretability of mammograms, improper breast positioning stands as a principal adversary, precipitating a cascade of adverse outcomes including unwarranted re-examinations, escalated radiation exposure, elevated recall rates, and potential diagnostic delays. Emerging research endeavors are leveraging artificial intelligence (AI) as a complementary tool to identify and rectify positioning errors during mammographic examinations. However, notwithstanding the integration of AI support, the indispensable role of radiologists and technologists in discerning the hallmarks of a meticulously executed mammography remains unequivocal. Their proficiency is imperative in mitigating the propensity for unnecessary recalls, mitigating radiation exposure, curtailing healthcare expenditures, assuaging patient apprehensions, alleviating procedural discomfort, and averting diagnostic delays.

### TABLE OF CONTENTS/OUTLINE

This study aims to emphasize the importance of obtaining high-quality mammographic images by evaluating factors such as the patient's medical history, anatomy, equipment parameters, with a strong emphasis on proper positioning during the exam.

## BREE-136 EXPLORING IMAGING CHARACTERISTICS IN EXTRAMAMMARY METASTASES IN BREAST: A MULTIMODALITY APPROACH

Bong Joo Kang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Han Song Mun, MD (*Abstract Co-Author*) Nothing to Disclose
Sung Hun Kim (*Abstract Co-Author*) Nothing to Disclose
Ga-Eun Park, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

*Metastases to the breast are rare, with a reported incidence of 0.3-2%. Among these, lymphoma is the most common, followed by melanoma, lung, ovarian, and gastrointestinal tract origins. *Breast tissue confirmation is performed to verify the origin in patients with extensive metastasis. Additionally, breast biopsy is conducted as clinically indicated in patients with known cancer origins, given the rarity of metastases to the breast despite breast cancer's prevalence. *Imaging features may vary depending on the primary tumor and route of dissemination, with a circumscribed solid mass being the most frequent presentation. Hematogenous metastases, in particular, often manifest as multiple or bilateral masses.

### TABLE OF CONTENTS/OUTLINE

1. Literature reviews on breast metastasis. 2. Analysis of incidence and origin distribution. 3. Cases with various imaging characteristics using a multimodality approach.

## BREE-137 CONE BEAM BREAST CT IMAGE CHARACTERISTICS OF DIFFERENT PATHOLOGICAL TYPES OF BREAST PAPILLARY CARCINOMA

Wei Kang, MD (*Abstract Co-Author*) Nothing to Disclose

Yanxia Huang (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The distinct image characteristics of different pathological types of papillary carcinoma on Cone Beam Breast CT (CBBCT)

### TABLE OF CONTENTS/OUTLINE

1.Objective To explore the image characteristics of different pathological types of papillary carcinoma using Cone Beam Breast CT (CBBCT).2. Methods: Retrospective analysis was conducted on CBBCT image characteristics and time-density curves from 23 cases of different pathological types of papillary carcinoma, confirmed by pathology at our hospital between July 2019 and December 2023. 3. Results: 13 had intraductal papillary carcinoma, primarily characterized by multi-focal tumors of equal density, with clear boundaries. The long axis of these lesions generally aligned with the breast ducts and was often accompanied by calcification. The time-density curve was predominantly type II. Two cases had invasive papillary carcinoma, mainly with presenting as oval cystic- solid masses. They had indistinct margins, with heterogeneous internal enhancement patterns and prominently enhanced wall nodules. The cystic areas were smooth and with a time-density curve of type III. Two cases were of encapsulated papillary carcinoma, mainly with cystic- solid masses, circumscribed margins and smooth cystic walls, featuring a single enhanced wall nodule and a type III time-density curve. Six cases had solid papillary carcinoma, mainly with multiple cystic- solid masses or a diffuse enhancement pattern. They had indistinct margins, with lobulation and spiculation, and were accompanied by enhanced wall nodules, with time-density curves of mainly type II.4. Conclusion: CBBCT can be effective in differentiating between the various pathological types of papillary carcinoma.

## BREE-138 CLINICAL PERFORMANCE OF NEW IMAGE RECOMBINATION ALGORITHM (NIRA) FOR ARTIFACT REDUCTION IN CONTRAST-ENHANCED MAMMOGRAPHY

Huizhi Cao (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Contrast-enhanced mammography (CEM) emerges as a promising imaging tool for breast cancer diagnosis. However, CEM is susceptible to artifacts that can compromise image quality and diagnostic accuracy. The objectives of this exhibit are: 1. To introduce readers to contrast-enhanced mammography (CEM) as an emerging modality for breast imaging and discuss its implementation. 2. To examine common artifacts encountered in contrast-enhanced mammography, including those related to patients, contrast agents, such as ripple artifact, scatter radiation artifact, and misregistration artifact. 3. To showcase the efficacy of the New Image Recombination Algorithm (NIRA) in reducing artifacts on CEM images through practical application and clinical examples. 4. To highlight the clinical value of NIRA in quality assurance for CEM images, thereby reducing interpretation errors. 5. To explore technical and diagnostic limitations, including false-negative and false-positive results, associated with contrast-enhanced mammography.

**TABLE OF CONTENTS/OUTLINE**

1. Brief overview of different approaches in contrast-enhanced mammography and their features in imaging interpretation. 2. Identification and illustration of artifacts apparent on CEM images, including those caused during image acquisition, contrast agent-related artifacts, and typical digital mammography artifacts. 3. Practical application of the NIRA technique, accompanied by illustrated clinical examples, to demonstrate its effectiveness in reducing various artifacts. 4. Discussion on technical and diagnostic limitations, including false-negative and false-positive results, encountered in contrast-enhanced mammography.

## BREE-139 BLEEDING RISKS IN IMAGING-GUIDED BREAST BIOPSIES; A PRIMER FOR RADIOLOGISTS

Anand K. Narayan, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Amy M. Fowler, MD, PhD (*Abstract Co-Author*) Author with royalties, RELX
Thomas Loduca, MD (*Abstract Co-Author*) Nothing to Disclose
Clara Nemr (*Abstract Co-Author*) Nothing to Disclose

Alison R. Gegios, MD (*Abstract Co-Author*) Nothing to Disclose
Mai A. Elezaby, MD (*Presenter*) Investigator, Exact Sciences Corporation;Research Grant, Exact Sciences Corporation

**TEACHING POINTS**

Image-guided breast biopsies (BrBx) are the standard of care for suspicious breast findings. Bleeding complications of BrBx can lead to patient anxiety, additional imaging exams, and increased treatment costs. Historically, paucity of national data and lack of guidelines for management of periprocedural bleeding risk of BrBx is reflected in the significant variability among practicing radiologists. The Society of Interventional Radiology in 2019 published consensus-based approach for assessment of bleeding risk in patients undergoing interventional procedures. However, the management of patients on AT medications and those with inheritable bleeding disorders is still a source of confusion and can potentially delay critical interventions. Recent breast-specific data on risk of significant bleeding in BrBx, even without cessation of antithrombotic (AT) medications, is low (1%). This data weighed against thrombotic risk from temporarily stopping AT medications may warrant updated management protocols. Thus, clinical need dictates for better understanding of the complex coagulation pathway, learn the current antithrombotic medications as well as understand risk management protocols before, during, and after BrBx. In addition, the knowledge of proper management strategies if bleeding occurs is critical for improved patient care and outcomes.

**TABLE OF CONTENTS/OUTLINE**

- Pathophysiology of coagulation pathway and pharmacokinetics of common AT medications.
- Recent data on incidence and significance of bleeding complications after BrBx
- Steps to decrease bleeding risk before, during, and after BrBx.
- How to recognize and manage bleeding complications of BrBx through case-based, image-rich examples.

## BREE-14 ARTIFACTS IN BREAST ELASTOGRAPHY AND HOW TO RECOGNIZE AND AVOID THEM

Jonathan Langdon, MD (*Abstract Co-Author*) Nothing to Disclose
Richard G. Barr, MD, PhD (*Presenter*) Consultant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Siemens AG;Consultant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Consultant, Canon Medical Systems Corporation;Advisor, Hologic, Inc;Research Grant, Hologic, Inc

**TEACHING POINTS**

1. Artifacts in breast elastography are common and can lead to false positive and false negative results. 2. Recognizing breast elastography artifacts and knowing how to avoid them is critical for accurate breast lesion assessment 3. Artifacts can occur both in strain and shear wave elastography 4. Performing both strain and shear wave elastography will help recognize artifacts 5. Learn the optimal technique for both strain and shear wave elastography

**TABLE OF CONTENTS/OUTLINE**

A. Review of the principals of strain and shear wave elastography of the breast B. Review the literature on strain and shear wave imaging of the breast C. Describe common breast elastography artifacts and how to recognize them and avoid them 1. Artifacts associated with cystic lesions 2. The "blue" or "soft" cancers 3. The Bang artifact 4. Artifacts due to poor position of the transducer 5. How to recognize noise 6. The sliding artifact 7. The effect of precompression or preload8. Use of the quality map in shear wave elastography D. Summary of the optimal technique for both strain and shear wave elastography for breast lesion evaluation

## BREE-140 DECODING BENIGN BREAST LESIONS: IMAGING CHALLENGES & CHEMO-RESPONSE

Juliana H. Catani, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia T. Lima (*Abstract Co-Author*) Nothing to Disclose
Lidia B. Rodrigues, MD (*Abstract Co-Author*) Nothing to Disclose

Vera Christina C. Ferreira, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza A. Oliveira Gatto, MD (*Abstract Co-Author*) Nothing to Disclose
Naomi Murakami SR, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Fibroadenoma is a benign breast neoplasm characterized by a composition of fibrous and glandular tissue, representing the most prevalent benign neoplasm of the female breast and is typically observed in women under 30 years of age, although it can occur at any point in the reproductive years.2. After chemotherapy, fibroadenomas and other benign breast lesions can exhibit changes in their imaging features. They may show decreased enhancement or may demonstrate a reduction in size on Magnetic Resonance Imaging (MRI) or Computed Tomography (CT). Such changes can sometimes make it challenging to distinguish between a benign and a malignant lesion.3. In cases where lesions exhibiting benign imaging characteristics have responded to chemotherapy, the decision regarding further management should take into consideration the initial level of suspicion.

**TABLE OF CONTENTS/OUTLINE**

1. Emphasize the importance of benign breast lesions findings in the different methods, as it is a common finding of benign breast lesions.2. Show the pathology, epidemiology, histological origin, imaging aspects in the different methods of benign breast lesions.3. Review on imaging findings of the effects of neoadjuvant or adjuvant chemotherapy on fibroadenomas and other benign breast lesions through illustrative cases with different imaging methods, including Ultrasound, Mammography, Tomosynthesis, Magnetic Resonance Imaging and Computed Tomography.4. Discuss the management approach in cases where a lesion presents imaging characteristics indicative of benignity, yet demonstrates decreased enhancement or dimensions following chemotherapy.

## BREE-141 FREE MARGINS AFTER BREAST CANCER SURGERY: USEFULNESS OF MRI GUIDED ROLL, RADIOGUIDED OCCULT LESION LOCALIZATION, TECHNIQUE

Javier Sanchez-Bordona Marques, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Paula Andrea Arias Cadena, MD (*Abstract Co-Author*) Nothing to Disclose
Manuel R. Recio Rodriguez, PhD (*Abstract Co-Author*) Nothing to Disclose
Leire Alvarez Perez, BMedSc (*Abstract Co-Author*) Nothing to Disclose
Vicente Martinez de Vega, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Presurgical MRI guided ROLL/SNOLL localization in breast cancer may be useful in selected cases to obtain surgical free margins. This technique is accurate, safe and fast. How to perform radioguided breast surgery for those malignant lesions displayed only with breast MRI and sentinel node detection.

**TABLE OF CONTENTS/OUTLINE**

Suspicious lesions detected only seen by MRI (not seen with mammography or ultrasound) require histological diagnosis. This is performed by an MRI-guided VAB, after which a marker is left in case the patient requires surgery. Titanium markers placed can move because of the relatively large size of the resulting cavity and subsequent hematoma formation after the procedure.On the other hand, in some cases, the malignant lesion detected by MRI is more extensive than that visualized by mammography and ultrasound.In both situations, marking the previously biopsied lesion or its boundaries with MRI-guided procedure reduces the number of surgical positive margins.Radioguided occult lesion localization (ROLL) has emerged as a novel technique in surgery for non-palpable breast lesions, inspired by sentinel node biopsy (SNB). With MRI guidance, we can practice the ROLL technique and add SNOLL (sentinel node and occult lesion localization) in the same procedure.We present our experience in presurgical MRI guided ROLL/SNOLL localization in 93 patients.

## BREE-142 DEFINING SUCCESS IN CRYOABLATION: LONG TERM OUTCOMES FROM A SINGLE INSTITUTION

Sehar Salman, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Mary Schwartz, MD (*Abstract Co-Author*) Nothing to Disclose
Modupe M. Adeyefa, MD (*Abstract Co-Author*) Nothing to Disclose
Luz A. Venta, MD (*Abstract Co-Author*) Nothing to Disclose
Mimi Haghshenas, MD (*Abstract Co-Author*) Nothing to Disclose
Sasha Kurumety, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The goal of this presentation is to educate radiology trainees on the use of cryoablation as a treatment option for breast malignancies, when cryoablation may be appropriate, and outcomes that can be deemed successful when cryoablation is used for breast malignancies. Using a select series of cases from our institution, we will describe the multiple potential roles of cryoablation and mechanism of action, as well as demonstrate post treatment imaging findings over the course of months to years. After this presentation, learners will be able to describe the utility of cryoablation in treating breast malignancies, long term outcomes and imaging findings after treatment, and future directions for cryoablation.

**TABLE OF CONTENTS/OUTLINE**

Background: Current FDA approved indications for cryoablation and investigation of cryoablation in breast cancer. Discussion of ongoing trials (ICE3, FROST). Goals of cryoablation when used for malignancies: palliative vs curative, long term outcomes of cryoablation when used in breast malignancies. Discussion of mechanisms of action: Direct freezing and cell death, indirect immune response activation. Cryoablation at our institution: Cases of cryoablation with pathologic findings on biopsies, intraprocedural imaging, and sequential long term follow up imaging findings. Comparison of outcomes to standard of care without cryoablation. Future directions: Defining indications of cryoablation, increasing accessibility, utility with palliative intent.

## BREE-143 METHOD OF DETECTION IN BREAST CANCER IMAGING: PROOF OF CONCEPT OF AUTOMATED MOD DESIGNATION

Laurie R. Margolies, MD (*Abstract Co-Author*) Stock options, Nuevozen Corporation Medical Advisory Board, Screenpoint Medical
Arielle Sasson (*Presenter*) Medical Advisory Board, Screenpoint Medical

**TEACHING POINTS**

• Method of Detection (MOD) is the first clinical event or imaging study to trigger a workup which may lead to the diagnosis of breast cancer. It is expected to be included in the 6th edition of the BI-RADS atlas.• Documenting MOD allows quantification of the impact of breast cancer screening on treatment and patient outcomes.• Some breast radiology reporting tools provide an advanced algorithm to automate MOD assignment to simplify MOD data collection.

**TABLE OF CONTENTS/OUTLINE**

• **Background**• Ongoing debate related to breast cancer screening frequency and age range• These controversies are in part due to dependence on old film screen historical clinical trial data and varying interpretations/misinterpretations of the data. Additionally, this data may not speak for the diversity of the current population, increasing incidence of breast cancer and/or recent advances made in breast cancer imaging.• Many nations utilize a centralized

breast cancer screening program that monitors the results of screening mammography for every patient.• **What is MOD and why should we care about it?**• Comprehensive definition and proposed categories of initial MOD• Reasons why we should track initial MOD data for every patient• Methods of assigning MOD• Retrospective versus prospective assignment of MOD• Breast radiology reporting tools can automate MOD assignment• Present example images of MOD automation • Discuss difficult scenarios in assigning MOD, such as when a patient presents with a palpable abnormality in one breast but malignancy is detected in the opposite breast • Barriers to collecting MOD data• **References**

### BREE-144 NAVIGATING THROUGH THE FOG: MAMMOGRAPHIC FINDINGS IN THE CONTEXT OF SYSTEMIC DISEASES

Rosaura E. Fuentes Corona, MD (*Abstract Co-Author*) Nothing to Disclose
Javier Rios Valencia (*Abstract Co-Author*) Nothing to Disclose
Sara Eugenia Vazquez Manjarrez, MD (*Abstract Co-Author*) Nothing to Disclose
Denny Lara Nunez, MD (*Abstract Co-Author*) Nothing to Disclose

Ernesto D. Elizondo Zepeda, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To describe and to recognize the most common findings of Systemic Diseases reflected in mammography. To learn that understanding the patients' pathological background is important to comprehend the described findings.

#### TABLE OF CONTENTS/OUTLINE

Introduction Mammographic findings in Systemic Diseases:- Autoimmune / Autoinflammatory- Endocrine- Cutaneous- Infectious- Edema- Extramammary malignancies Conclusions

### BREE-145 REVOLUTIONIZING DETECTION: LOCALLY ADVANCED BREAST CANCER IN YOUNG WOMEN UNVEILED BY AB MRI DESPITE MORPHOLOGICALLY NEGATIVE EXAMS

Flavia B. Sarquis, MD (*Abstract Co-Author*) Nothing to Disclose
Maria A. Acha I, MD (*Abstract Co-Author*) Nothing to Disclose
Angelica M. Rivera (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Breast cancer is the second leading cause of cancer deaths in women aged 20-39, and it often presents with more aggressive features compared to breast cancer in older women.Mammography is the standard imaging modality for breast cancer detection, but it has limitations.Young women with locally advanced breast cancer may have negative mammograms and ultrasounds due to their dense breast tissue. It is generally associated with palpatory findings not related to mastitis.Abbreviated Breast MRI (AB-MRI) can detect locally advanced breast cancer in young women with negative mammograms and ultrasounds.AB-MRI can provide valuable information to clinicians for early detection and treatment of breast cancer in young women.After reading this educational exhibit, the radiologist will know :AB-MRI can be used as an imaging modality in young women with negative mammograms and ultrasounds for early detection and treatment of breast cancer, avoiding delays in diagnosis.

#### TABLE OF CONTENTS/OUTLINE

Introduction: The Challenge of Detecting Breast Cancer in Young Women.AB-MRI in Young Women with Negative Mammograms and Ultrasound.AB-MRI vs. Mammography: Comparing Sensitivity and Specificity.Future Directions: The Potential of AB-MRI in Breast Cancer Diagnosis and Management.Conclusion

### BREE-15 BREAST OR NOT BREAST: CHEST WALL AND AXILLARY ABNORMALITIES IN BREAST IMAGING

Muhayman Sadiq, MBBS (*Abstract Co-Author*) Nothing to Disclose
Claudia Cotes, MD (*Abstract Co-Author*) Nothing to Disclose
Tiffany A. Kumala (*Abstract Co-Author*) Nothing to Disclose
Vidhyulatha Sanata, MD, MBBS (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

It's not uncommon for patients with chest wall and axillary abnormalities unrelated to the breast to initially present to the breast imaging department. Mammography and breast ultrasound, although helpful for excluding breast related malignancies, may not always be the most suitable modalities for evaluation, often leading to inconclusive results. These scenarios present challenges for radiologists, particularly concerning biopsy approaches and appropriate recommendations for additional imaging to comprehensively assess these patients. This exhibit showcases the chest wall and axillary anatomy on mammography, breast ultrasound, and breast MRI, delineates the role of breast imagers in the evaluation of abnormalities within these regions, and offers guidance on the subsequent imaging steps and biopsy approaches for evaluating non-breast chest wall and axillary findings through illustrative case examples.

#### TABLE OF CONTENTS/OUTLINE

1. Chest wall and axillary anatomy: Mammography, Ultrasound, Breast MRI 2. Differential diagnoses based on location:Chest wall: Anterior chest wall muscle: Poland syndrome, Physiological hypertrophy, Pectoralis muscle Lipoma, Spindle cell sarcoma Ribs: Osteomyelitis, Benign and Malignant Bone tumors Posterolateral Chest wall: Lipoma, Elastofibroma Dorsi, Lymphatic malformations Axilla: Muscle: Sarcoma Lymphatic system: Atypical Lymphoma, Lymphangioma Shoulder Joint: Ganglion Cyst

### BREE-16 DECIPHERING ATYPICAL DUCTAL HYPERPLASIA: NAVIGATING IMAGING FINDINGS, DIAGNOSIS, AND EXPLORING MRI POTENTIAL

Sofia B. Maksoud, MD (*Abstract Co-Author*) Nothing to Disclose
Isabela Ferreira (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Atypical ductal hyperplasia (ADH) is part of the high-risk lesions group due to its association and potential progression to ductal carcinoma in situ (DCIS) and invasive carcinoma, being found in about 5 to 20% of biopsies performed. The histopathological features of ADH and DCIS are highly similar, distinguished primarily by size (less than 2 mm) and involvement in fewer than two ducts. The risk of progression to invasive carcinoma is estimated to range from 3.7% to 22%. ADH does not present defined radiological characteristics on its own. Mammography may reveal nodules, asymmetric densities, calcifications, and architectural distortions, often with amorphous calcifications within the lesion. On ultrasound, lesions typically appear as hypoechoic nodules with irregular shape, microlobulated margins, and abrupt interface, often due to coexisting processes. Magnetic resonance imaging (MRI) shows non-nodular enhancement, with patterns varying from progressive to plateau or wash-out. Given the potential for diagnostic underestimation and its propensity to coexist with DCIS and invasive carcinoma, surgical excision is advised post its histopathological diagnosis. Recent studies have been discussing the role of MRI in cases of ADH where no suspicious enhancement is observed in the biopsied area, which could potentially obviate the need for surgery in these cases.

**TABLE OF CONTENTS/OUTLINE**

To explore the histopathological characteristics of ADH, differential diagnoses, and its relationship with breast carcinoma, demonstrate the imaging findings of ADH across various imaging modalities using cases from our institution, discuss the role of MRI in the treatment decision-making.

## BREE-17 CLARITY IN CONTRAST: THE PICTORIAL ATLAS OF BENIGN BREAST LESIONS

Ernesto D. Elizondo Zepeda, MD (*Abstract Co-Author*) Nothing to Disclose
Sara Eugenia Vazquez Manjarrez, MD (*Abstract Co-Author*) Nothing to Disclose
Rosaura E. Fuentes Corona, MD (*Abstract Co-Author*) Nothing to Disclose
Javier Rios Valencia (*Abstract Co-Author*) Nothing to Disclose
Mariana Amaya, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Case-based presentation of benign breast lesions on diverse imaging modalities, with special focus on contrast-enhanced mammography.Every case has pathological correlation, enhancing diagnostic accuracy, some cases with histology images to augment understanding of lesion characteristics.Some of the featured lesions to review: Abscess, Mastitis, PASH, Simple Cyst, Adenosis, Ductal Hyperplasia, Fibrocystic Changes, Adenomas, and Fibroadenomas.Discussion on the utility of advanced imaging techniques in characterizing benign breast lesions. Highlighting key imaging features that aid in the differentiation of benign lesions from malignant ones, including shape, margin characteristics, internal architecture, and enhancement patterns.Exploration of potential challenges encountered in diagnosing benign breast lesions, with strategies for overcoming them.Consideration of the impact of patient demographics, such as age and hormonal status, on the imaging appearance of benign breast lesions, with implications for management decisions.

**TABLE OF CONTENTS/OUTLINE**

IntroductionAbscess and mastitis: Imaging CharacteristicsPseudoangiomatous Stromal Hyperplasia (PASH): A Comprehensive Imaging ReviewSimple Cyst: Diagnostic Imaging Findings and Clinical ImplicationsAdenosis: Imaging Spectrum and Differential DiagnosisDuctal Hyperplasia: Radiologic Patterns.Fibrocystic Changes: Imaging Manifestations.Adenomas: Radiological Features and Pathological CorrelationFibroadenomas: Imaging Spectrum and Patient ConsiderationsConclusion

## BREE-18 RADIOLOGICAL INSIGHTS: UNDERSTANDING BREAST PATHOLOGY IN PREGNANCY AND LACTATION

Ana Berasategui Criado, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Review physiological breast tissue changes and illustrate common breast disorders during pregnancy and lactation.Discuss the radiological approach to breast pathology in this period and deepen the understanding of pregnancy-associated breast cancer.

**TABLE OF CONTENTS/OUTLINE**

Breast pathology during pregnancy and lactation poses diagnostic challenges. Radiologists must be well-versed in the physiological changes and specific conditions of this period, considering the strengths and limitations of each imaging method. A multidisciplinary approach is paramount for optimal outcomes. Clinical manifestations include palpable mass, pain, or nipple discharge. While most lesions are benign, consideration of pregnancy-associated breast is crucial concerning prognosis impact.Radiological evaluation is pivotal in characterizing breast pathologies in these states. Ultrasound is the first-line choice for its safety and real-time evaluation. Mammography remains a complementary tool, especially in lactation and malignancy. MRI is reserved for clear risk-benefit ratio situations and local-regional staging in lactating women. Core biopsy is necessary for new/growing masses.Frequent findings include engorgement, lactational changes, benign lesions (fibroadenomas, galactoceles), and, rarely, breast cancer. Overlapping features and hormonal influences complicate interpretation. Timely diagnosis is crucial to guide subsequent management, balancing safety with diagnostic accuracy.This poster provides a pictorial review of illustrative cases from our institution encompassing benign, inflammatory, and malignant conditions underlying the hallmark findings that lead to accurate diagnosis.

## BREE-19 EXPLORING VISUAL TRAPS IN CONTRAST MAMMOGRAPHY

Rosaura E. Fuentes Corona, MD (*Abstract Co-Author*) Nothing to Disclose
Sara Eugenia Vazquez Manjarrez, MD (*Abstract Co-Author*) Nothing to Disclose
Fabio D. Tovar Aldana I, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To identify artifacts of image in CEM to avoid misdiagnosisExplain the underlying causes and mechanisms that contribute to the formation of artifacts in CEM, including technical, biological, and physical factors

**TABLE OF CONTENTS/OUTLINE**

-Brief definitions-Technical considerations-Artifices in contrasted mammographyTechnical Artifacts Patient related Artifacts Contrast Agent-related Artifacts -False positive diagnoses - Incomplete or Inadequate visualization in CEM- Conclusions

## BREE-2 DERMAL DILEMMAS: A REVIEW OF BREAST ABNORMALITIES INVOLVING THE EPIDERMIS, DERMIS, AND HYPODERMIS

**Awards**
**Certificate of Merit**

John M. Lewin, MD (*Abstract Co-Author*) Officer, Novian Health Inc
Manroop Kaur, MD (*Abstract Co-Author*) Nothing to Disclose
William J. Hoover, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Kuehne, MD (*Abstract Co-Author*) Nothing to Disclose
Caroline Merriam, DO (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- The breast skin is comprised of three distinct layers - epidermis, dermis, and hypodermis.
- Each layer harbors unique anatomic components, which may give rise to benign and malignant abnormalities.
- Breast skin lesions may pose a diagnostic challenge when detected incidentally on breast imaging.
- Several hallmark features, such as a sonographic “claw sign” or “dermal tail”, can localize and narrow the differential diagnoses for a breast skin lesion.
- This exhibit will discuss normal breast skin anatomy, and will illustrate the expected appearance of dermal layers on ultrasound, mammogram, and breast MRI.
- The presentation will include a case-based review of benign and malignant breast skin abnormalities.
- For each skin abnormality, we will describe the typical clinical presentation, multimodality imaging features, malignant potential, and appropriate next steps of management.

**TABLE OF CONTENTS/OUTLINE**

- Review of normal breast skin anatomy.
- Expected appearance of dermal layers on ultrasound, mammogram, and breast MRI.
- Key imaging features indicating dermal origin of a breast lesion.
- Multimodality imaging review of breast skin abnormalities, which will be organized into the following categories:
- Inherited abnormalities
- Vascular lesions
- Dermal cystic lesions
- Abnormal skin thickening
- Infectious and inflammatory lesions
- Malignancy

## BREE-20 LUMPECTOMY AND MASTECTOMY RECURRENCE: CASE REVIEW AND WHAT THE RADIOLOGIST CAN LEARN

Mary C. Mahoney, MD (*Abstract Co-Author*) Nothing to Disclose
Ann L. Brown, MD (*Abstract Co-Author*) Consultant, Elucent Medical
Erich J. Boomgarden, MD (*Abstract Co-Author*) Nothing to Disclose
Brian J. Guarnieri, MD (*Abstract Co-Author*) Nothing to Disclose
Rifat A. Wahab, DO (*Abstract Co-Author*) Nothing to Disclose
Charmi Vijapura, MD (*Abstract Co-Author*) Nothing to Disclose
Asir Chishti, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) List treatment options after diagnosing breast malignancy, including breast conservation, and review associated recurrence rates.2) Recognize risk factors which can lead to higher incidence of recurrent malignancy.3) Compare and contrast imaging findings consistent with recurrent malignancy and post-therapeutic changes.4) Review imaging pitfalls leading to misdiagnosis of recurrence and post-therapeutic changes.5) Discuss the management and treatment of recurrent malignancy.

**TABLE OF CONTENTS/OUTLINE**

1) Introduction2) Review of surgical and therapeutic options including breast conservation therapy.3) Discuss rates of recurrence associated with different types of therapy.4) Risk factors associated with higher rate of recurrence, including the following:- Tumor size- Positive margins- Type of malignancy and biomarkers- Lack of staging MRI- Incomplete management therapy5) Discussion of imaging and clinical surveillance for recurrence.6) Review of multimodality imaging findings suggestive of post-therapeutic changes versus recurrent malignancy.7) Cases reinforcing imaging findings consistent with post-therapeutic changes and recurrent malignancy.8) Overview of management and prognosis of recurrent breast malignancy.9) Multiple choice questions to reinforce key teaching points.

## BREE-21 MULTIMODALITY IMAGING REVIEW OF BREAST SARCOMAS

**Awards**
**Cum Laude**

Mary C. Mahoney, MD (*Abstract Co-Author*) Nothing to Disclose
Lauren E. Rosen, MD (*Abstract Co-Author*) Nothing to Disclose
Erich J. Boomgarden, MD (*Abstract Co-Author*) Nothing to Disclose
Charmi Vijapura, MD (*Abstract Co-Author*) Nothing to Disclose
Gustavo Leon (*Abstract Co-Author*) Nothing to Disclose
Brian J. Guarnieri, MD (*Abstract Co-Author*) Nothing to Disclose
Tristan A. Toca, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Provide an overview of sarcomas of the breast including risk factors, presentation, prognosis, and imaging characteristics2) Recognize unique imaging and clinical features of the different breast sarcomas3) Understand the importance of early diagnosis given the aggressive nature breast sarcomas as well as their management and treatment4) Review histopathologic similarities and differences between sarcomas within the breast

**TABLE OF CONTENTS/OUTLINE**

1) Introduction2) Graphic breakdown of the different types of sarcomas in the breast3) Risk Factors4) Characteristics and imaging overview of breast sarcomas5) Overview of prognosis, management, and treatment6) Case by case review including unique imaging findings, teaching points, and management-- Angiosarcoma-- Leiomyosarcoma-- Dermatofibrosarcoma Protuberans-- Spindle Cell Sarcoma-- Liposarcoma-- Fibrosarcoma-- Malignant Fibrous Histiocytoma-- Sarcomatous Transformation of a Phyllodes Tumor7) Review histopathologic features of sarcomas including similarities and differences8) Multiple choice questions to wrap up learning and reinforce important teaching points

## BREE-22 SPECIAL SUBTYPES OF INVASIVE BREAST CARCINOMA: UPDATE ON MULTIMODALITY IMAGING FINDINGS AND MANAGEMENT

Mary C. Mahoney, MD (*Abstract Co-Author*) Nothing to Disclose
Ann L. Brown, MD (*Abstract Co-Author*) Consultant, Elucent Medical
Rifat A. Wahab, DO (*Abstract Co-Author*) Nothing to Disclose

Lauren E. Rosen, MD (*Abstract Co-Author*) Nothing to Disclose
Hannah Levine (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Review the most current WHO pathologic classification of breast tumors.2) Recognize sonographic, mammographic, and MRI findings that are specific to the special subtypes of invasive breast carcinoma.3) Characterize histopathology of the special subtypes.4) Discuss special considerations of each special subtype with the goal of targeted management and improved pathologic correlation.

**TABLE OF CONTENTS/OUTLINE**

IntroductionWHO ClassificationGraphic breakdown of invasive no special type versus these Special SubtypesOverview of imaging workup (Screening and Diagnostic)-Mammogram-Ultrasound-MRI Detailed Cases with Histopathology:-Mucinous-Micropapillary-Neuroendocrine-Tubular-Cribriform-Papillary-Medullary-Metaplastic-Lobular-Metaplastic-Apocrine-Salivary gland-type tumors (Acinic cell, Adenoid cystic, Secretory, etc.)Summary tableReview questionsConclusions: 1) Improved knowledge of specific sonographic, mammographic, and MRI findings of these special subtypes of invasive breast carcinoma is important for developing a comprehensive differential.2) Appropriate histopathologic correlation leads to improved targeted management of these special subtypes avoiding delays in care.

## BREE-23 SHARPENING SKILLS, SHAPING FUTURES: NEXT-LEVEL BREAST BIOPSY TECHNIQUES FOR RESIDENTS

Fernanda Louise Sothe, MD (*Abstract Co-Author*) Nothing to Disclose
Lucy T. Sato, MD (*Abstract Co-Author*) Nothing to Disclose
Giselle G. Mello, PhD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Abstract Co-Author*) Nothing to Disclose
Marcela P. Viana, MD (*Abstract Co-Author*) Nothing to Disclose
Luciano F. Chala, MD (*Abstract Co-Author*) Nothing to Disclose
Tatiana C. Tucunduva, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Training Importance: Stress on training residents before they begin procedures.
- Percutaneous Biopsy Skills: Enable residents to perform core needle biopsy, fine needle aspiration, vacuum-assisted biopsy (ultrasound and stereotaxy-guided), and pre-surgical marking (ultrasound, mammography, stereotaxy-guided).
- Preparation Areas:
- Conducting focused pre-procedure anamnesis.
- Informing patients about procedure steps and risks.
- Executing procedures with correct technique.
- Handling in-procedure complications and queries.
- Managing post-procedure complications (e.g., hematomas, infections).

**TABLE OF CONTENTS/OUTLINE**

- Precision in Detection: Crucial for invasive breast procedures, affecting diagnostics and treatment.
- Specialized Training: Key for resident safety and efficacy in breast procedures.
- Innovative Training Methods:
- Core biopsy with olives in chicken for nodules.
- Stereotactic biopsy with eggshells in mortadella for microcalcifications.
- FNA with water in gloves for cysts.
- Ultrasound biopsy with quail eggs for solid-cystic lesions.
- Pre-surgical marking with chicken and metallic clips.
- Training Structure: Merges theory and practice over a month with weekly skill sessions.
- Training Objectives: Prepare residents for real scenarios, focusing on technical skills and decision-making.
- Professional Development Impact: Enhances skills, precision, and efficiency, transitioning novices to experts.
- Patient Safety Contribution: Simulations reduce learning risks, lower complications, and improve outcomes.

## BREE-24 BEYOND THE LINES: UNVEILING ARCHITECTURAL DISTORTION THROUGH IMAGING MODALITIES

Carla C. Benetti, MD (*Abstract Co-Author*) Nothing to Disclose
Danielle Teles Leal (*Abstract Co-Author*) Nothing to Disclose
Carla C. Tajima (*Abstract Co-Author*) Nothing to Disclose
Carlos H. Rosas, MD (*Abstract Co-Author*) Nothing to Disclose
Sofia B. Maksoud, MD (*Abstract Co-Author*) Nothing to Disclose

Aline C. Oliveira (*Abstract Co-Author*) Nothing to Disclose
Leticia T. Oliveira, MD (*Abstract Co-Author*) Nothing to Disclose
Livia P. Souza, MD (*Abstract Co-Author*) Nothing to Disclose
Isabela Ferreira (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Defined as a distortion of the usual architecture of the breast parenchyma without visible nodules, architectural distortion (AD) is the third most commonly observed abnormality in cases of false-negative mammography and the third most common finding in nonpalpable breast cancer; - The AD can be an associated finding with other alterations and involves benign causes such as complex sclerosing lesion, radial scar, fat necrosis, post-surgical changes, and others; - Digital breast tomosynthesis (DBT) has played a relevant role in detecting AD, especially in dense breasts, by reducing overlapping tissue, allowing for better visualization of true lesions. However, literature studies demonstrate that AD found in DBT have a lower chance of representing malignancy and the AD is less likely to represent malignancy if there is no ultrasound correlation. Though, even in these cases, biopsy is still necessary since there is a risk of about 30% malignancy.

**TABLE OF CONTENTS/OUTLINE**

- To explore the imaging patterns of AD across various imaging modalities using cases from our institution and correlate them with histopathological findings; - To discuss the significant role of DBT in cases of AD; To discuss the malignant and benign causes of AD and their management.

## BREE-25 CURRENT INSIGHTS INTO COMMON GENETIC MUTATIONS IN BREAST CANCER: A COMPREHENSIVE REVIEW OF GUIDELINES AND IMAGING FINDINGS

Su Kim Hsieh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Aiah Alatoum, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Genetic mutations increase the risk of developing breast cancer. Mutations in genes BRCA1, BRCA2, TP53, PTEN, CDH1, STK11, ATM, CHEK2, and PALB2 are being considered to change recommendations for screening and management.
- Genetic panels are evolving, and the Institutional guidelines frequently update their recommendations.
- Some genetic mutations are more associated with specific biomarkers, for instance, BRCA 1 and 2 mutation carriers have a higher prevalence of triple negative cancers.
- Identifying a genetic mutation in a patient can impact their family members, and they should be tested.
- The knowledge of a particular genetic mutation can lead to a more extensive surgical treatment like mastectomy and contralateral prophylactic mastectomy or expand treatment options, like the use of poly (ADP-ribose) polymerase (PARP) inhibitor therapy for early-stage HER-2 negative cancer or metastatic disease.

**TABLE OF CONTENTS/OUTLINE**

1. Definition of somatic and germline mutations. 2. Definition of a wild gene and low and moderate-risk genes. 3. Definition of the possible genetic testing results. 4. Review the main genetic mutations that increase the risk of breast cancer. 5. Review of current indications for genetic testing. 6. Review of recommendations for patients with positive genetic testing regarding screening, treatment management, and prophylaxis. 7. Review of characteristics of breast cancer and lesions with potential for upgrade in patients with genetic mutation. 8. Illustrative cases of patients with genetic mutations and breast cancer or lesions with potential for an upgrade from our Institution.

## BREE-26 NON MASS LESIONS (NMLS) ON BREAST ULTRASOUND - THE GOOD, THE BAD AND THE UGLY

Alexandra Pop, MD (*Abstract Co-Author*) Nothing to Disclose
Roxana Pintican, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The incidence of non-mass lesions (NMLs) in breast US has been reported to range from 1% to 5.3%, with malignancy accounting for 6.3% to 53.8%, underscoring the importance of their accurate identification and diagnosis. GOALS:1. Describe the NML terminology on US2. Present typical benign (The GOOD) and malignant (The BAD) NML cases together with their pathology correlates: a. The GOOD - fibro-cystic changes, fibrosis, adenosis, ductal epithelial hyperplasia (typical and atypical), plasma cell mastitis, idiopathic granulomatous mastitis b. The BAD - DCIS with/without invasive component, IDC, invasive lobular carcinoma, solid papillary carcinoma, adenoid cystic carcinoma3. Discuss challenging cases (The UGLY) where NMLs may obscure or mimic benign/malignant features, leading to diagnostic uncertainty or misinterpretation; emphasize the added role of mammography and breast MR4. Provide a brief literature overview of different scoring and malignancy predicting systems a. The GOOD - presence of small cysts, absence of microcalcifications b. The BAD - linear-segmental distribution (50-76.6% associated with malignancy, mainly DCIS), associated microcalcifications (OR = 11.7), architectural distortion (OR 3.14), hypervascularity (Adler 3), stiffness (elasticity score 4 or 5, OR = 5.84).

**TABLE OF CONTENTS/OUTLINE**

1. Overview of NML definitions 2. The GOOD - benign NML 3. The BAD - malignant NML 4. The UGLY - masking/pitfalls NML 5. Scoring and malignancy prediction NML systems

## BREE-27 INTERPRETATIVE AND NON-INTERPRETATIVE USES OF ARTIFICIAL INTELLIGENCE IN BREAST IMAGING: A GUIDE FOR PRACTICING RADIOLOGISTS

Mai A. Elezaby, MD (*Abstract Co-Author*) Investigator, Exact Sciences Corporation;Research Grant, Exact Sciences Corporation
Roberta M. Strigel, MD, MS (*Abstract Co-Author*) Research support, General Electric Company
Pamela A. Propeck, MD (*Abstract Co-Author*) Nothing to Disclose
Lonie R. Salkowski, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ryan W. Woods, MD, MPH (*Abstract Co-Author*) Author, MRI Online
Alison R. Gegios, MD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth S. Burnside, MD, MPH (*Abstract Co-Author*) Research Grant, Hologic, Inc
Anand K. Narayan, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Thanh Phuong Nguyen, BS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Artificial intelligence (AI) algorithms have reinvigorated interest in its utility in radiology. Breast imaging is uniquely poised to both evaluate the utility of assistive AI and advance the integration of AI into real world clinical practice. Since AI is a diverse field, it has the potential to impact both non-

interpretive and interpretive applications extending beyond breast cancer detection. This exhibit reviews current and potential real world clinical applications of AI in breast imaging before, during, and after the acquisition of imaging examinations.

**TABLE OF CONTENTS/OUTLINE**

1. Artificial Intelligence Definitions 2. Historical challenges (a. Medicolegal/liability, b. Quality assurance, c. Racial biases, d. Variability in image sizes/quality, e. Multimodality imaging) 3. Unique features of breast imaging for AI applications (a. Standardized technique for screening mammography, b. BI-RADS lexicon and structured reporting, c. Mandated accreditation systems, d. Large repository of images, reports, and outcomes, e. Implications for individual and population health) 4. Non-interpretive AI for breast imaging (a. Patient scheduling and outreach, b. Patient education and communication, c. Cancer risk assessment, d. Workflow triage, e. Image enhancement, f. Image quality assessment) 5. Interpretive AI for breast imaging (a. Lesion detection, b. Decision support, c. Breast density assessment, d. Response to neoadjuvant therapy) 6. Anticipated barriers for integration (a. Payment models for individual and population health, b. Accessibility in low resource settings, c. Interpretation of audit metrics, d. Impact on training/assessments of physicians, residents, and fellows)

## BREE-28 ACE THE BREAST IMAGING TUMOR BOARD: A MULTIDISCIPLINARY APPROACH TO BREAST CANCER

Charisma DeSai, MD (*Abstract Co-Author*) Nothing to Disclose
Kiran N. Chang, MD (*Abstract Co-Author*) Nothing to Disclose
Claudia Cotes, MD (*Abstract Co-Author*) Nothing to Disclose
Vidhyulatha Sanata, MD, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Radiology, pathology, and surgical/oncological treatment discussions are common practices in the management of breast cancer patients. Trainees, including residents and fellows, often participate in such discussions. In the era of personalized cancer treatment, it is crucial to understand not only the imaging findings of breast malignancies, but to correlate imaging and pathological characteristics to define molecular subtypes and guide oncological and surgical treatment strategies. This exhibit simplifies receptor definitions, breast cancer molecular subtypes and radiology-pathology correlation. Through representative radiological tumor board cases, we highlight patient treatments and outcomes. The goal is to prepare trainees and early radiologists with the necessary knowledge to provide valuable contributions to patient care and ace the breast imaging tumor board!

**TABLE OF CONTENTS/OUTLINE**

Receptor definitions: ER, PR, HER 2, Ki67 Breast Cancer Molecular Subgroups: Luminal A, Luminal B, HER 2 Positive, Basal-Like Imaging features of the different molecular subtypes on mammography, ultrasound, and MRI. Cancer treatment: Surgical and oncological treatment based on receptor status with review of patient's expected outcomes.

## BREE-29 THINK OUTSIDE THE BREAST: A PICTORAL ESSAY OF EXTRAMAMMARY LESIONS FOUND ON BREAST MRI AND HOW YOU DO NOT LOSE THEM

Aline C. Oliveira (*Abstract Co-Author*) Nothing to Disclose
Leticia T. Oliveira, MD (*Abstract Co-Author*) Nothing to Disclose
Livia P. Souza, MD (*Abstract Co-Author*) Nothing to Disclose
Sofia B. Maksoud, MD (*Abstract Co-Author*) Nothing to Disclose
Carla C. Benetti, MD (*Abstract Co-Author*) Nothing to Disclose
Carlos H. Rosas, MD (*Abstract Co-Author*) Nothing to Disclose
Danielle Teles Leal (*Abstract Co-Author*) Nothing to Disclose
Carla C. Tajima (*Abstract Co-Author*) Nothing to Disclose
Isabela Ferreira (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The primary utility of breast magnetic resonance imaging (MRI) is in screening of high-risk patients, detecting breast lesions, staging breast cancer, and assessing neoadjuvant treatment and breast implants. Although the examination primarily focuses on the breasts, it also allows visualization of surrounding structures. Between 17% to 34% of cases reveal at least one extramammary incidental finding, with around 20% of these findings being malignant and 14% to 20% clinically relevant benign conditions. The liver is the most common site of reported incidental findings (52-60%), followed by the lung and pleural cavity, with the gastrointestinal tract being the least common on Breast MRI. Breast MRI is primarily utilized for breast cancer staging and high-risk screening, findings in these extramammary structures hold significant importance, often influencing diagnostic investigation and subsequent follow-up.

**TABLE OF CONTENTS/OUTLINE**

To investigate the imaging of numerous extramammary findings using cases from our institution and correlate them with personal history. To examine the significance of describing these findings on breast MRI. To assess the prevalence of extramammary malignant lesions detected in the images and their subsequent therapeutic management. To give hints and tips for general radiologists of how they can remember to evaluate these structures on breast exams.

## BREE-3 MULTI-MODALITY REVIEW OF VASCULAR CONDITIONS OF THE BREAST

**Awards**
**Certificate of Merit**

Roberta M. Strigel, MD, MS (*Abstract Co-Author*) Research support, General Electric Company
Ryan W. Woods, MD, MPH (*Abstract Co-Author*) Author, MRI Online
Mai A. Elezaby, MD (*Abstract Co-Author*) Investigator, Exact Sciences Corporation;Research Grant, Exact Sciences Corporation
Thomas Loduca, MD (*Abstract Co-Author*) Nothing to Disclose
Lonie R. Salkowski, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Anand K. Narayan, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Amy M. Fowler, MD, PhD (*Abstract Co-Author*) Author with royalties, RELX
Alison R. Gegios, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

This educational exhibit aims to establish a framework for radiologists to identify imaging characteristics of vascular breast conditions, including those of arterial, venous, and lymphatic origins, and associated management recommendations. Although most vascular breast conditions are benign, it is important to recognize imaging findings that necessitate a biopsy to evaluate for possible underlying malignancy. It also may be helpful to communicate benign vascular conditions to the clinician as intervention for symptomatic relief or treatment of underlying systemic conditions may be indicated.

**TABLE OF CONTENTS/OUTLINE**

1. Review of Vascular Anatomy of the Breast 2. Overview of Techniques to Evaluate Vascularity in the Breast 3. Benign Vascular Conditions of the Breast (including systemic conditions) a. Atherosclerosis b. Congestive Heart Failure c. Unilateral breast edema secondary to central venous obstruction 4. Benign Vascular Lesions of the Breast a. Pseudoaneurysm b. Superficial thrombophlebitis (Mondor Disease) c. Lymphatic malformation d. Venous malformation e. Hemangioma and variants of hemangiomas (e.g., infantile hemangioma) 5. Role of Radiologic-Pathologic Correlation in Management of Certain Vascular Variants (e.g., anastomosing hemangioma) 6. Malignant Vascular Conditions of the Breast and Sequelae of Breast Malignancy a. Angiosarcoma b. Solitary Fibrous Tumor c. Portal Vein Tumor Thrombus

## BREE-30 PALPABLE BREAST LUMPS IN THE PEDIATRIC AND ADOLESCENT POPULATION: SONOGRAPHIC REVIEW OF COMMON AND LESS COMMON BENIGN DISORDERS

**Awards**
**Certificate of Merit**

Cory Z. Trivax, MD (*Abstract Co-Author*) Nothing to Disclose
Mehrvaan Kaur, MBBS (*Abstract Co-Author*) Nothing to Disclose
Alexander Satei, MBBS (*Abstract Co-Author*) Nothing to Disclose
Tima Tawil, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purpose of this exhibit is to learn about the normal development of the female breast, including in-utero, prepubertal, and pubertal stages. Understanding normal sonographic findings of the different Tanner stages of breast development can help radiologists recognize underlying abnormal breast disorders. Discussion of breast disorders in the pediatric and adolescent population will focus primarily on sonographic findings with review of etiology, pathology, follow up imaging/management if applicable, and more. Covered breast disorders will include, for example, juvenile fibroadenoma, gynecomastia, asymmetric breast buds, non-puerperal abscess, subcutaneous cyst, and others. Understanding benign and self-limiting breast disorders will help radiologists recognize suspicious sonographic findings warranting further investigation and/or management.

**TABLE OF CONTENTS/OUTLINE**

Normal breast development at birth and during puberty. Tanner stages of normal breast development. Normal sonographic findings of Tanner stages. Case-based discussion of variant developmental processes including: Premature thelarche, asymmetric breast bud development, gynecomastia. Case-based discussion of miscellaneous lesions including abscess, furuncle, lymph node, and subcutaneous cyst. Case-based discussion of benign neoplastic lesions including fibroadenoma/juvenile fibroadenoma, pseudoangiomatous stromal hyperplasia of the breast, and juvenile papillomatosis. Suspicious sonographic features prompting further imaging evaluation.

## BREE-31 MRI'S ROLE IN THE PUZZLE OF PAPILLARY BREAST LESIONS

Paula C. Moraes, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Abstract Co-Author*) Nothing to Disclose
Heni D. Skaf, MD (*Abstract Co-Author*) Nothing to Disclose
Vivian S. Ogata, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia Orthmann, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purpose of this exhibit is:1. To highlight the significance of papillary breast lesions and their varied diagnostic considerations.2. To delineate the characteristics of papillary breast neoplasms as depicted by magnetic resonance imaging (MRI) and establish correlations across different modalities such as ultrasound (US), mammography (MG), and tomosynthesis (TS).3. To underscore the pivotal role of MRI in the management of papillary neoplasms and explore its potential in guiding appropriate treatment strategies. 4. To explore MRI protocols tailored for evaluating breast papillary lesions. To exemplify, through clinical cases, how MRI can augment daily practice in assessing papillary lesions.

**TABLE OF CONTENTS/OUTLINE**

The presentation will follow the following structure: - Reviewing Breast Papillary Lesions and Their Differential Diagnosis; - Illustrating Papillary Lesions Cases on MRI with Correlations to Mammography, Ultrasound, and Pathology; - Demonstrating the Role of MRI in the Management of Papillary Lesions; - Evaluating the Optimal Timing and Method for Biopsy Procedures; - Summary and conclusion.

## BREE-32 PEDIATRIC BREAST ASSESSMENT: WHAT CAN WE FIND?

Tatiane M. Oliveira, MD (*Abstract Co-Author*) Nothing to Disclose
Jose Galdino S. Santana, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana Rodrigues, MD (*Abstract Co-Author*) Nothing to Disclose
Leandro Dias Almeida, MD (*Abstract Co-Author*) Nothing to Disclose
Julio Nather, MD (*Abstract Co-Author*) Nothing to Disclose
Jorge Elias JR, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Larissa De Andrade Defendi, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Pediatric breast complaints are relatively common in the general and pediatric radiologist's routine. Although breast pathology in this population is mostly benign, ruling out malignant neoplasms and pointing out differential diagnosis to guide management is crucial. Ultrasonography is the main tool to evaluate pediatric breast changes. The aim of this exhibit is: 1. To describe the sonographic technique in the assessment of pediatric breast pathology, highlighting tips and for an adequate evaluation in the pediatric scenario; 2. To review clinical and radiological features of common and unusual breast pathology in children.

**TABLE OF CONTENTS/OUTLINE**

1) Brief review of breast development and physiology; 2) Ultrasonography of the pediatric breast: exam technique, value of B-Mode and Doppler, imaging acquisition/documentation; 3) Practical tips to ensure child's collaboration; 4) Breast pathology in the pediatric population: epidemiology, brief clinical aspects regarding presentation, outcome and follow up; 5) Radiological features of usual and rare pediatric breast findings: a) Developmental Disorders (neonatal breast hypertrophy; gynecomastia); b) Infection (abscess); c) Benign masses (fibrocystic changes; juvenile fibroadenoma; venolymphatic malformation; hamartoma; lipoma; steatonecrosis; pseudoangiomatous stromal hyperplasia); d) Malignant masses (primary carcinoma); 6) When biopsy should be performed: clinical and radiological findings that elicit referral.

## BREE-33 IT IS NOT ONLY A FEMALE PROBLEM: RADIOLOGIC FINDINGS IN IMAGING MALE BREAST

**TEACHING POINTS**

Outline and describe the various male breast diseases, exploring the most common, benign and non benign neoplasms, and how they relate to the imaging findings.Describe different imaging methods and their significance in distinguishing differential diagnosis.Discuss the significance of understanding the male breast disease, especially as the diagnosis is more delayed.Build a flowchart to describe differential diagnosis on male breast disease.

**TABLE OF CONTENTS/OUTLINE**

Introduction;Clinical and epidemiological aspects of different male breast diseases; A flowchart to summarize differential diagnosis on male breast disease;A case-based review of original cases from breast centers of a tertiary hospital and a specialized clinic, showing different imaging findings aimed to improve diagnostic efficiency;Explore the imaging features of each male breast disease described in this education exhibit to assist in early detection;Take-home messages;References.

## BREE-34 BREAST CANCER STAGING USING CONTRAST-ENHANCED IMAGING: ROLE OF MRI, CEM AND MDCT

Laura S. Lima, MD (*Abstract Co-Author*) Nothing to Disclose
Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Vinicius C. Felipe SR, PhD (*Abstract Co-Author*) Nothing to Disclose
Mariana Galupo (*Abstract Co-Author*) Nothing to Disclose
Mariah C. Wanderley (*Abstract Co-Author*) Nothing to Disclose
Leticia Cavalcante (*Abstract Co-Author*) Nothing to Disclose
Soraia Damiao, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Contrast-enhanced breast imaging methods can improve locoregional staging compared to conventional non-enhanced breast imaging (mammography, DBT, and ultrasound).• Breast MRI with dynamic contrast enhancement (DCE) is the most accurate method to assess breast cancer extent through measurement of tumor size, detection of intraductal components and additional lesions, as well as signs of invasion of the nipple, skin, and chest wall.• Contrast-enhanced mammography (CEM) has emerged as an alternative for locoregional staging, with similar accuracy to breast MRI to assess tumor size and additional lesions. However, CEM is not widely available yet, and it has limited value in some cases, such as in patients with implants and peripherally or posteriorly located tumors.• Contrast-enhanced multidetector computed tomography (MDCT) with contrast enhancement is used for distant staging in advanced breast cancer patients. Studies show it can also assess breast lesions when performed in a prone position with a dedicated breast evaluation protocol, without additional radiation or contrast doses. MDCT is a viable alternative to MRI and contrast-enhanced mammography, particularly in low- to middle-income regions.

**TABLE OF CONTENTS/OUTLINE**

Overview of contrast-enhanced breast imaging methods (MRI, CEM, and MDCT) and its role in breast cancer management.Examples of breast cancer locoregional staging using MRI, CEM, and MDCT for tumor size assessment and detection of intraductal components, additional lesions, and invasion of the nipple, skin, and chest wall.Suggested decision-making workflow for selecting the appropriate imaging technique based on clinical needs, imaging availability, and cost-effectiveness.

## BREE-35 ORIGIN OR SPREAD - MULTIMODALITY IMAGING APPROACH FOR DISTINGUISHING BREAST METASTASES AND PRIMARY MALIGNANCIES

Juliana A. Souza (*Abstract Co-Author*) Nothing to Disclose
Bruna Isabela S. Tavares, MD (*Abstract Co-Author*) Nothing to Disclose
Leticia Cavalcante (*Abstract Co-Author*) Nothing to Disclose
Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Victoria Pacheco, MD (*Abstract Co-Author*) Nothing to Disclose
Laura B. De Melo, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To distinguish the most common multimodality imaging features between breast metastases from extramammary cancer and primary breast malignancies.2. To understand the relevance of integrating multiple imaging techniques alongside the clinical context to discern between primary and secondary breast lesions, establishing an accurate diagnosis, staging, and treatment plan.

**TABLE OF CONTENTS/OUTLINE**

BREAST METASTASES FROM EXTRAMAMMARY CANCERS1. Location: Typically peripheral and superficial, notably in the upper outer quadrant.2. Imaging Features: Exhibits variability, often appearing as round or oval masses with well-defined margins; presentation varies based on the primary tumor3. Clinical Context: Typically associated with a known metastatic cancerPRIMARY BREAST CARCINOMAS1. Locations: Varied, with a higher prevalence in the central breast (fibroglandular tissue area)2. Imaging Features: Spiculated margins, calcifications, posterior acoustic shadowing, and axillary lymph node involvement are suggestive features of primary breast cancer3. Clinical Context: More prevalent than metastases, even in patients with documented extramammary neoplasms.

## BREE-36 CHOSEN: THE IMPACT OF BREAST BIOPSY MARKER (CLIP) SELECTION ON BREAST IMAGING PROCEDURES, FOLLOW-UP, AND COSTS

Christine U. Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Miral M. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Megha M. Kapoor, MD (*Abstract Co-Author*) Nothing to Disclose
Mary S. Guirguis, MD (*Abstract Co-Author*) Nothing to Disclose
Beatriz E. Adrada, MD (*Abstract Co-Author*) Nothing to Disclose
Gary J. Whitman, MD (*Abstract Co-Author*) Consultant, Siemens AG;Editor, Wolters Kluwer nv

Elsa M. Arribas, MD (*Abstract Co-Author*) Stockholder, 3D Systems, Inc
Tanya W. Moseley, MD, PhD (*Presenter*) Consultant, Hologic, Inc;Consultant, Merit Medical Systems, Inc;Owner, TW Moseley, LLC;CEO, TW Moseley, LLC

**TEACHING POINTS**

1. Review the history and the role of biopsy markers in breast imaging 2. Review the features of markers from the lenses of radiologists, pathologists, and surgeons 3. Review the impact of marker selection on subsequent breast imaging interpretation and costs 4. Evaluate best practices for identifying markers on ultrasound

**TABLE OF CONTENTS/OUTLINE**

I. History and role of biopsy markers II. Features of markers A. Size and configuration B. Makeup 1. Consideration for patients with allergies and inflammatory reactions C. Embedding materials 1. Consideration for patients with allergies and inflammatory reactions III. Impact of marker selection A. Visibility and stability of markers on various breast imaging modalities B. Visibility of markers in the breast and lymph nodes after neoadjuvant chemotherapy C. Localization of clips on follow-up imaging and surgical planning D. Markers for patients with nickel allergies E. Costs IV. Best marker practices V. Conclusion VI. References

## BREE-37 MULTIMODALITY IMAGING REVIEW OF CALCIFIED AND NONCALCIFIED DCIS WITH RADIOLOGIC-PATHOLOGIC CORRELATION

Janice Thai, MD (*Abstract Co-Author*) Nothing to Disclose
Rachel E. Grenier, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) DCIS can manifest as both calcifications and noncalcified lesions. 2) Pathologic subtypes of DCIS are classified based on microscopic growth pattern.

**TABLE OF CONTENTS/OUTLINE**

1) Review of multimodality imaging appearances of calcified and noncalcified DCIS. 2) Review of the spectrum of pathologic subtypes of DCIS and variants. 3) Review of current management options for DCIS.

## BREE-38 DISTINGUISHING MALIGNANT FROM BENIGN CAUSES OF BREAST SIZE CHANGES: A CASE-BASED PRIMER FOR THE RADIOLOGIST

**Awards**
**Cum Laude**

Wendi A. Owen, MD (*Abstract Co-Author*) Nothing to Disclose
Fara Y. Shikoh, MD (*Abstract Co-Author*) Nothing to Disclose
Aurela I. Clark, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaoqin J. Wang, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hannah Conley, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Review current literature for guidance in the evaluation and management of breast size changes. Illustrate the imaging features of both malignant and non-malignant causes of breast shrinkage and enlargement. Elucidate clinical context that aids in distinguishing malignant from benign causes of breast size fluctuations. Highlight teaching points for each case to bolster confidence in making a timely diagnosis.

**TABLE OF CONTENTS/OUTLINE**

Not infrequently, women visit breast clinics with concerns of breast size changes. Radiologists play a pivotal role in combining clinical findings and imaging features to guide appropriate management. We will stress the importance of a thorough clinical history and physical exam and provide evidence-based guidance of management for radiologists encountering patients with this concern. Notably, the "shrinking breast" in invasive lobular carcinoma (ILC) which comprises 10-15% of breast cancer will be highlighted. Imaging features of ILC are often occult and a high level of suspicion must be maintained when clinical complaints are present. Conversely, swollen breasts raise concern for inflammatory breast cancer (IBC) which presents with the characteristic imaging findings of diffuse skin thickening ("peau d'orange"). When available, imaging findings will be correlated to histopathologic diagnosis. Numerous benign conditions can also influence breast size changes and will be contrasted with malignant causes. We will educate learners on the telltale benign versus malignant imaging features and provide a summary of teaching points.

## BREE-39 PASH RADIOLOGICAL PRESENTATION

Ligia A. Yamashita, MD (*Abstract Co-Author*) Nothing to Disclose
Patricia A. De Camargo Teixeira, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela G. Giannotti, MD (*Abstract Co-Author*) Nothing to Disclose
Vera Christina C. Ferreira, MD (*Abstract Co-Author*) Nothing to Disclose
Larissa Moyses, MD (*Abstract Co-Author*) Nothing to Disclose
Vivian N. Omura, MD (*Abstract Co-Author*) Nothing to Disclose
Carolina R. Saccarelli, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela F. Vieira Vendramini (*Abstract Co-Author*) Nothing to Disclose
Debora Mayumi Takamune, MD (*Abstract Co-Author*) Nothing to Disclose
Rafael R. Santos Ferreira, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Pseudoangiomatous stromal hyperplasia (PASH) is a benign stromal proliferation that mimics a vascular lesion histologically. It affects individuals of varying ages, including men, with women in reproductive age and elderly women on estrogen replacement therapy being the most affected group. Clinically, PASH may present as a mass or thickening upon physical examination, with incidental histological findings being the most common presentation. While a hormonal etiology is considered, the pathophysiology is not fully understood. On mammography, PASH typically appears as focal asymmetry, while on ultrasound it presents as a solid, well-defined, non-calcified mass. PASH has a varied appearance on MRI but most commonly manifests as a region of non-mass enhancement with persistent kinetic features.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction. 2. Classical PASH images on US and MG. 3. Diferent forms of PASH presentantion on US. 4. PASH being a diferential diagnosis from invasive breast carcinoma. 5. PASH associated with gigantomastia on a teenager.

## BREE-4 COMPLEX SOLID AND CYSTIC BREAST LESIONS

Liva Andrejeva-Wright, MD (*Abstract Co-Author*) Nothing to Disclose
Riddhi Borse, MBBS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. The exhibit focuses on enhancing the interpreting radiologist's ability for evaluating complex solid and cystic breast lesions using different modalities including ultrasound, computed tomography, and magnetic resonance imaging.2. It will enlist various examples of benign and malignant complex solid and cystic breast lesions visualized on different imaging modalities.3. The exhibit will provide insights into key differentiating imaging features of benign versus malignant complex and cystic breast lesions using several case examples and illustrations to help radiologists build an appropriate understanding of reassuring versus worrisome imaging findings.4. It will help the interpreting radiologist build optimal use of BIRADS nomenclature to help efficiently report complex solid and cystic breast lesions and ultimately guide efficient clinical management.

### TABLE OF CONTENTS/OUTLINE

1. Introduction to use of different imaging modalities for assessment of solid and cystic lesions of the breast.2. Enlisting salient imaging features, illustrations and case examples of benign complex solid and cystic lesions of the breast using different imaging modalities. 3. Enlisting salient imaging features, illustrations and case examples of malignant complex solid and cystic lesions of the breast using different imaging modalities. 4. Comparison and contrast of various imaging features to help differentiate benign from malignant cystic and solid lesions including reassuring vs worrisome findings.5. Optimal use of BIRADS nomenclature to help efficiently report complex solid and cystic breast lesions and guide clinical management.

## BREE-40 HEAR YE, HEAR YE: HOW TO BE AN EFFECTIVE ADVOCATE

Amy K. Patel, MD (*Abstract Co-Author*) Medical Advisor, Kheiron Medical Technologies Ltd;Consultant, Hologic, Inc
Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*) Royalties, Wolters Kluwer nv
Stamatia V. Destounis, MD (*Abstract Co-Author*) Medical Advisory Board, iCad, Inc
Ann L. Brown, MD (*Abstract Co-Author*) Consultant, Elucent Medical
Fatima Elahi, DO, MS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

In breast imaging, ensuring equitable access to cancer screening is critical to improving health outcomes for all women, especially those from vulnerable groups. Ensuring appropriate reimbursement for existing and emerging imaging techniques is also important. Therefore, it is essential that all breast radiologists possess the skills to be effective advocates for our subspecialty and patients.

### TABLE OF CONTENTS/OUTLINE

In this exhibit, we will provide a step-by-step guide covering the essential skills to become an effective advocate. The topics that will be covered include: personal and practice branding, social media use, public speaking tips, developing an elevator speech, coalition building, lobbying tactics, impactful written communication including drafting resolutions and legislative bills and creating fact sheets, story telling, and leadership skills.

## BREE-41 THE MULTIPLE FACES OF BREAST VASCULAR PATHOLOGY; TUMORS AND BEYOND

Maria Guerrero Martin (*Abstract Co-Author*) Nothing to Disclose
Nancy Sanchez Rubio, MD (*Abstract Co-Author*) Nothing to Disclose
Myriam F. Montes, MD (*Abstract Co-Author*) Nothing to Disclose
Manuel Lopez Herrero, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

There is a great variety of breast vascular diseases, with abnormalities that affect both arteries and veins, as well as benign and malignant tumors. These lesions are unusual, unknown and may appear on imaging in different ways; therefore, several techniques are frequently required to approach the diagnosis (even histologic study if there is a mass). For these reasons, the objectives of this presentation are to know the anatomy of breast vasculature and to identify its main disorders, with their typical and multimodal imaging features. Particular attention is focused on tumors, with radio-pathologic correlation; this aspect is especially important for breast imagers, because they need to ensure the concordance after biopsy. Thus, the radiologist will be able to reach an accurate diagnosis, and the patient will get a correct treatment or follow-up plan.

### TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Normal breast vasculature. 3. Vascular disorders of the breast: atherosclerosis, congestive heart failure, superficial thrombophlebitis, breast varyx and other entities. 4. Vascular tumors of the breast 4.1. Benign proliferations: hemangioma (cavernous and others), angiolipoma and papillary endothelial hyperplasia (Masson’s tumor). 4.2. Malignant proliferations: angiosarcoma (primary and secondary). 5. Differential diagnosis of vascular tumors of the breast (pathologic mimics): pseudoangiomatous stromal hyperplasia, myofibroblastoma, Phyllodes tumor and metaplastic carcinoma. 6. Conclusions.

## BREE-42 RADIOLOGIC-DERMATOLOGIC ATLAS OF SKIN PATHOLOGIES FOR THE BREAST RADIOLOGIST

**Awards**
**Cum Laude**

Derek L. Nguyen, MD (*Abstract Co-Author*) Nothing to Disclose
Dorothy A. Lowell, MD (*Abstract Co-Author*) Nothing to Disclose
Shelby Breit, BS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Skin changes of the breast such as rashes, erythema, or raised cutaneous lesions frequently present as a diagnostic challenge for breast imaging radiologists. These patients often present with either no relevant imaging findings or imaging findings which are nonspecific. Currently, there are limited resources available that serve as a clinical reference atlas for breast radiologists concerning skin pathologies associated with the breast. It is imperative for breast radiologists to assess the patient's clinical history in conjunction with any cutaneous changes and imaging findings, in order to determine whether a skin punch biopsy is warranted. The purpose of this educational exhibit is to provide a detailed review of common benign and malignant cutaneous conditions of the breast, enhanced with dermatologic and radiologic images, to serve as a comprehensive reference for breast imaging radiologists.

**TABLE OF CONTENTS/OUTLINE**

1. Review the normal anatomy of the skin of the breast as well as the normal mammographic, ultrasound and MRI appearance. 2. Review common benign dermatologic conditions of the skin of the breast with clinical photos and multimodality imaging correlates including epidermal inclusion/sebaceous cysts, folliculitis, candidiasis infections, herpes zoster, mastitis, edema, keloids, neurofibromas, and granular cell tumors.3. Review malignant cutaneous manifestations of the breast with clinical photos and multimodality imaging correlates including inflammatory breast cancer, local recurrence, angiosarcoma, Paget's disease, and melanoma.

## BREE-43 BI-RADS 3 IN BREAST MRI INTERPRETATION: APPROPRIATE AND INAPPROPRIATE USE

**Awards**
**Certificate of Merit**

Laura Heacock, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Alana A. Lewin, MD (*Abstract Co-Author*) Nothing to Disclose
Beatriu Reig, MD, MPH (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Criteria for use of BI-RADS 3 in MRI are less well-established than for MG and US. 2. Oval T2 hyperintense mass with circumscribed margins and homogeneous internal enhancement or dark internal septations on baseline MRI may be given BI-RADS 3. 3. Masses lacking T2 hyperintensity, with suspicious morphologic or kinetic characteristics, new or enlarging findings, and most nonmass enhancements should not be given BI-RADS 3.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction a. Criteria for use of BI-RADS 3 in MRI have not been well-established b. Frequency of use of BI-RADS 3 c. Cancer yield i. Population undergoing MRI screening is different than population undergoing mammography or ultrasound 2. Indications for BI-RADS 3 a. Mass on baseline MR with benign morphologic and kinetic features b. Unique focus i. Exercise caution if new or enlarging ii. Balance of sensitivity with specificity and PPV. Some foci will represent small cancers, which will be identified on subsequent exam. c. Regional NME on baseline 3. Inappropriate use a. BPE should be BI-RADS 2 b. NME - new, asymmetric, or suspicious distributions should be BI-RADS 4 c. Patients beginning breast cancer treatment 4. Follow up interval a. 5th edition of BI-RADS Atlas recommends 6 mo f/u b. Evidence 12 mo f/u may be appropriate c. Evidence for 6 mo f/u after benign concordant biopsy 5. Future directions a. Expected changes with the next BI-RADS atlas i. Goal: </= 5% of examinations given BI-RADS 3 ii. Indications iii. Focus no longer part of the lexicon b. Improving specificity using DWI, AI c. Impact of abbreviated MRI i. Do patients on a yearly MRI schedule need six month follow up of BI-RADS 3 lesions? ii. Lack of T2 d. Using personalized risk assessment to refine BI-RADS assessments

## BREE-44 BREAST CANCER SUBTYPES BASED ON MAMMOGRAMS: APPROACH FOR NEW RADIOMICS FEATURES USING VISION TRANSFORMER

Hideaki Tamori (*Abstract Co-Author*) Nothing to Disclose
Akifumi Yoshida, MSc, RT (*Abstract Co-Author*) Konica Minolta, Inc
Satoshi Kasai, PhD (*Abstract Co-Author*) Konica Minolta, Inc;TOITU Co, Ltd;Marubeni Corporation
Chiharu Kai (*Presenter*) Former Employee, Konica Minolta, Inc

**TEACHING POINTS**

We will present our research that have applied new Radiomics features to classifying subtypes of breast cancers on mammograms. The purpose of this exhibit is to: - Understand an overview of Radiomics research and the diversified Radiomics features, - Recognize Radiomics features using Vision Transformer (ViT), - Learn about a new model for calculating Radiomics features combining ViT, Convolutional Neural Network (CNN) and Principal Component Analysis (PCA), - Review mammograms with cancers, and how related to the new Radiomics features with breast subtype classification.

**TABLE OF CONTENTS/OUTLINE**

1) Common Radiomics research, 2) Types of Radiomics features, 3) Radiomics features with ViT, 4) The new model for calculating Radiomics features combining ViT, CNN, and PCA •ViT (global features): identifying relationships between distant regions •CNN (Local features): identifying relationships between close regions •PCA (Super-global features): identifying the image features of an entire image, 5) The advantage of the combining new model, 6) Our research: classifying subtypes of breast cancers on mammograms •The results of the classification •The characteristics of the feature importance of the top five features •To review mammograms with cancers and the new Radiomic features : triple-negative, HER2, Luminal A, Luminal B breast cancers •Scatter plots for each feature importance, 7) Summary

## BREE-45 AN ATLAS OF BIRADS FOR CONTRAST ENHANCED MAMMOGRAPHY: BEARING THE WEIGHT OF PRECISE REPORTING

**Awards**
**Certificate of Merit**

Derek L. Nguyen, MD (*Abstract Co-Author*) Nothing to Disclose
Sujata V. Ghate, MD (*Abstract Co-Author*) Research Grant, Bracco Group;Reader, QT Ultrasound, LLC;Travel support, QT Ultrasound, LLC
Eun L. Langman, MD (*Abstract Co-Author*) Nothing to Disclose
Victoria A. Wells, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Contrast enhanced mammography (CEM), similar to MRI, is a functional imaging technique with a higher sensitivity for breast cancer detection than mammography or ultrasound. In 2011, the FDA approved CEM as an adjunct diagnostic tool, resulting in increased implementation of CEM in breast imaging practices. CEM can be utilized to evaluate breast symptoms or screen detected abnormalities, to assess extent of newly diagnosed breast cancer, response to neoadjuvant chemotherapy, and to interrogate for occult breast malignancy in the setting of metastatic axillary lymphadenopathy with unknown primary. It is an effective alternative to MRI for those with a contraindication or intolerance. More recently in 2022, the BIRADS lexicon for CEM was introduced to ensure consistency of reporting through standardized terminology. Therefore, it is important for breast imaging radiologists to be familiar with the technique and lexicon to ensure proper use and accurate reporting. Utilizing a case-based approach, this exhibit will demonstrate the utility of CEM in different clinical indications and provide examples of appropriate use of the BIRADS CEM lexicon.

**TABLE OF CONTENTS/OUTLINE**

- Review CEM technique. - Present commonly encountered benign and malignant breast findings on CEM with appropriate BI-RADS descriptors - Discuss the diagnostic clinical indications for CEM using case-based examples. - For each case, highlight the imaging findings using the appropriate BIRADS lexicon.

## BREE-46 NEW BREASTS MAY NOT BE BEST: IMAGING OF BREAST AUGMENTATION AND ENHANCEMENT PROCEDURES AND THEIR COMPLICATIONS

Mine Sorkun, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Sasse, BA (*Abstract Co-Author*) Nothing to Disclose
Douglas S. Katz, MD (*Abstract Co-Author*) Nothing to Disclose
Liva Andrejeva-Wright, MD (*Abstract Co-Author*) Nothing to Disclose
Margarita V. Revzin, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Nadia Solomon, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Riddhi Borse, MBBS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. This exhibit will help the radiologist build a foundation in recognizing salient imaging features of breast implants and injectables, understanding their medical and surgical implications, and facilitate accurate reporting to best guide medical and surgical teams. 2. It will describe the imaging appearances of different types of breast implants and injectables, including normal post-operative findings and the range of short and long-term complications which can be seen. 3. Cases examples will also be used to highlight which imaging modality - ultrasound, CT, or MRI - would be best employed for optimal assessment of normal and critical findings.

### TABLE OF CONTENTS/OUTLINE

1. Imaging features of Saline implants:a. Appearance on Mammography vs ultrasound.b. Normal vs ruptured implants. 2. Imaging features of Silicone implants:a. Intracapsular vs Extracapsular rupture.b. Contractures, herniations, leaks and folds. 3. Imaging appearance of various cosmetic injectables:a. Fat injections.b. Silicone and other cosmetic injectables. 4. Infection and inflammation of breast implants: Salient imaging features. 5. Fluid collections associated with implants: Hematoma, Seroma, Abscess etc.

## BREE-47 BIRADS 3 UNVEILED: YOUR MULTIMODAL MAP TO SAFETY

Andrea Di Ninno, MD (*Abstract Co-Author*) Nothing to Disclose
Luciano F. Chala, MD (*Abstract Co-Author*) Nothing to Disclose
Giselle G. Mello, PhD (*Abstract Co-Author*) Nothing to Disclose
Tatiana C. Tucunduva, MD (*Abstract Co-Author*) Nothing to Disclose
Vinicius Nobre, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Understanding BIRADS 3 Classification: Emphasize the definition, criteria, and significance of BIRADS 3 in breast imaging, highlighting its role as an indicator for probably benign findings with a recommendation for short-term follow-up.
- Decision-Making Process: Discuss the critical thinking process involved in categorizing a finding as BIRADS 3, including the evaluation of imaging characteristics and patient history.
- Management Strategies: Outline the recommended follow-up protocols for BIRADS 3 findings, such as the appropriate intervals for re-imaging and factors influencing the decision to advance to biopsy.
- Risk Assessment and Communication: Teach how to assess the risk associated with BIRADS 3 lesions and the next steps.

### TABLE OF CONTENTS/OUTLINE

- Introduction to BIRADS 3: Overview of the BIRADS system, focusing on the BIRADS 3 category, its purpose, and importance.
- Criteria for BIRADS 3 Classification: Examination of imaging features and patient history that justify a BIRADS 3 classification, with examples.
- Imaging Modalities and BIRADS 3: How different imaging modalities contribute to identifying and classifying BIRADS 3 findings.
- Follow-Up Protocols for BIRADS 3 Lesions: Guidelines for monitoring, including follow-up intervals and additional imaging tests.
- Biopsy Considerations for BIRADS 3 Findings: When a biopsy may be considered for a BIRADS 3 lesion, including patient-specific factors.
- Case Studies and Review of Literature: Analysis of case studies and literature review on the management of BIRADS 3 lesions.

## BREE-48 BEFORE IT POPS: MRI FEATURES OF BREAST AUGMENTATION SURGERY AND IMPLANT COMPLICATIONS

Ilany L. Valdivia I, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica A. Perdomo SR, MD (*Abstract Co-Author*) Nothing to Disclose
Rocio D. Trevino, MD (*Abstract Co-Author*) Nothing to Disclose
Margarita L. Garza, MD (*Abstract Co-Author*) Nothing to Disclose
Elena M. Sanchez Siller, MD (*Abstract Co-Author*) Nothing to Disclose

Ia M. Sanchez Carenzo, MD (*Abstract Co-Author*) Nothing to Disclose
Karla I. Soto, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Guerra, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Recognize the normal imaging appearance of breast implants with MRI.- Describe the technical characteristics of the MRI protocol for patients who have undergone breast augmentation surgery.- Discuss the normal findings after breast augmentation surgery by MRI.- Identify imaging signs of early and late complications of breast augmentation surgery.

### TABLE OF CONTENTS/OUTLINE

- MRI protocol in the evaluation of the augmented breast- Implant locations- Implant types- Normal findings after breast augmentation surgery- Acute complications:Peri-implant fluid: hematoma, infection, seromaInfection- Late complications: Rupture: intracapsular rupture, extracapsular rupture. Capsular contracture. Fat necrosis and gel bleed. Anaplastic large cell lymphoma

## BREE-49 BEYOND THE SCAN: UNDERSTANDING THE JOURNEY OF YOUNG WOMEN WITH BREAST CANCER

Amy K. Patel, MD (*Abstract Co-Author*) Medical Advisor, Kheiron Medical Technologies Ltd;Consultant, Hologic, Inc
Lakshmi Priya, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Breast cancer cases in young women are rising and are often more aggressive and present in later stages due to delay in screening. Risk factors include genetic mutations, smoking, alcohol use, OCPs, older age of first pregnancy, high BMI, sedentary lifestyles, and low socioeconomic status. All women should undergo a risk assessment by age 25 and if high risk adhere to the latest screening guidelines. Breast cancer in young women can present in various forms, and this exhibit will review the multimodality presentation of some common forms of breast cancer in young women. Multimodal treatment options are available with special consideration of treatment impact on breast conservation, fertility, and mental health in young women. Clinicians should recognize that mammography is safe during breast feeding and pregnancy to prevent delays in diagnosis.

**TABLE OF CONTENTS/OUTLINE**

Background, epidemiology, and clinical presentation Risk factors and genetics High-risk screening guidelines Case based imaging review of breast cancer in young women Managment, treatment, and breast conserving techniques Psychosocial impact and effect on fertility Imaging guidelines during breast feeding and pregnancy

## BREE-50 A SPECTRUM OF BREAST SARCOMAS WITH RADIOLOGIC-PATHOLOGIC CORRELATION

Katja Pinker-Domenig, MD, PhD (*Abstract Co-Author*) Speakers Bureau, European Society of Breast Imaging;Speakers Bureau, Siemens AG;Speakers Bureau, IDKD;Speakers Bureau, Canon Medical Systems Corporation;Consultant, F. Hoffmann-La Roche Ltd;Consultant, Merantix Healthcare;Consultant, AURA Health
Dilip Giri (*Abstract Co-Author*) Nothing to Disclose
Jorge L. Huayanay, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Primary breast sarcomas are a very rare and heterogeneous group of aggressive malignant neoplasms that arise from connective tissue. Sarcomas constitute less than 1% of all breast cancers and account for less than 5% of all soft tissue sarcomas. 2. This exhibit will review the spectrum of imaging and histopathology features of breast sarcomas. 3. This review will emphasize diagnostic difficulties, potential imaging pitfalls and differential diagnoses.

**TABLE OF CONTENTS/OUTLINE**

The goals of this exhibit are to: Provide a pictorial review of the diverse imaging appearances of breast sarcomas. Discuss specific imaging and pathological characteristics of breast sarcomas. Familiarize the audience with the imaging features of breast sarcomas, thereby helping to provide a complete differential diagnosis. These major featured entities include: • Angiosarcoma • Leiomyosarcoma • Osteosarcoma • Rhabdomyosarcoma • Synovial sarcoma • Undifferentiated pleomorphic sarcoma • Malignant phyllodes tumors and metaplastic carcinomas that develop areas of sarcomatous differentiation.

## BREE-51 UNDERSTANDING UNIQUE BREAST CANCER RISK FACTORS AMONG WOMEN VETERANS

Lucy B. Spalluto, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Pooja Agrawal, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Guideline-based early and supplemental breast cancer screening for women at high risk for breast cancer is an evidence-based practice that improves morbidity and mortality through early detection and treatment. 2. Young women Veterans represent a unique population who may be at high risk for breast cancer due to additional risk factors beyond those of the general population. 3. Understanding the unique risk factors of young women Veterans diagnosed with breast cancer may offer an opportunity to reduce morbidity and mortality among women Veterans.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction: a) Describe breast cancer morbidity and mortality statistics, including existing disparities, for women in the general U.S. population, b) Compare these statistics to those of women Veterans. 2. Breast cancer risk factors: a) Review breast cancer risk factors for the general population, b) Review unique breast cancer risk factors among women Veterans, such as chemicals (agent Orange, contaminated water), radiation (nuclear weapons), air pollutants (burn pit smoke), occupational hazards (asbestos, industrial solvents), warfare agents (chemical and biological weapons). 3. Case review: a) Present an example case (with supplemental imaging) of a young woman Veteran with breast cancer to showcase the patient's diagnosis and outcome. 4. Conclusion: a) Understanding unique breast cancer risk factors among young women Veterans can facilitate strategies that can ultimately reduce breast cancer mortality in this population.

## BREE-52 ATYPICALS FIBROADENOMAS: REBELS WITHOUT A CAUSE OR JUST MISUNDERSTOOD?

Daniel Sandoval Guerra, MD (*Abstract Co-Author*) Nothing to Disclose
Sara S. Herrera Lemus, MD (*Abstract Co-Author*) Nothing to Disclose
Raquel Balbas Lara, MD (*Abstract Co-Author*) Nothing to Disclose
Luz E. Bastidas Caicedo, MD (*Abstract Co-Author*) Nothing to Disclose
Kictzia Yigal Larios Cruz (*Abstract Co-Author*) Nothing to Disclose
Ilse G. Gonzalez Palma I, BMBCh (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Investigate the clinical and radiological characteristics of atypical fibroadenomas to enhance their diagnosis and clinical management.• Evaluate the diagnostic accuracy of different imaging modalities, such as mammography and ultrasound, in identifying atypical fibroadenomas.• Analyze the risk factors associated with the development of atypical fibroadenomas and their relationship with progression to malignancy.• Explore current therapeutic approaches and their impact on clinical outcomes in patients with atypical fibroadenomas.• Investigate the correlation between imaging findings and pathological characteristics of atypical fibroadenomas to improve diagnostic accuracy and clinical management. • Determine the effectiveness of a multidisciplinary approach including coordination among radiologists, pathologists, and surgeons.

**TABLE OF CONTENTS/OUTLINE**

This study examines atypical fibroadenomas, an important variant of benign breast tumors, which present diagnostic and therapeutic challenges. Imaging modalities are reviewed, highlighting characteristics on mammography and ultrasound, as well as the importance of imaging-pathology correlation in accurate diagnosis. Additionally, therapeutic approaches, including observation, image-guided biopsy, and surgical excision, are discussed. The importance of a multidisciplinary approach to optimize management of patients with atypical fibroadenomas is emphasized. This abstract provides a comprehensive and updated insight into this clinical entity, offering relevant information for clinicians and radiologists involved in the diagnosis and treatment of atypical fibroadenomas. Presentation Type: Research Abstract.

## BREE-53 ENCOUTERING INTRUDERS: FOREIN BODIES DETECTED IN MAMMOGRAPHY

Rodrigues, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana A. Miranda, MD (*Abstract Co-Author*) Nothing to Disclose
Regina C. Pereira SR, MD (*Abstract Co-Author*) Nothing to Disclose
Aline Morley (*Abstract Co-Author*) Nothing to Disclose

**TEACHING POINTS**

Help radiologists to recognize different types of foreign bodies in mammograms, including medical devices, aesthetic procedures, metal artifacts and devices related to diagnosis and treatment of breast cancer.Identify mammographic characteristics that help distinguish a several foreign bodies.Avoid additional investigations due to misinterpretations.

**TABLE OF CONTENTS/OUTLINE**

Foreign bodies definitionOverview of the importance of recognizing foreign bodies in mammography.Description of various foreign bodies usual and unusual encountered in mammography divided into medical devices, aesthetic procedures, metal artifacts and devices related to diagnosis and treatment of breast cancer, and others.Presentation of several cases illustrating the recognition, localizations, and management of foreign bodies in mammographySummary of key points covered and final thoughts on the importance of recognizing foreign bodies in mammography.

## BREE-54 IMPLANTS ILLUSTRATED: A TUTORIAL FOR ULTRASONOGRAPHIC EVALUATION OF IMPLANTS

Erica E. Francolin Federicci, PhD (*Abstract Co-Author*) Nothing to Disclose
Heni D. Skaf, MD (*Abstract Co-Author*) Nothing to Disclose
Alessandra Silva Malta, MD (*Abstract Co-Author*) Nothing to Disclose

Juliana H. Catani, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia T. Lima (*Abstract Co-Author*) Nothing to Disclose
Renato L. Ribeiro, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To teach ultrasound technique parameters to an adequate evaluation while avoiding common pitfalls;To describe normal appearance and the usual composition of breast implants on ultrasound;To show cases of complications related to breast implants on this method;To propose a checklist to evaluate implants and to diagnose complications;To provide tools and examples in order to write a structured report.

**TABLE OF CONTENTS/OUTLINE**

A significant change in the 2022 Food and Drug Administration (FDA) guidelines affecting radiologists is the inclusion of ultrasound as an alternative to magnetic resonance imaging for initial imaging surveillance for implant ruptures in asymptomatic patients and it is essential for any radiologist interpreting these studies.Breast implants are frequently encountered in breast imaging studies. There are many variations in lumens, positioning, morphology and other components among implants. Ultrasonographic characterization serves as a powerful tool in identifying gross structural abnormalities, ruptures and other complications.This pictorial essay aims to delve into the normal and abnormal imaging appearances of breast implants on ultrasound, including illustrative cases of ruptures, fractures and complications.Moreover, we will propose a checklist for recognizing the type of implant and identifying potential abnormalities or complications. We will also present strategies for equipping radiologists with the tools necessary to compose a structured report. This comprehensive approach aims to improve the understanding and management of breast implants using ultrasound imaging.

## BREE-55 INVASIVE LOBULAR CARCINOMA: CATCH ME EARLY, IF YOU CAN!

Patricia M. Gomes El Bacha, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana Couto De Mores, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Invasive lobular carcinoma (ILC) is the second most common type of breast cancer. It originates in the lobes of the glands, invades the surrounding tissues and often does not form a palpable nodule. The diagnosis of ILC is challenging, especially in MG and clinical examinations, and is often diagnosed by MRI or US. Understanding the radiological features of ILC is essential for accurate diagnosis. It is often clinically silent, resulting in late-stage diagnosis and more frequently manifests with distant metastatic disease. It tends to occur in older women with a maximum incidence in postmenopausal. The hormone replacement therapy increases the risk of ILC. The US is better than MG to detect non mass lesions and for evaluation of axillary nodes. Hypoechoic irregular mass is the most common ultrasonographic appearance, but non-mass lesions may occur on US and MRI less frequently. In histopathological evaluation, the pleomorphic pattern there is little or no desmoplastic reaction of the invaded tissue. In the macroscopy it often presents as irregular and poorly delimited tumors that can be difficult to define macroscopically due to the diffuse growth pattern of the cellular infiltrate.The objective of this exhibition is to present, through illustrative cases, a practical approach to the imaging and histopathological findings of ILC manifestations.

**TABLE OF CONTENTS/OUTLINE**

Introduction. Histopathological and imaging aspects. A case-based review of original cases from the breast department of hospitals showing characteristics of manifestations and challenges in the diagnosis of ILC, through the perspective and purpose of a practical approach. Take-home messages. References.

## BREE-56 BENEATH THE SURFACE: A RADIOLOGICAL VOYAGE INTO DEEP LESIONS ON BREAST EXAMS

Paula C. Moraes, MD (*Abstract Co-Author*) Nothing to Disclose
Larissa M. Yano, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Abstract Co-Author*) Nothing to Disclose
Heni D. Skaf, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia Orthmann, MD (*Abstract Co-Author*) Nothing to Disclose
Vivian S. Ogata, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To discuss the basic breast anatomy and to define the three breast zones: premammary, mammary and retromammary;To present the anatomical landmarks and imaging clues to determine the origin of such lesions as mammary or not;To present the radiological aspects of various posterior breast

lesions, pectoralis and chest wall lesions, illustrating these with multimodality imaging from our archives.To familiarize general radiologists with such findings in order to improve the diagnostic rate and avoid misinterpretation and pitfalls of such lesions, reducing false positive rates and unnecessary biopsies.

**TABLE OF CONTENTS/OUTLINE**

The human breast's basic anatomy can be categorized into three distinct zones: the premammary, mammary, and retromammary zones.Located posterior to the retromammary fat is the pectoralis muscle. It's important to note that this is not considered an anatomical component of the chest wall, and therefore, it is not interpreted as such for staging and management purposes.However, these structures are contemplated in breast exams and should be well-known to radiologists.The task of differentiating primary lesions of the mammary parenchyma from those originating from the pectoral musculature and the thoracic wall can be challenging. Nevertheless, it is crucial for the effective management and diagnosis of such lesions.There exist certain anatomical parameters and defining image criteria that assist in determining the origin of these lesions and the extent of tumor involvement. These include the presence of enhancement or the angle between the lesions and the structures of interest. These factors play a significant role in the diagnosis and subsequent treatment of these conditions.

## BREE-57 UNMASKING THE MYSTERY: A DEEP DIVE INTO IDIOPATHIC GRANULOMATOUS MASTITIS

Antonio Jose Cueva Guerrero, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Understand the typical presentation of IGM in women of childbearing age and its variable symptoms. • Recognize the diverse mammographic, ultrasound, and MRI findings associated with IGM, including masses, distortion, and skin thickening. • Distinguish IGM from breast cancer and other inflammatory breast lesions using key imaging features. • Emphasize the crucial role of core needle biopsy with pathological confirmation for definitive diagnosis of IGM. • Briefly discuss the treatment options for IGM, including medical management and surgical intervention.

**TABLE OF CONTENTS/OUTLINE**

- Introduction- Anatomy - Pathogenesis - Clinical presentation - Differential diagnosis - Imaging methods- Management strategies - Conclusions

## BREE-58 CURRENT USES OF CONTRAST-ENHANCED MAMMOGRAPHY (CEM). A PICTORIAL REVIEW OF THE UTILITY OF CEM IN DIFFERENT SETTINGS

Carlos Oliva Fonte (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia Arman, MD (*Abstract Co-Author*) Nothing to Disclose
Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-To review contrast-enhanced mammography (CEM) technique. -To analyze the different applications of contrast-enhanced mammography (CEM) including work-up of symptoms or equivocal findings, breast cancer detection and local staging, supplemental technique for screening, follow-up of breast cancer, monitoring neoadjuvant systemic therapy response. - To illustrate imaging findings of CEM with correlation with imaging (US, MRI) and pathology. - To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

**TABLE OF CONTENTS/OUTLINE**

We review current applications and state-of-the-art of contrast-enhanced mammography highlighting the benefits and potential use in different settings. We present:
- Basics and technique of contrast enhanced mammography (CEM)
- Indications of CEM. CEM increases sensitivity and specificity of digital mammography.
- Imaging in different settings: -breast cancer diagnosis in symptomatic patients: palpable mass, nipple retraction, breast pain, or bloody nipple discharge; - problem solving for inconclusive findings; - recalls from screening: CEM helps in detection of multiple lesions and to safely reduce benign breast biopsies;- local staging and surgical planning: accurate size correlation with surgical specimen, US and MRI and detection of multifocal and bilateral disease similar to MRI with less false positives;- follow-up of breast conservation therapy;- neoadjuvant chemotherapy response evaluation, CEM shows similar sensitivity and PPV than MRI to detect residual lesion and detects pathological complete response better than MRI.
- Future directions. Screening in dense breast, high risk, intermediate risk.

## BREE-59 THE USE OF VERY HIGH FREQUENCY TRANSDUCERS BEYOND DERMATOLOGY - DIAGNOSIS AND FOLLOW-UP OF BREAST LESIONS

Luciana Graziano, MD (*Abstract Co-Author*) Nothing to Disclose
Laura B. De Melo, MD (*Abstract Co-Author*) Nothing to Disclose
Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Bruna Isabela S. Tavares, MD (*Abstract Co-Author*) Nothing to Disclose
Vinicius C. Felipe SR, PhD (*Abstract Co-Author*) Nothing to Disclose
Soraia Damiao, MD (*Abstract Co-Author*) Nothing to Disclose
Mariah C. Wanderley (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Demonstrate how the development of transducers with frequencies above 15MHz, initially aimed at dermatological ultrasound, has shown an important role in the evaluation of breast lesions;- Present the main applications of very high frequency transducers in the diagnosis, follow-up and image-guided biopsies of breast lesions;- Differentiate breast from skin lesions and offer a better definition for the analysis of ducts and subcutaneous tissue;- Describe the use of very high frequency transducers in guiding ultrasound biopsies through radiological correlation between imaging methods.

**TABLE OF CONTENTS/OUTLINE**

Physical characteristics of linear transducers traditionally used for screening and diagnosing breast lesions and the very high frequency transducers;Ductal ectasias, intraductal masses and retroareolar lesions:utilizing very high-frequency transducers for detailed analysis;advantages of monitoring and biopsying these lesions using very high frequency transducers.Skin calcifications:detecting skin calcifications when mammographic findings are inconclusive.Ultrasound-guided biopsy of calcifications with the use of very high frequency transducers:cases of very superficial or retroareolar suspicious calcifications, whose location is a limiting factor for stereotaxis and traditional transducers do not guarantee adequate image definition;Identification of calcifications via ultrasound, placement of a metallic marker on the skin surface covering the calcifications, followed by tangential mammography to validate the correspondence between the calcifications visualized in mammography and ultrasound, enabling the biopsy procedure to proceed.Final considerations.

## BREE-6 LESS IS MORE: DE-ESCALATION OF SURGERY IN THE BREAST AND AXILLA - THE ROLE OF IMAGING

**Certificate of Merit**

**TEACHING POINTS**

1.Breast cancer management has transformed significantly over the last decades, specifically through the integration of neoadjuvant systemic therapy (NST) and the evolving understanding of tumor biology, enabling more tailored treatment strategies.2.Increasing adaptation of limited axillary surgery, such as sentinel lymph node biopsy and targeted axillary dissection raised questions on role of imaging for axillary nodal disease assessment.3.Advances in NST with up to 60-70% of patients achieving pathologic complete response for certain biological subtypes of breast cancer produced growing evidence on potential omission of surgery based on use of minimally invasive biopsy.4.Radiologists should be familiar with contemporary evidence and role of the imaging and image guided procedures for de-escalation of breast and axillary surgery in breast cancer patients.

**TABLE OF CONTENTS/OUTLINE**

I. Introduction II. Axillary management • Clinically node negative breast cancer & 7; Role of imaging & 7; Overview of clinical trials • Clinically node positive breast cancer undergoing NST & 7; Role of imaging & 7; Overview of clinical trials III. Omission of breast surgery in exceptional responders to NST based on tumor biology • Proof of concept • Minimally invasive image guided biopsy• Overview of clinical trials IV. De-escalation of breast surgery in patients with DCIS • Role of imaging • Overview of clinical trials V. Future directions •Advancements in imaging and image guided procedures • Artificial Intelligence VI. Conclusion VII. References

## BREE-60 STABILITY IS NOT SYNONYMOUS WITH BENIGNITY: THE DIAGNOSTIC CHALLENGE OF SLOW-GROWING BREAST CANCERS

**Awards**
**Certificate of Merit**

Marcela C. Lauar, MD (*Abstract Co-Author*) Nothing to Disclose
Caio D. Pinheiro, MD (*Abstract Co-Author*) Nothing to Disclose
Aline Lemgruber Prado Costa, MD (*Abstract Co-Author*) Nothing to Disclose
Roberta Linhares, MD (*Abstract Co-Author*) Nothing to Disclose

Juliana H. Catani, MD (*Abstract Co-Author*) Nothing to Disclose
Erica E. Francolin Federicci, PhD (*Abstract Co-Author*) Nothing to Disclose
Alessandra Silva Malta, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To describe the main histological types of tumors that have slow growth;To review the most recent literature on sensitivity, specificity and diagnostic accuracy regarding this matter;To evaluate of the false negatives cases retrospectively for a more comprehensive characterization of the diagnosis;To propose strategies to prevent diagnostic imaging errors in these types of cancer.

**TABLE OF CONTENTS/OUTLINE**

Slow-growing breast tumors are mostly indolent and have lower mortality rates. However, they are responsible for a significant portion of false negatives in screening exams due to their slow growth. Additionally, difficulty of these lesions from potentially invasive ones can lead to imaging diagnostic errors and it is essential for any radiologist interpreting these studies.The main histological subtypes of slow-growing breast tumors include ductal carcinoma in situ, invasive non-specific luminal carcinoma, invasive tubular carcinoma and invasive lobular carcinoma. It stands out as the ductal carcinoma in situ (DCIS) that represents most common lesions that remain indolent.This review thoroughly explains the histological types of slow-growing breast cancer and shows information of the natural history, about mortality or survival rates.Furthermore, recent literature on the sensitivity, specificity, and diagnostic accuracy of slow-growing breast cancer will be discussed, accompanied by illustrative cases of false negatives to highlight diagnostic pitfalls.Strategies to prevent diagnostic imaging errors in these types of cancer are proposed to aid in clinical management.

## BREE-61 NAVIGATING THROUGH TUBERCULOSIS MASTITIS: RADIOLOGICAL PRESENTATIONS AND DIAGNOSIS RELEVANCE IN TROPICAL COUNTRIES

**TEACHING POINTS**

Tuberculosis (TB) mastitis is a rare extrapulmonary condition caused by Mycobacterium tuberculosis. It can affect the breast either primarily (through abrasions) or secondarily (via lymphatic backflow or contiguity with intrathoracic foci). It presents in varied clinical and radiological forms, often mimicking various other chronic granulomatous conditions, infectious and otherwise, and is frequently diagnosed late due to its nonspecific imaging

characteristics.It is important to emphasize that although mammary tuberculosis is not the primary cause of chronic granulomatous mastitis, it remains epidemiologically relevant in tropical countries and has considerable clinical importance.In this context, this exhibition reviews clinical findings, main radiological findings and proposes a workflow for diagnosis and management, highlighting tips that may help the diagnosis.

**TABLE OF CONTENTS/OUTLINE**

Review the epidemiology and the most clinical findings of Tuberculosis (TB) mastitis and their differential diagnosis.Explore the main radiological findings on ultrasound (US), mammography (MG), and magnetic resonance imaging (MRI) of Tuberculosis (TB) mastitis illustrating with different cases.Demonstrate the role of the appropriate investigation for TB mastitis and the workflow that may help an early diagnosis

## BREE-62 LEARNING THE ROPES: CONTRAST-ENHANCED MAMMOGRAPHY

Ekta Gupta, MD (*Abstract Co-Author*) Nothing to Disclose
Suzanne McElligott, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica J. DeSabato, MD (*Abstract Co-Author*) Nothing to Disclose
Nina S. Vincoff, MD (*Abstract Co-Author*) Nothing to Disclose
Amna Aslam (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Contrast-enhanced mammography (CEM) is an emerging diagnostic and screening tool in breast imaging that uses iodinated contrast to visualize tumor vascularity. In CEM, a dual-energy mammogram is acquired 2 minutes after the IV injection of iodinated contrast. Low and high energy views offer excellent anatomic detail and breast perfusion. CEM has higher sensitivity for detecting breast cancer compared to digital mammography, tomosynthesis, and ultrasound combined. It has comparable sensitivity and specificity to breast MRI for cancer detection at lower cost and greater comfort for patients who are unable to undergo breast MRI (4,5,6). In this review, we will discuss our experience interpreting CEM and discuss common artifacts and pitfalls. CEM is new for many breast imagers. As it continues to grow in clinical practice, it is important that radiologists understand how CEM can be utilized, how to read and interpret these images, perform CEM biopsies when needed and tackle challenges faced with these cases.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction and Background 2. Indications a. Screening b. Diagnostic i. Symptomatic patients ii. Screen recall iii. Extent of disease 3. Imaging Protocol and Acquisition a. Artifacts 4. Reporting findings a. BPE b. BI-RADS c. Lesion description i. Benign ii. Malignant 5. Biopsy of CEM findings - early experience and challenges 6. Conclusion and References

## BREE-63 BREAKING THE ICE: CRYOABLATION'S ROLE IN BREAST LESIONS

**TEACHING POINTS**

To demystify the mechanism of cellular injury due to cryoablation;To illustrate how cryoablation is performed in practice on breast lesions as well as the subsequent imaging repercussions with cases from our digital archive;To clarify the clinical scenarios where cryoablation is indicated and its limitations.

**TABLE OF CONTENTS/OUTLINE**

Cryoablation involves the application of successive cycles of freezing and thawing of neoplastic tissue using cryoprobes inserted into the tumor under radiological guidance (typically ultrasound), promoting tissue destruction through rupture of cell membranes.The hallmark of cryoablation technique is the formation of an "ice sphere" in the tissue, ideally encompassing the tumor with a safety margin of at least 5 mm, easily identified by conventional imaging methods, resulting from tissue necrosis.The freezing mechanism occurs through the thermodynamic properties of argon or nitrogen gasses, which suffer significant heat loss during their expansion. Defrosting is achieved by helium gas, which allows the system to heat up.Its indications include benign breast lesions such as fibroadenomas and malignant tumors smaller than 2,5 cm, breast carcinomas of any histological subtype without distant metastases and with clinically negative axilla.To provide a comprehensive understanding of cryoablation, we have compiled a series of cases from our institution's digital archive. These cases illustrate the step-by-step technique of cryoablation, its imaging consequences, and the clinical rationale behind its use, as well as the method's inherent limitations.

## BREE-64 BEWARE OF THE RARE: A PICTORIAL CASE-BASED REVIEW OF MESENCHYMAL BREAST TUMORS

Norma P. Arroyo Lopez, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To know the origin and histologic classification of mesenchymal breast tumors Identify characteristics clinical and pathological of each tumor Identify imaging key features of each tumor of cases from our databases

**TABLE OF CONTENTS/OUTLINE**

Introduction. WHO classification of mesenchymal breast tumors. Clinical features and histological Imaging findings by ultrasound and mammography modalities. Illustrative cases of mesenchymal breast tumors. Conclusions References

## BREE-65 EXPANDING THE BRACKET: OPTIMIZING LOCALIZATION TECHNIQUES FOR MULTIFOCAL AND MULTICENTRIC DISEASE

Neha Khemani, MD (*Abstract Co-Author*) Nothing to Disclose
Amy Maduram, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

(1) Breast surgeries are progressively trending towards de-escalation of therapy such as breast conserving surgery (BCS), downstaging cancer after neoadjuvant therapy, and lower number of axillary nodes removed. Radiologists play an important role in planning localizations and interpreting specimen radiographs for BCS. (2) Although multifocal and multicentric disease is often thought as an exclusion criterion for BCS, it is possible to achieve comparable disease free and overall survival rates to mastectomy in select patients when negative margins are achieved. Therefore, it is increasingly important for radiologists to have the technical acumen to approach complex localizations utilizing 3-4 wires or covering multiple quadrants of the breast with confidence. (3) Feedback on surgical specimen radiographs play a vital partnership with surgeons in achieving negative final pathology margins and improving patient outcomes.

**TABLE OF CONTENTS/OUTLINE**

(1) Overview of trends towards BCS and introduction to wire-guided localization. (2) Cases of multicentric and multifocal malignancy requiring 4 wire localization with technical pearls and pitfalls. (3) Cases of multi-wire lesion localization using tomosynthesis and complications requiring follow-up imaging. (4) Guidelines for optimal surgical margins of invasive cancer, DCIS, and pleomorphic LCIS. (5) Cases of actionable specimen radiographs requiring notification to the surgeon. (6) Review of pathologic description of margin assessment. (7) Self-assessment quiz.

## BREE-66 RADIANT CLARITY: DISCOVERING THE BEAUTY OF CONTRAST MAMMOGRAPHY IN THE DETECTION OF MALIGNANT CALCIFICATIONS

Renata Feres, MD (*Abstract Co-Author*) Nothing to Disclose
Marcelo Z. Bringel Martins, MD (*Abstract Co-Author*) Nothing to Disclose
Caroline Colombo, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To explain the role of imaging in the detection of residual postoperative breast cancer for optimal therapeutic management;To discuss the possible causes of residual tumor after breast-conserving surgery or mastectomy;To explain the role of specimen mammogram and histological evaluation of surgical margins as a means to avoid residual cancer.

**TABLE OF CONTENTS/OUTLINE**

The main goal of surgery in the treatment of breast cancer, whether breast-conserving surgery or mastectomy, is the removal of all malignant lesions. Nevertheless, postoperative residual breast cancer is a possible outcome after any surgery, regardless if surgical margins are positive or negative. In the setting of residual cancer, re-excision is the standard treatment.The main cause of residual cancer is underestimation of lesion size prior to surgery; preoperative breast MRI is the optimal imaging modality for local staging, determining tumor extent and multifocal disease. Other causes include inappropriate surgical choice, errors in preoperative lesion localization and incomplete axillary dissection of metastatic lymph nodes. Prevention of residual cancer can be achieved by performing specimen mammograms of mammography-visible lesions (calcifications, biopsy markers) and histological evaluation of surgical margins. In patients with positive surgical margins, imaging aids in determining extent of residual disease prior to re-excision. In patients with negative margins, residual cancer may be detected in subsequent screening exams.We have compiled a series of cases from our institution's digital archive to discuss possible causes of residual tumors and the role of imaging in reducing them.

## BREE-68 EMERGENCY BREAST IMAGING UNCOVERED: NAVIGATING TRIAGE, IMAGING FEATURES, MIMICS, TREATMENT, AND FOLLOW-UP

Shruti Kumar, MBBS (*Abstract Co-Author*) Nothing to Disclose
George K. Vilanilam, MD (*Abstract Co-Author*) Nothing to Disclose
Aditi Chaurasia, MBBS (*Abstract Co-Author*) Nothing to Disclose
Giridhar Dasegowda, MD (*Abstract Co-Author*) Nothing to Disclose
Heta Ladumor, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Identify causes of breast-related complaints presenting to the emergency department 2. Describe characteristic imaging features of common and uncommon emergent breast conditions and mimics 3. Discuss triage, management, and appropriate follow-up protocol

**TABLE OF CONTENTS/OUTLINE**

A. Traumatic: contusions/hematoma/seatbelt injury, fat necrosis (mimics cancer) B. Non traumatic B.1 Inflammatory: puerperal mastitis, Mondor's disease B.2 Infectious: non-puerperal mastitis, granulomatous mastitis (mimics cancer) C. Implant related: infection, rupture following trauma D. Post-procedural: hematoma, pseudoaneurysm E. Mimics: cancer F. Non emergent findings in the emergency department: palpable mass, discharge, skin changes

## BREE-69 ALWAYS LOOK BEYOND THE BREAST: EXTRAMAMMARY FINDINGS ON MRI

**Awards**
**Certificate of Merit**

Karla I. Soto, MD (*Abstract Co-Author*) Nothing to Disclose
Yesika Davila Zablah, MD (*Abstract Co-Author*) Nothing to Disclose
Ia M. Sanchez Carenzo, MD (*Abstract Co-Author*) Nothing to Disclose
Ilany L. Valdivia I, MD (*Abstract Co-Author*) Nothing to Disclose

Elena M. Sanchez Siller, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Guerra, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica A. Perdomo SR, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purpose of this exhibit is to describe extramammary findings discovered on breast magnetic resonance images, including location, frequency and relevance. Review the imaging characteristics of the extramammary findings and the appropriate imaging modality when further evaluation is required. Identify suspicious features that may suggest malignancy among extramammary lesions. Learn a systematic assessment for active search of extramammary lesions. Recognize when additional imaging work-up or follow-up is necessary for further characterization of extramammary findings.

**TABLE OF CONTENTS/OUTLINE**

We review the location and features of extramammary findings on breast magnetic resonance, presenting the most frequent locations of benign and malignant findings, including an approach for further imaging work-up and follow-up. Benign findings: liver cyst, pleural effusion, liver hemangiomas, sternum hemangiomas, lung atelectasis, post-radiation changes, mesenteric cyst, mediastinum cyst, epidermal inclusion cyst, accessory spleen, axillary lipoma, pulmonary nodules, cervical reactive lymph node, rib hemangiomas, lung consolidation, thyroid nodule. Malignant findings: muscle, bone, lymph nodes, pulmonary and liver metastases and malignant pleural effusion. A systematic approach when evaluating extramammary structures.

## BREE-7 EXPLORING THE AXILLARY REGION IN BREAST CANCER PATIENTS: CT FINDINGS

Miguel Chiva de Agustin (*Abstract Co-Author*) Nothing to Disclose
Irene Vicente Zapata, MD (*Abstract Co-Author*) Nothing to Disclose
Lucia Martinez De Vega, MD (*Abstract Co-Author*) Nothing to Disclose
Elisa Antolinos Macho, MD (*Abstract Co-Author*) Nothing to Disclose
Teresa Presa, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Describe the imaging appearances of normal and abnormal axillary nodes on CT in breast cancer patients, with focus on morphology and localization • Explain how the axillary node burden can be assessed with CT before and after NAC • Describe axillary CT findings in follow up breast cancer patients

**TABLE OF CONTENTS/OUTLINE**

1. Describe the normal and abnormal appearances of axillary nodes on CT staging and its role in therapeutic management decisions for breast cancer patients. a. The Amonkar classification used in ultrasound has similar appearances on CT and categorizes nodes as: i. Normal: UN2, UN3 ii. Abnormal or suspicious: UN4 and UN5 b. The Berge levels aid in localizing nodes: i. Level 1: lower axilla, lateral to the minor pectoralis muscle ii. Level 2: middle axilla, behind the minor pectoralis muscle iii. Level 3: upper axilla, medial to the minor pectoralis muscle iv. Interpectoral region2. Describe axillary node burden and the importance of understanding diagnostic procedures (SNB, LA, TAD) for successful treatment: a. Pre-neoadjuvant chemotherapy: crucial for node counting and localization: i. Patients with <3 nodes in level 1: candidates for targeted axillary dissection (avoiding LA) ii. Patients with >3 nodes or nodes in level 2: candidates for lymphadenectomy (LA) b. Post-NAC evaluation should report: i. Good response - nodes return to normal size or >50% reduction ii. No response - no changes 3. Evaluate CT findings in follow-up breast cancer patients: a. Postsurgical changes from SNB or LA b. Surgical techniques and complications: extracapsular silicone in breast reconstruction, autologous reconstructions, or postsurgical seromas c. Axillary recurrence.

**TEACHING POINTS**

1. Non-calcified ductal carcinoma in situ presents with different appearances: mass, asymmetries or distortions.2. Non-calcifield DCIS can be occult on screening mammography.3. Non-calcifield DCIS is common to find it on staging or screening MRI as a non-mass enhacement lesion.

**TABLE OF CONTENTS/OUTLINE**

Non calcified ductal carcinoma in situPathologic featuresMultimodality imaging findingsMRI biopsyCases

## BREE-71 BREAST EDEMA. UNDERSTANDING THE UNDERLYING PATHOLOGY. A PICTORIAL REVIEW

Karina Pesce, PhD (*Abstract Co-Author*) Nothing to Disclose
Maria Jose Chico (*Abstract Co-Author*) Nothing to Disclose
Karen L. Caro, PhD (*Abstract Co-Author*) Nothing to Disclose
Liliana Pacheco Mendoza (*Abstract Co-Author*) Nothing to Disclose
Maria P. Swiecicki, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To display the different pathologies that can clinically manifest with breast edema: mastitis, granulomatous mastitis, inflammatory breast carcinoma, post radiotherapy edema and systemic diseases such as renal failure or congestive heart failure.2. To illustrate using clinical cases tips and tricks that can help achieve a proper diagnosis of these entities.

### TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Physiopathology of breast edema.3. Mastitis: puerperal, non-puerperal and granulomatous mastitis.4. Breast edema after conserving treatment, post radiotherapy edema.5. Inflammatory breast cancer.6. Systemic diseases that can produce breast edema: renal failure, congestive heart failure.7. Conclusions.In conclusion, this educational exhibit is intended to aid the radiologists in training in understanding the multiple differential diagnosis that should be considered when encountering a patient with breast edema and give them tips for achieving an accurate diagnosis within this broad spectrum of entities.

## BREE-72 BEYOND METASTATIC LYMPHADENOPATHY IN BREAST CANCER: AN APPROACH TO AXILLARY MASSES

**Awards**
**Certificate of Merit**

Tanya W. Moseley, MD, PhD (*Abstract Co-Author*) Consultant, Hologic, Inc;Consultant, Merit Medical Systems, Inc;Owner, TW Moseley, LLC;CEO, TW Moseley, LLC
Gaiane M. Rauch, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Emily S. Nia, MD (*Abstract Co-Author*) Nothing to Disclose
Mary S. Guirguis, MD (*Abstract Co-Author*) Nothing to Disclose
Beatriz E. Adrada, MD (*Abstract Co-Author*) Nothing to Disclose
Miral M. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Megha M. Kapoor, MD (*Abstract Co-Author*) Nothing to Disclose
Elsa M. Arribas, MD (*Presenter*) Stockholder, 3D Systems, Inc

### TEACHING POINTS

• Review the differential diagnosis of benign and malignant masses in the axillary region. • Review the imaging modalities and key imaging features used in the assessment of axillary masses. • Highlight the importance of appropriate correlation of the patient's clinical presentation, pertinent clinical history, and imaging clues to distinguish these.• Review biopsy techniques and challenges.• Discuss the clinical management.

### TABLE OF CONTENTS/OUTLINE

I. IntroductionII. Algorithm on how to approach benign and malignant masses in the axillary region across different imaging modalities. III. Highlight the importance of correlation of the patient's clinical symptoms and their clinical history to establish the differential diagnosis. IV. Review of the different imaging techniques to biopsy axillary masses. V. Tips, pitfalls, and practical approaches will be emphasized through a case-based multi-modality approach. VI. Rad-path correlation of the axillary pathology.

## BREE-73 THE DIAGNOSTIC VALUE OF A NEW MAMMOGRAPHY TECHNIQUE IN BREAST DISEASES: CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY (CESM)

Ruixue Cao (*Presenter*) Nothing to Disclose

### TEACHING POINTS

CESM greatly increased the positive detection rate for breast cancer.Various methods have been applied to the diagnosis of breast diseases alone or in combination in clinical application. This exhibition aims to demonstrate the value of CESM in breast disease diagnosis by conducting research surveys on previous studies.

### TABLE OF CONTENTS/OUTLINE

1) Introduction 2) CESM imaging principle : CESM based on dual-energy breast exposure after contrast administration, It reflects the blood flow dynamics of the lesion by utilizing the uptake of iodine contrast agent in the tumor tissue. 3) Technique and protocols: contrast dose of 1.5 mL/kg, factory-set kVp ranges for low- and high-energy acquisitions, beginning image acquisition after 2min from contrast agent injection and completing the examination within 8 min. 4) Diagnostic value: a. evaluation of symptomatic women b. screening recalls c. local staging d. pre-and post-operative evaluations e. neoadjuvant chemotherapy response monitoring f. guide biopsy for the lesion 5) Advantages and limitations of CESM

## BREE-74 FROM ATYPIA TO CARCINOMA A REVIEW OF LOBULAR NEOPLASIAS OF THE BREAST

Harnoor Singh, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Elaine G. Khalil, MD (*Abstract Co-Author*) Nothing to Disclose
Muhayman Sadiq, MBBS (*Abstract Co-Author*) Nothing to Disclose
Kiran N. Chang, MD (*Abstract Co-Author*) Nothing to Disclose
Claudia Cotes, MD (*Abstract Co-Author*) Nothing to Disclose
Shima Aran, MD (*Abstract Co-Author*) Nothing to Disclose
Abeer H. Abdel Hameed, MBChB (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Definition of Lobular neoplasia LN and invasive lobular carcinoma ILC Pathological classification of LN .Clinical presentation and epidemiology of LN and ILC Review of common imaging findings in LN and ILC Review of imaging caveats and radiological pathological concordance Review of the multidisciplinary approach for management of LN and ILC

**TABLE OF CONTENTS/OUTLINE**

Definition of LN Including Atypical lobular hyperplasia ALH Lobular carcinoma in situ LCIS and invasive lobular carcinoma ILCReview of common imaging findingsOutline the breast radiologist role inDetection of subtle imaging findings in cases of ILCAssessment of multifocal multicentric disease and the contralateral breast in ILClocal staging of ILC and planning for surgical managementSelection of sampling method and targetDetermine radiological pathological concordanceProper follow up for non surgical patients Factors influencing radiological pathological concordancePatient factorsLesion factorsThe biopsy modality guidanceNumber of biopsy core samples needle Gauge successful targetingSize of original lesion Residual non sampled abnormality Management of LN and ILCUpfront surgical management versus neo adjuvant systemic therapy for ILCFactors influencing management of LNClinical presentation Pathological factors Number of involved TDLU and presence of other high risk breast lesions.Patient lifetime risk for breast cancer.Radiological pathological concordance.Consideration of chemo-preventive treatment.Proper choice of imaging modality for follow up.

## BREE-75 SUPERFICIAL AND SKIN LESIONS IN BREAST IMAGING.MULTIMODALITY IMAGING ANDDIFFERENTIAL DIAGNOSIS

Brian D. Norena Rengifo, MD (*Abstract Co-Author*) Nothing to Disclose
Cristina Saldarriaga, MD (*Abstract Co-Author*) Nothing to Disclose
Haydee Ojeda-Fournier, MD (*Abstract Co-Author*) Research Consultant, View Point Medical, Inc;Stock options, CureMetrix, Inc
Beatriz E. Adrada, MD (*Abstract Co-Author*) Nothing to Disclose
Fernando Ahumada (*Abstract Co-Author*) Nothing to Disclose
Ana Beatriz Luengas (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Superficial lesions in the breast can be an incidental finding or can manifestas a palpable abnormality.Knowledge of the skin anatomy is crucial in the assessment of superficiallesions in breast.Breast ultrasound is the imaging of choice for characterization of superficiallesions in breast imaging. A meticulous technique is necessary to determinelesion localization.Establishing a differential diagnosis according to the localization of thesuperficial lesion is critical to avoid a cancer misdiagnosis.

**TABLE OF CONTENTS/OUTLINE**

This educational electronic exhibit will review the anatomy of the skin,multimodality imaging findings and differential diagnosis of superficial and skinlesions in the breast. An overview of the US technique to evaluate superficial andskin lesions will be given.

## BREE-76 NEW STRATEGIES IN CANCER SURVEILLANCE AFTER BREAST CANCER TREATMENT

Lorena Melian Iribar, MD (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia Arman, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Teresa Montero Alameda (*Abstract Co-Author*) Nothing to Disclose
Itxaso Galan-Gonzalez (*Abstract Co-Author*) Nothing to Disclose
Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To review current strategies of surveillance of patients after breast cancer surgical treatment. 2. To discuss the specific management of those patients, including imaging and interventional procedures. 3. To illustrate imaging in different techniques including contrast-enhanced mammography, US, MRI, CT, and PET with pathologic correlation in cases of cancer recurrence and in different benign postoperative entities (fat necrosis, seroma, mastitis). 4. To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

**TABLE OF CONTENTS/OUTLINE**

The different therapeutic options employed for breast disease cause different breast changes, complications and frequently difficulties in diagnosis. We present: 1. Current recommendations in surveillance after different breast cancer surgical treatment strategies (mastectomy, breast reconstruction, breast conserving surgery). 2. Techniques in evaluation of treated breasts. Contrast-enhanced mammography, US, MRI, CT, PET. 3. Imaging findings. Postsurgery changes acute/subacute (architectural distortion, hematoma, seroma, fat necrosis, residual lesion), late (scar, fibrous reaction, suture granuloma, breast Implant rupture and silicone granuloma, lymphadenopathy). Posttreatment changes: Hormonotherapy (Increased density), Radiotherapy (skin thickening, edema). Breast cancer recurrence, metachronous breast cancer. 4. Tips for differential diagnosis, diagnostic work-up and recommendations for management

## BREE-77 DON’T FORGET TO DESCRIBE THE BREAST FINDINGS ON CHEST TC.TIPS AND PEARLS TO IDENTIFY THEM

Maria P. Swiecicki, MD (*Abstract Co-Author*) Nothing to Disclose
Karina Pesce, PhD (*Abstract Co-Author*) Nothing to Disclose
MONICA OTILIA MACHUCA CASTILLO (*Abstract Co-Author*) Nothing to Disclose
Maria Jose Chico (*Abstract Co-Author*) Nothing to Disclose
Karen L. Caro, PhD (*Abstract Co-Author*) Nothing to Disclose
Agustina Graziani, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To describe breast and axillary findings on chest computed tomography.Recognize breast and axillary findings of clinical significance that must be reported in chest CT scan.To discuss the clinical management of these findings.

**TABLE OF CONTENTS/OUTLINE**

1-Introduction:Chest CT is a frequently performed radiologic study and can reveal breast and axillary findings in both genders. Radiology residents should be accurate in reporting these findings is essential to guide clinical decision-making and prevent unnecessary procedures.2-Normal Appearance of Breasts and Axilla on Chest CT:The normal appearance of breast parenchyma on chest CT can vary based on breast density. Familiarity with normal variations in breast density is crucial to avoid misinterpretation of findings. The axilla should also be carefully evaluated for lymph nodes.3-Benign and malignant Imaging findings in female breast on Chest CT4-Benign Imaging Findings in Male Breast on Chest CT:Gynecomastia is a common benign finding in the male breast on chest CT. It is important to recognize and accurately describe this finding in the report to prevent unnecessary workup.5-Malignant imaging findings in male breast on Chest CT6-Clinical Cases:Several clinical cases will be presented to illustrate the accurate reporting of breast and axillary findings on chest CT scans.7-Management.

## BREE-78 BREAST RESONANCE, FINDINGS THAT SHINE ON T2, A PICTORIAL REVIEW

Dayana K. Pastor Gutierrez, PhD (*Abstract Co-Author*) Nothing to Disclose
Karla X. Gutierrez, MD (*Abstract Co-Author*) Nothing to Disclose

Liliana M. Bustamante Rodas, MD (*Abstract Co-Author*) Nothing to Disclose
Liana M. Falcon, MD (*Abstract Co-Author*) Nothing to Disclose
Rowena A. Hammond, MD (*Abstract Co-Author*) Nothing to Disclose
Federica Pediconi, MD (*Abstract Co-Author*) Nothing to Disclose
Sonia P. Guillen-Bravo, MD (*Abstract Co-Author*) Nothing to Disclose
Marycarmen E. Flores Duenas, MD (*Abstract Co-Author*) Nothing to Disclose
Lisett N. Cruzado-Quiroz, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Most lesions that shine on T2 are benign, however there are some malignant lesions that also shine on T2.The most common benign hyperintense lesions on T2 are: cysts, fibroadenomas, lymph nodes, fat necrosis, etc.Mucinous carcinomas, papillary carcinomas, triple negative tumors with a necrotic component, etc., are malignant lesions that present high signal on T2.A single sequence does not make the diagnosis. In MRI, it is important to evaluate the morphological and dynamic sequences in parallel, which will help us narrow the differential diagnosis.In this presentation, we want to illustrate the MRI features of most common and rare T2 hyperintense breast lesions, with emphasis on morphologic features and differential diagnoses.

**TABLE OF CONTENTS/OUTLINE**

Breast cancer; MRI; malignant lesions; T2 hyperintense; necrotic component; papillary carcinomas; mucinous carcinomas.

## BREE-79 MORE THAN WORDS: COMPLETE REPORT FOR OPTIMAL TREATMENT TNM 8TH EDITION

Maria Jose Chico (*Abstract Co-Author*) Nothing to Disclose
Karen L. Caro, PhD (*Abstract Co-Author*) Nothing to Disclose
MONICA OTILIA MACHUCA CASTILLO (*Abstract Co-Author*) Nothing to Disclose
Maria P. Swiecicki, MD (*Abstract Co-Author*) Nothing to Disclose
Karina Pesce, PhD (*Abstract Co-Author*) Nothing to Disclose
Agustina Graziani, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To analyze the 8th edition of the breast cancer staging system.To discuss the modifications in the 8th edition.Describe findings that cannot be missing from the report.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction: Breast cancer is an heterogeneous tumor, very frequent among women and, if not diagnosed and treated in timely manner, leads to significant morbidity and mortality 2. 8th TNM edition: Anatomic staging: considering tumor extension (according to size), affects lymph nodes (classified according to their level) and the presence or absence of metastases.Prognostic staging part: based on the expression of hormone receptors and oncogenes (estrogen, progesterone and HER2 receptors) and tumor grade (low, intermediate and high) and the results of the multigentics panel (evaluates genes in order to predict the probability of recurrence). Genomic analysis helps to understand the biological behavior of breast cancer that causes changes in the management and treatment of the patients.3. Modifications in the 8th edition of the TNM.4. Clinical Cases:Several clinical cases will be presented to illustrate the findings that should be taken into account for anatomic staging and tips for remembering them.5. Conclusion: Although the role of the radiologist is crucial in the anatomical stage, as the 8th edition of the TNM also takes into account prognostic staging, it is necessary to have knowledge about tumor genes and hormone receptors in order to provide patients with the optimal treatment.

## BREE-8 PRIMARY AND SECONDARY BREAST ANGIOSARCOMA: MULTIMODALITY IMAGING APPROACH WITH PATHOLOGIC CORRELATION

**Awards**
**Certificate of Merit**

Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*) Royalties, Wolters Kluwer nv
Jordana Phillips, MD (*Abstract Co-Author*) Research Grant, General Electric Company;Consultant, General Electric Company;Consultant, Hologic, Inc
Jenna Pellegrino, MD (*Abstract Co-Author*) Nothing to Disclose
Dunya M. Imad, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Breast angiosarcoma, an infrequent yet highly aggressive cancer, originates from spindle cells and is more prevalent in the breast compared to any other organ. It manifests in two primary forms: sporadic angiosarcoma and post-radiation angiosarcoma. A causative factor remains unidentified in primary breast angiosarcomas. Conversely, secondary breast sarcomas are associated to previous radiation therapy (RT) and conditions leading to chronic lymphedema. Despite its rarity, this disease necessitates specialized diagnostic and therapeutic approaches, necessitating collaboration among radiologists, oncologists, surgeons, and pathologists.

**TABLE OF CONTENTS/OUTLINE**

In this exhibit, we will discuss the various presentations of primary and secondary angiosarcoma, conduct a systematic review of clinical findings, and examine multimodality radiological findings through case studies, including PET-CT. Additionally, we will explore treatment modalities and discuss prognosis to provide a comprehensive understanding of this challenging condition.

## BREE-80 CONTRAST ENCHANCED MAMMOGRAPHY APPLICATIONS: A CASE BASED REVIEW

Kictzia Y. Larios Cruz, MD, MD (*Abstract Co-Author*) Nothing to Disclose
Luz E. Bastidas Caicedo, MD (*Abstract Co-Author*) Nothing to Disclose
Raquel Balbas Lara, MD (*Abstract Co-Author*) Nothing to Disclose

Daniel Sandoval Guerra, MD (*Abstract Co-Author*) Nothing to Disclose
Sara S. Herrera Lemus, MD (*Abstract Co-Author*) Nothing to Disclose
Angela J. Urbina Ibarra SR, MD,BSC (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Contrast mastography uses intravenous contrast agents, being an effective technique to improve the early detection of breast cancer and reduce the false positive rate, as well as to evaluate the extension and occult cancers among other indications, due to the accurate characterization of lesions.Contrast mastography stands out for its ability to improve the detection of breast lesions, especially in cases of dense breast tissue or inconclusive findings on conventional mammography. Its role in preoperative evaluation is illustrated, allowing a more accurate characterization of the extent of disease and optimal surgical planning. Indications, contraindications and practical considerations for performing the study are also reviewed. This review highlights the

value of contrast-enhanced mastography as an important diagnostic tool in the comprehensive management of breast pathologies, with important implications for early detection and personalized treatment of patients.*Review contrast enchanced mammography basics (acquisition protocol, diagnostic performance, and current indications).*Ilustrate the applications and added value of contrast enchanced mammography through the review of everyday clinical scenarios.

**TABLE OF CONTENTS/OUTLINE**

1.Contrast enchanced mammography lexicón overview (categories, terms, features and definitions)2.Ilustrated case based review2a. Staging2b. Microcalcifications2c. Occult breast cancer2d.Residual and recurrent disease2e.Paget disease2f.Telorrhage2g.High risk screening2h.Focal asymmetry. 3. Conclusions

## BREE-81 LOOK WHAT YOU MADE ME DO...A CORRELATION BETWEEN MRI FINDINGS AND TUMORAL INMUNOPHENOTYPE OF BREAST CANCER

Elena M. Sanchez Siller, MD (*Abstract Co-Author*) Nothing to Disclose
Karla I. Soto, MD (*Abstract Co-Author*) Nothing to Disclose
Yesika Davila Zablah, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica A. Perdomo SR, MD (*Abstract Co-Author*) Nothing to Disclose
Margarita L. Garza, MD (*Abstract Co-Author*) Nothing to Disclose
Ilany L. Valdivia I, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Guerra, MD (*Abstract Co-Author*) Nothing to Disclose
Ia M. Sanchez Carenzo, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The main objective of this work is to communicate if there is a relationship between breast cancer findings by MRI and immunohistochemistry, and how we get to that information. The secondary objective is to make a practical and concise description of the findings that we can identify in breast cancer lesions on MRI, as well as the appropriate vocabulary to use about these characteristics. Present more relevant information about the usefulness of the BI-RADS and the Kaiser Score for the proper classification of breast cancer lesions. Review the basic acquisition protocol recommended for the evaluation of suspected or proven breast cancer lesions by MRI, as well as the key points to have an appropriately structured report that contains all the required information about the findings.

**TABLE OF CONTENTS/OUTLINE**

The usefulness of performing immunohistochemistry in patients diagnosed with breast cancer for the management of the disease. The importance of correct and complete evaluation of lesions by MRI, following a protocol in both the acquisition and interpretation of the images, in order to be a guide for those residents in training who are starting out on the subject. Concise descriptions are included with illustrations and real examples representative of our institution that include mass and non-mass lesions with all those characteristics that must be identified and characterized in the interpretation. The information included is how the statistical analysis was performed, selection and exclusion of patients, and results on the prevalence of the reviewed characteristics as well as their correlation with the types of immunophenotype in our study population.

## BREE-82 PET/MRI IN BREAST CANCER: WHAT RADIOLOGY RESIDENTS NEED TO KNOW

**Awards**
**Certificate of Merit**

Itzell Reyes Garcia, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• To review: Breast Anatomy in MRI• To understand the basics of PET-MRI• To recognize the opportunities for synergistic use of multimodal information• To present protocols and procedures for Breast PET-MRI• To discuss the advantages and disadvantages of PET-MRI in breast cancer

**TABLE OF CONTENTS/OUTLINE**

• Introduction• Breast Anatomy in MRI• Principles of PET/MRI and Clinical Applications• Most Common Radiotracers Used in Breast PET-MRI• Representative Cases on Breast Cancera. Stagingb. Prognosisd. Treatment Response Assessment• Take home points• Discussion• Conclusion

## BREE-83 DEEP LEARNING FOR BREAST CANCER RISK PREDICTION: LEARNING FROM THE PAST TO ENSURE AN EQUITABLE FUTURE

Laura Heacock, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Alana A. Lewin, MD (*Abstract Co-Author*) Nothing to Disclose
Beatriu Reig, MD, MPH (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Including imaging information such as breast density improves the accuracy of clinical models of breast cancer risk. 2. Accurate risk assessment identifies women who would benefit from supplemental screening and/or chemoprevention. 3. Training and validating models on a multi-racial and multi-ethnic dataset is essential to ensure accurate risk assessment across groups.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction a. Risk prediction using clinical models b. Imaging data incorporated into Tyrer-Cuzick and other models c. Time-frame of risk prediction: near-term versus long-term risk 2. Summary of risk prediction research a. FFDM i. Radiomics evaluation of parenchymal complexity ii. Deep learning models including Mirai b. DBT - challenge of generalizing FFDM models to DBT c. US - parenchymal echogenicity reflects glandular composition d. MRI - BPE as a marker of risk 3. Future directions a. Multimodality b. Incorporating prior studies c. Including polygenic risk scores d. Modeling the impact of different screening intervals 4. Improving generalizability and equity a. Deep learning models show similar performance across racial and ethnic groups, compared to clinical models that have poor performance in non-white groups b. Importance of multi-racial and multi-ethnic datasets, validation

## BREE-84 GRANULOMATOUS MASTITIS. A RARE BENIGN ENTITY THAT CAN SIMULATE BREAST CANCER. WHAT THE RADIOLOGIST SHOULD KNOW!

Maria C. Ona Hurtado SR, MMed,BA (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1 Analyze the imaging characteristics of the (IMG) 2 Discuss the management of the heterogeneous group of IGM •Introduction and review of the literature •Review of the imaging characteristics •Description of the results of the IGM images in mammograms, ultrasounds and MRI •Clinical cases •Diagnostic algorithm

**TABLE OF CONTENTS/OUTLINE**

Granulomatous mastitis(GM) is a benign inflammatory breast disease that its becoming more commonly seen during our daily practice of unknown etiology, has a persistent and recurrent clinical course and occurs most commonly in parous women; it typically manifests as a tender palpable mass and inflammatory breast changes characterized by granulomatous inflammation at histopathologic analysis.The most common clinical sign is a painful palpable mass associated with erythema, and purulent discharge. However, the nonspecific manifestations and varied demographic features of this condition, as well as the other similar-appearing and superimposed breast entities, pose substantial diagnostic challenges, like inflammatory breast cancer(IBC), infective mastitis, foreign body injection granulomas, mammary duct ectasia, diabetic fibrous mastopathy, and systemic granulomatous processes and tuberculosis. Targeted ultrasonography, mammography, and less commonly, magnetic resonance imaging have proven to be useful for imaging evaluation. Core-needle biopsy, with or without fine-needle aspiration for cytopathologic examination, and culture analysis are usually required to exclude IBC and other benign inflammatory processes.

## BREE-85 EXTRAMAMMARY FINDINGS ON BREAST MRI FOR THE BREAST RADIOLOGIST

Sujata V. Ghate, MD (*Abstract Co-Author*) Research Grant, Bracco Group;Reader, QT Ultrasound, LLC;Travel support, QT Ultrasound, LLC
Victoria A. Wells, MD (*Abstract Co-Author*) Nothing to Disclose
Jay A. Baker, MD (*Abstract Co-Author*) Research Consultant, Siemens AG
Karen S. Johnson, MD (*Abstract Co-Author*) Nothing to Disclose
Derek L. Nguyen, MD (*Abstract Co-Author*) Nothing to Disclose
Theresa X. Pham, MD, BS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Breast Magnetic Resonance Imaging (MRI) is frequently utilized in breast imaging for high-risk screening, evaluation of implant integrity, evaluation of disease extent in the preoperative setting, and evaluation of tumor response to neoadjuvant chemotherapy. Given the varying field of view of breast MRI examinations, incidental extramammary findings may be visible in the lower cervical neck, thorax, upper abdomen, and even thoracic spine. Therefore, it is important for breast radiologists to include these areas in their search pattern and to have a comprehensive understanding of the distinctive imaging findings and pathology—both benign and malignant—observed in these anatomical areas. The purpose of this educational exhibit is to review cases with incidental extramammary findings on breast MRI and to highlight the importance of looking at all of the imaging sequences, including localizers, and areas beyond the breasts.

**TABLE OF CONTENTS/OUTLINE**

1. Highlight and discuss the importance of looking at all the available MRI sequences for incidental extramammary findings on breast MRI.2. Review common extramammary benign and malignant imaging findings that can be incidentally detected on breast MRI.3. Present image-rich multimodality case examples of incidental extramammary findings detected on breast MRI.

## BREE-86 BEYOND CANCER: REVEALING BI-RADS 5 MIMICS

Natalia T. Lima (*Abstract Co-Author*) Nothing to Disclose
Carlos Shimizu, MD (*Abstract Co-Author*) Nothing to Disclose
Elisa M. Carvalho, MD (*Abstract Co-Author*) Nothing to Disclose
Leticia Cardoso Ern, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Identify the BI-RADS 5 imaging standards for ultrasound, mammography, and MRI;- Outline and illustrate the main benign differential diagnoses for BI-RADS 5;- Propose a diagnostic flowchart to determine biopsy concordance;

**TABLE OF CONTENTS/OUTLINE**

The system currently used to report and classify mammography, ultrasound, and breast MRI findings is the BI-RADS system. It ensures uniformity in the lexicon and a degree of homogeneity in the interpretation of exams. The ACR BI-RADS 5 classification is used when the probability of malignancy is greater than or equal to 95%.However, not all lesions classified as BI-RADS 5 are malignant. Some pathologies have imaging features that mimic findings characteristic of highly malignant lesions and are ultimately classified with them, such as atypical infections, radiated scar, fat necrosis, desmoid tumor, granulosa cell tumor, mastitis (inflammatory, lymphocytic/diabetic, and infectious) and myofibroblastoma.his is a retrospective study using images from the database of a quaternary hospital that is a national reference for highly complex cases. Ultrasound, mammography, and MRI scans between 2015 and 2023 were used, all with anatomical-radiological matching.The breast radiologist must be aware of this group of agents and determine whether a new biopsy is necessary in the case of a discordant result, or whether the result is benign and concordant according to well-established criteria.

## BREE-87 CONTRAST-ENHANCED MAMMOGRAPHY FINDINGS. A PICTORIAL REVIEW OF BENIGN AND MALIGNANT LESIONS WITH RADIOLOGIC-PATHOLOGIC CORRELATION

**Awards**
**Certificate of Merit**

Elena Romero (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia Arman, MD (*Abstract Co-Author*) Nothing to Disclose
Soledad Alonso Garcia (*Abstract Co-Author*) Nothing to Disclose
Ana Ines Rubio Aguilera, MD (*Abstract Co-Author*) Nothing to Disclose
Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-To describe contrast-enhanced mammography (CEM) technique.-To review the appearances of benign and malignant lesions in CEM, including different patterns of enhancement and correlation with low-energy images. - To illustrate imaging findings of CEM with correlation with imaging (US, MRI) and pathology. - To emphasize pitfalls, diagnostic difficulties and differential diagnosis and discussion of management.

**TABLE OF CONTENTS/OUTLINE**

Contrast-enhanced mammography (CEM) is currently used in diagnostic work-up of breast lesions. Advantages include well-tolerated studies, short duration, lower cost than MRI, and immediate review of results after the study. Radiologists should be familiar with normal findings and commonly encountered benign and malignant entities on CEM.
- Basics and technique of CEM.
- Study evaluation: low-energy findings (mass, calcifications, architectural distortion, asymmetries), patterns of enhancement (background parenchymal enhancement, mass, non-mass enhancement, and enhancing asymmetry).
- Images in different pathologic entities. Through sample cases, a variety of imaging and pathology findings from lesions detected in CEM studies with correlation with US, MRI and pathology, illustrating benign lesions (cyst, fibroadenoma, phyllodes tumor, papilloma, fat necrosis, pseudoangiomatous stromal hyperplasia (PASH), skin-related lesions, lymph nodes, granulomatous and lymphocytic mastitis, abscess), malignant entities (DCIS, ductal and lobular invasive cancer, colloid and papillary cancer, lymphoma) and high risk lesions (atypical ductal hyperplasia (ADH), radial scar, flat epithelial atypia).
- Clues for differential diagnosis and pitfalls.

## BREE-88 THE CHALLENGE OF DEPICTING BREAST MICROCALCIFICATIONS ON PHOTON-COUNTING DETECTOR CT

Misugi Urano, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Photon-counting detector computed tomography (PCD-CT) has several advantages over conventional energy-integrating computed tomography (EID-CT). The higher spatial resolution of PCD-CT may provide a precise visualization of microcalcifications related to breast cancer. This can contribute to preoperative planning by identifying the distribution of microcalcifications.This presentation will focus on depicting breast microcalcifications in breast cancer patients on PCD-CT, comparing it to EID-CT and other imaging modalities, including mammography, tomosynthesis, ultrasound, and magnetic resonance imaging, with pathological results. We will also discuss the reconstruction settings of kernel sharpness, iterative reconstruction, or slice thickness to depict and identify breast microcalcifications on PCD-CT.

**TABLE OF CONTENTS/OUTLINE**

1. The types of breast calcifications 2. The reconstruction settings, including kernel sharpness, iterative reconstruction, or slice thickness of PCD-CT to depict and identify breast microcalcifications 3. Case-based review of breast calcifications on PCD-CT compared to EID-CT, other imaging modalities, and pathological results 4. Discussion of the advantages and pitfalls of breast microcalcifications on PCD-CT compared to other modalities

## BREE-89 LATERAL ARM APPROACH FOR STEREOTACTIC BREAST GUIDED BIOPSIES: PEARLS AND PITFALLS

Alejandra Varela, MD (*Abstract Co-Author*) Nothing to Disclose
Agostina B. Peralta (*Abstract Co-Author*) Nothing to Disclose

Claudia A. Fernandez, MD (*Abstract Co-Author*) Nothing to Disclose
Leidy Imitola Romo (*Abstract Co-Author*) Nothing to Disclose
Maria C. Freire, DMD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-Discuss the basic principles for performing a lateral arm approach stereotactic breast guided biopsy.-Describe the patient’s indications for carrying out this approach.-Recognize potential challenging cases and complications when performing a lateral arm approach stereotactic breast guided biopsy.-Illustrate techniques to overcome problems and successfully resolve challenging cases.

**TABLE OF CONTENTS/OUTLINE**

Stereotactic breast biopsies have proven to be a feasible alternative to surgical breast biopsies. Nowadays, this method is the standard of care in patients with suspicious findings on mammography or tomosynthesis. Performing a successful stereotactic breast guided biopsy requires planning and a correct evaluation of the lesion location and of the patient’s breast anatomy. When this procedure can not be safely performed a surgical approach should be considered. The lateral arm approach for stereotactic breast biopsies permits procedures to be done using a needle insertion parallel to the compression plate allowing to successfully sample lesions that would have been excluded with a conventional approach, therefore avoiding surgical biopsy as well as improving patients care and comfort. -Illustrate the basic principles of this technique.-Discuss how to plan, patient select and perform a lateral arm stereotactic breast biopsy.-Examine advantages and limitations of this approach. -Identificate and illustrate with case examples potentially challenging cases as well as provide tips and tricks to troubleshoot and successfully perform this procedure.

## BREE-9 RADIAL SCLEROSING LESIONS - IMAGING FINDINGS AND MANAGEMENT

Patricia A. De Camargo Teixeira, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela G. Giannotti, MD (*Abstract Co-Author*) Nothing to Disclose
Thais Mayor Simonatto, MD (*Abstract Co-Author*) Nothing to Disclose
Ulisses Ferreira (*Abstract Co-Author*) Nothing to Disclose
Ligia A. Yamashita, MD (*Abstract Co-Author*) Nothing to Disclose
Larissa Moyses, MD (*Abstract Co-Author*) Nothing to Disclose
Vivian N. Omura, MD (*Abstract Co-Author*) Nothing to Disclose
Vera Christina C. Ferreira, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela F. Vieira Vendramini (*Abstract Co-Author*) Nothing to Disclose
Carolina R. Saccarelli, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-Describe the histological pattern of radial sclerosing lesions (RSL).-Describe and define the possible imaging presentations of radial sclerosing lesions, according to different imaging methods, such as mammogram (MG), ultrasound (US) and magnetic resonance (MRI).-Discuss the malignancy upgrade rates of radial scars according to it's histological associations and the possibility of follow-up of these lesions.

**TABLE OF CONTENTS/OUTLINE**

-Review the histological findings defining RSL, in addition to its possible histological patterns and associations to malignant lesions or atypia.-Enlist the possible differential diagnosis of RSL.-Illustrate RSL characteristics on various imaging methods, which can or cannot occur simultaneously.-Correlate simultaneous findings in each method. Discuss the possibility of malignancy upgrade of the RSL lesions, and correlate these rates with imaging and histological findings.-Discuss the different managing propositions of these lesions, according to its imaging and histological patterns. -Summary and take home messages.

## BREE-90 UNRAVELING THE UNCOMMON: RARE BREAST CANCER VARIANTS AND COMMON IMAGING FINDINGS

Erica Endo, MD (*Abstract Co-Author*) Nothing to Disclose
Marco A. Costenaro, MD (*Abstract Co-Author*) Nothing to Disclose
Vera Christina C. Ferreira, MD (*Abstract Co-Author*) Nothing to Disclose
Fernanda de Oliveira Cirino, MD (*Abstract Co-Author*) Nothing to Disclose
Lidia B. Rodrigues, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia Orthmann, MD (*Abstract Co-Author*) Nothing to Disclose
Juliana H. Catani, MD (*Abstract Co-Author*) Nothing to Disclose
Carlos Shimizu, MD (*Abstract Co-Author*) Nothing to Disclose
Alessandra d. Borges, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Recognition of the radiological peculiarities of rare types of breast cancer in mammography, ultrasonography, and magnetic resonance imaging. Special histological subtypes are rare in breast cancer and knowing some of their peculiarities helps us recognize atypical imaging patterns and make appropriate anatomopathological correlations.

**TABLE OF CONTENTS/OUTLINE**

Malignant Phyllodes Tumor: Large solid or complex solid-cystic mass; differential diagnosis with rapidly growing fibroadenoma. Mucinous Carcinoma: High signal intensity in T2. Medullary Carcinoma: Mass with circumscribed or microlobulated margins with posterior enhancement.Ring enhancement with internal septations. Tubular Carcinoma Slow growth small spiculated mass associated with architectural distortion and calcifications. Heterogeneous enhancement with washout curve. High association with DCIS. Invasive Papillary Carcinoma: solid or complex solid-cystic mass; calcifications are common. May present with ductal dilatation. Hemorrhage with high signal in T1WI. Pleomorphic Lobular Carcinoma: Larger spiculated masses with calcifications, architectural distortion and local invasiveness. May present as focal asymmetry. Non-mass enhancement and necrosis. Metaplastic Carcinoma Large, rapidly growing, round and circumscribed mass. Heterogeneous and ring enhancement with necrosis or intratumoral hemorrhage. Neuroendocrine Carcinoma Spiculated mass or asymmetry with calcifications, architectural distortion. Diffusion restriction and washout curve. Micropapillary Carcinoma: Spiculated mass with calcifications, architectural distortion. Lymph node metastasis are common even in small lesions.

## BREE-91 TRIANGULATION AND ADDITIONAL VIEWS IN MAMMOGRAPHY. BACK TO BASICS OF PROBLEM- SOLVING TECHNIQUES STILL ALIVE

**Awards**
**Magna Cum Laude**

Rodrigo Pastorin (*Abstract Co-Author*) Nothing to Disclose
Rosa M. Lorente-Ramos, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Candela Munoz Roldan (*Abstract Co-Author*) Nothing to Disclose
Maria Teresa Montero Alameda (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia Arman, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- To review the basics of breast triangulation in mammography.
- To illustrate the correlation of lesion position on mammograms through diagrams and illustrative cases of US and MRI.
- To describe additional views employed in work-up of mammographic findings.
- To emphasize pitfalls, diagnostic difficulties and provide clue points.

**TABLE OF CONTENTS/OUTLINE**

- Introduction. Despite the use of new technologies in mammography, different problems may still occur in standard two view mammograms. We review the classic and basic problem-solving approach.
- Breast triangulation. Mammograms are essential to detect non-palpable breast lesions. The relative lack of anatomical landmarks in the breast, makes sometimes correlation of the location of the lesions a problem even more important with the frequent detection of multiple lesions with new technologies such as contrast-enhanced mammography. We review the basic geometric concept of triangulation, discuss common mistakes in lesion location estimates and their causes.
- Additional views. Magnification and spot-compression views. Tangential views for dermal calcifications (rarely employed with the use of tomosynthesis). 'Exaggerated' views for lesions included in the oblique but not in craniocaudal views ('Cleopatra' view).
- Quiz with difficult cases from our series of mammograms with correlation with US and MRI.

## BREE-92 WHEN THE UGLY IS NOT SO BAD: COMMON AND RARE BENIGN BREAST LESIONS THAT CAN MIMIC MALIGNANCY

Nilton Onari (*Abstract Co-Author*) Nothing to Disclose
Erika M. Negrao (*Abstract Co-Author*) Nothing to Disclose
Silvia M. Sabino, MD (*Abstract Co-Author*) Nothing to Disclose
Edmundo C. Mauad, MD,PhD (*Abstract Co-Author*) Nothing to Disclose

Anapaula H. Watanabe, MD (*Abstract Co-Author*) Nothing to Disclose

Chrissie Amirati (*Abstract Co-Author*) Nothing to Disclose
Ruth H. Bonini, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The BI-RADS categories 4C and 5 are used when the suspicion of malignancy ranges between 50-95% and is >95%, respectively and histopathological investigation is mandatory, typically through percutaneous biopsy. Following a biopsy, encountering a benign result in a lesion classified in these categories can be challenging for the radiologist, particularly in category 5. According to BI-RADS, any non-malignant diagnosis from a needle biopsy in category 5 should be considered discordant, necessitating a recommendation for repeat biopsy, often surgical. Some breast conditions can mimic malignancy, and in these scenarios, it is crucial to be familiar with these benign entities, some of which may be unfamiliar even to breast imaging specialists. After a thorough radiological-pathological correlation, taking into account biopsy technical aspects, lesion characteristics across different imaging modalities, and the patient's clinical history, some results may be accepted, potentially averting the need for additional biopsies or surgeries. The objective of this presentation is to acquaint the radiologist with both common and rare benign lesions that can mimic malignancy through cases encountered in daily practice.

**TABLE OF CONTENTS/OUTLINE**

In a didactic manner, several cases selected from our institution's archive of benign lesions, histological proven, with mammographic and ultrasonographic correlations will be presented. These cases encompass lesions of infectious/inflammatory origin, autoimmune diseases, benign proliferative conditions, and benign tumors.The common clinical and imaging manifestations of these entities will be discussed, along with a review of the pathological aspects.

## BREE-93 ULTRAFAST DYNAMIC CONTRAST ENHANCED BREAST MRI WITH A MODIFIED SENSE ACCELERATED 3DTFE SEQUENCE: CASE BASED REVIEW

Shreya Poddar, MBBS (*Abstract Co-Author*) Nothing to Disclose
Nirali S. Mehta, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Smruti Mulani, MD, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Ultrafast Breast MRI [UFBMRI] can be performed using conventional parallel imaging with accelerated 3DTFE sequence on conventional scanners.2. Qualitative assessment of UFBMRI adds to the diagnostic specificity and guides patient management by indicating the possible extent of vascularity and hence aggressiveness of the lesion. Hence, optimal site for tissue sampling can be determined. 3.UFBMRI can be incorporated in routine practice on most scanner platforms without additional postprocessing, ensuring accessibility to a larger patient population.

**TABLE OF CONTENTS/OUTLINE**

Introduction: UFBMRI requires acceleration techniques like k-space sharing, compressed sensing and/or AI based reconstruction. These techniques are available only on newer scanners and not all centers performing breast MR have access to them. Furthermore, UFBMRI data has been analyzed quantitatively using Max Slope of Increase and TTE [Time to enhance] as compared to Aorta which involve additional calculations. Methods: We set up a Ultrafast Dynamic Contrast Enhanced [UFDCE] protocol using a 3DTFE sequence with parallel imaging, to achieve a temporal resolution of 6secs. We analyzed the images qualitatively, with reference to the presence, synchronicity and rapidity of enhancement. Principle of UFDCE, Sequence parameters and Breast MRI protocol will be discussed. Representative cases will be presented where qualitative analysis of UFBMRI contributed to the histopathologic diagnosis and patient management. Conclusion: Qualitative assessment of SENSE accelerated UFDCE sequence using 3D Fast Gradient Echo sequence [temporal resolution ~ 6secs] can also improve the diagnostic specificity and guide patient management.

## BREE-94 CAN FAST MRI AND NON-CONTRAST MRI REPLACE CONVENTIONAL DYNAMIC CONTRAST MRI? - FOCUS ON MORPHOLOGICAL EVALUATION AND IMAGE QUALITY IN BREAST MRI

Yoshito Ichiba, RT (*Abstract Co-Author*) Employee, Siemens AG
Masako Y. Kataoka, MD, PhD (*Abstract Co-Author*) Speaker, Siemens AG Speaker, Bayer AG Speaker, Devicor Medical Products, Inc Speaker, Guerbet SA
Rie Ota, MD (*Abstract Co-Author*) Nothing to Disclose

Tsutomu Okada, MD (*Abstract Co-Author*) Nothing to Disclose
Yuji Nakamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Maya Honda, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Ultrafast dynamic contrast-enhanced (UF-DCE) MRI and DWI are novel sequences in the breast that have accumulated evidence for diagnosing and characterization of breast cancer, though are not used as stand-alone sequences. One of the strengths of these sequences is that they can be evaluated quantitatively (time-intensity curves (TIC) and apparent diffusion coefficient (ADC). On the other hand, various methods have been devised to reduce artifacts or increase the spatial resolution of these sequences to improve qualitative assessment. Some DWI sequences like readout segmentation of long variable echo-trains (RESOLVE) and diffusion-weighted spatiotemporal encoding (SPEN), can achieve higher in-plane resolution than conventional single-shot echo-planar DWI, and tumor morphology assessment using them is being investigated. Currently, Breast Imaging and Data System (BI-RADS) prioritizes morphological evaluation to estimate the malignant potential of breast lesions. Therefore, morphological evaluation may be the key for these sequences to be used as alternatives to conventional DCE MRI. This exhibit will focus on the morphological evaluation and image quality of UF-DCE MRI and DWI in the breast.

**TABLE OF CONTENTS/OUTLINE**

1: Image quality and morphological evaluation using UF-DCE MRI: A) view sharing technique B) compressed sensing C) pitfalls in TIC evaluation2: Image quality and morphological evaluation using DWI: A) RESOLVE B) SPEN C) other sequences

## BREE-95 AN OUNCE OF PREVENTION IS WORTH A POUND OF CURE: SCREENING GUIDELINES AND IMAGING OF BREAST CANCER IN BRCA MUTATION CARRIERS

Katerina Dodelzon, MD (*Abstract Co-Author*) Nothing to Disclose
Alexia R. Tatem, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Tatiana Kelil, MD (*Abstract Co-Author*) Nothing to Disclose

Heather I. Greenwood, MD (*Presenter*) Support, Endomagnetics Ltd;Support, Devicor Medical Products, Inc

**TEACHING POINTS**

1. To review the recently updated American College of Radiology (ACR) high-risk screening guidelines for BRCA1 and BRCA2 mutation carriers including transgender patients 2.To review the different imaging features of BRCA1 and BRCA2 specific tumors and correlate the imaging features with histopathology 3. To review the evidence behind various imaging modalities for screening patients with BRCA1 and BRCA2 mutations

**TABLE OF CONTENTS/OUTLINE**

1. Background information reviewing BRCA1 and BRCA2 genes: transmission, lifetime risk of cancers, prevalence in overall population and specific higher risk populations, risk assessment 2. Review of the 2023 updated ACR high-risk screening breast cancer guidelines, with emphasis on updates for BRCA1 and BRCA2 mutation carriers 3. Review the current state of available data and guidelines for high-risk screening in transgender BRCA mutation carrier patients 4. Multi-modality case examples of BRCA1 vs BRCA2 associated tumors: imaging features with histopathologic correlation 5. Review of the evidence behind various imaging modalities in screening BRCA1 and BRCA2 mutation carriers with imaging examples: Digital Mammography/Digital Breast Tomosynthesis, Ultrasound, Dynamic Contrast Enhanced Breast MRI (DCE-MRI), Abbreviated Breast MRI (AB-MRI), Contrast Enhanced Mammography (CEM)

## BREE-96 UNLOCKING THE SECRETS OF BREAST FIBROEPITHELIAL LESIONS: A COMPREHENSIVE GUIDE FOR RADIOLOGISTS

**TEACHING POINTS**

Embark on an exciting journey through the complex world of breast fibroepithelial lesions (FELs) with our interactive learning center exhibit. FELs are a diverse group of tumors that originate from the stromal and epithelial tissues of the breast, and can range from benign to malignant. This exhibit focuses on three main types of FELs: fibroadenomas, phyllodes tumors, and benign fibroepithelial tumors.By exploring this exhibit, radiologists will:Gain a deep understanding of the diverse spectrum of breast fibroepithelial lesions.Master the latest diagnostic imaging techniques for detecting and characterizing FELs.Appreciate the crucial role of imaging in differential diagnosis and management of FELs.Stay up-to-date with the latest emerging imaging modalities and guidelines for FELs.Enhance multidisciplinary collaboration and communication for optimal patient care.Join us in this exciting learning journey and unlock the secrets of breast fibroepithelial lesions.

**TABLE OF CONTENTS/OUTLINE**

Introduction to breast fibroepithelial lesions.Pathophysiology and histopathological features.Clinical presentation and diagnostic workup: Learn how to recognize and diagnose FELs through our daily practice case studies and clinical pearls.Multidisciplinary approach to management.Future directions.Conclusion and summary

## BREE-97 UNRAVELING THE COMPLEXITY OF BREAST MASSES WITH ASSOCIATED NECROSIS: SIGNIFICANCE AND MANAGEMENT

**TEACHING POINTS**

Breast masses with associated necrotic changes pose a diagnostic and management challenge for radiologists. Both benign and malignant etiologies can lead to a mass presenting with central necrosis. Triple-negative breast cancer is notorious for presenting with necrosis. However, tumor necrosis has not been associated as an imaging characteristic to predict response to systemic therapy. Benign masses that grow rapidly can demonstrate necrosis or infarction and can, in rare instances, become infected. Multimodality imaging is critical for formulating a differential and guiding biopsy into a non-necrotic region to obtain an accurate histopathologic diagnosis. By the end of this educational exhibit, learners will: 1. Define tumor necrosis 2. Explain the mechanisms that lead to necrosis 3. List benign and malignant etiologies associated with central necrosis 4. Choose the appropriate location to biopsy the lesion with necrosis

**TABLE OF CONTENTS/OUTLINE**

Introduction; Definition of tumor necrosis; Incidence of, and risk factors that lead to, necrotic masses; Mechanisms of tumor necrosis; Clinical presentation of necrotic masses; Differential considerations including benign and malignant etiologies; Distinguishing necrotic tumors from abscess and fluid collections. Multimodality imaging examples of necrotic masses including necrotic lymph nodes; Systematic approach for characterization of masses associated with necrosis; Pitfalls in the sonographic assessment of necrotic masses; Strategies for successful core biopsy and radiology-pathology correlation. Algorithm for management of benign and malignant necrotic masses; Conclusion.

## BREE-98 MULTIMODALITY EVALUATION OF REGIONAL BREAST LYMPH NODES: IMPACT OF BI-RADS 6$^{TH}$EDITION

James Stepenosky, MD (*Abstract Co-Author*) Nothing to Disclose
Soudabeh Fazeli, MD,MPH (*Abstract Co-Author*) Nothing to Disclose
Tara A. Retson, MD, PhD (*Abstract Co-Author*) Research Consultant, CureMetrix, IncStock options, CureMetrix, Inc
Haydee Ojeda-Fournier, MD (*Presenter*) Research Consultant, View Point Medical, Inc;Stock options, CureMetrix, Inc

**TEACHING POINTS**

Evaluation of regional breast lymph nodes is an integral part of breast cancer imaging, it will affect clinical management. The radiologist must understand how to evaluate lymph nodes, stage the axilla, be proficient in image-guided interventions involving lymph nodes, and select the most appropriate

imaging modalities to evaluate breast regional lymph nodes. Ultrasound-guided core biopsy or fine needle aspiration can be performed for histologic confirmation of nodal metastasis. In the expected 6th edition of BI-RDS, lymph nodes will be their own category across modalities with expanded discussion regarding location and morphology. The purpose of this educational exhibit is to preview expected BI-RADS 6th edition changes that will impact the evaluation of regional lymph nodes. By the end of this educational exhibit, learners will: 1. List morphologic criteria for lymph node assessment; 2. Identify the location of lymph nodes; 3. Recognize the relationship of the pectoralis minor to axillary lymph node levels; 4. Summarize expected lymph node updates in BI-RADS 6th edition.

**TABLE OF CONTENTS/OUTLINE**

Introduction; Morphology of lymph nodes; lymph node locations: intramammary, axillary, internal mammary, supra-clavicular; Clinical presentation of adenopathy; Differential considerations of abnormal lymph nodes; Multimodality imaging regional lymph nodes: Mammogram, US, MRI; Learn a systematic approach to the characterization of abnormal lymph nodes; How to apply BI-RADS 6th edition lexicon for regional lymph nodes appropriately; Pitfalls in providing nodes BI-RADS categories; Image-guided interventions to assess nodes; Algorithm for management of regional lymph node findings; Conclusion.

## BREE-99 DON'T BE RASH, IT'S JUST PASH !

Bruna M. Thompson, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Fabiana C. Policeni, MD (*Abstract Co-Author*) Nothing to Disclose
Danielli Matsuura (*Abstract Co-Author*) Nothing to Disclose
Fabiola P. Kestelman, MD (*Abstract Co-Author*) Nothing to Disclose
Su Kim Hsieh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Japnit Singh, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Breast pseudoangiomatous breast hyperplasia (PASH) can have a variety of different presentations. It can be asymptomatic, found incidentally on a breast biopsy or present itself as a mass, asymmetry or gigantomastia. PASH can be found in a wide age range but is more common in pre-menopausal and post-menopausal women on hormone replacement therapy. It has been commonly seen associated with gynecomastia. Even though benign, PASH can be admixed with malignancies, hence warrants a careful imaging-pathology correlation to establish concordance with biopsy. In some patients, PASH can have an uncommon presentation and outcome, such as a large and fast-growing mass leading to gigantomastia. In such cases, extreme treatments, like mastectomy may be required for local control. In order to help clinicians make the right treatment decision, an effective diagnosis can be made by correlating imaging findings with pathological features.

**TABLE OF CONTENTS/OUTLINE**

To illustrate the various imaging aspects of breast pseudoangiomatous stromal hyperplasia (PASH) and its correlation with pathologic and clinical findings. To review the clinical presentations, key pathologic features along with current management of PASH. Lastly, to illustrate the imaging and pathological differential diagnosis of PASH.

RSNA 2024

BREE-1

## KEEPING UP WITH THE CUTTING EDGE: MULTIMODALITY REVIEW OF ONCOPLASTIC BREAST SURGERY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Alexander Kuehne, MD (*Abstract Co-Author*) Nothing to Disclose
William J. Hoover, MD (*Abstract Co-Author*) Nothing to Disclose
John M. Lewin, MD (*Abstract Co-Author*) Officer, Novian Health Inc
Caroline Merriam, DO (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Surgical management of breast cancer continues to evolve as oncoplastic surgery (OPS) grows in popularity.
- OPS allows for tumor resection with lumpectomy or mastectomy, followed by breast reconstruction.
- To improve cosmetic outcomes after breast reconstruction, several plastic surgery techniques are utilized including volume replacement, volume rearragement, and volume displacement.
- This educational exhibit will provide a description and illustration of several common oncoplastic breast surgeries.
- For each procedure, we will review expected post-operative imaging features on mammogram, ultrasound, and breast MRI.
- The exhibit will conclude with a discussion of acute and long-term complications of OPS including breast abscess, fat necrosis, hematoma, flap necrosis, and breast cancer recurrence.

### TABLE OF CONTENTS/OUTLINE

1. Brief history of oncoplastic breast surgery (OPS)2. Who is a candidate for OPS?3. Pictorial review of eight OPS techniques, including expected post-operative imaging findings for each technique:
- Reduction mammoplasty
- Nipple areolar complex centralization
- Latissimus dorsi flap
- Deep inferior epigastric perforator (DIEP) flap
- Transverse rectus abdominis myocutaneous (TRAM) flap
- Superior gluteal artery flap
- Autologous fat grafting
- Omental flap4. Case-based review of acute and long-term complications of OPS

BREE-10

## WHEN A MASS IS MELANOMA: VARIABLE IMAGING PRESENTATIONS OF A RARE BREAST DIAGNOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Molly Hill, MD (*Abstract Co-Author*) Nothing to Disclose
Allison Aripoli, MD (*Abstract Co-Author*) Nothing to Disclose
Ashley I. Huppe, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica K. Peterson, MD (*Abstract Co-Author*) Nothing to Disclose
Camron B. Smith, DO (*Abstract Co-Author*) Nothing to Disclose
Onalisa D. Winblad, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela E. Wermuth, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Extramammary metastases to the breast are rare, with melanoma being the most common.2. Metastatic melanoma to the breast may be identified in symptomatic or asymptomatic patients with or without a known history of melanoma.3. Imaging features of melanoma metastases to the breast overlap with findings of primary breast malignancy.4. A thorough understanding of common and unusual imaging presentations of metastatic melanoma is key to maintaining a high clinical suspicion, with biopsy ultimately necessary for diagnosis.

### TABLE OF CONTENTS/OUTLINE

1. Background: Review the prevalence of melanoma metastases (including those to the breast), mechanism of metastatic spread, timeline of presentation, and appropriate workup.2. Case-based imaging review: Multimodality examples of metastatic melanoma to the breast, emphasizing common and unique imaging presentations on:- Mammography- Ultrasound- MRI3. Clinical importance: Discuss the frequency of melanoma, importance of careful clinical history and accurate diagnosis, and general prognosis of melanoma metastases to the breast.

### TEACHING POINTS

- Understanding Implant Types and Anatomy - Imaging Techniques for Implant Assessment - MRI Protocols and Implant Evaluation - Managing Complications and Reviewing Cases

### TABLE OF CONTENTS/OUTLINE

Basic Principles of Breast Implant Evaluation: Understand implant types (saline vs. silicone, single vs. double lumen, expanders), relevant anatomy, and terminology. Imaging Methods for Implant Evaluation: Mammography: Use and limitations in implant evaluation; Ultrasound: Applicability in detecting ruptures and other changes; MRI Imaging: Exam protocols, essential sequences (T1, T2, STIR, fat-suppression sequences), and its importance in the comprehensive evaluation of implants and surrounding tissue. MRI Exam Protocols: Recommended sequences for a detailed evaluation; Location and positioning of the patient. Implant Evaluation: Identification and interpretation of normal findings (position, lumen integrity); Recognition of changes and complications: folds, axis rotation, ruptures (intracapsular and extracapsular), capsular contracture; Complications and Associated Pathologies: Granulomas: Identification and implications; Breast Implant-Associated Anaplastic Large Cell Lymphoma (BIA-ALCL): Signs, symptoms, and imaging diagnosis; Hemangioma: Imaging characteristics and relevance. Management of Complications: Strategies for early diagnosis of complications; Multidisciplinary approach in managing complications and pathologies associated with implants. Case Discussion and Literature Review: Analysis of case studies to illustrate the principles of evaluation and management; Updated literature review on the latest trends and findings related to breast implants.

Hayley McKee, MSc, BSc (*Abstract Co-Author*) Nothing to Disclose
Kaitlin M. Zaki-Metias, MD, FRCPC (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The purpose of this educational exhibit is to review the association of breast arterial calcifications (BAC) and cardiovascular disease (CVD), detection and reporting methods, and perceptions of radiologists, referring physicians, and patients. 1. BAC are associated with an increased risk of CVD, incident CVD events, and correlate with other methods of cardiovascular risk stratification. 2. BAC are positively correlated with multiparity, menopausal status, metabolic syndrome, hyperlipidemia, hypertension, diabetes, and chronic renal disease, among other comorbidities. 3. Several methods of BAC detection and reporting have been proposed, including binary assessment, subjective quantification or grading, digital measurement, and AI-based detection and reporting models. 4. Reporting of BAC on mammography may allow for supplementary screening for CVD on screening and diagnostic mammography, leading to earlier identification of asymptomatic individuals at high risk for adverse cardiac events and allowing for more targeted preventive care.

### TABLE OF CONTENTS/OUTLINE

1. Understand the association between BAC on mammography and cardiovascular risk. 2. Review the various methods to identify, quantify, and grade BAC including visual binary assessment, subjective severity grading, digital measurement and quantification, and artificial intelligence-based models. 3. Discuss the awareness and attitudes surrounding BAC of radiologists, referring physicians, and patients over the past 5 years. 4. Describe the current gaps, next steps, and challenges in implementation of BAC reporting and clinical management guidelines, including the necessity of interdisciplinary collaboration.

## MULTIMODALITY DETECTION OF BREAST CANCER RECURRENCE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jean M. Kunjummen, DO (*Abstract Co-Author*) Nothing to Disclose
Maria Piraner, MD (*Abstract Co-Author*) Nothing to Disclose
Rebecca L. Seidel, MD (*Abstract Co-Author*) Consultant, Therapixel SA;Consultant, Delphinus Medical Technologies, Inc
Nishitha Reddy, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Breast cancer is the most common cancer in the female population, for which oncologic and surgical treatment options continue to be developed. Breast cancer recurrence rates vary from 5-20% depending on the tumor subtype. Expected postoperative changes of the breast can be difficult to distinguish from tumor recurrence. Knowledge of multimodality appearances of the postsurgical breast is essential to detecting breast cancer recurrence. Understanding the role of multimodality breast cancer surveillance (ultrasound, mammography, MRI, PET/CT) allows for early detection of recurrent or new breast cancer.

### TABLE OF CONTENTS/OUTLINE

Review the risk factors for breast cancer recurrence. Review current postsurgical breast screening recommendations. Evaluate the role of multimodality imaging, specifically pertaining to the postsurgical breast. Distinguish between expected postsurgical change versus features suspicious for breast cancer recurrence.

RSNA 2024
Building Intelligent Connections

# Abstract Archives of the RSNA, 2024

BREE-103

## POSTSURGICAL BREAST REDUCTION IMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Laurie R. Margolies, MD (*Abstract Co-Author*) Stock options, Nuevozen Corporation Medical Advisory Board, Screenpoint Medical
Stephanie B. Shamir, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Reduction mammoplasty is a common surgery that results in predictable imaging patterns. 2. Reduction mammoplasty can result in imaging changes such as new asymmetries, calcifications, architectural distortion, and areas of enhancement that may appear suspicious, especially when a surgical history is not provided. 3. It is important to not dismiss potentially concerning asymmetries as part of post-surgical change unless they clearly follow the specific expected imaging patterns.

### TABLE OF CONTENTS/OUTLINE

1. Background • Reduction mammoplasty is performed using classic surgical techniques involving removal and displacement of parenchymal tissue, particularly from the inferior breast • The procedure results in a predictable post-surgical appearance 2. Demonstrate normal post-reduction imaging features • Asymmetries, architectural distortions, fat necrosis and calcifications are expected • Scarring should typically stabilize or decrease with time, and calcifications should coarsen 3. Case Series • Cases of invasive cancer in the post-surgical breast that illustrate ways to recognize areas to be further queried 4. Considerations • Consideration of pre-operative mammogram to confirm the absence of pre-existing malignancy, and to establish a baseline imaging appearance prior to surgery 5. References

## IS IT A RECURRENCE OR NOT? MULTIMODALITY IMAGING OF BREAST CANCER RECURRENCE: LITERATURE REVIEW AND CASE BASED PRESENTATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Inci Kizildag Yirgin (*Abstract Co-Author*) Nothing to Disclose
Mustafa Durmaz, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The timely and accurate follow-up of patients with a history of breast cancer is mandatory. Women with a personal history of breast cancer are at an increased risk of either a local recurrence or a new primary breast cancer. Local recurrence can increase the risk of distant metastasis or breast cancer-related deaths, and previous studies have shown that early detection of second breast cancers can decrease the mortality rates.Surveillance is essential for the detection of recurrent disease at the earliest possible stage, allowing for prompt treatment, and potentially improving overall survival. International guidelines recommend annual mammography as the only surveillance technique (ASCO, NCCN, ESMO), but a mammogram is less sensitive in the post-surgical period due to post-treatment changes (fat necrosis, surgical scars). Breast MRI is a highly sensitive imaging modality to detect local recurrence in certain patient groups. The purpose of this educational exhibit will be to learn the role of imaging methods and findings due to treatment and findings of recurrence in breast cancer surveillance patients.

### TABLE OF CONTENTS/OUTLINE

Review of incidence, risk factors, diagnostic performance of multimodality surveillance, and presentation of breast cancer recurrence. Review of post-breast-conserving treatment imaging findings and their timing of evolution. Review of available guidelines for multimodality surveillance after curative treatment for locoregional breast cancer. To learn to deal with complex findings between different imaging methods to avoid unnecessary biopsies. To learn the importance of serial follow-up Imaging. Case-based review of different presentations of breast cancer recurrence.

Nancy Sanchez Rubio, MD (*Abstract Co-Author*) Nothing to Disclose
Beatriz Lannegrand Menendez (*Abstract Co-Author*) Nothing to Disclose
Virginia Luxmila Arias Torrealba, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The majority of brest lesions found in breast routine studies are benign and incidental findings. Most lesions have identifiable radiological characteristics suggesting benign findings without the need for additional tests. To a lesser extent, others require radiological followup tests, with diagnosis possibly achieved solely through imaging behavior. There is a group of uncommon benign lesions that, due to their imaging characteristics and clinical findings, may mimic a suspicious malignancy, requiring definitive diagnosis through a biopsy. The objective of this presentation is to provide a guide to the radiological characteristics of sarcoidosis, granulomatous mastitis, diabetic mastopathy, pseudoangiomatous stromal hyperplasia, and traumatic neuroma at the mastectomy site, in different imaging studies available to us today (mammography, ultrasound, and MRI), allowing for a more detailed characterization, as these particular lesions exhibit significant radiological similarity to malignant lesions. We will briefly describe their clinical, epidemiological, and pathological manifestations. Our description help broaden the diagnostic options when faced with a suspicious image of malignancy in patients presenting some of the clinical-radiological characteristics described here.

### TABLE OF CONTENTS/OUTLINE

1. Sarcoidosis.2. Neutrophilic granulomatous mastitis.3. Diabetic mastopathy.4. Pseudoangiomatous stromal hyperplasia.5. Traumatic neuroma at the mastectomy site.

## THE MORE YOU KNOW: TEACHING POINTS OF DISCORDANT BREAST BIOPSIES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Ann L. Brown, MD (*Abstract Co-Author*) Consultant, Elucent Medical
Rifat A. Wahab, DO (*Abstract Co-Author*) Nothing to Disclose
Kyle M. Lewis, MD (*Abstract Co-Author*) Nothing to Disclose
Erich J. Boomgarden, MD (*Abstract Co-Author*) Nothing to Disclose
Charmi Vijapura, MD (*Abstract Co-Author*) Nothing to Disclose
Mary C. Mahoney, MD (*Abstract Co-Author*) Nothing to Disclose
Katherine Mulquin, DO, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1) Define radiology-pathology concordance as it pertains to breast imaging interventions.2) Detail scenarios in clinical practice that can contribute to biopsy discordance.3) Review clinical implications of discordant biopsies and management strategies including instituting breast radiology-pathology correlation conference.

### TABLE OF CONTENTS/OUTLINE

1) Definitions of benign discordant and malignant discordant biopsies2) Specific and non-specific discordance3) Overview of 5 major categories that contribute to discordant biopsieso Technical Factors--Undersampling (small gauge needle, low number of samples)--Missing the targeted lesion (small target, difficult location)o Complications (bleeding after first sample, vasovagal reaction)o Multiple suspicious lesionso Large or heterogenous finding--Cystic/Necrotic MassNew finding in region with extensive post-treatment changes4) Benefit of incorporating radiology-pathology correlation conference into breast practiceso Consensus management to maximize cancer detection, identify discordant cases in a timely fashion, and avoid unnecessary followup/surgeryCONCLUSIONS1. Discordant biopsies are uncommon, but they can result in delays of care or misdiagnosis when they occur.2. Identification of imaging and clinical features associated with discordant biopsies is important for timely and accurate diagnoses.

## FEELING GOOD AND FEELING NEW (BREAST MASSES) ON GLUCAGON-LIKE PEPTIDE-1 (GLP-1) AGONISTS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Bonmyong Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Sophia R. O'Brien, MD, MEd (*Abstract Co-Author*) Nothing to Disclose
Elizabeth S. McDonald, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Samantha P. Zuckerman, MD (*Abstract Co-Author*) Nothing to Disclose
Joseph J. Villavicencio, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Use of glucagon-like peptide-1 (GLP-1) agonists for weight loss is associated with both mammographic changes and clinical breast symptoms.2. Patients may present with symptoms (lumps, pain) following the use of GLP-1 agonists that warrant ultrasound evaluation. This may yield actionable findings that may have otherwise been occult on screening mammography. 3. Changes in density following the use of GLP-1 agonists may obfuscate previously identified findings; this may create a clinical dilemma in the setting of actionable BI-RADS findings. 4. Changes in density following the use of GLP-1 agonists may prompt more recommendations for supplemental screening. 5. There may be no discernible mammographic changes even in cases of significant weight loss while on GLP-1 agonists.

### TABLE OF CONTENTS/OUTLINE

Case 1: 41F, screening. Interval decrease in breast size and increased breast density following 50 lb weight loss on semaglutide. Case 2: 44F, screening. Interval decrease in breast size and increased breast density following 40 lb weight loss on semaglutide with obfuscation of a focal asymmetry.Case 3: 62F with a palpable right axillary lymph node following 50 lb weight loss on tirzepatide and semaglutide. Targeted ultrasound of the right axilla demonstrated an abnormal lymph node yielding metastatic breast cancer which was mammographically occult. Subsequent breast MR demonstrates a correlate for a primary malignancy in the right breast. Weight loss may have prompted a palpable finding.Case 4: 60F with new palpable areas of concern in the bilateral breasts which demonstrate benign findings on ultrasound evaluation. Case 5: 60F, screening. No significant change on mammography despite 50 lb weight loss.

### TEACHING POINTS

Review the clinical and radiological manifestations of Idiopathic Granulomatous Mastitis (IGM). Explain the diagnostic approach and appropriate management. Describe the main entities included in the differential diagnosis

### TABLE OF CONTENTS/OUTLINE

IGM is a rare chronic inflammatory disease that can mimic carcinoma. Typically affects young women with history of pregnancy and breastfeeding. IGM is usually presented as palpable painful breast lump with inflammatory skin changes. It can also associate fluid collections and sinus tracts. Radiological findings in the different imaging modalities are non-specific and a percutaneous biopsy is always needed for diagnosis. We will revise a series of cases diagnosed with IGM in the last eight years, to illustrate the most frequent radiological findings and go through the main steps we should take to achieve the final diagnosis. Depending on age, radiological studies started with ultrasound or a mammography, but all the patients underwent an us-guided biopsy to confirm the diagnosis. The most common us-findings in our cases were hypoechoic images of tubular and nodular morphology with a tendency to join, hypoechoic irregular masses and sinus tracts. Some patients also had fluid collections and axillary involvement. All the women in our series were treated conservatively with good results, except for two who needed surgery.

BREE-109

## WHAT CALCIFICATIONS? RADIOLOGIC PRESENTATIONS OF NONCALCIFIED DCIS WITH PATHOLOGIC CORRELATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Vidushani S. Perera, MD (*Abstract Co-Author*) Nothing to Disclose
Ayah Ali (*Abstract Co-Author*) Nothing to Disclose
Amy Maduram, MD (*Abstract Co-Author*) Nothing to Disclose
Syeda R. Zaidi, MD (*Abstract Co-Author*) Nothing to Disclose
Michelle Kraay, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

(1) DCIS represents 20 to 25% of all breast cancer diagnoses in the United States and is considered to be a precursor of invasive breast cancer. Although the majority of DCIS (80-90%) presents as calcifications seen on mammography, 10-20% of DCIS diagnoses may present as noncalcified findings on mammography, ultrasound, and MRI. It is vital for radiologists to be aware of the different presentations of noncalcified DCIS, including as a palpable mass, bloody nipple discharge, noncalcified findings on mammography such as architectural distortion and focal asymmetry, and non-mass enhancement on MRI. (2) DCIS is a heterogeneous lesion with five major architectural patterns seen on pathology, including comedo, cribriform, micropapillary, papillary, and solid. The comedo type is most commonly associated with the formation of calcifications mammographically. (3) Noncalcified DCIS lesions may be larger at presentation than calcified DCIS due to the difficulty in mammographic detection and has a reported upgrade rate of 21.8% at a single institution. DCIS can be treated with a combination of surgery, radiation, and hormone therapy.

### TABLE OF CONTENTS/OUTLINE

(1) Overview of DCIS epidemiology and histopathology. (2) Common imaging presentation of DCIS as calcifications. (3) Noncalcified DCIS cases presenting as a palpable mass, focal asymmetry, architectural distortion, non-mass enhancement on MR with corresponding pathology. (4) Cases presenting as symptoms including bloody nipple discharge, Paget’s disease, and pregnancy-associated enlarging fibroadenoma. (5) Management of DCIS. (6) Self-assessment quiz.

## BEYOND CONVENTIONAL: ADVANCED T2 WEIGHTED IMAGING IN BREAST MRI - EMPOWERING EDUCATION AND DIAGNOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Mami Iima, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kazushige Ichikawa (*Abstract Co-Author*) Nothing to Disclose
Shinji Naganawa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Satoko Ishigaki, MD (*Abstract Co-Author*) Nothing to Disclose
Yutaka Kato (*Abstract Co-Author*) Nothing to Disclose
Hiroko Satake, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Advanced T2-weighted imaging (T2WI) techniques, such as 3D T2WI and deep learning (DL) based T2WI, are explored in breast imaging. We start with an overview of conventional T2WI, discussing its fundamental role in diagnosing breast cancer. The focus then shifts to advanced methods that reduce scan times and improve image resolution, highlighting their benefits in educational settings. Detailed analyses illustrate how these advancements enhance the visualization of crucial T2WI findings like focal edema and intratumoral necrosis in breast cancer. Additionally, the educational value of these technologies in teaching radiologic-pathologic correlation through case studies is explored. The session also addresses the challenges and opportunities presented by cases with lymph node (LN) metastasis, proposing strategies to incorporate these insights to improve diagnostic skills in breast imaging.

### TABLE OF CONTENTS/OUTLINE

1. Imaging Sequence• Overview of conventional T2WI in breast MRI• Introduction to advanced T2WI such as 3D or DL-based T2WI, emphasizing the reduced acquisition time with high resolution2. Focal Edema and Intratumoral Necrosis in Breast Cancer• Detailed analysis of how advanced T2WI can improve the visualization• Discussion on the clinical relevance of these findings in diagnosis3. Radiologic-Pathologic Correlation• Exploration of morphology and signal intensity using advanced T2WI• Case studies highlighting the correlation between radiologic findings and pathologic results, demonstrating the educational value of breast imaging4. Challenges in the Diagnosis of LN Metastasis• Addressing the challenges and learning opportunities presented by cases with LN metastasis

### TEACHING POINTS

• Learn the clinical and biological features of 18F-fluoroestradiol (FES), an estrogen receptor targeting PET tracer. • Learn characteristics of dedicated breast PET (dbPET) imaging in comparison with whole body PET imaging. • Learn differences and similarities between dynamic contrast enhanced (DCE) breast MRI and FES-dbPET imaging. • Learn potential clinical benefit of FES-dbPET when used in conjunction with DCE breast MRI for treatment response evaluation during neoadjuvant endocrine therapy (NET).

### TABLE OF CONTENTS/OUTLINE

1. 18F-fluoroestradiol (FES) - Biological characteristics of FES - Review of literature on whole-body PET with FES 2. Dedicated breast PET (dbPET) - dbPET scanner characteristics - Imaging protocol 3. Clinical workflow of FES-dbPET 4. Comparison of DCE breast MRI and FES-dbPET 5. Case presentation of FES-dbPET and DCE breast MRI during neoadjuvant endocrine therapy (NET) 6. Discussion of the imaging findings of the cases presented at #5 - mechanisms of underlying tumor depiction at FES-dbPET vs. DCE breast MRI - influence of menopausal status on FES-dbPET - influence of NET regimen on FES-dbPET findings 7. Future directions of dbPET application in breast cancer therapy 8. Summary of the educational points

**Certificate of Merit**

Jaimee E. Mannix, MD (*Abstract Co-Author*) Nothing to Disclose
Kate Walter (*Abstract Co-Author*) Nothing to Disclose
Nawar Aljundi (*Abstract Co-Author*) Nothing to Disclose
Gianmarco Calderara (*Abstract Co-Author*) Nothing to Disclose
Julia C. Kirsten, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Discuss increased incidence of breast cancer in women aged 20-49 over the past 20 years, with significant increase after 2016.2. Review differences in breast cancer incidence rates by age group, race, hormone receptor status, and stage.3. Discuss modifiable risk factors and social determinants of health which may play a role in increased incidence.

### TABLE OF CONTENTS/OUTLINE

1) Clinical manifestations/pathology of breast cancer in young patients. Recommended diagnostic workup in young patients.2) Incidence of breast cancer is increasing over time in young women aged 20-49, especially after 2016.3) Differences in breast cancer incidence rates by age group, race, hormone receptor status, and stage.4) New data regarding trends and incidence in young women with breast cancer.(a) Increased incidence is due almost entirely to an increase in tumors which are estrogen-receptor positive. Higher rates of breast cancer are seen among Black women, especially among those ages 20 to 29.(b) An increase in diagnosis of stage 1 and 4 tumors in young women has been observed. Data suggests that when stage 1 tumors are missed in younger women, the tumors tend not to be found until they reach stage 4.5) Differences in overall survival and disease free survival rates in young patients vs those diagnosed when older.6) Identification of risk factors for breast cancer such as maternal parity, age of first birth, and family history as well as modifiable risk factors such as obesity, caloric intake, alcohol intake, smoking, chemical exposures, and exercise.7) Treatment differences in young women versus older women and evaluation of effect on quality of life, sexuality, and fertility.8) Role of support groups with age matched peers.9) Conclusion

## INCIDENTAL BREAST FINDINGS ON NON-BREAST IMAGING: A COMPREHENSIVE REVIEW FROM BENIGN TO ACTIONABLE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Fatima Salah, MD, FRCR (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This educational exhibit aims to: 1. Present example cases and outcomes of incidental breast findings seen on non-breast imaging: both benign and malignant. 2. Review suspicious findings that warrant additional work-up with dedicated breast imaging. 3. Illustrate examples in which additional imaging could have been omitted. 4. Highlight value of accurate evaluation of incidental breast findings and their effect on subsequent patient management.

### TABLE OF CONTENTS/OUTLINE

1. Define and introduce importance of incidental breast findings on non-breast cross sectional imaging. 2. Illustrate cases whereby breast findings were clearly negative or benign, BIRADS 1 or 2. 3. Present incidental breast findings in which additional dedicated breast imaging was warranted in both benign and malignant outcomes: a. BIRADS 4: Benign outcome after recommended biopsy. b. Malignant Outcome: Primary breast cancer and Metastasis.

### TEACHING POINTS

Approaching axillary findings by ultrasound, mammography, CT scan and MRI. Differential diagnosis for axillary findings. Significance of accurate diagnosis in disease management

### TABLE OF CONTENTS/OUTLINE

There are numerous diseases that can lead to axillary masses or lymphadenopathy, each requiring a specific approach. Some may benefit from percutaneous biopsies, others may need blood tests or specific diagnostic tools. Radiologists must be proficient in distinguishing axillary lesions originating from other sites to ensure optimal patient care. To comprehensively understand the patient's condition, it's crucial to study not only the lesion itself but also its location, associated findings, patient epidemiology and personal history.This study presents a series of cases involving axillary lesions caused by atypical conditions. It aims to familiarize radiologists with a wide range of non-breast lesions affecting axillary tissue, enabling them to provide accurate diagnoses.Axillary anatomySkin and appendages (Epidermoid cyst - Apocrine sweat gland adenocarcinoma)Fat and connective tissues (Axillary lipoma - Rhabdomyosarcoma - Hemangioma)Vascular abnormalities (Traumatic axillary artery pseudoaneurysm - Mondor disease)Lymph nodes metastasis (Ovarian cancer - Sarcoma -Thymus cancer)Reactive lymph nodes, systemic diseases (Cat scratch disease - Human Immunodeficiency Virus)Congenital anomalies (Fibroadenoma and cysts in axillary accessory breast)Axillary post-surgical complications (Lymphocele - Abscess)Musculoskeletal (Synovial cyst)

BREE-115

## BRCA1 AND 2 MUTATION- THE RADIOLOGIST'S PIVOTAL ROLE IN CHANGING PATIENT'S FATE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Aline D. Guimaraes, MD, MBA (*Presenter*) Nothing to Disclose

### TEACHING POINTS

BRCA 1 and 2 mutation carriers have an increased risk of developing breast cancer. They have 3% greater risk before 30 years and their lifetime risk increases 50 to 80% by the age of 70 years. The increased risk and the early onset of cancer implies a different screening strategy with guidelines around the world recommending to start breast cancer screening at an earlier age and to include MRI as an adjunct to mammography. Furthermore, there are differences between these two groups of high-risk patients regarding the age of appearance of breast cancer, the histologic and nuclear grades, molecular subtypes, lesion's location and imaging features at different breast imaging modalities. It is essential that the radiologists know the epidemiological aspects involved in BRCA1 and BRCA2 mutation carriers, as well as the imaging aspects most commonly found in these patients, specially because BRCA1 carriers tend to present lesions with benign morphological aspects, despite the aggressive pathological features, imposing increased caution on this group of patients. In this case based didactic exhibit, we will explore the clinical, pathological and imaging features in this two subgroups of patients, discuss the screening implications and demonstrate that the radiologist has a pivotal role in changing the fate of these mutation carriers.

### TABLE OF CONTENTS/OUTLINE

1) BRCA1 and 2 Epidemiology 2) Screening recommendation in BRCA1 and 2 mutation carriers 3) Differences between BRCA1 and 2 breast cancer 3.1) Clinical 3.2) Pathological 3.3) Imaging 3.3.1) Mammography, 3.3.2) Ultrasound 3.3.3) MRI 4) Multimodality case based review (BRCA1 and 2 breast cancers) 5) Implications of the knowledge acquired in the radiologist’s practice

## AUGMENTED BUT CHALLENGED - IMPLANT DIAGNOSTIC DILEMMAS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Dunya M. Imad, MD (*Abstract Co-Author*) Nothing to Disclose
Jenna Pellegrino, MD (*Abstract Co-Author*) Nothing to Disclose
Priscilla J. Slanetz, MD, MPH (*Presenter*) Royalties, Wolters Kluwer nv

### TEACHING POINTS

Introduced in the 1960's, breast implant augmentation has become one of the most popular cosmetic procedures globally. As a result, there are a substantial number of women with implants that present for imaging, whether it be for cancer screening or for a symptom such as a lump or pain. In most cases, radiologists can readily determine if a breast implant is intact or if there is a rupture. However, the imaging evaluation can sometimes be more challenging as not all patients present with classic findings. Therefore, breast radiologists need to develop problem-solving skills to troubleshoot such cases so that any issue with an implant is quickly diagnosed and addressed.

### TABLE OF CONTENTS/OUTLINE

In this exhibit, we will provide a systematic approach to evaluating breast implants for rupture or other complications, such as implant-associated malignancy, capsular fat necrosis, implant infection, postoperative collections/hematomas, and alloderm grafting. We will then present examples of challenging cases where clinical history and multi-modality imaging allowed the radiologist to accurately characterize the implant complication.

Kathryn W. Zamora, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Stefanie B. Zalasin, MD (*Abstract Co-Author*) Nothing to Disclose
Stephanie D. Colvin, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Understand indications for contrast enhanced mammography-guided biopsies (CEM-Bx). Apply appropriate BI-RADS terminology to contrast enhanced mammography (CEM) findings. Review cases of CEM-Bx performed at our institution. Correlate radiology imaging findings and pathology results for malignant and benign cases.

### TABLE OF CONTENTS/OUTLINE

Background: CEM is an emerging technology with increasing popularity and utilization. Contrast enhanced imaging demonstrates a higher sensitivity for detection of breast cancer and detects abnormalities not identified on non-contrast examinations. CEM has many indications including screening of high-risk patients who cannot undergo magnetic resonance imaging (MRI). CEM-Bx enables sampling of enhancing lesions that are occult on other modalities including 2D/synthesized mammogram, tomosynthesis, and ultrasound. CEM-Bx also has potential to improve cancer detection in our most at-risk patient population that cannot be screened by MRI. Malignant cases: Present a series of at least 5 breast cancer cases diagnosed by CEM-Bx at our institution. Benign cases: Present a series of at least 5 benign cases diagnosed by CEM-Bx at our institution.

## BREAST IMAGING FINDINGS OF MESENCHYMAL MASSES WITH CLINICAL-RADIOLOGIC-PATHOLOGIC CORRELATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Ramapriya Ganti, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shanna Mayorov, BS, MS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

; Describe the constellation of imaging findings of breast masses of mesenchymal origin. ; Delineate classic mimickers of mesenchymal tumors. ; Familiarize readers with radiologic-histopathologic correlation. ; Discuss available management options for each entity.

### TABLE OF CONTENTS/OUTLINE

1. Background : Mesenchymal masses pose a diagnostic challenge for the breast imager as this category of lesions encompasses both benign and malignant masses, demonstrates similar imaging appearances, and has varied pathologic and treatment related paradigms. Both groups typically manifest in the breast as a single mass that is often palpable. 2. Discussion: Pictorial review of approximately 12 breast masses of mesenchymal origin with emphasis on imaging findings, including benign lipoma, hamartoma, angiolipoma, hemangioma, pseudoangiomatous stromal hyperplasia, leiomyoma, phyllodes tumor, primary and secondary sarcoma, neurogenic tumors, granular cell tumors, myofibroblastoma, and desmoid tumors. Brief epidemiology, clinical symptoms if any, diagnostic assessment including imaging findings, the role of biopsy, histopathologic correlation including staining techniques and their role in identification, and treatment considerations will be described. 3. Conclusion: Knowledge of the imaging manifestations, histopathologic features, and management strategies of mesenchymal tumors allows breast radiologists to improve the identification of these lesions and direct appropriate work-up and management.

### TEACHING POINTS

• Understand the clinical implications of Li-Fraumeni Syndrome (LFS) in women • Review the current breast cancer screening guidelines for LFS in women • Review the appropriateness criteria of breast imaging modalities to screen women with LFS • Illustrate imaging findings of LFS in the breast

### TABLE OF CONTENTS/OUTLINE

1. Review the biology and inheritance pattern of Li-Fraumeni Syndrome (LFS). 2. Review the tumors which patients with LFS are susceptible to, with a particular emphasis on the types of breast cancers associated with LFS. 3. Highlight the screening guidelines and appropriateness criteria in patients with LFS. 4. Showcase illustrative breast imaging cases in patients with LFS.

## "DO THEY MATCH?" HOW TO ACHIEVE AN ACCURATE SECOND LOOK ULTRASOUND FOR BREAST LESIONS IDENTIFIED AT MR IMAGING. PICTORIAL REVIEW FOR RADIOLOGISTS IN TRAINING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Maria P. Swiecicki, MD (*Abstract Co-Author*) Nothing to Disclose
Karina Pesce, PhD (*Abstract Co-Author*) Nothing to Disclose
Giannina M. Secco, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Jose Chico (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To help localize MRI detected lesions at second look ultrasound by giving imaging tips for the radiologist in training.2. To illustrate with clinical cases the correlation between both imaging techniques.

### TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Technique for a good second look US using lesion morphology and localization within the breast.3. Anatomical details that can assist in proper lesion localization.4. Illustration with clinical cases to show how to achieve an adequate correlation between MRI and US images for an accurate lesion localization.5. Conclusions.In conclusion, this educational exhibit is intended to be a guide for radiologists in training that are beginning to perform second look US, describing the technique and illustrating parameters that can assist them in this task.

## ONE-STEP QUALITATIVE AND QUANTITATIVE EVALUATION OF AXILLARY LYMPH NODE METASTASIS IN BREAST CANCER USING DUAL-ENERGY SPECTRAL CT COMBINED WITH CONTRAST ENHANCED SPECTRAL MAMMOGRAPHY: THE EVIDENCE AND ITS LIMITS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Huizhi Cao (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Contrast-enhanced spectral mammography (CESM) and dual-energy spectral CT (DECT) are both exciting technology in potential clinical application. The focus of this presentation is: 1. To understand the concepts and imaging principles of contrast-enhanced mammography and spectral CT imaging technology.2. To learn about how CESM combined with CT spectral imaging technology can assess axillary lymph node metastasis in preoperative breast cancer. 3. To delve into qualitative and quantitative evaluation criteria derived from pathological results of axillary lymph node metastasis post-surgery. 4. To understanding the pros and cons of CESM and spectral CT imaging technology in axillary lymph node metastasis evaluation.

### TABLE OF CONTENTS/OUTLINE

1. Background introduction to contrast-enhanced mammography and spectral CT Imaging technology, along with post-processing techniques such as monochromatic Images (keV) and material density images (iodine-based, calcium-based), and spectral Hounsfield unit curve analysis.2. Strategies for preoperative diagnosis of metastatic sentinel lymph nodes in breast cancer utilizing DECT and CESM.3. Clinical exemplification of CESM coupled with spectral CT imaging technology in evaluating axillary lymph node metastasis in preoperative breast cancer.4. Qualitative and quantitative evaluation methods for assessing breast cancer axillary lymph node metastasis using CESM and spectral CT technology.5. Examination of advantages and limitations of both technologies in axillary lymph node metastasis evaluation.

### TEACHING POINTS

Mastitis is an inflammation of the mammary gland that can affect different parts of the breast, such as the tissue, nipple, areola, ducts, and skin. It can occur with or without the presence of bacteria. There are various forms of mastitis, including those related to the neonatal and pubertal periods, as well as more common cases during the postpartum period. Additionally, there are less common specific inflammations, such as tuberculosis, syphilis, and actinomycosis. These inflammations can be classified as lactational (during breastfeeding) or non-lactational. Ultrasound is used as the initial method to evaluate women with acute mastitis, especially when abscesses are suspected. Ultrasound imaging findings include edema of the skin and subcutaneous tissue, areas with increased echogenicity permeated by parenchymal areas, loss of definition of the breast planes, hyperechogenicity of perilobular fat and axillary lymph nodes with cortical thickening. Mammography is recommended to rule out cancer and can be performed outside the peripartum period, especially for women over 30 years old. Magnetic resonance imaging (MRI) is not usually necessary and is reserved for atypical cases. The main differential diagnosis to consider is inflammatory carcinoma when a patient presents with redness and swelling in the breast, without evidence of abscess on ultrasound.

### TABLE OF CONTENTS/OUTLINE

- Review clinical, pathophysiological, and imaging aspects of mastitis.- Illustrate common and uncommon findings of mastitis in a didactic manner.

### TEACHING POINTS

The probable changes for the sixth edition of BI-RADS® (Breast Imaging Reporting and Data System) have already been made available, including the introduction of “non-mass lesion” in the ultrasound lexicon. It is defined as a discrete echotexture alteration area, distinct from the adjacent parenchyma, that does not meet the criteria for nodule, identifiable in at least two planes, but may be visualized in only one plane. In most cases, it has a benign etiology, but it can be the initial manifestation of breast cancer, most commonly in situ. It is cathegorized by terms of echogenicity, distribution and associated findings. Calcifications, architectural distortion, posterior acoustic shadowing, abnormal ductal extension or changes, echogenic halo and hypervascularity are examples of associated findings that suggest malignancy. In the face of a non-mass lesion finding on the ultrasound, it is important to correlate it with other imaging exams, as the identification in different methods can increase the degree of suspicion, as well as association with papillary flow or palpable alteration. Definitive diagnosis is made by tissue sampling, most commonly percutaneous core-needle biopsy.

### TABLE OF CONTENTS/OUTLINE

- To be familiar with the likely changes in the next edition of BI-RADS®, in order to standardize its description.- Suggest the description of ultrasound, in accordance with the expectations of the lexicon changes of the new BI-RADS®, correlating with other imaging modalities.

## SO, YOU THINK YOU CAN IDENTIFY BREAST CANCER? UNCOMMON PRESENTATIONS OF THE MOST COMMON CANCER IN WOMEN

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Himeghna Deepak (*Abstract Co-Author*) Nothing to Disclose
Milin Rana, MD (*Abstract Co-Author*) Nothing to Disclose
Rachel Klapper, MD (*Abstract Co-Author*) Nothing to Disclose
Nayanatara Swamy, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1.Breast cancers exhibit a diverse array of imaging presentations, staying updated on these presentations will help us detect them early. 2.Fat containing masses in the breast are largely benign, except in those cases where the breast cancer has engulfed fat. 3.Although rare, interval breast cancers do occur. Therefore, it's crucial to educate women not to disregard a palpable lump, even if they had a benign screening mammogram within the past year. 4.Identifying suspicious asymmetries and focal asymmetries can be challenging on screening mammography. By learning from both positive and negative call-backs, we can set our threshold of suspicion optimally. 5.Maintaining high standards for image quality of screening mammograms will help ensure that the cancers located far posteriorly and anteriorly are identified. 6.Women who have undergone reduction mammoplasty have post-operative changes which make identification of breast cancers daunting. 7.Cross-sectional imaging can be a useful tool in identifying breast cancers in subsets of the population that do not yet undergo routine screening mammography.

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Case-based review o The fat engulfing breast cancer o The interval breast cancer o The low density mass o The subtle asymmetry o The subtle focal asymmetry o The anteriorly located breast Cancer o The posteriorly located breast cancer - not one, but two masses!! o DCIS presenting as microcalcifications and a mass in same patient o DCIS detected by breast MRI (focal asymmetry on mammogram) o Breast cancers in two women with history of reduction mammoplasty o The Breast cancer initially detected by PET-CT o The breast cancer initially detected by CT 3. Conclusion

Sofia B. Maksoud, MD (*Abstract Co-Author*) Nothing to Disclose
Ruth H. Bonini, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Foreign bodies in the breast topography are uncommon and exhibit a variable imaging spectrum, contingent upon the nature and location of the material. The most frequently encountered foreign bodies are those intentionally inserted by radiologists, such as metallic clips during or after biopsy procedures and pre-surgical localization wires or by breast surgeons in surgical interventions. Less frequently, metallic foreign bodies associated with trauma, such gunshot fragments or glass fragments related to car accidents may be encountered.Materials related to cosmetic procedures, and even implantable medical devices like pacemakers and catheters are other foreign bodies that can be present and sometimes interfere with mammography interpretation.Patients may either be asymptomatic or present with localized pain or abscess. A comprehensive clinical history linked with prior mammograms will often lead to a conclusive or presumptive diagnosis, without the need for additional diagnostic tests or unnecessary biopsies.

### TABLE OF CONTENTS/OUTLINE

In a didactic manner several cases of breast or thoracic foreign bodies seen on mammograms, selected from the digital archives of our institutions, will be presented. Illustrate instances where foreign bodies within or next to the breast impede the thorough evaluation of examinations.

### TEACHING POINTS

Identify the different types of artifacts in breast magnetic resonance imaging. Several examples of technical and patient-related artifacts that one might encounter will be illustrated.

### TABLE OF CONTENTS/OUTLINE

Breast magnetic resonance imaging has become an important tool for high risk screening, breast cancer staging, response to treatment, assessment of recurrence after treatment, and evaluation of breast implants. However, the challenge arises in identifying artifacts generated in breast magnetic resonance images that can degrade image quality and obscure important diagnostic findings. The present work aims to recognize the artifacts and understand how to address them and optimize breast magnetic resonance image quality and avoid interpretive errors.

Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

-To review the different breast lesions containing lymphocytes. - To describe features of breast lymphomas. - To analyze the concept of TILS (tumor infiltrating lymphocytes) in breast tumors. - To illustrate imaging findings in different imaging modalities (CEM, US, MRI) with correlation with pathology. - To emphasize pitfalls, diagnostic difficulties, and differential diagnosis

### TABLE OF CONTENTS/OUTLINE

Lesions containing different types of lymphocytic infiltration may appear within the breast. Understanding TILS concept and knowledge of lymphocyte containing lesions is essential for the radiologist.We present: - Lymphoid tissue in the breast. Anatomy and physiology. - Breast lymphoma. Images of primary and secondary breast lymphomas from our series will be presented. Usually, non-specific, most frequently enlarging masses. -Medullary carcinoma. A circumscribed mass in which lymphocytic infiltrate is a key diagnostic criterion. -Lymphocytic mastitis/diabetic mastopathy. Lymphocytes may also appear in inflammatory lesions. Lymphocytic mastitis is unusual and probably immune-mediated. If associated with diabetes called Diabetic mastopathy, with lobular atrophy and sclerosis called Sclerosing type. Usually, non-circumscribed masses or focal asymmetry. -TILS are clinically relevant regarding implications on response to treatment and prognosis. This lymphocytic infiltrate might represent a form of host resistance to the tumor. TILS are most frequently found in triple negative breast cancer, followed by HER2 positive and less frequently in luminal breast cancer.

## ENHANCING DIAGNOSTIC VALUE WITH CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY THROUGH QUANTITATIVE ENHANCEMENT ANALYSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Huizhi Cao (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To understand the mechanism and clinical utility of contrast-enhanced spectral mammography (CESM) in breast cancer screening, staging, and treatment monitoring. 2. To demonstrate quantitative variables and kinetic enhancement patterns of breast lesions on CESM in enhancing diagnostic accuracy and differential diagnosis. 3. To discuss the diagnostic performance of radiomics in combination with CESM for suspicious malignant lesions characterization. 4. To present case studies with the integration of history, imaging findings, and tissue diagnosis for utilizing quantitative CESM characteristics in challenging or equivocal mammographic abnormalities.

### TABLE OF CONTENTS/OUTLINE

1. To introduce the principle of CESM, contrast protocol, abnormal enhancing characteristics and illustrative cases in demonstrating CESM's role in BIRADS assessment and management of equivocal mammographic lesions. 2. To demonstrate quantitative analysis of kinetic enhancement patterns on CESM in distinguishing benign from malignant breast lesions. 3. To understand the concept of radiomics and its integration with CESM in identifying suspicious malignant microcalcifications (BIRADS 4). 4. To discuss strategies for appropriately utilizing quantitative CESM characteristics in complex or ambiguous mammographic abnormalities.

## ENHANCING PREDICTIVE POWER OF CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY (CESM) IN ASSESSING RESPONSE TO NEO-ADJUVANT CHEMOTHERAPY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Huizhi Cao (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To grasp the technical foundations of contrast-enhanced spectral mammography (CESM) and its Operationalization. 2. To identify lesion types amenable to evaluation via CESM. 3. To unveil CESM's capacity for accurate assessment of tumor response post Neo-adjuvant chemotherapy (NAC), comparable to MRI. 4. To employe quantitative objective measures in predicting response to NAC through RECIST 1.1 and combined evaluation approaches. 5. To appreciate the scope and nuances of CESM's utility in treatment monitoring.

### TABLE OF CONTENTS/OUTLINE

1. Unveiling the underlying principles and physics of contrast-enhanced spectral mammography. 2. Exploring CESM's clinical application as a promising follow-up modality post-NAC. 3. Understanding the variables influencing tumor shrinkage and assessment during NAC, including primary tumor Size, edema, or necrosis. 4. Qualitative and quantitative assessment of CESM in predicting response to NAC. 5. Weighing the advantages and constraints of CESM.

## AXILLARY IMAGING: PEARLS AND PITFALLS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Caroline Merriam, DO (*Abstract Co-Author*) Nothing to Disclose
Liva Andrejeva-Wright, MD (*Abstract Co-Author*) Nothing to Disclose
Manroop Kaur, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. The axilla is normally comprised of lymph nodes, axillary neurovascular bundles, and adipose tissue.2. Accessory breast tissue is categorized into classes, and the axilla is the most common location for fibroglandular accessory breast tissue (Class IV).3. Recognizing abnormalities in ectopic breast tissue is important as malignancies may arise at an earlier age in aberrant tissue.4. The purpose of the exhibit is to review benign and malignant pathologies in the axilla through a multi-modality case-based presentation.5. Benign features of axillary lesions include well-circumscribed margins in parallel orientation with posterior acoustic enhancement and absence of early enhancement. 6. Malignant features of axillary lesions include spiculated/angulated margins in taller than wide orientation, posterior acoustic shadowing, and early enhancement characteristics.

### TABLE OF CONTENTS/OUTLINE

1. Normal anatomical structure of the breast and axilla.2. Imaging characteristics of normal axillary tissue versus accessory breast tissue.3. Multi-modality case-based review of benign pathologies in the axilla: accessory breast tissue, fibroadenoma, sebaceous cyst, Hidranitis suppurativa, reactive lymph nodes, lymphatic malformation, capillary hemangioma 4. Multi-modality case-based (US, Mammography, MRI) review of malignant pathologies in the axilla: primary breast cancer (DCIS/LCIS), metastatic lymph nodes from breast-primary cancer, metastatic lymph nodes from non-breast primary cancer. 5. BI-RADS application for lesions in the axilla and next steps for follow-up.

### TEACHING POINTS

Mammography assumes a pivotal role in breast cancer screening, renowned for its efficacy in early disease detection and subsequent reduction in mortality rates. Nevertheless, the efficacy of mammography is contingent upon various factors, encompassing the proficiency of mammography technologists, accurate calibration of equipment parameters, and the unique anatomical features of each patient. These multifaceted considerations can attenuate the sensitivity of the modality. Among the manifold factors influencing the interpretability of mammograms, improper breast positioning stands as a principal adversary, precipitating a cascade of adverse outcomes including unwarranted re-examinations, escalated radiation exposure, elevated recall rates, and potential diagnostic delays. Emerging research endeavors are leveraging artificial intelligence (AI) as a complementary tool to identify and rectify positioning errors during mammographic examinations. However, notwithstanding the integration of AI support, the indispensable role of radiologists and technologists in discerning the hallmarks of a meticulously executed mammography remains unequivocal. Their proficiency is imperative in mitigating the propensity for unnecessary recalls, mitigating radiation exposure, curtailing healthcare expenditures, assuaging patient apprehensions, alleviating procedural discomfort, and averting diagnostic delays.

### TABLE OF CONTENTS/OUTLINE

This study aims to emphasize the importance of obtaining high-quality mammographic images by evaluating factors such as the patient's medical history, anatomy, equipment parameters, with a strong emphasis on proper positioning during the exam.

Sung Hun Kim (*Abstract Co-Author*) Nothing to Disclose
Ga-Eun Park, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

*Metastases to the breast are rare, with a reported incidence of 0.3-2%. Among these, lymphoma is the most common, followed by melanoma, lung, ovarian, and gastrointestinal tract origins. *Breast tissue confirmation is performed to verify the origin in patients with extensive metastasis. Additionally, breast biopsy is conducted as clinically indicated in patients with known cancer origins, given the rarity of metastases to the breast despite breast cancer's prevalence. *Imaging features may vary depending on the primary tumor and route of dissemination, with a circumscribed solid mass being the most frequent presentation. Hematogenous metastases, in particular, often manifest as multiple or bilateral masses.

### TABLE OF CONTENTS/OUTLINE

1. Literature reviews on breast metastasis. 2. Analysis of incidence and origin distribution. 3. Cases with various imaging characteristics using a multimodality approach.

### TEACHING POINTS

The distinct image characteristics of different pathological types of papillary carcinoma on Cone Beam Breast CT (CBBCT)

### TABLE OF CONTENTS/OUTLINE

1.Objective To explore the image characteristics of different pathological types of papillary carcinoma using Cone Beam Breast CT (CBBCT).2. Methods: Retrospective analysis was conducted on CBBCT image characteristics and time-density curves from 23 cases of different pathological types of papillary carcinoma, confirmed by pathology at our hospital between July 2019 and December 2023. 3. Results: 13 had intraductal papillary carcinoma, primarily characterized by multi-focal tumors of equal density, with clear boundaries. The long axis of these lesions generally aligned with the breast ducts and was often accompanied by calcification. The time-density curve was predominantly type II. Two cases had invasive papillary carcinoma, mainly with presenting as oval cystic- solid masses. They had indistinct margins, with heterogeneous internal enhancement patterns and prominently enhanced wall nodules. The cystic areas were smooth and with a time-density curve of type III. Two cases were of encapsulated papillary carcinoma, mainly with cystic- solid masses, circumscribed margins and smooth cystic walls, featuring a single enhanced wall nodule and a type III time-density curve. Six cases had solid papillary carcinoma, mainly with multiple cystic- solid masses or a diffuse enhancement pattern. They had indistinct margins, with lobulation and spiculation, and were accompanied by enhanced wall nodules, with time-density curves of mainly type II.4. Conclusion: CBBCT can be effective in differentiating between the various pathological types of papillary carcinoma.

## CLINICAL PERFORMANCE OF NEW IMAGE RECOMBINATION ALGORITHM (NIRA) FOR ARTIFACT REDUCTION IN CONTRAST-ENHANCED MAMMOGRAPHY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Huizhi Cao (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Contrast-enhanced mammography (CEM) emerges as a promising imaging tool for breast cancer diagnosis. However, CEM is susceptible to artifacts that can compromise image quality and diagnostic accuracy. The objectives of this exhibit are: 1. To introduce readers to contrast-enhanced mammography (CEM) as an emerging modality for breast imaging and discuss its implementation. 2. To examine common artifacts encountered in contrast-enhanced mammography, including those related to patients, contrast agents, such as ripple artifact, scatter radiation artifact, and misregistration artifact. 3. To showcase the efficacy of the New Image Recombination Algorithm (NIRA) in reducing artifacts on CEM images through practical application and clinical examples. 4. To highlight the clinical value of NIRA in quality assurance for CEM images, thereby reducing interpretation errors. 5. To explore technical and diagnostic limitations, including false-negative and false-positive results, associated with contrast-enhanced mammography.

### TABLE OF CONTENTS/OUTLINE

1. Brief overview of different approaches in contrast-enhanced mammography and their features in imaging interpretation. 2. Identification and illustration of artifacts apparent on CEM images, including those caused during image acquisition, contrast agent-related artifacts, and typical digital mammography artifacts. 3. Practical application of the NIRA technique, accompanied by illustrated clinical examples, to demonstrate its effectiveness in reducing various artifacts. 4. Discussion on technical and diagnostic limitations, including false-negative and false-positive results, encountered in contrast-enhanced mammography.

### TEACHING POINTS

Image-guided breast biopsies (BrBx) are the standard of care for suspicious breast findings. Bleeding complications of BrBx can lead to patient anxiety, additional imaging exams, and increased treatment costs. Historically, paucity of national data and lack of guidelines for management of periprocedural bleeding risk of BrBx is reflected in the significant variability among practicing radiologists. The Society of Interventional Radiology in 2019 published consensus-based approach for assessment of bleeding risk in patients undergoing interventional procedures. However, the management of patients on AT medications and those with inheritable bleeding disorders is still a source of confusion and can potentially delay critical interventions. Recent breast-specific data on risk of significant bleeding in BrBx, even without cessation of antithrombotic (AT) medications, is low (1%). This data weighed against thrombotic risk from temporarily stopping AT medications may warrant updated management protocols. Thus, clinical need dictates for better understanding of the complex coagulation pathway, learn the current antithrombotic medications as well as understand risk management protocols before, during, and after BrBx. In addition, the knowledge of proper management strategies if bleeding occurs is critical for improved patient care and outcomes.

### TABLE OF CONTENTS/OUTLINE

- Pathophysiology of coagulation pathway and pharmacokinetics of common AT medications.
- Recent data on incidence and significance of bleeding complications after BrBx
- Steps to decrease bleeding risk before, during, and after BrBx.
- How to recognize and manage bleeding complications of BrBx through case-based, image-rich examples.

## ARTIFACTS IN BREAST ELASTOGRAPHY AND HOW TO RECOGNIZE AND AVOID THEM

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jonathan Langdon, MD (*Abstract Co-Author*) Nothing to Disclose
Richard G. Barr, MD, PhD (*Presenter*) Consultant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Siemens AG;Consultant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Consultant, Canon Medical Systems Corporation;Advisor, Hologic, Inc;Research Grant, Hologic, Inc

### TEACHING POINTS

1. Artifacts in breast elastography are common and can lead to false positive and false negative results. 2. Recognizing breast elastography artifacts and knowing how to avoid them is critical for accurate breast lesion assessment 3. Artifacts can occur both in strain and shear wave elastography 4. Performing both strain and shear wave elastography will help recognize artifacts 5. Learn the optimal technique for both strain and shear wave elastography

### TABLE OF CONTENTS/OUTLINE

A. Review of the principals of strain and shear wave elastography of the breast B. Review the literature on strain and shear wave imaging of the breast C. Describe common breast elastography artifacts and how to recognize them and avoid them 1. Artifacts associated with cystic lesions 2. The "blue" or "soft" cancers 3. The Bang artifact 4. Artifacts due to poor position of the transducer 5. How to recognize noise 6. The sliding artifact 7. The effect of precompression or preload8. Use of the quality map in shear wave elastography D. Summary of the optimal technique for both strain and shear wave elastography for breast lesion evaluation

### TEACHING POINTS

1. Fibroadenoma is a benign breast neoplasm characterized by a composition of fibrous and glandular tissue, representing the most prevalent benign neoplasm of the female breast and is typically observed in women under 30 years of age, although it can occur at any point in the reproductive years.2. After chemotherapy, fibroadenomas and other benign breast lesions can exhibit changes in their imaging features. They may show decreased enhancement or may demonstrate a reduction in size on Magnetic Resonance Imaging (MRI) or Computed Tomography (CT). Such changes can sometimes make it challenging to distinguish between a benign and a malignant lesion.3. In cases where lesions exhibiting benign imaging characteristics have responded to chemotherapy, the decision regarding further management should take into consideration the initial level of suspicion.

### TABLE OF CONTENTS/OUTLINE

1. Emphasize the importance of benign breast lesions findings in the different methods, as it is a common finding of benign breast lesions.2. Show the pathology, epidemiology, histological origin, imaging aspects in the different methods of benign breast lesions.3. Review on imaging findings of the effects of neoadjuvant or adjuvant chemotherapy on fibroadenomas and other benign breast lesions through illustrative cases with different imaging methods, including Ultrasound, Mammography, Tomosynthesis, Magnetic Resonance Imaging and Computed Tomography.4. Discuss the management approach in cases where a lesion presents imaging characteristics indicative of benignity, yet demonstrates decreased enhancement or dimensions following chemotherapy.

Leire Alvarez Perez, BMedSc (*Abstract Co-Author*) Nothing to Disclose
Vicente Martinez de Vega, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Presurgical MRI guided ROLL/SNOLL localization in breast cancer may be useful in selected cases to obtain surgical free margins. This technique is accurate, safe and fast. How to perform radioguided breast surgery for those malignant lesions displayed only with breast MRI and sentinel node detection.

### TABLE OF CONTENTS/OUTLINE

Suspicious lesions detected only seen by MRI (not seen with mammography or ultrasound) require histological diagnosis. This is performed by an MRI-guided VAB, after which a marker is left in case the patient requires surgery. Titanium markers placed can move because of the relatively large size of the resulting cavity and subsequent hematoma formation after the procedure.On the other hand, in some cases, the malignant lesion detected by MRI is more extensive than that visualized by mammography and ultrasound.In both situations, marking the previously biopsied lesion or its boundaries with MRI-guided procedure reduces the number of surgical positive margins.Radioguided occult lesion localization (ROLL) has emerged as a novel technique in surgery for non-palpable breast lesions, inspired by sentinel node biopsy (SNB). With MRI guidance, we can practice the ROLL technique and add SNOLL (sentinel node and occult lesion localization) in the same procedure.We present our experience in presurgical MRI guided ROLL/SNOLL localization in 93 patients.

## DEFINING SUCCESS IN CRYOABLATION: LONG TERM OUTCOMES FROM A SINGLE INSTITUTION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Sehar Salman, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Mary Schwartz, MD (*Abstract Co-Author*) Nothing to Disclose
Modupe M. Adeyefa, MD (*Abstract Co-Author*) Nothing to Disclose
Luz A. Venta, MD (*Abstract Co-Author*) Nothing to Disclose
Mimi Haghshenas, MD (*Abstract Co-Author*) Nothing to Disclose
Sasha Kurumety, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The goal of this presentation is to educate radiology trainees on the use of cryoablation as a treatment option for breast malignancies, when cryoablation may be appropriate, and outcomes that can be deemed successful when cryoablation is used for breast malignancies. Using a select series of cases from our institution, we will describe the multiple potential roles of cryoablation and mechanism of action, as well as demonstrate post treatment imaging findings over the course of months to years. After this presentation, learners will be able to describe the utility of cryoablation in treating breast malignancies, long term outcomes and imaging findings after treatment, and future directions for cryoablation.

### TABLE OF CONTENTS/OUTLINE

Background: Current FDA approved indications for cryoablation and investigation of cryoablation in breast cancer. Discussion of ongoing trials (ICE3, FROST). Goals of cryoablation when used for malignancies: palliative vs curative, long term outcomes of cryoablation when used in breast malignancies. Discussion of mechanisms of action: Direct freezing and cell death, indirect immune response activation. Cryoablation at our institution: Cases of cryoablation with pathologic findings on biopsies, intraprocedural imaging, and sequential long term follow up imaging findings. Comparison of outcomes to standard of care without cryoablation. Future directions: Defining indications of cryoablation, increasing accessibility, utility with palliative intent.

## METHOD OF DETECTION IN BREAST CANCER IMAGING: PROOF OF CONCEPT OF AUTOMATED MOD DESIGNATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Laurie R. Margolies, MD (*Abstract Co-Author*) Stock options, Nuevozen Corporation Medical Advisory Board, Screenpoint Medical
Arielle Sasson (*Presenter*) Medical Advisory Board, Screenpoint Medical

### TEACHING POINTS

• Method of Detection (MOD) is the first clinical event or imaging study to trigger a workup which may lead to the diagnosis of breast cancer. It is expected to be included in the 6th edition of the BI-RADS atlas.• Documenting MOD allows quantification of the impact of breast cancer screening on treatment and patient outcomes.• Some breast radiology reporting tools provide an advanced algorithm to automate MOD assignment to simplify MOD data collection.

### TABLE OF CONTENTS/OUTLINE

• **Background**• Ongoing debate related to breast cancer screening frequency and age range• These controversies are in part due to dependence on old film screen historical clinical trial data and varying interpretations/misinterpretations of the data. Additionally, this data may not speak for the diversity of the current population, increasing incidence of breast cancer and/or recent advances made in breast cancer imaging.• Many nations utilize a centralized breast cancer screening program that monitors the results of screening mammography for every patient.• **What is MOD and why should we care about it?**• Comprehensive definition and proposed categories of initial MOD• Reasons why we should track initial MOD data for every patient• Methods of assigning MOD• Retrospective versus prospective assignment of MOD• Breast radiology reporting tools can automate MOD assignment• Present example images of MOD automation • Discuss difficult scenarios in assigning MOD, such as when a patient presents with a palpable abnormality in one breast but malignancy is detected in the opposite breast • Barriers to collecting MOD data• **References**

## REVOLUTIONIZING DETECTION: LOCALLY ADVANCED BREAST CANCER IN YOUNG WOMEN UNVEILED BY AB MRI DESPITE MORPHOLOGICALLY NEGATIVE EXAMS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Flavia B. Sarquis, MD (*Abstract Co-Author*) Nothing to Disclose
Maria A. Acha I, MD (*Abstract Co-Author*) Nothing to Disclose
Angelica M. Rivera (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Breast cancer is the second leading cause of cancer deaths in women aged 20-39, and it often presents with more aggressive features compared to breast cancer in older women.Mammography is the standard imaging modality for breast cancer detection, but it has limitations.Young women with locally advanced breast cancer may have negative mammograms and ultrasounds due to their dense breast tissue. It is generally associated with palpatory findings not related to mastitis.Abbreviated Breast MRI (AB-MRI) can detect locally advanced breast cancer in young women with negative mammograms and ultrasounds.AB-MRI can provide valuable information to clinicians for early detection and treatment of breast cancer in young women.After reading this educational exhibit, the radiologist will know :AB-MRI can be used as an imaging modality in young women with negative mammograms and ultrasounds for early detection and treatment of breast cancer, avoiding delays in diagnosis.

### TABLE OF CONTENTS/OUTLINE

Introduction: The Challenge of Detecting Breast Cancer in Young Women.AB-MRI in Young Women with Negative Mammograms and Ultrasound.AB-MRI vs. Mammography: Comparing Sensitivity and Specificity.Future Directions: The Potential of AB-MRI in Breast Cancer Diagnosis and Management.Conclusion

## BREAST OR NOT BREAST: CHEST WALL AND AXILLARY ABNORMALITIES IN BREAST IMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Muhayman Sadiq, MBBS (*Abstract Co-Author*) Nothing to Disclose
Claudia Cotes, MD (*Abstract Co-Author*) Nothing to Disclose
Tiffany A. Kumala (*Abstract Co-Author*) Nothing to Disclose
Vidhyulatha Sanata, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

It's not uncommon for patients with chest wall and axillary abnormalities unrelated to the breast to initially present to the breast imaging department. Mammography and breast ultrasound, although helpful for excluding breast related malignancies, may not always be the most suitable modalities for evaluation, often leading to inconclusive results. These scenarios present challenges for radiologists, particularly concerning biopsy approaches and appropriate recommendations for additional imaging to comprehensively assess these patients. This exhibit showcases the chest wall and axillary anatomy on mammography, breast ultrasound, and breast MRI, delineates the role of breast imagers in the evaluation of abnormalities within these regions, and offers guidance on the subsequent imaging steps and biopsy approaches for evaluating non-breast chest wall and axillary findings through illustrative case examples.

### TABLE OF CONTENTS/OUTLINE

1. Chest wall and axillary anatomy: Mammography, Ultrasound, Breast MRI 2. Differential diagnoses based on location:Chest wall: Anterior chest wall muscle: Poland syndrome, Physiological hypertrophy, Pectoralis muscle Lipoma, Spindle cell sarcoma Ribs: Osteomyelitis, Benign and Malignant Bone tumors Posterolateral Chest wall: Lipoma, Elastofibroma Dorsi, Lymphatic malformations Axilla: Muscle: Sarcoma Lymphatic system: Atypical Lymphoma, Lymphangioma Shoulder Joint: Ganglion Cyst

### TEACHING POINTS

Atypical ductal hyperplasia (ADH) is part of the high-risk lesions group due to its association and potential progression to ductal carcinoma in situ (DCIS) and invasive carcinoma, being found in about 5 to 20% of biopsies performed. The histopathological features of ADH and DCIS are highly similar, distinguished primarily by size (less than 2 mm) and involvement in fewer than two ducts. The risk of progression to invasive carcinoma is estimated to range from 3.7% to 22%. ADH does not present defined radiological characteristics on its own. Mammography may reveal nodules, asymmetric densities, calcifications, and architectural distortions, often with amorphous calcifications within the lesion. On ultrasound, lesions typically appear as hypoechoic nodules with irregular shape, microlobulated margins, and abrupt interface, often due to coexisting processes. Magnetic resonance imaging (MRI) shows non-nodular enhancement, with patterns varying from progressive to plateau or wash-out. Given the potential for diagnostic underestimation and its propensity to coexist with DCIS and invasive carcinoma, surgical excision is advised post its histopathological diagnosis. Recent studies have been discussing the role of MRI in cases of ADH where no suspicious enhancement is observed in the biopsied area, which could potentially obviate the need for surgery in these cases.

### TABLE OF CONTENTS/OUTLINE

To explore the histopathological characteristics of ADH, differential diagnoses, and its relationship with breast carcinoma, demonstrate the imaging findings of ADH across various imaging modalities using cases from our institution, discuss the role of MRI in the treatment decision-making.

### TEACHING POINTS

Review physiological breast tissue changes and illustrate common breast disorders during pregnancy and lactation.Discuss the radiological approach to breast pathology in this period and deepen the understanding of pregnancy-associated breast cancer.

### TABLE OF CONTENTS/OUTLINE

Breast pathology during pregnancy and lactation poses diagnostic challenges. Radiologists must be well-versed in the physiological changes and specific conditions of this period, considering the strengths and limitations of each imaging method. A multidisciplinary approach is paramount for optimal outcomes. Clinical manifestations include palpable mass, pain, or nipple discharge. While most lesions are benign, consideration of pregnancy-associated breast is crucial concerning prognosis impact.Radiological evaluation is pivotal in characterizing breast pathologies in these states. Ultrasound is the first-line choice for its safety and real-time evaluation. Mammography remains a complementary tool, especially in lactation and malignancy. MRI is reserved for clear risk-benefit ratio situations and local-regional staging in lactating women. Core biopsy is necessary for new/growing masses.Frequent findings include engorgement, lactational changes, benign lesions (fibroadenomas, galactoceles), and, rarely, breast cancer. Overlapping features and hormonal influences complicate interpretation. Timely diagnosis is crucial to guide subsequent management, balancing safety with diagnostic accuracy.This poster provides a pictorial review of illustrative cases from our institution encompassing benign, inflammatory, and malignant conditions underlying the hallmark findings that lead to accurate diagnosis.

William J. Hoover, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Kuehne, MD (*Abstract Co-Author*) Nothing to Disclose
Caroline Merriam, DO (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- The breast skin is comprised of three distinct layers - epidermis, dermis, and hypodermis.
- Each layer harbors unique anatomic components, which may give rise to benign and malignant abnormalities.
- Breast skin lesions may pose a diagnostic challenge when detected incidentally on breast imaging.
- Several hallmark features, such as a sonographic “claw sign” or “dermal tail”, can localize and narrow the differential diagnoses for a breast skin lesion.
- This exhibit will discuss normal breast skin anatomy, and will illustrate the expected appearance of dermal layers on ultrasound, mammogram, and breast MRI.
- The presentation will include a case-based review of benign and malignant breast skin abnormalities.
- For each skin abnormality, we will describe the typical clinical presentation, multimodality imaging features, malignant potential, and appropriate next steps of management.

### TABLE OF CONTENTS/OUTLINE

- Review of normal breast skin anatomy.
- Expected appearance of dermal layers on ultrasound, mammogram, and breast MRI.
- Key imaging features indicating dermal origin of a breast lesion.
- Multimodality imaging review of breast skin abnormalities, which will be organized into the following categories:
- Inherited abnormalities
- Vascular lesions
- Dermal cystic lesions
- Abnormal skin thickening
- Infectious and inflammatory lesions
- Malignancy

## SHARPENING SKILLS, SHAPING FUTURES: NEXT-LEVEL BREAST BIOPSY TECHNIQUES FOR RESIDENTS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Fernanda Louise Sothe, MD (*Abstract Co-Author*) Nothing to Disclose
Lucy T. Sato, MD (*Abstract Co-Author*) Nothing to Disclose
Giselle G. Mello, PhD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Abstract Co-Author*) Nothing to Disclose
Marcela P. Viana, MD (*Abstract Co-Author*) Nothing to Disclose
Luciano F. Chala, MD (*Abstract Co-Author*) Nothing to Disclose
Tatiana C. Tucunduva, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Training Importance: Stress on training residents before they begin procedures.
- Percutaneous Biopsy Skills: Enable residents to perform core needle biopsy, fine needle aspiration, vacuum-assisted biopsy (ultrasound and stereotaxy-guided), and pre-surgical marking (ultrasound, mammography, stereotaxy-guided).
- Preparation Areas:
- Conducting focused pre-procedure anamnesis.
- Informing patients about procedure steps and risks.
- Executing procedures with correct technique.
- Handling in-procedure complications and queries.
- Managing post-procedure complications (e.g., hematomas, infections).

### TABLE OF CONTENTS/OUTLINE

- Precision in Detection: Crucial for invasive breast procedures, affecting diagnostics and treatment.
- Specialized Training: Key for resident safety and efficacy in breast procedures.
- Innovative Training Methods:
- Core biopsy with olives in chicken for nodules.
- Stereotactic biopsy with eggshells in mortadella for microcalcifications.
- FNA with water in gloves for cysts.
- Ultrasound biopsy with quail eggs for solid-cystic lesions.
- Pre-surgical marking with chicken and metallic clips.
- Training Structure: Merges theory and practice over a month with weekly skill sessions.
- Training Objectives: Prepare residents for real scenarios, focusing on technical skills and decision-making.
- Professional Development Impact: Enhances skills, precision, and efficiency, transitioning novices to experts.
- Patient Safety Contribution: Simulations reduce learning risks, lower complications, and improve outcomes.

Isabela Ferreira (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Defined as a distortion of the usual architecture of the breast parenchyma without visible nodules, architectural distortion (AD) is the third most commonly observed abnormality in cases of false-negative mammography and the third most common finding in nonpalpable breast cancer; - The AD can be an associated finding with other alterations and involves benign causes such as complex sclerosing lesion, radial scar, fat necrosis, post-surgical changes, and others; - Digital breast tomosynthesis (DBT) has played a relevant role in detecting AD, especially in dense breasts, by reducing overlapping tissue, allowing for better visualization of true lesions. However, literature studies demonstrate that AD found in DBT have a lower chance of representing malignancy and the AD is less likely to represent malignancy if there is no ultrasound correlation. Though, even in these cases, biopsy is still necessary since there is a risk of about 30% malignancy.

### TABLE OF CONTENTS/OUTLINE

- To explore the imaging patterns of AD across various imaging modalities using cases from our institution and correlate them with histopathological findings; - To discuss the significant role of DBT in cases of AD; To discuss the malignant and benign causes of AD and their management.

## CURRENT INSIGHTS INTO COMMON GENETIC MUTATIONS IN BREAST CANCER: A COMPREHENSIVE REVIEW OF GUIDELINES AND IMAGING FINDINGS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Su Kim Hsieh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Aiah Alatoum, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Genetic mutations increase the risk of developing breast cancer. Mutations in genes BRCA1, BRCA2, TP53, PTEN, CDH1, STK11, ATM, CHEK2, and PALB2 are being considered to change recommendations for screening and management.
- Genetic panels are evolving, and the Institutional guidelines frequently update their recommendations.
- Some genetic mutations are more associated with specific biomarkers, for instance, BRCA 1 and 2 mutation carriers have a higher prevalence of triple negative cancers.
- Identifying a genetic mutation in a patient can impact their family members, and they should be tested.
- The knowledge of a particular genetic mutation can lead to a more extensive surgical treatment like mastectomy and contralateral prophylactic mastectomy or expand treatment options, like the use of poly (ADP-ribose) polymerase (PARP) inhibitor therapy for early-stage HER-2 negative cancer or metastatic disease.

### TABLE OF CONTENTS/OUTLINE

1. Definition of somatic and germline mutations. 2. Definition of a wild gene and low and moderate-risk genes. 3. Definition of the possible genetic testing results. 4. Review the main genetic mutations that increase the risk of breast cancer. 5. Review of current indications for genetic testing. 6. Review of recommendations for patients with positive genetic testing regarding screening, treatment management, and prophylaxis. 7. Review of characteristics of breast cancer and lesions with potential for upgrade in patients with genetic mutation. 8. Illustrative cases of patients with genetic mutations and breast cancer or lesions with potential for an upgrade from our Institution.

## NON MASS LESIONS (NMLS) ON BREAST ULTRASOUND - THE GOOD, THE BAD AND THE UGLY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Alexandra Pop, MD (*Abstract Co-Author*) Nothing to Disclose
Roxana Pintican, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The incidence of non-mass lesions (NMLs) in breast US has been reported to range from 1% to 5.3%, with malignancy accounting for 6.3% to 53.8%, underscoring the importance of their accurate identification and diagnosis. GOALS:1. Describe the NML terminology on US2. Present typical benign (The GOOD) and malignant (The BAD) NML cases together with their pathology correlates: a. The GOOD - fibro-cystic changes, fibrosis, adenosis, ductal epithelial hyperplasia (typical and atypical), plasma cell mastitis, idiopathic granulomatous mastitis b. The BAD - DCIS with/without invasive component, IDC, invasive lobular carcinoma, solid papillary carcinoma, adenoid cystic carcinoma3. Discuss challenging cases (The UGLY) where NMLs may obscure or mimic benign/malignant features, leading to diagnostic uncertainty or misinterpretation; emphasize the added role of mammography and breast MR4. Provide a brief literature overview of different scoring and malignancy predicting systems a. The GOOD - presence of small cysts, absence of microcalcifications b. The BAD - linear-segmental distribution (50-76.6% associated with malignancy, mainly DCIS), associated microcalcifications (OR = 11.7), architectural distortion (OR 3.14), hypervascularity (Adler 3), stiffness (elasticity score 4 or 5, OR = 5.84).

### TABLE OF CONTENTS/OUTLINE

1. Overview of NML definitions 2. The GOOD - benign NML 3. The BAD - malignant NML 4. The UGLY - masking/pitfalls NML 5. Scoring and malignancy prediction NML systems

### TEACHING POINTS

Artificial intelligence (AI) algorithms have reinvigorated interest in its utility in radiology. Breast imaging is uniquely poised to both evaluate the utility of assistive AI and advance the integration of AI into real world clinical practice. Since AI is a diverse field, it has the potential to impact both non-interpretive and interpretive applications extending beyond breast cancer detection. This exhibit reviews current and potential real world clinical applications of AI in breast imaging before, during, and after the acquisition of imaging examinations.

### TABLE OF CONTENTS/OUTLINE

1. Artificial Intelligence Definitions 2. Historical challenges (a. Medicolegal/liability, b. Quality assurance, c. Racial biases, d. Variability in image sizes/quality, e. Multimodality imaging) 3. Unique features of breast imaging for AI applications (a. Standardized technique for screening mammography, b. BI-RADS lexicon and structured reporting, c. Mandated accreditation systems, d. Large repository of images, reports, and outcomes, e. Implications for individual and population health) 4. Non-interpretive AI for breast imaging (a. Patient scheduling and outreach, b. Patient education and communication, c. Cancer risk assessment, d. Workflow triage, e. Image enhancement, f. Image quality assessment) 5. Interpretive AI for breast imaging (a. Lesion detection, b. Decision support, c. Breast density assessment, d. Response to neoadjuvant therapy) 6. Anticipated barriers for integration (a. Payment models for individual and population health, b. Accessibility in low resource settings, c. Interpretation of audit metrics, d. Impact on training/assessments of physicians, residents, and fellows)

## ACE THE BREAST IMAGING TUMOR BOARD: A MULTIDISCIPLINARY APPROACH TO BREAST CANCER

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Charisma DeSai, MD (*Abstract Co-Author*) Nothing to Disclose
Kiran N. Chang, MD (*Abstract Co-Author*) Nothing to Disclose
Claudia Cotes, MD (*Abstract Co-Author*) Nothing to Disclose
Vidhyulatha Sanata, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Radiology, pathology, and surgical/oncological treatment discussions are common practices in the management of breast cancer patients. Trainees, including residents and fellows, often participate in such discussions. In the era of personalized cancer treatment, it is crucial to understand not only the imaging findings of breast malignancies, but to correlate imaging and pathological characteristics to define molecular subtypes and guide oncological and surgical treatment strategies. This exhibit simplifies receptor definitions, breast cancer molecular subtypes and radiology-pathology correlation. Through representative radiological tumor board cases, we highlight patient treatments and outcomes. The goal is to prepare trainees and early radiologists with the necessary knowledge to provide valuable contributions to patient care and ace the breast imaging tumor board!

### TABLE OF CONTENTS/OUTLINE

Receptor definitions: ER, PR, HER 2, Ki67 Breast Cancer Molecular Subgroups: Luminal A, Luminal B, HER 2 Positive, Basal-Like Imaging features of the different molecular subtypes on mammography, ultrasound, and MRI. Cancer treatment: Surgical and oncological treatment based on receptor status with review of patient’s expected outcomes.

Danielle Teles Leal (*Abstract Co-Author*) Nothing to Disclose
Carla C. Tajima (*Abstract Co-Author*) Nothing to Disclose
Isabela Ferreira (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The primary utility of breast magnetic resonance imaging (MRI) is in screening of high-risk patients, detecting breast lesions, staging breast cancer, and assessing neoadjuvant treatment and breast implants. Although the examination primarily focuses on the breasts, it also allows visualization of surrounding structures. Between 17% to 34% of cases reveal at least one extramammary incidental finding, with around 20% of these findings being malignant and 14% to 20% clinically relevant benign conditions. The liver is the most common site of reported incidental findings (52-60%), followed by the lung and pleural cavity, with the gastrointestinal tract being the least common on Breast MRI. Breast MRI is primarily utilized for breast cancer staging and high-risk screening, findings in these extramammary structures hold significant importance, often influencing diagnostic investigation and subsequent follow-up.

### TABLE OF CONTENTS/OUTLINE

To investigate the imaging of numerous extramammary findings using cases from our institution and correlate them with personal history. To examine the significance of describing these findings on breast MRI. To assess the prevalence of extramammary malignant lesions detected in the images and their subsequent therapeutic management. To give hints and tips for general radiologists of how they can remember to evaluate these structures on breast exams.

### TEACHING POINTS

This educational exhibit aims to establish a framework for radiologists to identify imaging characteristics of vascular breast conditions, including those of arterial, venous, and lymphatic origins, and associated management recommendations. Although most vascular breast conditions are benign, it is important to recognize imaging findings that necessitate a biopsy to evaluate for possible underlying malignancy. It also may be helpful to communicate benign vascular conditions to the clinician as intervention for symptomatic relief or treatment of underlying systemic conditions may be indicated.

### TABLE OF CONTENTS/OUTLINE

1. Review of Vascular Anatomy of the Breast 2. Overview of Techniques to Evaluate Vascularity in the Breast 3. Benign Vascular Conditions of the Breast (including systemic conditions) a. Atherosclerosis b. Congestive Heart Failure c. Unilateral breast edema secondary to central venous obstruction 4. Benign Vascular Lesions of the Breast a. Pseudoaneurysm b. Superficial thrombophlebitis (Mondor Disease) c. Lymphatic malformation d. Venous malformation e. Hemangioma and variants of hemangiomas (e.g., infantile hemangioma) 5. Role of Radiologic-Pathologic Correlation in Management of Certain Vascular Variants (e.g., anastomosing hemangioma) 6. Malignant Vascular Conditions of the Breast and Sequelae of Breast Malignancy a. Angiosarcoma b. Solitary Fibrous Tumor c. Portal Vein Tumor Thrombus

Mehrvaan Kaur, MBBS (*Abstract Co-Author*) Nothing to Disclose
Alexander Satei, MBBS (*Abstract Co-Author*) Nothing to Disclose
Tima Tawil, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The purpose of this exhibit is to learn about the normal development of the female breast, including in-utero, prepubertal, and pubertal stages. Understanding normal sonographic findings of the different Tanner stages of breast development can help radiologists recognize underlying abnormal breast disorders. Discussion of breast disorders in the pediatric and adolescent population will focus primarily on sonographic findings with review of etiology, pathology, follow up imaging/management if applicable, and more. Covered breast disorders will include, for example, juvenile fibroadenoma, gynecomastia, asymmetric breast buds, non-puerperal abscess, subcutaneous cyst, and others. Understanding benign and self-limiting breast disorders will help radiologists recognize suspicious sonographic findings warranting further investigation and/or management.

### TABLE OF CONTENTS/OUTLINE

Normal breast development at birth and during puberty. Tanner stages of normal breast development. Normal sonographic findings of Tanner stages. Case-based discussion of variant developmental processes including: Premature thelarche, asymmetric breast bud development, gynecomastia. Case-based discussion of miscellaneous lesions including abscess, furuncle, lymph node, and subcutaneous cyst. Case-based discussion of benign neoplastic lesions including fibroadenoma/juvenile fibroadenoma, pseudoangiomatous stromal hyperplasia of the breast, and juvenile papillomatosis. Suspicious sonographic features prompting further imaging evaluation.

## MRI'S ROLE IN THE PUZZLE OF PAPILLARY BREAST LESIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Paula C. Moraes, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Abstract Co-Author*) Nothing to Disclose
Heni D. Skaf, MD (*Abstract Co-Author*) Nothing to Disclose
Vivian S. Ogata, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia Orthmann, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The purpose of this exhibit is:1. To highlight the significance of papillary breast lesions and their varied diagnostic considerations.2. To delineate the characteristics of papillary breast neoplasms as depicted by magnetic resonance imaging (MRI) and establish correlations across different modalities such as ultrasound (US), mammography (MG), and tomosynthesis (TS).3. To underscore the pivotal role of MRI in the management of papillary neoplasms and explore its potential in guiding appropriate treatment strategies. 4. To explore MRI protocols tailored for evaluating breast papillary lesions. To exemplify, through clinical cases, how MRI can augment daily practice in assessing papillary lesions.

### TABLE OF CONTENTS/OUTLINE

The presentation will follow the following structure: - Reviewing Breast Papillary Lesions and Their Differential Diagnosis; - Illustrating Papillary Lesions Cases on MRI with Correlations to Mammography, Ultrasound, and Pathology; - Demonstrating the Role of MRI in the Management of Papillary Lesions; - Evaluating the Optimal Timing and Method for Biopsy Procedures; - Summary and conclusion.

### TEACHING POINTS

Pediatric breast complaints are relatively common in the general and pediatric radiologist's routine. Although breast pathology in this population is mostly benign, ruling out malignant neoplasms and pointing out differential diagnosis to guide management is crucial. Ultrasonography is the main tool to evaluate pediatric breast changes. The aim of this exhibit is: 1. To describe the sonographic technique in the assessment of pediatric breast pathology, highlighting tips and for an adequate evaluation in the pediatric scenario; 2. To review clinical and radiological features of common and unusual breast pathology in children.

### TABLE OF CONTENTS/OUTLINE

1) Brief review of breast development and physiology; 2) Ultrasonography of the pediatric breast: exam technique, value of B-Mode and Doppler, imaging acquisition/documentation; 3) Practical tips to ensure child's collaboration; 4) Breast pathology in the pediatric population: epidemiology, brief clinical aspects regarding presentation, outcome and follow up; 5) Radiological features of usual and rare pediatric breast findings: a) Developmental Disorders (neonatal breast hypertrophy; gynecomastia); b) Infection (abscess); c) Benign masses (fibrocystic changes; juvenile fibroadenoma; venolymphatic malformation; hamartoma; lipoma; steatonecrosis; pseudoangiomatous stromal hyperplasia); d) Malignant masses (primary carcinoma); 6) When biopsy should be performed: clinical and radiological findings that elicit referral.

Mariah C. Wanderley (*Abstract Co-Author*) Nothing to Disclose
Leticia Cavalcante (*Abstract Co-Author*) Nothing to Disclose
Soraia Damiao, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Contrast-enhanced breast imaging methods can improve locoregional staging compared to conventional non-enhanced breast imaging (mammography, DBT, and ultrasound).• Breast MRI with dynamic contrast enhancement (DCE) is the most accurate method to assess breast cancer extent through measurement of tumor size, detection of intraductal components and additional lesions, as well as signs of invasion of the nipple, skin, and chest wall.• Contrast-enhanced mammography (CEM) has emerged as an alternative for locoregional staging, with similar accuracy to breast MRI to assess tumor size and additional lesions. However, CEM is not widely available yet, and it has limited value in some cases, such as in patients with implants and peripherally or posteriorly located tumors.• Contrast-enhanced multidetector computed tomography (MDCT) with contrast enhancement is used for distant staging in advanced breast cancer patients. Studies show it can also assess breast lesions when performed in a prone position with a dedicated breast evaluation protocol, without additional radiation or contrast doses. MDCT is a viable alternative to MRI and contrast-enhanced mammography, particularly in low- to middle-income regions.

### TABLE OF CONTENTS/OUTLINE

Overview of contrast-enhanced breast imaging methods (MRI, CEM, and MDCT) and its role in breast cancer management.Examples of breast cancer locoregional staging using MRI, CEM, and MDCT for tumor size assessment and detection of intraductal components, additional lesions, and invasion of the nipple, skin, and chest wall.Suggested decision-making workflow for selecting the appropriate imaging technique based on clinical needs, imaging availability, and cost-effectiveness.

Victoria Pacheco, MD (*Abstract Co-Author*) Nothing to Disclose
Laura B. De Melo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To distinguish the most common multimodality imaging features between breast metastases from extramammary cancer and primary breast malignancies.2. To understand the relevance of integrating multiple imaging techniques alongside the clinical context to discern between primary and secondary breast lesions, establishing an accurate diagnosis, staging, and treatment plan.

### TABLE OF CONTENTS/OUTLINE

BREAST METASTASES FROM EXTRAMAMMARY CANCERS1. Location: Typically peripheral and superficial, notably in the upper outer quadrant.2. Imaging Features: Exhibits variability, often appearing as round or oval masses with well-defined margins; presentation varies based on the primary tumor3. Clinical Context: Typically associated with a known metastatic cancerPRIMARY BREAST CARCINOMAS1. Locations: Varied, with a higher prevalence in the central breast (fibroglandular tissue area)2. Imaging Features: Spiculated margins, calcifications, posterior acoustic shadowing, and axillary lymph node involvement are suggestive features of primary breast cancer3. Clinical Context: More prevalent than metastases, even in patients with documented extramammary neoplasms.

Aurela I. Clark, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaoqin J. Wang, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hannah Conley, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Review current literature for guidance in the evaluation and management of breast size changes. Illustrate the imaging features of both malignant and non-malignant causes of breast shrinkage and enlargement. Elucidate clinical context that aids in distinguishing malignant from benign causes of breast size fluctuations. Highlight teaching points for each case to bolster confidence in making a timely diagnosis.

### TABLE OF CONTENTS/OUTLINE

Not infrequently, women visit breast clinics with concerns of breast size changes. Radiologists play a pivotal role in combining clinical findings and imaging features to guide appropriate management. We will stress the importance of a thorough clinical history and physical exam and provide evidence-based guidance of management for radiologists encountering patients with this concern. Notably, the "shrinking breast" in invasive lobular carcinoma (ILC) which comprises 10-15% of breast cancer will be highlighted. Imaging features of ILC are often occult and a high level of suspicion must be maintained when clinical complaints are present. Conversely, swollen breasts raise concern for inflammatory breast cancer (IBC) which presents with the characteristic imaging findings of diffuse skin thickening ("peau d'orange"). When available, imaging findings will be correlated to histopathologic diagnosis. Numerous benign conditions can also influence breast size changes and will be contrasted with malignant causes. We will educate learners on the telltale benign versus malignant imaging features and provide a summary of teaching points.

Rafael R. Santos Ferreira, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Pseudoangiomatous stromal hyperplasia (PASH) is a benign stromal proliferation that mimics a vascular lesion histologically. It affects individuals of varying ages, including men, with women in reproductive age and elderly women on estrogen replacement therapy being the most affected group. Clinically, PASH may present as a mass or thickening upon physical examination, with incidental histological findings being the most common presentation. While a hormonal etiology is considered, the pathophysiology is not fully understood. On mammography, PASH typically appears as focal asymmetry, while on ultrasound it presents as a solid, well-defined, non-calcified mass. PASH has a varied appearance on MRI but most commonly manifests as a region of non-mass enhancement with persistent kinetic features.

### TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Classical PASH images on US and MG. 3. Diferent forms of PASH presentantion on US. 4. PASH being a diferential diagnosis from invasive breast carcinoma. 5. PASH associated with gigantomastia on a teenager.

### TEACHING POINTS

1. The exhibit focuses on enhancing the interpreting radiologist's ability for evaluating complex solid and cystic breast lesions using different modalities including ultrasound, computed tomography, and magnetic resonance imaging.2. It will enlist various examples of benign and malignant complex solid and cystic breast lesions visualized on different imaging modalities.3. The exhibit will provide insights into key differentiating imaging features of benign versus malignant complex and cystic breast lesions using several case examples and illustrations to help radiologists build an appropriate understanding of reassuring versus worrisome imaging findings.4. It will help the interpreting radiologist build optimal use of BIRADS nomenclature to help efficiently report complex solid and cystic breast lesions and ultimately guide efficient clinical management.

### TABLE OF CONTENTS/OUTLINE

1. Introduction to use of different imaging modalities for assessment of solid and cystic lesions of the breast.2. Enlisting salient imaging features, illustrations and case examples of benign complex solid and cystic lesions of the breast using different imaging modalities. 3. Enlisting salient imaging features, illustrations and case examples of malignant complex solid and cystic lesions of the breast using different imaging modalities. 4. Comparison and contrast of various imaging features to help differentiate benign from malignant cystic and solid lesions including reassuring vs worrisome findings.5. Optimal use of BIRADS nomenclature to help efficiently report complex solid and cystic breast lesions and guide clinical management.

## HEAR YE, HEAR YE: HOW TO BE AN EFFECTIVE ADVOCATE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Amy K. Patel, MD (*Abstract Co-Author*) Medical Advisor, Kheiron Medical Technologies Ltd;Consultant, Hologic, Inc
Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*) Royalties, Wolters Kluwer nv
Stamatia V. Destounis, MD (*Abstract Co-Author*) Medical Advisory Board, iCad, Inc
Ann L. Brown, MD (*Abstract Co-Author*) Consultant, Elucent Medical
Fatima Elahi, DO, MS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

In breast imaging, ensuring equitable access to cancer screening is critical to improving health outcomes for all women, especially those from vulnerable groups. Ensuring appropriate reimbursement for existing and emerging imaging techniques is also important. Therefore, it is essential that all breast radiologists possess the skills to be effective advocates for our subspecialty and patients.

### TABLE OF CONTENTS/OUTLINE

In this exhibit, we will provide a step-by-step guide covering the essential skills to become an effective advocate. The topics that will be covered include: personal and practice branding, social media use, public speaking tips, developing an elevator speech, coalition building, lobbying tactics, impactful written communication including drafting resolutions and legislative bills and creating fact sheets, story telling, and leadership skills.

## THE MULTIPLE FACES OF BREAST VASCULAR PATHOLOGY; TUMORS AND BEYOND

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Maria Guerrero Martin (*Abstract Co-Author*) Nothing to Disclose
Nancy Sanchez Rubio, MD (*Abstract Co-Author*) Nothing to Disclose
Myriam F. Montes, MD (*Abstract Co-Author*) Nothing to Disclose
Manuel Lopez Herrero, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

There is a great variety of breast vascular diseases, with abnormalities that affect both arteries and veins, as well as benign and malignant tumors. These lesions are unusual, unknown and may appear on imaging in different ways; therefore, several techniques are frequently required to approach the diagnosis (even histologic study if there is a mass). For these reasons, the objectives of this presentation are to know the anatomy of breast vasculature and to identify its main disorders, with their typical and multimodal imaging features. Particular attention is focused on tumors, with radio-pathologic correlation; this aspect is especially important for breast imagers, because they need to ensure the concordance after biopsy. Thus, the radiologist will be able to reach an accurate diagnosis, and the patient will get a correct treatment or follow-up plan.

### TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Normal breast vasculature. 3. Vascular disorders of the breast: atherosclerosis, congestive heart failure, superficial thrombophlebitis, breast varyx and other entities. 4. Vascular tumors of the breast 4.1. Benign proliferations: hemangioma (cavernous and others), angiolipoma and papillary endothelial hyperplasia (Masson’s tumor). 4.2. Malignant proliferations: angiosarcoma (primary and secondary). 5. Differential diagnosis of vascular tumors of the breast (pathologic mimics): pseudoangiomatous stromal hyperplasia, myofibroblastoma, Phyllodes tumor and metaplastic carcinoma. 6. Conclusions.

## RADIOLOGIC-DERMATOLOGIC ATLAS OF SKIN PATHOLOGIES FOR THE BREAST RADIOLOGIST

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Cum Laude**

Derek L. Nguyen, MD (*Abstract Co-Author*) Nothing to Disclose
Dorothy A. Lowell, MD (*Abstract Co-Author*) Nothing to Disclose
Shelby Breit, BS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Skin changes of the breast such as rashes, erythema, or raised cutaneous lesions frequently present as a diagnostic challenge for breast imaging radiologists. These patients often present with either no relevant imaging findings or imaging findings which are nonspecific. Currently, there are limited resources available that serve as a clinical reference atlas for breast radiologists concerning skin pathologies associated with the breast. It is imperative for breast radiologists to assess the patient's clinical history in conjunction with any cutaneous changes and imaging findings, in order to determine whether a skin punch biopsy is warranted. The purpose of this educational exhibit is to provide a detailed review of common benign and malignant cutaneous conditions of the breast, enhanced with dermatologic and radiologic images, to serve as a comprehensive reference for breast imaging radiologists.

### TABLE OF CONTENTS/OUTLINE

1. Review the normal anatomy of the skin of the breast as well as the normal mammographic, ultrasound and MRI appearance. 2. Review common benign dermatologic conditions of the skin of the breast with clinical photos and multimodality imaging correlates including epidermal inclusion/sebaceous cysts, folliculitis, candidiasis infections, herpes zoster, mastitis, edema, keloids, neurofibromas, and granular cell tumors.3. Review malignant cutaneous manifestations of the breast with clinical photos and multimodality imaging correlates including inflammatory breast cancer, local recurrence, angiosarcoma, Paget’s disease, and melanoma.

## BI-RADS 3 IN BREAST MRI INTERPRETATION: APPROPRIATE AND INAPPROPRIATE USE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Laura Heacock, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Alana A. Lewin, MD (*Abstract Co-Author*) Nothing to Disclose
Beatriu Reig, MD, MPH (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Criteria for use of BI-RADS 3 in MRI are less well-established than for MG and US. 2. Oval T2 hyperintense mass with circumscribed margins and homogeneous internal enhancement or dark internal septations on baseline MRI may be given BI-RADS 3. 3. Masses lacking T2 hyperintensity, with suspicious morphologic or kinetic characteristics, new or enlarging findings, and most nonmass enhancements should not be given BI-RADS 3.

### TABLE OF CONTENTS/OUTLINE

1. Introduction a. Criteria for use of BI-RADS 3 in MRI have not been well-established b. Frequency of use of BI-RADS 3 c. Cancer yield i. Population undergoing MRI screening is different than population undergoing mammography or ultrasound 2. Indications for BI-RADS 3 a. Mass on baseline MR with benign morphologic and kinetic features b. Unique focus i. Exercise caution if new or enlarging ii. Balance of sensitivity with specificity and PPV. Some foci will represent small cancers, which will be identified on subsequent exam. c. Regional NME on baseline 3. Inappropriate use a. BPE should be BI-RADS 2 b. NME - new, asymmetric, or suspicious distributions should be BI-RADS 4 c. Patients beginning breast cancer treatment 4. Follow up interval a. 5th edition of BI-RADS Atlas recommends 6 mo f/u b. Evidence 12 mo f/u may be appropriate c. Evidence for 6 mo f/u after benign concordant biopsy 5. Future directions a. Expected changes with the next BI-RADS atlas i. Goal: </= 5% of examinations given BI-RADS 3 ii. Indications iii. Focus no longer part of the lexicon b. Improving specificity using DWI, AI c. Impact of abbreviated MRI i. Do patients on a yearly MRI schedule need six month follow up of BI-RADS 3 lesions? ii. Lack of T2 d. Using personalized risk assessment to refine BI-RADS assessments

## BREAST CANCER SUBTYPES BASED ON MAMMOGRAMS: APPROACH FOR NEW RADIOMICS FEATURES USING VISION TRANSFORMER

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Hideaki Tamori (*Abstract Co-Author*) Nothing to Disclose
Akifumi Yoshida, MSc, RT (*Abstract Co-Author*) Konica Minolta, Inc
Satoshi Kasai, PhD (*Abstract Co-Author*) Konica Minolta, Inc;TOITU Co, Ltd;Marubeni Corporation
Chiharu Kai (*Presenter*) Former Employee, Konica Minolta, Inc

### TEACHING POINTS

We will present our research that have applied new Radiomics features to classifying subtypes of breast cancers on mammograms. The purpose of this exhibit is to: - Understand an overview of Radiomics research and the diversified Radiomics features, - Recognize Radiomics features using Vision Transformer (ViT), - Learn about a new model for calculating Radiomics features combining ViT, Convolutional Neural Network (CNN) and Principal Component Analysis (PCA), - Review mammograms with cancers, and how related to the new Radiomics features with breast subtype classification.

### TABLE OF CONTENTS/OUTLINE

1) Common Radiomics research, 2) Types of Radiomics features, 3) Radiomics features with ViT, 4) The new model for calculating Radiomics features combining ViT, CNN, and PCA •ViT (global features): identifying relationships between distant regions •CNN (Local features): identifying relationships between close regions •PCA (Super-global features): identifying the image features of an entire image, 5) The advantage of the combining new model, 6) Our research: classifying subtypes of breast cancers on mammograms •The results of the classification •The characteristics of the feature importance of the top five features •To review mammograms with cancers and the new Radiomic features : triple-negative, HER2, Luminal A, Luminal B breast cancers •Scatter plots for each feature importance, 7) Summary

Victoria A. Wells, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Contrast enhanced mammography (CEM), similar to MRI, is a functional imaging technique with a higher sensitivity for breast cancer detection than mammography or ultrasound. In 2011, the FDA approved CEM as an adjunct diagnostic tool, resulting in increased implementation of CEM in breast imaging practices. CEM can be utilized to evaluate breast symptoms or screen detected abnormalities, to assess extent of newly diagnosed breast cancer, response to neoadjuvant chemotherapy, and to interrogate for occult breast malignancy in the setting of metastatic axillary lymphadenopathy with unknown primary. It is an effective alternative to MRI for those with a contraindication or intolerance. More recently in 2022, the BIRADS lexicon for CEM was introduced to ensure consistency of reporting through standardized terminology. Therefore, it is important for breast imaging radiologists to be familiar with the technique and lexicon to ensure proper use and accurate reporting. Utilizing a case-based approach, this exhibit will demonstrate the utility of CEM in different clinical indications and provide examples of appropriate use of the BIRADS CEM lexicon.

### TABLE OF CONTENTS/OUTLINE

- Review CEM technique. - Present commonly encountered benign and malignant breast findings on CEM with appropriate BI-RADS descriptors - Discuss the diagnostic clinical indications for CEM using case-based examples. - For each case, highlight the imaging findings using the appropriate BIRADS lexicon.

Riddhi Borse, MBBS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. This exhibit will help the radiologist build a foundation in recognizing salient imaging features of breast implants and injectables, understanding their medical and surgical implications, and facilitate accurate reporting to best guide medical and surgical teams. 2. It will describe the imaging appearances of different types of breast implants and injectables, including normal post-operative findings and the range of short and long-term complications which can be seen. 3. Cases examples will also be used to highlight which imaging modality - ultrasound, CT, or MRI - would be best employed for optimal assessment of normal and critical findings.

### TABLE OF CONTENTS/OUTLINE

1. Imaging features of Saline implants:a. Appearance on Mammography vs ultrasound.b. Normal vs ruptured implants. 2. Imaging features of Silicone implants:a. Intracapsular vs Extracapsular rupture.b. Contractures, herniations, leaks and folds. 3. Imaging appearance of various cosmetic injectables:a. Fat injections.b. Silicone and other cosmetic injectables. 4. Infection and inflammation of breast implants: Salient imaging features. 5. Fluid collections associated with implants: Hematoma, Seroma, Abscess etc.

## BIRADS 3 UNVEILED: YOUR MULTIMODAL MAP TO SAFETY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Andrea Di Ninno, MD (*Abstract Co-Author*) Nothing to Disclose
Luciano F. Chala, MD (*Abstract Co-Author*) Nothing to Disclose
Giselle G. Mello, PhD (*Abstract Co-Author*) Nothing to Disclose
Tatiana C. Tucunduva, MD (*Abstract Co-Author*) Nothing to Disclose
Vinicius Nobre, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Zanetta, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Understanding BIRADS 3 Classification: Emphasize the definition, criteria, and significance of BIRADS 3 in breast imaging, highlighting its role as an indicator for probably benign findings with a recommendation for short-term follow-up.
- Decision-Making Process: Discuss the critical thinking process involved in categorizing a finding as BIRADS 3, including the evaluation of imaging characteristics and patient history.
- Management Strategies: Outline the recommended follow-up protocols for BIRADS 3 findings, such as the appropriate intervals for re-imaging and factors influencing the decision to advance to biopsy.
- Risk Assessment and Communication: Teach how to assess the risk associated with BIRADS 3 lesions and the next steps.

### TABLE OF CONTENTS/OUTLINE

- Introduction to BIRADS 3: Overview of the BIRADS system, focusing on the BIRADS 3 category, its purpose, and importance.
- Criteria for BIRADS 3 Classification: Examination of imaging features and patient history that justify a BIRADS 3 classification, with examples.
- Imaging Modalities and BIRADS 3: How different imaging modalities contribute to identifying and classifying BIRADS 3 findings.
- Follow-Up Protocols for BIRADS 3 Lesions: Guidelines for monitoring, including follow-up intervals and additional imaging tests.
- Biopsy Considerations for BIRADS 3 Findings: When a biopsy may be considered for a BIRADS 3 lesion, including patient-specific factors.
- Case Studies and Review of Literature: Analysis of case studies and literature review on the management of BIRADS 3 lesions.

## BEYOND THE SCAN: UNDERSTANDING THE JOURNEY OF YOUNG WOMEN WITH BREAST CANCER

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Amy K. Patel, MD (*Abstract Co-Author*) Medical Advisor, Kheiron Medical Technologies Ltd;Consultant, Hologic, Inc
Lakshmi Priya, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Breast cancer cases in young women are rising and are often more aggressive and present in later stages due to delay in screening. Risk factors include genetic mutations, smoking, alcohol use, OCPs, older age of first pregnancy, high BMI, sedentary lifestyles, and low socioeconomic status. All women should undergo a risk assessment by age 25 and if high risk adhere to the latest screening guidelines. Breast cancer in young women can present in various forms, and this exhibit will review the multimodality presentation of some common forms of breast cancer in young women. Multimodal treatment options are available with special consideration of treatment impact on breast conservation, fertility, and mental health in young women. Clinicians should recognize that mammography is safe during breast feeding and pregnancy to prevent delays in diagnosis.

### TABLE OF CONTENTS/OUTLINE

Background, epidemiology, and clinical presentation Risk factors and genetics High-risk screening guidelines Case based imaging review of breast cancer in young women Managment, treatment, and breast conserving techniques Psychosocial impact and effect on fertility Imaging guidelines during breast feeding and pregnancy

## A SPECTRUM OF BREAST SARCOMAS WITH RADIOLOGIC-PATHOLOGIC CORRELATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Katja Pinker-Domenig, MD, PhD (*Abstract Co-Author*) Speakers Bureau, European Society of Breast Imaging;Speakers Bureau, Siemens AG;Speakers Bureau, IDKD;Speakers Bureau, Canon Medical Systems Corporation;Consultant, F. Hoffmann-La Roche Ltd;Consultant, Merantix Healthcare;Consultant, AURA Health
Dilip Giri (*Abstract Co-Author*) Nothing to Disclose
Jorge L. Huayanay, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Primary breast sarcomas are a very rare and heterogeneous group of aggressive malignant neoplasms that arise from connective tissue. Sarcomas constitute less than 1% of all breast cancers and account for less than 5% of all soft tissue sarcomas. 2. This exhibit will review the spectrum of imaging and histopathology features of breast sarcomas. 3. This review will emphasize diagnostic difficulties, potential imaging pitfalls and differential diagnoses.

### TABLE OF CONTENTS/OUTLINE

The goals of this exhibit are to: Provide a pictorial review of the diverse imaging appearances of breast sarcomas. Discuss specific imaging and pathological characteristics of breast sarcomas. Familiarize the audience with the imaging features of breast sarcomas, thereby helping to provide a complete differential diagnosis. These major featured entities include: • Angiosarcoma • Leiomyosarcoma • Osteosarcoma • Rhabdomyosarcoma • Synovial sarcoma • Undifferentiated pleomorphic sarcoma • Malignant phyllodes tumors and metaplastic carcinomas that develop areas of sarcomatous differentiation.

## UNDERSTANDING UNIQUE BREAST CANCER RISK FACTORS AMONG WOMEN VETERANS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Lucy B. Spalluto, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Pooja Agrawal, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Guideline-based early and supplemental breast cancer screening for women at high risk for breast cancer is an evidence-based practice that improves morbidity and mortality through early detection and treatment. 2. Young women Veterans represent a unique population who may be at high risk for breast cancer due to additional risk factors beyond those of the general population. 3. Understanding the unique risk factors of young women Veterans diagnosed with breast cancer may offer an opportunity to reduce morbidity and mortality among women Veterans.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: a) Describe breast cancer morbidity and mortality statistics, including existing disparities, for women in the general U.S. population, b) Compare these statistics to those of women Veterans. 2. Breast cancer risk factors: a) Review breast cancer risk factors for the general population, b) Review unique breast cancer risk factors among women Veterans, such as chemicals (agent Orange, contaminated water), radiation (nuclear weapons), air pollutants (burn pit smoke), occupational hazards (asbestos, industrial solvents), warfare agents (chemical and biological weapons). 3. Case review: a) Present an example case (with supplemental imaging) of a young woman Veteran with breast cancer to showcase the patient’s diagnosis and outcome. 4. Conclusion: a) Understanding unique breast cancer risk factors among young women Veterans can facilitate strategies that can ultimately reduce breast cancer mortality in this population.

### TEACHING POINTS

Investigate the clinical and radiological characteristics of atypical fibroadenomas to enhance their diagnosis and clinical management.• Evaluate the diagnostic accuracy of different imaging modalities, such as mammography and ultrasound, in identifying atypical fibroadenomas.• Analyze the risk factors associated with the development of atypical fibroadenomas and their relationship with progression to malignancy.• Explore current therapeutic approaches and their impact on clinical outcomes in patients with atypical fibroadenomas.• Investigate the correlation between imaging findings and pathological characteristics of atypical fibroadenomas to improve diagnostic accuracy and clinical management. • Determine the effectiveness of a multidisciplinary approach including coordination among radiologists, pathologists, and surgeons.

### TABLE OF CONTENTS/OUTLINE

This study examines atypical fibroadenomas, an important variant of benign breast tumors, which present diagnostic and therapeutic challenges. Imaging modalities are reviewed, highlighting characteristics on mammography and ultrasound, as well as the importance of imaging-pathology correlation in accurate diagnosis. Additionally, therapeutic approaches, including observation, image-guided biopsy, and surgical excision, are discussed. The importance of a multidisciplinary approach to optimize management of patients with atypical fibroadenomas is emphasized. This abstract provides a comprehensive and updated insight into this clinical entity, offering relevant information for clinicians and radiologists involved in the diagnosis and treatment of atypical fibroadenomas. Presentation Type: Research Abstract.

### TEACHING POINTS

To teach ultrasound technique parameters to an adequate evaluation while avoiding common pitfalls;To describe normal appearance and the usual composition of breast implants on ultrasound;To show cases of complications related to breast implants on this method;To propose a checklist to evaluate implants and to diagnose complications;To provide tools and examples in order to write a structured report.

### TABLE OF CONTENTS/OUTLINE

A significant change in the 2022 Food and Drug Administration (FDA) guidelines affecting radiologists is the inclusion of ultrasound as an alternative to magnetic resonance imaging for initial imaging surveillance for implant ruptures in asymptomatic patients and it is essential for any radiologist interpreting these studies.Breast implants are frequently encountered in breast imaging studies. There are many variations in lumens, positioning, morphology and other components among implants. Ultrasonographic characterization serves as a powerful tool in identifying gross structural abnormalities, ruptures and other complications.This pictorial essay aims to delve into the normal and abnormal imaging appearances of breast implants on ultrasound, including illustrative cases of ruptures, fractures and complications.Moreover, we will propose a checklist for recognizing the type of implant and identifying potential abnormalities or complications. We will also present strategies for equipping radiologists with the tools necessary to compose a structured report. This comprehensive approach aims to improve the understanding and management of breast implants using ultrasound imaging.

## INVASIVE LOBULAR CARCINOMA: CATCH ME EARLY, IF YOU CAN!

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Patricia M. Gomes El Bacha, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana Couto De Mores, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Invasive lobular carcinoma (ILC) is the second most common type of breast cancer. It originates in the lobes of the glands, invades the surrounding tissues and often does not form a palpable nodule. The diagnosis of ILC is challenging, especially in MG and clinical examinations, and is often diagnosed by MRI or US. Understanding the radiological features of ILC is essential for accurate diagnosis. It is often clinically silent, resulting in late-stage diagnosis and more frequently manifests with distant metastatic disease. It tends to occur in older women with a maximum incidence in postmenopausal. The hormone replacement therapy increases the risk of ILC. The US is better than MG to detect non mass lesions and for evaluation of axillary nodes. Hypoechoic irregular mass is the most common ultrasonographic appearance, but non-mass lesions may occur on US and MRI less frequently. In histopathological evaluation, the pleomorphic pattern there is little or no desmoplastic reaction of the invaded tissue. In the macroscopy it often presents as irregular and poorly delimited tumors that can be difficult to define macroscopically due to the diffuse growth pattern of the cellular infiltrate.The objective of this exhibition is to present, through illustrative cases, a practical approach to the imaging and histopathological findings of ILC manifestations.

### TABLE OF CONTENTS/OUTLINE

Introduction. Histopathological and imaging aspects. A case-based review of original cases from the breast department of hospitals showing characteristics of manifestations and challenges in the diagnosis of ILC, through the perspective and purpose of a practical approach. Take-home messages. References.

### TEACHING POINTS

To discuss the basic breast anatomy and to define the three breast zones: premammary, mammary and retromammary;To present the anatomical landmarks and imaging clues to determine the origin of such lesions as mammary or not;To present the radiological aspects of various posterior breast lesions, pectoralis and chest wall lesions, illustrating these with multimodality imaging from our archives.To familiarize general radiologists with such findings in order to improve the diagnostic rate and avoid misinterpretation and pitfalls of such lesions, reducing false positive rates and unnecessary biopsies.

### TABLE OF CONTENTS/OUTLINE

The human breast’s basic anatomy can be categorized into three distinct zones: the premammary, mammary, and retromammary zones.Located posterior to the retromammary fat is the pectoralis muscle. It’s important to note that this is not considered an anatomical component of the chest wall, and therefore, it is not interpreted as such for staging and management purposes.However, these structures are contemplated in breast exams and should be well-known to radiologists.The task of differentiating primary lesions of the mammary parenchyma from those originating from the pectoral musculature and the thoracic wall can be challenging. Nevertheless, it is crucial for the effective management and diagnosis of such lesions.There exist certain anatomical parameters and defining image criteria that assist in determining the origin of these lesions and the extent of tumor involvement. These include the presence of enhancement or the angle between the lesions and the structures of interest. These factors play a significant role in the diagnosis and subsequent treatment of these conditions.

## UNMASKING THE MYSTERY: A DEEP DIVE INTO IDIOPATHIC GRANULOMATOUS MASTITIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Antonio Jose Cueva Guerrero, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Understand the typical presentation of IGM in women of childbearing age and its variable symptoms. • Recognize the diverse mammographic, ultrasound, and MRI findings associated with IGM, including masses, distortion, and skin thickening. • Distinguish IGM from breast cancer and other inflammatory breast lesions using key imaging features. • Emphasize the crucial role of core needle biopsy with pathological confirmation for definitive diagnosis of IGM. • Briefly discuss the treatment options for IGM, including medical management and surgical intervention.

### TABLE OF CONTENTS/OUTLINE

- Introduction- Anatomy - Pathogenesis - Clinical presentation - Differential diagnosis - Imaging methods- Management strategies - Conclusions

## CURRENT USES OF CONTRAST-ENHANCED MAMMOGRAPHY (CEM). A PICTORIAL REVIEW OF THE UTILITY OF CEM IN DIFFERENT SETTINGS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Carlos Oliva Fonte (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia Arman, MD (*Abstract Co-Author*) Nothing to Disclose
Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

-To review contrast-enhanced mammography (CEM) technique. -To analyze the different applications of contrast-enhanced mammography (CEM) including work-up of symptoms or equivocal findings, breast cancer detection and local staging, supplemental technique for screening, follow-up of breast cancer, monitoring neoadjuvant systemic therapy response. - To illustrate imaging findings of CEM with correlation with imaging (US, MRI) and pathology. - To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

### TABLE OF CONTENTS/OUTLINE

We review current applications and state-of-the-art of contrast-enhanced mammography highlighting the benefits and potential use in different settings. We present:
- Basics and technique of contrast enhanced mammography (CEM)
- Indications of CEM. CEM increases sensitivity and specificity of digital mammography.
- Imaging in different settings: -breast cancer diagnosis in symptomatic patients: palpable mass, nipple retraction, breast pain, or bloody nipple discharge; - problem solving for inconclusive findings; - recalls from screening: CEM helps in detection of multiple lesions and to safely reduce benign breast biopsies;- local staging and surgical planning: accurate size correlation with surgical specimen, US and MRI and detection of multifocal and bilateral disease similar to MRI with less false positives;- follow-up of breast conservation therapy;- neoadjuvant chemotherapy response evaluation, CEM shows similar sensitivity and PPV than MRI to detect residual lesion and detects pathological complete response better than MRI.
- Future directions. Screening in dense breast, high risk, intermediate risk.

Vinicius C. Felipe SR, PhD (*Abstract Co-Author*) Nothing to Disclose
Soraia Damiao, MD (*Abstract Co-Author*) Nothing to Disclose
Mariah C. Wanderley (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Demonstrate how the development of transducers with frequencies above 15MHz, initially aimed at dermatological ultrasound, has shown an important role in the evaluation of breast lesions;- Present the main applications of very high frequency transducers in the diagnosis, follow-up and image-guided biopsies of breast lesions;- Differentiate breast from skin lesions and offer a better definition for the analysis of ducts and subcutaneous tissue;- Describe the use of very high frequency transducers in guiding ultrasound biopsies through radiological correlation between imaging methods.

### TABLE OF CONTENTS/OUTLINE

Physical characteristics of linear transducers traditionally used for screening and diagnosing breast lesions and the very high frequency transducers;Ductal ectasias, intraductal masses and retroareolar lesions:utilizing very high-frequency transducers for detailed analysis;advantages of monitoring and biopsying these lesions using very high frequency transducers.Skin calcifications:detecting skin calcifications when mammographic findings are inconclusive.Ultrasound-guided biopsy of calcifications with the use of very high frequency transducers:cases of very superficial or retroareolar suspicious calcifications, whose location is a limiting factor for stereotaxis and traditional transducers do not guarantee adequate image definition;Identification of calcifications via ultrasound, placement of a metallic marker on the skin surface covering the calcifications, followed by tangential mammography to validate the correspondence between the calcifications visualized in mammography and ultrasound, enabling the biopsy procedure to proceed.Final considerations.

### TEACHING POINTS

1.Breast cancer management has transformed significantly over the last decades, specifically through the integration of neoadjuvant systemic therapy (NST) and the evolving understanding of tumor biology, enabling more tailored treatment strategies.2.Increasing adaptation of limited axillary surgery, such as sentinel lymph node biopsy and targeted axillary dissection raised questions on role of imaging for axillary nodal disease assessment.3.Advances in NST with up to 60-70% of patients achieving pathologic complete response for certain biological subtypes of breast cancer produced growing evidence on potential omission of surgery based on use of minimally invasive biopsy.4.Radiologists should be familiar with contemporary evidence and role of the imaging and image guided procedures for de-escalation of breast and axillary surgery in breast cancer patients.

### TABLE OF CONTENTS/OUTLINE

I. Introduction II. Axillary management • Clinically node negative breast cancer & 7; Role of imaging & 7; Overview of clinical trials • Clinically node positive breast cancer undergoing NST & 7; Role of imaging & 7; Overview of clinical trials III. Omission of breast surgery in exceptional responders to NST based on tumor biology • Proof of concept • Minimally invasive image guided biopsy• Overview of clinical trials IV. De-escalation of breast surgery in patients with DCIS • Role of imaging • Overview of clinical trials V. Future directions •Advancements in imaging and image guided procedures • Artificial Intelligence VI. Conclusion VII. References

### TEACHING POINTS

To describe the main histological types of tumors that have slow growth;To review the most recent literature on sensitivity, specificity and diagnostic accuracy regarding this matter;To evaluate of the false negatives cases retrospectively for a more comprehensive characterization of the diagnosis;To propose strategies to prevent diagnostic imaging errors in these types of cancer.

### TABLE OF CONTENTS/OUTLINE

Slow-growing breast tumors are mostly indolent and have lower mortality rates. However, they are responsible for a significant portion of false negatives in screening exams due to their slow growth. Additionally, difficulty of these lesions from potentially invasive ones can lead to imaging diagnostic errors and it is essential for any radiologist interpreting these studies.The main histological subtypes of slow-growing breast tumors include ductal carcinoma in situ, invasive non-specific luminal carcinoma, invasive tubular carcinoma and invasive lobular carcinoma. It stands out as the ductal carcinoma in situ (DCIS) that represents most common lesions that remain indolent.This review thoroughly explains the histological types of slow-growing breast cancer and shows information of the natural history, about mortality or survival rates.Furthermore, recent literature on the sensitivity, specificity, and diagnostic accuracy of slow-growing breast cancer will be discussed, accompanied by illustrative cases of false negatives to highlight diagnostic pitfalls.Strategies to prevent diagnostic imaging errors in these types of cancer are proposed to aid in clinical management.

### TEACHING POINTS

Tuberculosis (TB) mastitis is a rare extrapulmonary condition caused by Mycobacterium tuberculosis. It can affect the breast either primarily (through abrasions) or secondarily (via lymphatic backflow or contiguity with intrathoracic foci). It presents in varied clinical and radiological forms, often mimicking various other chronic granulomatous conditions, infectious and otherwise, and is frequently diagnosed late due to its nonspecific imaging characteristics.It is important to emphasize that although mammary tuberculosis is not the primary cause of chronic granulomatous mastitis, it remains epidemiologically relevant in tropical countries and has considerable clinical importance.In this context, this exhibition reviews clinical findings, main radiological findings and proposes a workflow for diagnosis and management, highlighting tips that may help the diagnosis.

### TABLE OF CONTENTS/OUTLINE

Review the epidemiology and the most clinical findings of Tuberculosis (TB) mastitis and their differential diagnosis.Explore the main radiological findings on ultrasound (US), mammography (MG), and magnetic resonance imaging (MRI) of Tuberculosis (TB) mastitis illustrating with different cases.Demonstrate the role of the appropriate investigation for TB mastitis and the workflow that may help an early diagnosis

Amna Aslam (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Contrast-enhanced mammography (CEM) is an emerging diagnostic and screening tool in breast imaging that uses iodinated contrast to visualize tumor vascularity. In CEM, a dual-energy mammogram is acquired 2 minutes after the IV injection of iodinated contrast. Low and high energy views offer excellent anatomic detail and breast perfusion. CEM has higher sensitivity for detecting breast cancer compared to digital mammography, tomosynthesis, and ultrasound combined. It has comparable sensitivity and specificity to breast MRI for cancer detection at lower cost and greater comfort for patients who are unable to undergo breast MRI (4,5,6). In this review, we will discuss our experience interpreting CEM and discuss common artifacts and pitfalls. CEM is new for many breast imagers. As it continues to grow in clinical practice, it is important that radiologists understand how CEM can be utilized, how to read and interpret these images, perform CEM biopsies when needed and tackle challenges faced with these cases.

### TABLE OF CONTENTS/OUTLINE

1. Introduction and Background 2. Indications a. Screening b. Diagnostic i. Symptomatic patients ii. Screen recall iii. Extent of disease 3. Imaging Protocol and Acquisition a. Artifacts 4. Reporting findings a. BPE b. BI-RADS c. Lesion description i. Benign ii. Malignant 5. Biopsy of CEM findings - early experience and challenges 6. Conclusion and References

### TEACHING POINTS

To demystify the mechanism of cellular injury due to cryoablation;To illustrate how cryoablation is performed in practice on breast lesions as well as the subsequent imaging repercussions with cases from our digital archive;To clarify the clinical scenarios where cryoablation is indicated and its limitations.

### TABLE OF CONTENTS/OUTLINE

Cryoablation involves the application of successive cycles of freezing and thawing of neoplastic tissue using cryoprobes inserted into the tumor under radiological guidance (typically ultrasound), promoting tissue destruction through rupture of cell membranes.The hallmark of cryoablation technique is the formation of an "ice sphere" in the tissue, ideally encompassing the tumor with a safety margin of at least 5 mm, easily identified by conventional imaging methods, resulting from tissue necrosis.The freezing mechanism occurs through the thermodynamic properties of argon or nitrogen gasses, which suffer significant heat loss during their expansion. Defrosting is achieved by helium gas, which allows the system to heat up.Its indications include benign breast lesions such as fibroadenomas and malignant tumors smaller than 2,5 cm, breast carcinomas of any histological subtype without distant metastases and with clinically negative axilla.To provide a comprehensive understanding of cryoablation, we have compiled a series of cases from our institution's digital archive. These cases illustrate the step-by-step technique of cryoablation, its imaging consequences, and the clinical rationale behind its use, as well as the method's inherent limitations.

## EXPANDING THE BRACKET: OPTIMIZING LOCALIZATION TECHNIQUES FOR MULTIFOCAL AND MULTICENTRIC DISEASE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Neha Khemani, MD (*Abstract Co-Author*) Nothing to Disclose
Amy Maduram, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

(1) Breast surgeries are progressively trending towards de-escalation of therapy such as breast conserving surgery (BCS), downstaging cancer after neoadjuvant therapy, and lower number of axillary nodes removed. Radiologists play an important role in planning localizations and interpreting specimen radiographs for BCS. (2) Although multifocal and multicentric disease is often thought as an exclusion criterion for BCS, it is possible to achieve comparable disease free and overall survival rates to mastectomy in select patients when negative margins are achieved. Therefore, it is increasingly important for radiologists to have the technical acumen to approach complex localizations utilizing 3-4 wires or covering multiple quadrants of the breast with confidence. (3) Feedback on surgical specimen radiographs play a vital partnership with surgeons in achieving negative final pathology margins and improving patient outcomes.

### TABLE OF CONTENTS/OUTLINE

(1) Overview of trends towards BCS and introduction to wire-guided localization. (2) Cases of multicentric and multifocal malignancy requiring 4 wire localization with technical pearls and pitfalls. (3) Cases of multi-wire lesion localization using tomosynthesis and complications requiring follow-up imaging. (4) Guidelines for optimal surgical margins of invasive cancer, DCIS, and pleomorphic LCIS. (5) Cases of actionable specimen radiographs requiring notification to the surgeon. (6) Review of pathologic description of margin assessment. (7) Self-assessment quiz.

### TEACHING POINTS

To explain the role of imaging in the detection of residual postoperative breast cancer for optimal therapeutic management;To discuss the possible causes of residual tumor after breast-conserving surgery or mastectomy;To explain the role of specimen mammogram and histological evaluation of surgical margins as a means to avoid residual cancer.

### TABLE OF CONTENTS/OUTLINE

The main goal of surgery in the treatment of breast cancer, whether breast-conserving surgery or mastectomy, is the removal of all malignant lesions. Nevertheless, postoperative residual breast cancer is a possible outcome after any surgery, regardless if surgical margins are positive or negative. In the setting of residual cancer, re-excision is the standard treatment.The main cause of residual cancer is underestimation of lesion size prior to surgery; preoperative breast MRI is the optimal imaging modality for local staging, determining tumor extent and multifocal disease. Other causes include inappropriate surgical choice, errors in preoperative lesion localization and incomplete axillary dissection of metastatic lymph nodes. Prevention of residual cancer can be achieved by performing specimen mammograms of mammography-visible lesions (calcifications, biopsy markers) and histological evaluation of surgical margins. In patients with positive surgical margins, imaging aids in determining extent of residual disease prior to re-excision. In patients with negative margins, residual cancer may be detected in subsequent screening exams.We have compiled a series of cases from our institution's digital archive to discuss possible causes of residual tumors and the role of imaging in reducing them.

Jessica A. Perdomo SR, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The purpose of this exhibit is to describe extramammary findings discovered on breast magnetic resonance images, including location, frequency and relevance. Review the imaging characteristics of the extramammary findings and the appropriate imaging modality when further evaluation is required. Identify suspicious features that may suggest malignancy among extramammary lesions. Learn a systematic assessment for active search of extramammary lesions. Recognize when additional imaging work-up or follow-up is necessary for further characterization of extramammary findings.

### TABLE OF CONTENTS/OUTLINE

We review the location and features of extramammary findings on breast magnetic resonance, presenting the most frequent locations of benign and malignant findings, including an approach for further imaging work-up and follow-up. Benign findings: liver cyst, pleural effusion, liver hemangiomas, sternum hemangiomas, lung atelectasis, post-radiation changes, mesenteric cyst, mediastinum cyst, epidermal inclusion cyst, accessory spleen, axillary lipoma, pulmonary nodules, cervical reactive lymph node, rib hemangiomas, lung consolidation, thyroid nodule. Malignant findings: muscle, bone, lymph nodes, pulmonary and liver metastases and malignant pleural effusion. A systematic approach when evaluating extramammary structures.

### TEACHING POINTS

• Describe the imaging appearances of normal and abnormal axillary nodes on CT in breast cancer patients, with focus on morphology and localization • Explain how the axillary node burden can be assessed with CT before and after NAC • Describe axillary CT findings in follow up breast cancer patients

### TABLE OF CONTENTS/OUTLINE

1. Describe the normal and abnormal appearances of axillary nodes on CT staging and its role in therapeutic management decisions for breast cancer patients. a. The Amonkar classification used in ultrasound has similar appearances on CT and categorizes nodes as: i. Normal: UN2, UN3 ii. Abnormal or suspicious: UN4 and UN5 b. The Berge levels aid in localizing nodes: i. Level 1: lower axilla, lateral to the minor pectoralis muscle ii. Level 2: middle axilla, behind the minor pectoralis muscle iii. Level 3: upper axilla, medial to the minor pectoralis muscle iv. Interpectoral region2. Describe axillary node burden and the importance of understanding diagnostic procedures (SNB, LA, TAD) for successful treatment: a. Pre-neoadjuvant chemotherapy: crucial for node counting and localization: i. Patients with <3 nodes in level 1: candidates for targeted axillary dissection (avoiding LA) ii. Patients with >3 nodes or nodes in level 2: candidates for lymphadenectomy (LA) b. Post-NAC evaluation should report: i. Good response - nodes return to normal size or >50% reduction ii. No response - no changes 3. Evaluate CT findings in follow-up breast cancer patients: a. Postsurgical changes from SNB or LA b. Surgical techniques and complications: extracapsular silicone in breast reconstruction, autologous reconstructions, or postsurgical seromas c. Axillary recurrence.

### TEACHING POINTS

• Review the differential diagnosis of benign and malignant masses in the axillary region. • Review the imaging modalities and key imaging features used in the assessment of axillary masses. • Highlight the importance of appropriate correlation of the patient's clinical presentation, pertinent clinical history, and imaging clues to distinguish these.• Review biopsy techniques and challenges.• Discuss the clinical management.

### TABLE OF CONTENTS/OUTLINE

I. IntroductionII. Algorithm on how to approach benign and malignant masses in the axillary region across different imaging modalities. III. Highlight the importance of correlation of the patient's clinical symptoms and their clinical history to establish the differential diagnosis. IV. Review of the different imaging techniques to biopsy axillary masses. V. Tips, pitfalls, and practical approaches will be emphasized through a case-based multi-modality approach. VI. Rad-path correlation of the axillary pathology.

## THE DIAGNOSTIC VALUE OF A NEW MAMMOGRAPHY TECHNIQUE IN BREAST DISEASES: CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY (CESM)

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Ruixue Cao (*Presenter*) Nothing to Disclose

### TEACHING POINTS

CESM greatly increased the positive detection rate for breast cancer.Various methods have been applied to the diagnosis of breast diseases alone or in combination in clinical application. This exhibition aims to demonstrate the value of CESM in breast disease diagnosis by conducting research surveys on previous studies.

### TABLE OF CONTENTS/OUTLINE

1) Introduction 2) CESM imaging principle : CESM based on dual-energy breast exposure after contrast administration, It reflects the blood flow dynamics of the lesion by utilizing the uptake of iodine contrast agent in the tumor tissue. 3) Technique and protocols: contrast dose of 1.5 mL/kg, factory-set kVp ranges for low- and high-energy acquisitions, beginning image acquisition after 2min from contrast agent injection and completing the examination within 8 min. 4) Diagnostic value: a. evaluation of symptomatic women b. screening recalls c. local staging d. pre-and post-operative evaluations e. neoadjuvant chemotherapy response monitoring f. guide biopsy for the lesion 5) Advantages and limitations of CESM

Beatriz E. Adrada, MD (*Abstract Co-Author*) Nothing to Disclose
Fernando Ahumada (*Abstract Co-Author*) Nothing to Disclose
Ana Beatriz Luengas (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Superficial lesions in the breast can be an incidental finding or can manifestas a palpable abnormality.Knowledge of the skin anatomy is crucial in the assessment of superficiallesions in breast.Breast ultrasound is the imaging of choice for characterization of superficiallesions in breast imaging. A meticulous technique is necessary to determinelesion localization.Establishing a differential diagnosis according to the localization of thesuperficial lesion is critical to avoid a cancer misdiagnosis.

### TABLE OF CONTENTS/OUTLINE

This educational electronic exhibit will review the anatomy of the skin,multimodality imaging findings and differential diagnosis of superficial and skinlesions in the breast. An overview of the US technique to evaluate superficial andskin lesions will be given.

## NEW STRATEGIES IN CANCER SURVEILLANCE AFTER BREAST CANCER TREATMENT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Lorena Melian Iribar, MD (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia Arman, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Teresa Montero Alameda (*Abstract Co-Author*) Nothing to Disclose
Itxaso Galan-Gonzalez (*Abstract Co-Author*) Nothing to Disclose
Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To review current strategies of surveillance of patients after breast cancer surgical treatment. 2. To discuss the specific management of those patients, including imaging and interventional procedures. 3. To illustrate imaging in different techniques including contrast-enhanced mammography, US, MRI, CT, and PET with pathologic correlation in cases of cancer recurrence and in different benign postoperative entities (fat necrosis, seroma, mastitis). 4. To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

### TABLE OF CONTENTS/OUTLINE

The different therapeutic options employed for breast disease cause different breast changes, complications and frequently difficulties in diagnosis. We present: 1. Current recommendations in surveillance after different breast cancer surgical treatment strategies (mastectomy, breast reconstruction, breast conserving surgery). 2. Techniques in evaluation of treated breasts. Contrast-enhanced mammography, US, MRI, CT, PET. 3. Imaging findings. Postsurgery changes acute/subacute (architectural distortion, hematoma, seroma, fat necrosis, residual lesion), late (scar, fibrous reaction, suture granuloma, breast Implant rupture and silicone granuloma, lymphadenopathy). Posttreatment changes: Hormonotherapy (Increased density), Radiotherapy (skin thickening, edema). Breast cancer recurrence, metachronous breast cancer. 4. Tips for differential diagnosis, diagnostic work-up and recommendations for management

Maria Jose Chico (*Abstract Co-Author*) Nothing to Disclose
Karen L. Caro, PhD (*Abstract Co-Author*) Nothing to Disclose
Agustina Graziani, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To describe breast and axillary findings on chest computed tomography.Recognize breast and axillary findings of clinical significance that must be reported in chest CT scan.To discuss the clinical management of these findings.

### TABLE OF CONTENTS/OUTLINE

1-Introduction:Chest CT is a frequently performed radiologic study and can reveal breast and axillary findings in both genders. Radiology residents should be accurate in reporting these findings is essential to guide clinical decision-making and prevent unnecessary procedures.2-Normal Appearance of Breasts and Axilla on Chest CT:The normal appearance of breast parenchyma on chest CT can vary based on breast density. Familiarity with normal variations in breast density is crucial to avoid misinterpretation of findings. The axilla should also be carefully evaluated for lymph nodes.3-Benign and malignant Imaging findings in female breast on Chest CT4-Benign Imaging Findings in Male Breast on Chest CT:Gynecomastia is a common benign finding in the male breast on chest CT. It is important to recognize and accurately describe this finding in the report to prevent unnecessary workup.5-Malignant imaging findings in male breast on Chest CT6-Clinical Cases:Several clinical cases will be presented to illustrate the accurate reporting of breast and axillary findings on chest CT scans.7-Management.

Marycarmen E. Flores Duenas, MD (*Abstract Co-Author*) Nothing to Disclose
Lisett N. Cruzado-Quiroz, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Most lesions that shine on T2 are benign, however there are some malignant lesions that also shine on T2.The most common benign hyperintense lesions on T2 are: cysts, fibroadenomas, lymph nodes, fat necrosis, etc.Mucinous carcinomas, papillary carcinomas, triple negative tumors with a necrotic component, etc., are malignant lesions that present high signal on T2.A single sequence does not make the diagnosis. In MRI, it is important to evaluate the morphological and dynamic sequences in parallel, which will help us narrow the differential diagnosis.In this presentation, we want to illustrate the MRI features of most common and rare T2 hyperintense breast lesions, with emphasis on morphologic features and differential diagnoses.

### TABLE OF CONTENTS/OUTLINE

Breast cancer; MRI; malignant lesions; T2 hyperintense; necrotic component; papillary carcinomas; mucinous carcinomas.

## MORE THAN WORDS: COMPLETE REPORT FOR OPTIMAL TREATMENT TNM 8TH EDITION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Maria Jose Chico (*Abstract Co-Author*) Nothing to Disclose
Karen L. Caro, PhD (*Abstract Co-Author*) Nothing to Disclose
MONICA OTILIA MACHUCA CASTILLO (*Abstract Co-Author*) Nothing to Disclose
Maria P. Swiecicki, MD (*Abstract Co-Author*) Nothing to Disclose
Karina Pesce, PhD (*Abstract Co-Author*) Nothing to Disclose
Agustina Graziani, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To analyze the 8th edition of the breast cancer staging system.To discuss the modifications in the 8th edition.Describe findings that cannot be missing from the report.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: Breast cancer is an heterogeneous tumor, very frequent among women and, if not diagnosed and treated in timely manner, leads to significant morbidity and mortality 2. 8th TNM edition: Anatomic staging: considering tumor extension (according to size), affects lymph nodes (classified according to their level) and the presence or absence of metastases.Prognostic staging part: based on the expression of hormone receptors and oncogenes (estrogen, progesterone and HER2 receptors) and tumor grade (low, intermediate and high) and the results of the multigentics panel (evaluates genes in order to predict the probability of recurrence). Genomic analysis helps to understand the biological behavior of breast cancer that causes changes in the management and treatment of the patients.3. Modifications in the 8th edition of the TNM.4. Clinical Cases:Several clinical cases will be presented to illustrate the findings that should be taken into account for anatomic staging and tips for remembering them.5. Conclusion: Although the role of the radiologist is crucial in the anatomical stage, as the 8th edition of the TNM also takes into account prognostic staging, it is necessary to have knowledge about tumor genes and hormone receptors in order to provide patients with the optimal treatment.

## PRIMARY AND SECONDARY BREAST ANGIOSARCOMA: MULTIMODALITY IMAGING APPROACH WITH PATHOLOGIC CORRELATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*) Royalties, Wolters Kluwer nv
Jordana Phillips, MD (*Abstract Co-Author*) Research Grant, General Electric Company;Consultant, General Electric Company;Consultant, Hologic, Inc
Jenna Pellegrino, MD (*Abstract Co-Author*) Nothing to Disclose
Dunya M. Imad, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Breast angiosarcoma, an infrequent yet highly aggressive cancer, originates from spindle cells and is more prevalent in the breast compared to any other organ. It manifests in two primary forms: sporadic angiosarcoma and post-radiation angiosarcoma. A causative factor remains unidentified in primary breast angiosarcomas. Conversely, secondary breast sarcomas are associated to previous radiation therapy (RT) and conditions leading to chronic lymphedema. Despite its rarity, this disease necessitates specialized diagnostic and therapeutic approaches, necessitating collaboration among radiologists, oncologists, surgeons, and pathologists.

### TABLE OF CONTENTS/OUTLINE

In this exhibit, we will discuss the various presentations of primary and secondary angiosarcoma, conduct a systematic review of clinical findings, and examine multimodality radiological findings through case studies, including PET-CT. Additionally, we will explore treatment modalities and discuss prognosis to provide a comprehensive understanding of this challenging condition.

Angela J. Urbina Ibarra SR, MD,BSC (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Contrast mastography uses intravenous contrast agents, being an effective technique to improve the early detection of breast cancer and reduce the false positive rate, as well as to evaluate the extension and occult cancers among other indications, due to the accurate characterization of lesions.Contrast mastography stands out for its ability to improve the detection of breast lesions, especially in cases of dense breast tissue or inconclusive findings on conventional mammography. Its role in preoperative evaluation is illustrated, allowing a more accurate characterization of the extent of disease and optimal surgical planning. Indications, contraindications and practical considerations for performing the study are also reviewed. This review highlights the value of contrast-enhanced mastography as an important diagnostic tool in the comprehensive management of breast pathologies, with important implications for early detection and personalized treatment of patients.*Review contrast enchanced mammography basics (acquisition protocol, diagnostic performance, and current indications).*Ilustrate the applications and added value of contrast enchanced mammography through the review of everyday clinical scenarios.

### TABLE OF CONTENTS/OUTLINE

1.Contrast enchanced mammography lexicón overview (categories, terms, features and definitions)2.Ilustrated case based review2a. Staging2b. Microcalcifications2c. Occult breast cancer2d.Residual and recurrent disease2e.Paget disease2f.Telorrhage2g.High risk screening2h.Focal asymmetry. 3. Conclusions

Maria Guerra, MD (*Abstract Co-Author*) Nothing to Disclose
Ia M. Sanchez Carenzo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The main objective of this work is to communicate if there is a relationship between breast cancer findings by MRI and immunohistochemistry, and how we get to that information. The secondary objective is to make a practical and concise description of the findings that we can identify in breast cancer lesions on MRI, as well as the appropriate vocabulary to use about these characteristics. Present more relevant information about the usefulness of the BI-RADS and the Kaiser Score for the proper classification of breast cancer lesions. Review the basic acquisition protocol recommended for the evaluation of suspected or proven breast cancer lesions by MRI, as well as the key points to have an appropriately structured report that contains all the required information about the findings.

### TABLE OF CONTENTS/OUTLINE

The usefulness of performing immunohistochemistry in patients diagnosed with breast cancer for the management of the disease. The importance of correct and complete evaluation of lesions by MRI, following a protocol in both the acquisition and interpretation of the images, in order to be a guide for those residents in training who are starting out on the subject. Concise descriptions are included with illustrations and real examples representative of our institution that include mass and non-mass lesions with all those characteristics that must be identified and characterized in the interpretation. The information included is how the statistical analysis was performed, selection and exclusion of patients, and results on the prevalence of the reviewed characteristics as well as their correlation with the types of immunophenotype in our study population.

## GRANULOMATOUS MASTITIS. A RARE BENIGN ENTITY THAT CAN SIMULATE BREAST CANCER. WHAT THE RADIOLOGIST SHOULD KNOW!

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Maria C. Ona Hurtado SR, MMed,BA (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1 Analyze the imaging characteristics of the (IMG) 2 Discuss the management of the heterogeneous group of IGM •Introduction and review of the literature •Review of the imaging characteristics •Description of the results of the IGM images in mammograms, ultrasounds and MRI •Clinical cases •Diagnostic algorithm

### TABLE OF CONTENTS/OUTLINE

Granulomatous mastitis(GM) is a benign inflammatory breast disease that its becoming more commonly seen during our daily practice of unknown etiology, has a persistent and recurrent clinical course and occurs most commonly in parous women; it typically manifests as a tender palpable mass and inflammatory breast changes characterized by granulomatous inflammation at histopathologic analysis.The most common clinical sign is a painful palpable mass associated with erythema, and purulent discharge. However, the nonspecific manifestations and varied demographic features of this condition, as well as the other similar-appearing and superimposed breast entities, pose substantial diagnostic challenges, like inflammatory breast cancer(IBC), infective mastitis, foreign body injection granulomas, mammary duct ectasia, diabetic fibrous mastopathy, and systemic granulomatous processes and tuberculosis. Targeted ultrasonography, mammography, and less commonly, magnetic resonance imaging have proven to be useful for imaging evaluation. Core-needle biopsy, with or without fine-needle aspiration for cytopathologic examination, and culture analysis are usually required to exclude IBC and other benign inflammatory processes.

Karen S. Johnson, MD (*Abstract Co-Author*) Nothing to Disclose
Derek L. Nguyen, MD (*Abstract Co-Author*) Nothing to Disclose
Theresa X. Pham, MD, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Breast Magnetic Resonance Imaging (MRI) is frequently utilized in breast imaging for high-risk screening, evaluation of implant integrity, evaluation of disease extent in the preoperative setting, and evaluation of tumor response to neoadjuvant chemotherapy. Given the varying field of view of breast MRI examinations, incidental extramammary findings may be visible in the lower cervical neck, thorax, upper abdomen, and even thoracic spine. Therefore, it is important for breast radiologists to include these areas in their search pattern and to have a comprehensive understanding of the distinctive imaging findings and pathology—both benign and malignant—observed in these anatomical areas. The purpose of this educational exhibit is to review cases with incidental extramammary findings on breast MRI and to highlight the importance of looking at all of the imaging sequences, including localizers, and areas beyond the breasts.

### TABLE OF CONTENTS/OUTLINE

1. Highlight and discuss the importance of looking at all the available MRI sequences for incidental extramammary findings on breast MRI.2. Review common extramammary benign and malignant imaging findings that can be incidentally detected on breast MRI.3. Present image-rich multimodality case examples of incidental extramammary findings detected on breast MRI.

## BEYOND CANCER: REVEALING BI-RADS 5 MIMICS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Natalia T. Lima (*Abstract Co-Author*) Nothing to Disclose
Carlos Shimizu, MD (*Abstract Co-Author*) Nothing to Disclose
Elisa M. Carvalho, MD (*Abstract Co-Author*) Nothing to Disclose
Leticia Cardoso Ern, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Identify the BI-RADS 5 imaging standards for ultrasound, mammography, and MRI;- Outline and illustrate the main benign differential diagnoses for BI-RADS 5;- Propose a diagnostic flowchart to determine biopsy concordance;

### TABLE OF CONTENTS/OUTLINE

The system currently used to report and classify mammography, ultrasound, and breast MRI findings is the BI-RADS system. It ensures uniformity in the lexicon and a degree of homogeneity in the interpretation of exams. The ACR BI-RADS 5 classification is used when the probability of malignancy is greater than or equal to 95%.However, not all lesions classified as BI-RADS 5 are malignant. Some pathologies have imaging features that mimic findings characteristic of highly malignant lesions and are ultimately classified with them, such as atypical infections, radiated scar, fat necrosis, desmoid tumor, granulosa cell tumor, mastitis (inflammatory, lymphocytic/diabetic, and infectious) and myofibroblastoma.his is a retrospective study using images from the database of a quaternary hospital that is a national reference for highly complex cases. Ultrasound, mammography, and MRI scans between 2015 and 2023 were used, all with anatomical-radiological matching.The breast radiologist must be aware of this group of agents and determine whether a new biopsy is necessary in the case of a discordant result, or whether the result is benign and concordant according to well-established criteria.

### TEACHING POINTS

-To describe contrast-enhanced mammography (CEM) technique.-To review the appearances of benign and malignant lesions in CEM, including different patterns of enhancement and correlation with low-energy images. - To illustrate imaging findings of CEM with correlation with imaging (US, MRI) and pathology. - To emphasize pitfalls, diagnostic difficulties and differential diagnosis and discussion of management.

### TABLE OF CONTENTS/OUTLINE

Contrast-enhanced mammography (CEM) is currently used in diagnostic work-up of breast lesions. Advantages include well-tolerated studies, short duration, lower cost than MRI, and immediate review of results after the study. Radiologists should be familiar with normal findings and commonly encountered benign and malignant entities on CEM.
- Basics and technique of CEM.
- Study evaluation: low-energy findings (mass, calcifications, architectural distortion, asymmetries), patterns of enhancement (background parenchymal enhancement, mass, non-mass enhancement, and enhancing asymmetry).
- Images in different pathologic entities. Through sample cases, a variety of imaging and pathology findings from lesions detected in CEM studies with correlation with US, MRI and pathology, illustrating benign lesions (cyst, fibroadenoma, phyllodes tumor, papilloma, fat necrosis, pseudoangiomatous stromal hyperplasia (PASH), skin-related lesions, lymph nodes, granulomatous and lymphocytic mastitis, abscess), malignant entities (DCIS, ductal and lobular invasive cancer, colloid and papillary cancer, lymphoma) and high risk lesions (atypical ductal hyperplasia (ADH), radial scar, flat epithelial atypia).
- Clues for differential diagnosis and pitfalls.

### TEACHING POINTS

Photon-counting detector computed tomography (PCD-CT) has several advantages over conventional energy-integrating computed tomography (EID-CT). The higher spatial resolution of PCD-CT may provide a precise visualization of microcalcifications related to breast cancer. This can contribute to preoperative planning by identifying the distribution of microcalcifications.This presentation will focus on depicting breast microcalcifications in breast cancer patients on PCD-CT, comparing it to EID-CT and other imaging modalities, including mammography, tomosynthesis, ultrasound, and magnetic resonance imaging, with pathological results. We will also discuss the reconstruction settings of kernel sharpness, iterative reconstruction, or slice thickness to depict and identify breast microcalcifications on PCD-CT.

### TABLE OF CONTENTS/OUTLINE

1. The types of breast calcifications 2. The reconstruction settings, including kernel sharpness, iterative reconstruction, or slice thickness of PCD-CT to depict and identify breast microcalcifications 3. Case-based review of breast calcifications on PCD-CT compared to EID-CT, other imaging modalities, and pathological results 4. Discussion of the advantages and pitfalls of breast microcalcifications on PCD-CT compared to other modalities

### TEACHING POINTS

-Discuss the basic principles for performing a lateral arm approach stereotactic breast guided biopsy.-Describe the patient’s indications for carrying out this approach.-Recognize potential challenging cases and complications when performing a lateral arm approach stereotactic breast guided biopsy.-Illustrate techniques to overcome problems and successfully resolve challenging cases.

### TABLE OF CONTENTS/OUTLINE

Stereotactic breast biopsies have proven to be a feasible alternative to surgical breast biopsies. Nowadays, this method is the standard of care in patients with suspicious findings on mammography or tomosynthesis. Performing a successful stereotactic breast guided biopsy requires planning and a correct evaluation of the lesion location and of the patient’s breast anatomy. When this procedure can not be safely performed a surgical approach should be considered. The lateral arm approach for stereotactic breast biopsies permits procedures to be done using a needle insertion parallel to the compression plate allowing to successfully sample lesions that would have been excluded with a conventional approach, therefore avoiding surgical biopsy as well as improving patients care and comfort. -Illustrate the basic principles of this technique.-Discuss how to plan, patient select and perform a lateral arm stereotactic breast biopsy.-Examine advantages and limitations of this approach. -Identificate and illustrate with case examples potentially challenging cases as well as provide tips and tricks to troubleshoot and successfully perform this procedure.

## RADIAL SCLEROSING LESIONS - IMAGING FINDINGS AND MANAGEMENT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Patricia A. De Camargo Teixeira, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela G. Giannotti, MD (*Abstract Co-Author*) Nothing to Disclose
Thais Mayor Simonatto, MD (*Abstract Co-Author*) Nothing to Disclose
Ulisses Ferreira (*Abstract Co-Author*) Nothing to Disclose
Ligia A. Yamashita, MD (*Abstract Co-Author*) Nothing to Disclose
Larissa Moyses, MD (*Abstract Co-Author*) Nothing to Disclose
Vivian N. Omura, MD (*Abstract Co-Author*) Nothing to Disclose
Vera Christina C. Ferreira, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela F. Vieira Vendramini (*Abstract Co-Author*) Nothing to Disclose
Carolina R. Saccarelli, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

-Describe the histological pattern of radial sclerosing lesions (RSL).-Describe and define the possible imaging presentations of radial sclerosing lesions, according to different imaging methods, such as mammogram (MG), ultrasound (US) and magnetic resonance (MRI).-Discuss the malignancy upgrade rates of radial scars according to it’s histological associations and the possibility of follow-up of these lesions.

### TABLE OF CONTENTS/OUTLINE

-Review the histological findings defining RSL, in addition to its possible histological patterns and associations to malignant lesions or atypia.-Enlist the possible differential diagnosis of RSL.-Illustrate RSL characteristics on various imaging methods, which can or cannot occur simultaneously.-Correlate simultaneous findings in each method. Discuss the possibility of malignancy upgrade of the RSL lesions, and correlate these rates with imaging and histological findings.-Discuss the different managing propositions of these lesions, according to its imaging and histological patterns. -Summary and take home messages.

Alessandra d. Borges, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Recognition of the radiological peculiarities of rare types of breast cancer in mammography, ultrasonography, and magnetic resonance imaging. Special histological subtypes are rare in breast cancer and knowing some of their peculiarities helps us recognize atypical imaging patterns and make appropriate anatomopathological correlations.

### TABLE OF CONTENTS/OUTLINE

Malignant Phyllodes Tumor: Large solid or complex solid-cystic mass; differential diagnosis with rapidly growing fibroadenoma. Mucinous Carcinoma: High signal intensity in T2. Medullary Carcinoma: Mass with circumscribed or microlobulated margins with posterior enhancement.Ring enhancement with internal septations. Tubular Carcinoma Slow growth small spiculated mass associated with architectural distortion and calcifications. Heterogeneous enhancement with washout curve. High association with DCIS. Invasive Papillary Carcinoma: solid or complex solid-cystic mass; calcifications are common. May present with ductal dilatation. Hemorrhage with high signal in T1WI. Pleomorphic Lobular Carcinoma: Larger spiculated masses with calcifications, architectural distortion and local invasiveness. May present as focal asymmetry. Non-mass enhancement and necrosis. Metaplastic Carcinoma Large, rapidly growing, round and circumscribed mass. Heterogeneous and ring enhancement with necrosis or intratumoral hemorrhage. Neuroendocrine Carcinoma Spiculated mass or asymmetry with calcifications, architectural distortion. Diffusion restriction and washout curve. Micropapillary Carcinoma: Spiculated mass with calcifications, architectural distortion. Lymph node metastasis are common even in small lesions.

Maria Teresa Montero Alameda (*Abstract Co-Author*) Nothing to Disclose
Javier Azpeitia Arman, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To review the basics of breast triangulation in mammography.
- To illustrate the correlation of lesion position on mammograms through diagrams and illustrative cases of US and MRI.
- To describe additional views employed in work-up of mammographic findings.
- To emphasize pitfalls, diagnostic difficulties and provide clue points.

### TABLE OF CONTENTS/OUTLINE

- Introduction. Despite the use of new technologies in mammography, different problems may still occur in standard two view mammograms. We review the classic and basic problem-solving approach.
- Breast triangulation. Mammograms are essential to detect non-palpable breast lesions. The relative lack of anatomical landmarks in the breast, makes sometimes correlation of the location of the lesions a problem even more important with the frequent detection of multiple lesions with new technologies such as contrast-enhanced mammography. We review the basic geometric concept of triangulation, discuss common mistakes in lesion location estimates and their causes.
- Additional views. Magnification and spot-compression views. Tangential views for dermal calcifications (rarely employed with the use of tomosynthesis). ‘Exaggerated’ views for lesions included in the oblique but not in craniocaudal views (‘Cleopatra’ view).
- Quiz with difficult cases from our series of mammograms with correlation with US and MRI.

Ruth H. Bonini, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The BI-RADS categories 4C and 5 are used when the suspicion of malignancy ranges between 50-95% and is >95%, respectively and histopathological investigation is mandatory, typically through percutaneous biopsy. Following a biopsy, encountering a benign result in a lesion classified in these categories can be challenging for the radiologist, particularly in category 5. According to BI-RADS, any non-malignant diagnosis from a needle biopsy in category 5 should be considered discordant, necessitating a recommendation for repeat biopsy, often surgical. Some breast conditions can mimic malignancy, and in these scenarios, it is crucial to be familiar with these benign entities, some of which may be unfamiliar even to breast imaging specialists. After a thorough radiological-pathological correlation, taking into account biopsy technical aspects, lesion characteristics across different imaging modalities, and the patient's clinical history, some results may be accepted, potentially averting the need for additional biopsies or surgeries. The objective of this presentation is to acquaint the radiologist with both common and rare benign lesions that can mimic malignancy through cases encountered in daily practice.

### TABLE OF CONTENTS/OUTLINE

In a didactic manner, several cases selected from our institution's archive of benign lesions, histological proven, with mammographic and ultrasonographic correlations will be presented. These cases encompass lesions of infectious/inflammatory origin, autoimmune diseases, benign proliferative conditions, and benign tumors.The common clinical and imaging manifestations of these entities will be discussed, along with a review of the pathological aspects.

## ULTRAFAST DYNAMIC CONTRAST ENHANCED BREAST MRI WITH A MODIFIED SENSE ACCELERATED 3DTFE SEQUENCE: CASE BASED REVIEW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Shreya Poddar, MBBS (*Abstract Co-Author*) Nothing to Disclose
Nirali S. Mehta, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Smruti Mulani, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Ultrafast Breast MRI [UFBMRI] can be performed using conventional parallel imaging with accelerated 3DTFE sequence on conventional scanners.2. Qualitative assessment of UFBMRI adds to the diagnostic specificity and guides patient management by indicating the possible extent of vascularity and hence aggressiveness of the lesion. Hence, optimal site for tissue sampling can be determined. 3.UFBMRI can be incorporated in routine practice on most scanner platforms without additional postprocessing, ensuring accessibility to a larger patient population.

### TABLE OF CONTENTS/OUTLINE

Introduction: UFBMRI requires acceleration techniques like k-space sharing, compressed sensing and/or AI based reconstruction. These techniques are available only on newer scanners and not all centers performing breast MR have access to them. Furthermore, UFBMRI data has been analyzed quantitatively using Max Slope of Increase and TTE [Time to enhance] as compared to Aorta which involve additional calculations. Methods: We set up a Ultrafast Dynamic Contrast Enhanced [UFDCE] protocol using a 3DTFE sequence with parallel imaging, to achieve a temporal resolution of 6secs. We analyzed the images qualitatively, with reference to the presence, synchronicity and rapidity of enhancement. Principle of UFDCE, Sequence parameters and Breast MRI protocol will be discussed. Representative cases will be presented where qualitative analysis of UFBMRI contributed to the histopathologic diagnosis and patient management. Conclusion: Qualitative assessment of SENSE accelerated UFDCE sequence using 3D Fast Gradient Echo sequence [temporal resolution ~ 6secs] can also improve the diagnostic specificity and guide patient management.

Tsutomu Okada, MD (*Abstract Co-Author*) Nothing to Disclose
Yuji Nakamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Maya Honda, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Ultrafast dynamic contrast-enhanced (UF-DCE) MRI and DWI are novel sequences in the breast that have accumulated evidence for diagnosing and characterization of breast cancer, though are not used as stand-alone sequences. One of the strengths of these sequences is that they can be evaluated quantitatively (time-intensity curves (TIC) and apparent diffusion coefficient (ADC). On the other hand, various methods have been devised to reduce artifacts or increase the spatial resolution of these sequences to improve qualitative assessment. Some DWI sequences like readout segmentation of long variable echo-trains (RESOLVE) and diffusion-weighted spatiotemporal encoding (SPEN), can achieve higher in-plane resolution than conventional single-shot echo-planar DWI, and tumor morphology assessment using them is being investigated. Currently, Breast Imaging and Data System (BI-RADS) prioritizes morphological evaluation to estimate the malignant potential of breast lesions. Therefore, morphological evaluation may be the key for these sequences to be used as alternatives to conventional DCE MRI. This exhibit will focus on the morphological evaluation and image quality of UF-DCE MRI and DWI in the breast.

### TABLE OF CONTENTS/OUTLINE

1: Image quality and morphological evaluation using UF-DCE MRI: A) view sharing technique B) compressed sensing C) pitfalls in TIC evaluation2: Image quality and morphological evaluation using DWI: A) RESOLVE B) SPEN C) other sequences

Heather I. Greenwood, MD (*Presenter*) Support, Endomagnetics Ltd;Support, Devicor Medical Products, Inc

### TEACHING POINTS

1. To review the recently updated American College of Radiology (ACR) high-risk screening guidelines for BRCA1 and BRCA2 mutation carriers including transgender patients 2.To review the different imaging features of BRCA1 and BRCA2 specific tumors and correlate the imaging features with histopathology 3. To review the evidence behind various imaging modalities for screening patients with BRCA1 and BRCA2 mutations

### TABLE OF CONTENTS/OUTLINE

1. Background information reviewing BRCA1 and BRCA2 genes: transmission, lifetime risk of cancers, prevalence in overall population and specific higher risk populations, risk assessment 2. Review of the 2023 updated ACR high-risk screening breast cancer guidelines, with emphasis on updates for BRCA1 and BRCA2 mutation carriers 3. Review the current state of available data and guidelines for high-risk screening in transgender BRCA mutation carrier patients 4. Multi-modality case examples of BRCA1 vs BRCA2 associated tumors: imaging features with histopathologic correlation 5. Review of the evidence behind various imaging modalities in screening BRCA1 and BRCA2 mutation carriers with imaging examples: Digital Mammography/Digital Breast Tomosynthesis, Ultrasound, Dynamic Contrast Enhanced Breast MRI (DCE-MRI), Abbreviated Breast MRI (AB-MRI), Contrast Enhanced Mammography (CEM)

### TEACHING POINTS

Embark on an exciting journey through the complex world of breast fibroepithelial lesions (FELs) with our interactive learning center exhibit. FELs are a diverse group of tumors that originate from the stromal and epithelial tissues of the breast, and can range from benign to malignant. This exhibit focuses on three main types of FELs: fibroadenomas, phyllodes tumors, and benign fibroepithelial tumors.By exploring this exhibit, radiologists will:Gain a deep understanding of the diverse spectrum of breast fibroepithelial lesions.Master the latest diagnostic imaging techniques for detecting and characterizing FELs.Appreciate the crucial role of imaging in differential diagnosis and management of FELs.Stay up-to-date with the latest emerging imaging modalities and guidelines for FELs.Enhance multidisciplinary collaboration and communication for optimal patient care.Join us in this exciting learning journey and unlock the secrets of breast fibroepithelial lesions.

### TABLE OF CONTENTS/OUTLINE

Introduction to breast fibroepithelial lesions.Pathophysiology and histopathological features.Clinical presentation and diagnostic workup: Learn how to recognize and diagnose FELs through our daily practice case studies and clinical pearls.Multidisciplinary approach to management.Future directions.Conclusion and summary

### TEACHING POINTS

Breast masses with associated necrotic changes pose a diagnostic and management challenge for radiologists. Both benign and malignant etiologies can lead to a mass presenting with central necrosis. Triple-negative breast cancer is notorious for presenting with necrosis. However, tumor necrosis has not been associated as an imaging characteristic to predict response to systemic therapy. Benign masses that grow rapidly can demonstrate necrosis or infarction and can, in rare instances, become infected. Multimodality imaging is critical for formulating a differential and guiding biopsy into a non-necrotic region to obtain an accurate histopathologic diagnosis. By the end of this educational exhibit, learners will: 1. Define tumor necrosis 2. Explain the mechanisms that lead to necrosis 3. List benign and malignant etiologies associated with central necrosis 4. Choose the appropriate location to biopsy the lesion with necrosis

### TABLE OF CONTENTS/OUTLINE

Introduction; Definition of tumor necrosis; Incidence of, and risk factors that lead to, necrotic masses; Mechanisms of tumor necrosis; Clinical presentation of necrotic masses; Differential considerations including benign and malignant etiologies; Distinguishing necrotic tumors from abscess and fluid collections. Multimodality imaging examples of necrotic masses including necrotic lymph nodes; Systematic approach for characterization of masses associated with necrosis; Pitfalls in the sonographic assessment of necrotic masses; Strategies for successful core biopsy and radiology-pathology correlation. Algorithm for management of benign and malignant necrotic masses; Conclusion.

## MULTIMODALITY EVALUATION OF REGIONAL BREAST LYMPH NODES: IMPACT OF BI-RADS 6TH EDITION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

James Stepenosky, MD (*Abstract Co-Author*) Nothing to Disclose
Soudabeh Fazeli, MD,MPH (*Abstract Co-Author*) Nothing to Disclose
Tara A. Retson, MD, PhD (*Abstract Co-Author*) Research Consultant, CureMetrix, IncStock options, CureMetrix, Inc
Haydee Ojeda-Fournier, MD (*Presenter*) Research Consultant, View Point Medical, Inc;Stock options, CureMetrix, Inc

### TEACHING POINTS

Evaluation of regional breast lymph nodes is an integral part of breast cancer imaging, it will affect clinical management. The radiologist must understand how to evaluate lymph nodes, stage the axilla, be proficient in image-guided interventions involving lymph nodes, and select the most appropriate imaging modalities to evaluate breast regional lymph nodes. Ultrasound-guided core biopsy or fine needle aspiration can be performed for histologic confirmation of nodal metastasis. In the expected 6th edition of BI-RDS, lymph nodes will be their own category across modalities with expanded discussion regarding location and morphology. The purpose of this educational exhibit is to preview expected BI-RADS 6th edition changes that will impact the evaluation of regional lymph nodes. By the end of this educational exhibit, learners will: 1. List morphologic criteria for lymph node assessment; 2. Identify the location of lymph nodes; 3. Recognize the relationship of the pectoralis minor to axillary lymph node levels; 4. Summarize expected lymph node updates in BI-RADS 6th edition.

### TABLE OF CONTENTS/OUTLINE

Introduction; Morphology of lymph nodes; lymph node locations: intramammary, axillary, internal mammary, supra-clavicular; Clinical presentation of adenopathy; Differential considerations of abnormal lymph nodes; Multimodality imaging regional lymph nodes: Mammogram, US, MRI; Learn a systematic approach to the characterization of abnormal lymph nodes; How to apply BI-RADS 6th edition lexicon for regional lymph nodes appropriately; Pitfalls in providing nodes BI-RADS categories; Image-guided interventions to assess nodes; Algorithm for management of regional lymph node findings; Conclusion.

## DON'T BE RASH, IT'S JUST PASH !

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Bruna M. Thompson, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Fabiana C. Policeni, MD (*Abstract Co-Author*) Nothing to Disclose
Danielli Matsuura (*Abstract Co-Author*) Nothing to Disclose
Fabiola P. Kestelman, MD (*Abstract Co-Author*) Nothing to Disclose
Su Kim Hsieh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Japnit Singh, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Breast pseudoangiomatous breast hyperplasia (PASH) can have a variety of different presentations. It can be asymptomatic, found incidentally on a breast biopsy or present itself as a mass, asymmetry or gigantomastia. PASH can be found in a wide age range but is more common in pre-menopausal and post-menopausal women on hormone replacement therapy. It has been commonly seen associated with gynecomastia. Even though benign, PASH can be admixed with malignancies, hence warrants a careful imaging-pathology correlation to establish concordance with biopsy. In some patients, PASH can have an uncommon presentation and outcome, such as a large and fast-growing mass leading to gigantomastia. In such cases, extreme treatments, like mastectomy may be required for local control. In order to help clinicians make the right treatment decision, an effective diagnosis can be made by correlating imaging findings with pathological features.

### TABLE OF CONTENTS/OUTLINE

To illustrate the various imaging aspects of breast pseudoangiomatous stromal hyperplasia (PASH) and its correlation with pathologic and clinical findings. To review the clinical presentations, key pathologic features along with current management of PASH. Lastly, to illustrate the imaging and pathological differential diagnosis of PASH.

### CAEE-1 HOW TO REPORT A CT CORONARY ANGIOGRAM? - A STEP BY STEP GUIDE FOR THE NOVICE READER

Srujana Ganti, MBChB, FRCR (*Abstract Co-Author*) Nothing to Disclose
Bimal Mayur Kumar Vora (*Abstract Co-Author*) Nothing to Disclose
Kang Ren Yong, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Understand how to report a CTCA study, in a step by step manner.

**TABLE OF CONTENTS/OUTLINE**

CT Coronary Angiograms (CTCAs) are rapidly becoming entrenched as mainstream, routine examinations performed for the assessment of coronary artery disease, in various settings, including acute, inpatient and outpatient settings.This poster will take the novice CT Coronary Angiogram (CTCA) reader through the reading of the study in a step by step fashion, covering all crucial aspects, review areas and highlighting the importance of each of these. It will cover the factors that need to be considered in optimising the patient, such as patient education and nursing management, as well as the technical parameters to ensure the best possible images are obtained.It will outline, in a systematic fashion, how the scan should be reviewed, providing review checklists covering the cardiac findings as well as the extra-cardiac findings. Crucial factors in reporting and critical alert notification will be discussed with a sample report template included. A series of cases will also be provided, with annotations, to demonstrate both common and uncommon pathology so that the reader will not only obtain a sound framework to use as a basis to commence CTCA reporting but also gain an understanding of the pathologies encountered.

**TEACHING POINTS**

Review cardiac sarcoidosis diagnostic criteria. Illustrate cardiac sarcoidosis imaging features in MRI, outlining the significance of late gadolinium enhancement (LGE). Highlight the prognostic implications of prompt diagnosis, emphasizing the importance of imaging in enhancing accuracy and predicting outcomes.

**TABLE OF CONTENTS/OUTLINE**

Cardiac sarcoidosis, a potentially life-threatening manifestation of systemic sarcoidosis, presents diagnostic challenges due to its variable clinical presentations and limited biopsy yield. Early assessment and a multidisciplinary approach are crucial for improved outcomes, given the potential for sudden cardiac events.Diagnostic criteria have evolved, with current guidelines underscoring the importance of advanced imaging in its detection and evaluation. Cardiac MRI offers a multi-dimensional assessment, allowing detection of myocardial inflammation, characterizing tissue involvement, assessing cardiac function and guiding treatment. PET-CT identifies active inflammation, enabling risk stratification, follow-up post-ICD implantation, and targeted biopsies.The primary MRI finding is the presence of LGE, typically exhibiting a sub-epicardial and mid-wall pattern along the basal septum or inferolateral wall, indicating fibrosis. Additional features encompass myocardial edema, perfusion defects, and abnormal 18-FDG uptake.Imaging findings hold prognostic significance, with extensive LGE patterns and impaired left ventricular function predicting a high risk of adverse cardiac events.We gathered representative cases of cardiac sarcoidosis at our institution to highlight the hallmark findings that leads to accurate diagnosis.

### CAEE-11 REVEALING THE HEART`S SKELETON: THE POWER OF WHOLE-HEART HIGH-RESOLUTION LATE GADOLINIUM ENHANCED IMAGING

Farah Cadour, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Elsie Nguyen, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Rushali Gandhi, BSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

We discuss the pathophysiology of intramyocardial hemorrhage (IMH), demonstrate CMR imaging and prognostic features of IMH, and its connection with microvascular obstruction (MVO). CMR is the gold standard for detecting IMH and MVO. MVO, also known as "no-reflow", is related to severe microcirculatory alterations with obstructed microvasculature and can occur alone or concomitantly with IMH. IMH is a reperfusion injury, related to extravasation of erythrocytes through severely damaged endothelial walls. Both IMH and MVO are associated with worse prognosis following acute MI.

**TABLE OF CONTENTS/OUTLINE**

IMH and MVO Pathophysiology and Evolution Post MI: Exact mechanism of microvascular injury and repair and temporal evolution of IMH and MVO are not well understood. These entities are early/subacute findings in the setting of acute MI, and typically resolve. Typical Imaging Features: MVO is identified as a subendocardial unenhanced region in the infarcted area due to lack of contrast within obstructed microvasculature. T2*-weighted sequences have higher sensitivity for demonstrating IMH. IMH can also appear as hypointense zone surrounded by myocardial edema (high T2 signal). Prognostic Value: The presence of IMH and MVO are strong predictors of adverse left ventricle remodelling and major adverse cardiovascular events after acute MI.

**TEACHING POINTS**

4D flow imaging represents an innovative technique that offers a comprehensive understanding of cardiovascular hemodynamics and related pathologies. This method provides functional cardiac information through the use of time-resolved four-dimensional cine sequences combined with 3D velocity encoding. The protocol enables the assessment of hemodynamic effects on vessel walls, myocardium, and flow pathways within the cardiovascular system. This imaging modality facilitates the evaluation of various cardiovascular pathologies, by analyzing multidirectional blood flow velocity data, providing valuable insights into conditions such as recurrent coarctation, aortic aneurysms, and valvular heart disease, contributing to the understanding of the natural history of cardiovascular disease. A notable example is the assessment of aortic dissection, where the technique identifies small fenestrations and characterizes flow dynamics between true and false lumens. This enhances patient risk assessment and treatment planning. In conclusion, 4D flow imaging emerges as a valuable tool for the comprehensive evaluation of cardiovascular hemodynamics and the precise diagnosis of associated pathologies. Its integration into clinical practice shows promise for optimizing patient management and treatment outcomes.

**TABLE OF CONTENTS/OUTLINE**

Introduction. Principles. Protocol. Applications review. Case examples.

## CAEE-15 WHAT RADIOLOGISTS MUST KNOW ABOUT PULMONARY HYPERTENSION

James C. Carr, MD (*Abstract Co-Author*) Institutional Research Grant, Siemens AG;Advisory Board, Siemens AG;Travel support, Siemens AG;Institutional Research Grant, Bayer AG;Advisory Board, Bayer AG;Travel support, Bayer AG;Speaker, Bayer AG;Institutional Research Grant, Guerbet SA;Advisory Board, Bracco Group

Sandra Quinn (*Abstract Co-Author*) Nothing to Disclose
Melika Shafeghat, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Pulmonary hypertension (PH) is a serious condition characterized by a gradual increase in mean pulmonary arterial pressure. The gold standard method to diagnose PH is right heart catheterization. However, heart catheterization is invasive and associated with a low, but not insignificant, risk of major complications, including fatality. Using noninvasive imaging modalities such as echocardiogram, chest CT, and cardiac MRI would be therefore more desirable as an alternative diagnostic method. While an echocardiogram is operator-dependent, and CT exposes the patient to ionizing radiation, MRI offers a comprehensive evaluation of cardiac anatomy, function, and focal and interstitial myocardial fibrosis without the risks associated with right heart catheterization or radiation exposure.

### TABLE OF CONTENTS/OUTLINE

1- What are the different types of PH, along with their WHO classification? 2- What are the etiologies of PH and its pathophysiology? 3 - What are the right heart catheterization findings as a gold standard method of diagnosis? 4- What are the noninvasive imaging modalities to diagnose PH? a. Echocardiogram findings in patients with PH along with pros and cons of echocardiogram to diagnose PH b. Chest CT findings in patients with PH and imaging features suggestive of PH b.1. Comparison of non-contrast chest CT vs. CT angiogram c. Cardiac MRI and 4D flow MRI imaging findings in patients with PH c.1. Comprehensive review of imaging sequences particularly CINE imaging, T1 mapping, delayed myocardial enhancement, 2D phase contrast, and 4D flow MRI

## CAEE-16 COMPLICATIONS OF THE CARDIOVASCULAR SURGERY WHAT RADIOLOGISTS SHOULD KNOW?

Iclal Ocak, MD (*Abstract Co-Author*) Nothing to Disclose
Furkan Ufuk, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Radiologists play a critical role in identifying early and late complications of cardiovascular surgery, which can improve patient outcomes.
- Familiarity with normal postoperative imaging appearances and common complications is essential.
- Key complications include infection, bleeding, edema, pseudoaneurysm and structural abnormalities.

### TABLE OF CONTENTS/OUTLINE

- Introduction
- Importance of imaging in cardiovascular surgery follow-up
- Role of the radiologist
- Normal Postoperative Appearances
- Typical imaging findings following different types of cardiovascular surgeries
- Early Complications
- Bleeding: Locations and imaging signs
- Infection: Diagnostic clues on imaging
- Graft Failure: Types and radiologic identification
- Late Complications
- Chronic graft occlusion
- Structural abnormalities: Valve malfunctions, aneurysm/pseudoaneurysm
- Advanced Imaging Techniques
- Use of CT, MRI, and ultrasound in the detection of complications
- Recent advances and their clinical applications
- Conclusion
- Summary of the radiologist’s role in managing post-surgical patients
- Future perspectives in imaging for cardiovascular surgery complications

## CAEE-17 GENETIC CARDIOMYOPATHY MINDSET: A PRACTICAL IMAGING APPROACH

Jose de Arimateia B. Araujo Filho, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Roberto V. Torres, MD (*Abstract Co-Author*) Nothing to Disclose
Rafaela Vieira Franklin Tapias (*Abstract Co-Author*) Nothing to Disclose
Marcus Vinicius Silva Ferreira, MD (*Abstract Co-Author*) Nothing to Disclose
Bruno Fuzissima (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To review the key concepts of the classification of cardiomyopathies, highlighting their classic phenotypes.2. To illustrate key imaging findings in the most important inherited cardiomyopathies, with genetic and epigenetic correlations.3. To discuss the value of cardiac MRI in identifying phenocopies and rare cardiomyopathies.4. To emphasize how the correlation between genotype and phenotypic expression can contribute to earlier diagnosis, risk stratification, prognostication and decision-making in patients with cardiomyopathy.

### TABLE OF CONTENTS/OUTLINE

1. Background Classification of the cardiomyopathies: contemporary definitions 2. Precision medicine and next-generation sequencing technologies: basic conceptsClassic phenotypes of cardiomyopathies and their expression in cardiac MRI 3. Identifying the main genomic variants and genotype-based classification in genetic cardiomyopathies: a practical approach4. The genotype-based classification background, pathophysiology, clinical presentation, and outcomes of patients with hereditary cardiomyopathy5. Genetic cardiomyopathies and genotype-phenotype correlations: a case-based review with cardiac MRI Pearls, pitfalls, and challenges6. Future directions: Multiomics research7. Take home messages

## CAEE-18 THE IMAGING APPEARANCE OF THORACIC AORTIC REPAIRS AND COMMON ASSOCIATED COMPLICATIONS

Cristina Fuss, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ronald Gathagan, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Aortic repair remains a critical aspect of cardiovascular medicine, with traditional surgical approaches continuing to play a prevalent role in addressing thoracic aortic pathologies. However, the landscape of aortic repair has significantly evolved with the advent of endovascular techniques, and multiple methods are often integrated for broader anatomical coverage, bringing increasing complexity to aortic disease management.By understanding the expected appearances of key components in thoracic aortic repair, radiologists can effectively identify deviations indicative of complications. Adopting a structured approach can aid in navigating the complex appearance of these complications. Specifically, attention should be given to the status of the aortic valve, the aortic root (including the sinuses of Valsalva), the ascending aorta, and the aortic arch as all of these structures may be repaired individually or repaired as a unit.Additionally, attention should be given to the management of coronary arteries when necessary. Similarly, if the repair extends into the region of the aortic arch, there must be further consideration of the management of the arch vessels. By implementing a systematic approach, radiologists can effectively identify and describe the majority of repairs, even with the constant advent of novel techniques.

### TABLE OF CONTENTS/OUTLINE

1. Describe the normal anatomy of the thoracic aorta including the ascending aorta and the aortic arch.2. Provide a brief overview of common variant anatomy.3. Review the types of ascending aortic repair techniques and their appearance on diagnostic imaging.4. Discuss common complications associated with thoracic aortic repair.

## CAEE-19 ATRIAL SEPTAL DEFECTS "WHAT RADIOLOGISTS NEED TO KNOW"

Shaimaa A. Fadl, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Understand the types of Atrial Septal Defects (ASD). Understand the associated anomalies. Understand imaging techniques for the full evaluation of ASD.Learn the role of imaging in different management options.

### TABLE OF CONTENTS/OUTLINE

Primum septal defectSecundum septal defectSinus venousus defectCoronary sinus defectThe role of imaging in the diagnosis and management in patients with septal defects.

## CAEE-2 NON-ATHEROSCLEROTIC CORONARY ARTERY DISEASE: A PICTORIAL REVIEW

Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*) Nothing to Disclose
Ingrid Stefanie Sarmento Debaco (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Although the majority of acute coronary events are the result of atherosclerotic lesions, some cases of myocardial infarction and sudden cardiac death may be related to non-atherosclerotic causes.The 2021 AHA Guideline for the Evaluation and Diagnosis of Chest Pain promotes the use of coronary computed tomography angiography (CCTA) as a diagnostic test in patients with an intermediate to high pretest probability of coronary artery disease (CAD), especially those younger than 65 years of age or when less obstructive CAD is suspected.CCTA provides information on intraluminal characteristics, and details of the coronary artery wall and surrounding tissue.

### TABLE OF CONTENTS/OUTLINE

IntroductionCAD is a diverse group of diseases with variable pathophysiology associated with myocardial infarction and sudden death, mostly in younger individuals. We review the imaging findings and the importance of the role of CCTA in the management of the major non-congenital causes of nonatherosclerotic CAD.MethodsNon-atherosclerotic CAD causes undergoing CCTA were retrospectively selected. Images were presented in the axial, sagittal, coronal, and curved multiplanar reconstruction planes. Conventional coronary angiography or 3D formatted images were added when available.Results DiscussionAmong other diagnoses, cases of dissection, thrombosis, coronary aneurysm, and extrinsic compression of the coronary arteries were included.An overview of CCTA findings and the role of imaging in the diagnostic process were provided.ConclusionThe increasing availability of CCTA and improvements in its technology have resulted in increased detection of nonatherosclerotic CADs, which was previously considered rare.

## CAEE-20 CAN YOU HEAR THE SYSTOLIC CLICK? YOU'D BETTER WATCH IT: MULTIMODALITY IMAGING OF MITRAL VALVE PROLAPSE

Maria J. Galante I, MD (*Abstract Co-Author*) Nothing to Disclose
Celia Cantolla Nates (*Abstract Co-Author*) Nothing to Disclose
Alejandra Somoano Marfull (*Abstract Co-Author*) Nothing to Disclose
Victor Fernandez Lobo (*Abstract Co-Author*) Nothing to Disclose
Ana Berasategui Criado, MD (*Abstract Co-Author*) Nothing to Disclose
Sofia Bretos Azcona, MD (*Abstract Co-Author*) Nothing to Disclose
Silvia Revuelta Gomez, MD (*Abstract Co-Author*) Nothing to Disclose
Marina Arroyo Olmedo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To review in detail the anatomy of the mitral valve and adjacent related structures. 2. To understand the different pathophysiological processes and their evolutionary stages by which the valve prolapses. 3. To analyse the utility of different imaging techniques in the diagnosis of prolapse and related features, planning of valve repair or replacement procedures and risk stratification.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction. 2. Anatomy of the valvular and subvalvular apparatus and its relation to adjacent structures. 3. Etiopathogenes of mitral valve degeneration: fibroelastic defficiency and myxomatous degeneration (Barlow's disease) . 4. Comparative utility and findings of different imaging techniques: 4.1. Echocardiography: TTE and TEE. 4.2. CT: coronary arteries and cardiac CT of morphology and function. 4.3. MRI. 5. Prognosis evaluation: 5.1. Severity of mitral insufficiency. 5.2. Severe myxomatous degeneration (Barlow's disease). 5.3. Mitral annulus disjuntion. 5.4. Late Gadolinium Enhacement of mitral apparatus: papillary muscles and myocardium.5.5. Other sequences 6. Treatment: percutaneous repair, surgical repair or valve replacement (multidisciplinary committees). 7. Conclusions. 8. Bibliography.

## CAEE-21 STRESSED ON CALL? YOUR GUIDE TO RECOGNIZING CLASSIC CARDIAC SIGNS ON A CHEST RADIOGRAPH

Nanditha Guruvaiah, MD (*Abstract Co-Author*) Nothing to Disclose
Namratha Guruvaiah Sridhara, MD, BSc (*Abstract Co-Author*) Nothing to Disclose
Janardhana Ponnatapura, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

A plain chest radiograph remains as the initial imaging modality of choice in evaluating patients with a history of cardiac pathology. A chest radiograph is convenient as it is easily accessible, low-cost, and a non-invasive diagnostic tool. A chest radiograph plays a key role in providing valuable information regarding underlying cardiac conditions. We aim to provide classic imaging signs of cardiac pathologies on a chest radiograph to boost the confidence and sharpen the skills of radiology residents and medical students. Since a chest radiograph is the initial imaging modality for patients with cardiac conditions, these classic signs can aid radiology residents and students to quickly recognize the underlying conditions and provide an accurate diagnosis for further patient management.

**TABLE OF CONTENTS/OUTLINE**

Introduction to normal cardiac silhouetteChest radiograph signs of cardiac pathologies case-based learning:- Double density sign- Hoffman-Rigler sign- Walking man sign- Oreo cookie sign- Straight left heart sign- Wide carina sign- Water bottle sign- Continuous diaphragm sign- Small heart sign- Left atrial impression on the esophagus in barium swallow- Third mogul sign- Stag’s antlers sign / reverse mustache sign

### TEACHING POINTS

Purpose of this exhibit: 1. Explore the diverse phenotypic landscape of sarcomeric hypertrophic cardiomyopathy (HCM) within the era of modern precision medicine. 2. Delve into diagnostic challenges of the left ventricular hypertrophy (LVH) phenotypes. 3. Showcase the seamless integration of genetic testing with cardiac magnetic resonance (CMR) to precisely identify the etiology of LVH.

### TABLE OF CONTENTS/OUTLINE

1. Background: Epidemiology and Pathophysiology of HCM. 2. Genetic mutations involved in sarcomeric HCM. 3. Phenotypic spectrum of HCM -EARLY HCM a. Non-hypertrophic (crypts, mitral valve, and papillary abnormalities), b. Incipient LVH (LVH does not fulfill diagnostic criteria). ESTABLISHED HCM c. Symmetric (concentric) HCM, d. Asymmetric septal, e. Asymmetric apical, f. Focal HCM, g. Midventricular HCM, h. Masslike HCM, i. Noncontiguous HCM, j. Sigmoidal, k. Reverse curve. ADVANCED HCM l. HCM in the active-inflammatory phase ("Hot HCM"), m. HCM with left ventricular systolic dysfunction (LVSD), n. Dilated with extensive fibrosis HCM ("burned-out"). 4. HCM post septal reduction therapy: ablation-myomectomy and myosin inhibitors. 5. HCM phenocopies: the role of integrating genetic testing a. Storage and infiltrative cardiomyopathies i. Amyloidosis (mutant TTR), ii. Cardiac sarcoidosis, iii. Hemochromatosis, iv. Lysosomal storage disease: 1. Anderson-Fabry, 2. Hurler's syndrome. v. Glycogen storage disease: 1. Danon disease, 2. PRKAG2, Desminopathy, RASopathies, 3. Pompe's, vi. Mitochondrial (MELAS, MIDD), vii. Syndromic HCM: 1. Friedrich Ataxia, 2. Noonan, 3. Leopard. b. Other differential diagnosis i. Athlete's heart ii, Hypertensive cardiomyopathy iii, Aortic stenosis.

## CAEE-25 OPTIMIZING RADIOLOGICAL APPROACH TO PREGNANCY-RELATED CARDIOVASCULAR DISEASES: STRATEGIES AND AWARENESS

Riccardo Marano, MD (*Abstract Co-Author*) Nothing to Disclose
Alessio Perazzolo, MD (*Abstract Co-Author*) Nothing to Disclose
Luigi Natale, MD (*Abstract Co-Author*) Nothing to Disclose
Giuseppe Rovere (*Abstract Co-Author*) Nothing to Disclose
Francesco Lauriero (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To enhance the awareness of radiologists in cardiovascular diseases (CVDs) during pregnancy. To highlight the role of imaging in diagnosing specific pregnancy-related CVDs. To illustrate strategies for minimizing radiation exposure and limiting the use of contrast agents when feasible.

### TABLE OF CONTENTS/OUTLINE

Background CVDs represent the primary cause of non-obstetric morbidity and mortality during or early after pregnancy in western countries. Timely diagnosis and effective management are crucial in mitigating these risks. Imaging plays a pivotal role in diagnosing some of the pregnancy-related CVDs, although radiation exposure and use of contrast agents should be minimized, adhering to the principle of as low as reasonably achievable (ALARA). If the disease occurs in late pregnancy, emergency cesarean delivery may be considered to prevent fetal exposure to radiation. Otherwise, magnetic resonance (MR) imaging is preferred over imaging examinations with ionizing radiation, particularly computed tomography (CT), whenever possible. Findings We present a series of illustrative cases focusing on the most common CVDs occurring in pregnant women, radiologists may run into their routine practice. We showcase different imaging techniques for each pathology, highlighting their distinct features and essential findings for accurate diagnosis. The discussed pathologies include pulmonary embolism (PE), sudden coronary artery dissection (SCAD), peripartum cardiomyopathy (PPCM), and aortic dissection. Conclusion Awareness of radiologists on pregnancy-related CVDs and radiation risks during gestation is crucial for optimizing imaging examination selection, diagnosis, and clinical management.

## CAEE-26 SEARCHING FOR SYNCHRONY: RADIOGRAPHY OF CONTEMPORARY CARDIAC DEVICES

Alan Wimmer (*Abstract Co-Author*) Nothing to Disclose
Melissa L. Rosado de Christenson, MD (*Abstract Co-Author*) Nothing to Disclose
Sherief Garrana, MD (*Abstract Co-Author*) Author, Reed Elsevier;Author, Oxford University Press
Santiago Martinez-Jimenez, MD (*Abstract Co-Author*) Support, Reed Elsevier
Alan V. Godfrey, DO (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Cardiovascular implantable electronic devices include a variety of technologies which are frequently visualized and assessed on chest radiography. Knowledge of the appropriate anatomical course and location of these devices is critical for radiologists in order to appropriately interpret chest radiographs and recognize device-related complications. An understanding of emerging devices and new approaches for their placement enables the radiologist to provide accurate information to the clinician, thus enhancing patient care. Furthermore, radiologists play a central role in identifying complications associated with hardware placement and on follow-up imaging evaluation of these devices. The goals of this exhibit are to help the learner: 1. Understand the radiographic anatomy pertinent to contemporary cardiac implantable devices and emerging techniques in device and lead placement 2. Identify common and critical complications associated with contemporary cardiac devices

### TABLE OF CONTENTS/OUTLINE

1. Introduction - Review radiographic anatomy as it relates to cardiac implantable conduction devices and leads 2. Overview of current electrophysiologic techniques and devices with emphasis on lead location on radiography 3. Discussion of radiographic features of common and critical complications associated with cardiac implantable devices 4. Conclusion

## CAEE-27 THE HEART IS BROKEN: A COMPREHENSIVE GUIDE FOR RADIOLOGISTS

Relevant epidemiology and clinical features of coronary dissectionPathophysiology of coronary dissection and its complicationsClassification for coronary spontaneous dissections base on the National Heart, Lung and Blood Institute (NHLBI):A) Type 1B) Type 2 (the most commonly diagnosed)C) Type 3Imaging findings on CCTAImaging findings on invasive coronary angiographyImaging coronary dissection complications: what the radiologist needs to look for

## CAEE-3 TIPS AND TRICKS TO IDENTIFY AND PROPERLY DIAGNOSE VASCULAR RINGS AND SLINGS

Omar Andres Pantoja Burbano, MD (*Abstract Co-Author*) Nothing to Disclose
Julian F. Forero, MD (*Abstract Co-Author*) Nothing to Disclose
Felipe Aluja, MD, MEd (*Abstract Co-Author*) Nothing to Disclose
Laura Acosta, MD (*Abstract Co-Author*) Nothing to Disclose
Andres F. Mejia Leon, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Utilizing embryology and normal anatomy as a framework, delineate the process through which vascular rings and pulmonary slings develop, making a comparison with the normal development of mediastinal vascular structures.2. Recognize distinct radiologic patterns indicative of vascular rings and pulmonary slings across imaging modalities for accurate diagnosis.3. Explore the repercussions of airway and esophageal compression caused by vascular rings and pulmonary slings, emphasizing their influence on blood flow dynamics and respiratory function.4. Understand how to differentiate vascular anomalies from other mediastinal masses and congenital heart diseases based on imaging characteristics to guide appropriate patient management.

**TABLE OF CONTENTS/OUTLINE**

-Embryological basis and developmental insights-Anatomy and classification on imaging-Radiological features aiding differential diagnosis-Pitfalls in imaging interpretation-Key take-home points for clinical practice.

## CAEE-30 IMPACT OF CMR MULTIPARAMETRIC MAPPING ON AUTOIMMUNE RHEUMATIC DISEASES (ARDS) - RELATED INFLAMMATORY CARDIOMYOPATHY DETECTION

**Awards**
**Certificate of Merit**

Francesco Lauriero (*Abstract Co-Author*) Nothing to Disclose
Agostino Meduri, MD (*Abstract Co-Author*) Nothing to Disclose
Giacomo Ottoni (*Abstract Co-Author*) Nothing to Disclose
Riccardo Marano, MD (*Abstract Co-Author*) Nothing to Disclose
Alessio Perazzolo, MD (*Abstract Co-Author*) Nothing to Disclose
Luigi Natale, MD (*Abstract Co-Author*) Nothing to Disclose
Camilla Vittoria Vita, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To overview inflammatory cardiomyopathy (I-CMP) in autoimmune rheumatic diseases (ARDs). To demonstrate the leading role of cardiac magnetic resonance (CMR) in detecting early cardiac inflammatory involvement in ARDs. To showcase imaging findings on multiparametric CMR approach of I-CMP in different ARDs.

### TABLE OF CONTENTS/OUTLINE

Introduction. Cardiac involvement is a common feature in ARDs. Traditional imaging varies in the diagnostic accuracy depending on pretest probability, type and severity of involvement. Conversely, CMR is the primary imaging tool for diagnosing I-CMP, offering unparalleled tissue characterization. The 2018 Lake Louise Criteria (LLC) enhanced its sensitivity, especially for early detection, leading to a rise in I-CMP incidence and revealing diverse CMR myocarditis patterns. Material and Methods. We showcase a series of CMR examination on ARDs patients with suspected myocarditis. Images were acquired following SCMR standard protocol (2020 update). Results. All patients met 2018 LLC criteria. Edema was not always evident in conventional T2-weighted images and distinct pattern of late gadolinium enhancement (LGE) were found. T1, T2 mapping, and ECV values were consistently elevated. Conclusions. Our aim is to emphasize the role of multiparametric mapping in detecting I-CMP in ARDs patients. Conventional T2-weighted images lack sensitivity for diffuse myocardial edema and different LGE patterns exist. Multiparametric mapping may overcome these limitations, providing quantitative maps of myocardial changes. Given the CMR sensitivity in I-CMP, even at early stages, a CMR screening for asymptomatic patients might increase ARDs-related I-CMP improving their prognosis.

## CAEE-31 PRACTICAL APPROACH TO IMAGING CHALLENGING AORTIC ARCH ANOMALIES: DOUBLE ARCH WITH ATRESIA AND MIMICS

Beverley M. Newman, MD, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Felipe A. Sanchez, MD (*Abstract Co-Author*) Nothing to Disclose
Rafael Alonso-Gonzalez (*Abstract Co-Author*) Nothing to Disclose
Osami Honjo (*Abstract Co-Author*) Nothing to Disclose
Frandics P. Chan, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kate Hanneman, MD, MPH (*Presenter*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc

### TEACHING POINTS

1. Double aortic arch is the most frequent cause of a symptomatic congenital vascular ring as the trachea and esophagus are completely encircled; typically, the right arch is higher and more cephalic than the left arch2. Part of the double arch can be atretic and replaced by a fibrosis cord, which is difficult to detect on imaging due to lack of luminal contrast in the atretic segment3. Double arch with atretic segment can mimic right aortic arch variants, depending on the level of atresia; however, timely differentiation is critical to guide management4. Double aortic arch with atresia distal to the left subclavian artery can mimic right aortic arch with type 1 mirror image branching5. Double aortic arch with atresia between the left common carotid and left subclavian arteries can mimic right aortic arch with aberrant retroesophageal left subclavian artery6. Key imaging features to differentiate double aortic arch with an atretic segment from mimics include 1) presence of 4 symmetrical arch branches at an axial level just above the arch, 2) posterior direction of the proximal aspect of the first arch branch, 3) tethering or tenting of the posterior segment of the patent segment of the left arch, and 4) anteriorly-directed diverticular outpouching from the descending aorta.

### TABLE OF CONTENTS/OUTLINE

1. Review aortic arch anomalies and congenital vascular rings: epidemiology, embryology, clinical presentation, and management2. Demonstrate imaging findings in typical double aortic arches3. Illustrate variants of double aortic arches with atretic segments and right aortic arch mimics4. Identify key imaging features to differentiate double aortic arch with atretic segment from mimics

## CAEE-32 NEW INSIGHTS INTO CARDIAC AMYLOIDOSIS IMAGING: A PRACTICAL GUIDE TO DIAGNOSIS, FOLLOW-UP AND OPTIMAL MANAGEMENT

Roberto N. Dantas JR, MD (*Abstract Co-Author*) Nothing to Disclose
Bruno Fuzissima (*Abstract Co-Author*) Nothing to Disclose
Jose de Arimateia B. Araujo Filho, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Thamara C. Morais, MD (*Abstract Co-Author*) Nothing to Disclose

Susannah Kay, MD (*Abstract Co-Author*) Nothing to Disclose
John Beute (*Abstract Co-Author*) Nothing to Disclose
Rosaura Suazo Aguero, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Sarcoidosis is a systemic disease characterized by the formation of non-necrotizing granulomas. It presents with respiratory symptoms in up to 53% of patients, and cardiac granulomas are present in up to 46.9% of cases. Radiography and CT are the most common imaging modalities used in the evaluation of thoracic sarcoidosis. However, 18F FDG-PET/CT have been shown to be increasingly useful. Findings include symmetric hilar and mediastinal lymphadenopathy, pulmonary nodules, subpleural reticular markings, groundglass changes, and pulmonary fibrosis.Findings of pulmonary sarcoid should prompt the evaluation for cardiac sarcoid.With respect to cardiac sarcoidosis, MRI and 18F FDG-PET/CT are useful tools. On MRI, cardiac sarcoidosis is typically associated with patchy and multifocal late gadolinium enhancement in the septum and lateral wall. The mid-myocardium and epicardium are commonly affected, whereas the subendocardium is usually spared. On 18 F FDG-PET/CT, cardiac sarcoidosis appears as patchy focal FDG uptake.Myocardial perfusion imaging using SPECT-CT can also be useful in the diagnosis of cardiac sarcoidosis by identifying focal perfusion defects at rest. Fixed defects or those that demonstrate reverse redistribution following vasodilation can distinguish cardiac sarcoidosis from non-sarcoid cardiac pathologies.

### TABLE OF CONTENTS/OUTLINE

1. Introduction on sarcoidosis and its systemic manifestations2. Focus on pulmonary and cardiac sarcoidosis3. Imaging findings with a focus on chest CT, cardiac MRI, and 18F FDG-PET/CT4. Case examples of sequential multi-modality evaluation for pulmonary and cardiac sarcoidosis5. Advances and future prospects in the imaging of sarcoidosis

## CAEE-34 MITRAL ANNULUS DISJUNCTION: A NOT SO RARE ENTITY. WHAT THE RADIOLOGIST NEEDS TO KNOW

Ana Berasategui Criado, MD (*Abstract Co-Author*) Nothing to Disclose
Marina Arroyo Olmedo, MD (*Abstract Co-Author*) Nothing to Disclose
Victor Fernandez-Lobo (*Abstract Co-Author*) Nothing to Disclose
Celia Cantolla, MD (*Abstract Co-Author*) Nothing to Disclose
Sofia Bretos Azcona, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To familiarize the radiologist with Mitral Annular Disjunction (MAD), a little known and potentially fatal pathology, with the secondary objective that its knowledge will improve the detection and reporting rates within clinical practice.To review the role of imaging techniques in the diagnosis of this entity, especially cardiac magnetic resonance.

### TABLE OF CONTENTS/OUTLINE

MAD is an abnormal displacement of the mitral valve (MV) posterior leaflet onto the left atrial wall with separation between the MV attachment and the atrium MV junction. This entity has been associated with a progressive risk of malignant ventricular arrhythmias and sudden cardiac death, likely related to progressive mitral apparatus fibrosis. Therefore, recognition of this anomaly and its risk stratification are highly important. Its diagnosis is done by cardiac imaging. However, a reference imaging technique has not yet been established.MAD is commonly found in patients with mitral valve prolapse (MVP) or myxomatose MV disease but can also occur in the absence of mitral valve pathology. In either case it has been shown by multiple studies to be associated with life-threatening arrhythmic events.Transthoracic or transesophageal echocardiography and cardiac magnetic resonance (CMR) are useful noninvasive imaging tools for the diagnosis of MAD. It will manifest as an absence of myocardium during systole between the posterior mitral valve annulus and adjacent basal segments of the ventricular wall. CMR offers a detailed anatomic three-dimensional imaging that provides useful information for risk stratification and prognosis, being considered the gold standard.

## CAEE-35 A PICTORIAL REVIEW: LEARNING CONGENITAL HEART DISEASE WITH EMBRYOLOGY

Katsutoshi Horiuchi, MD (*Abstract Co-Author*) Nothing to Disclose
Aya Yamada, MD (*Abstract Co-Author*) Nothing to Disclose
Kyosuke Matsuda (*Abstract Co-Author*) Nothing to Disclose
Dan Yamamoto, MD (*Abstract Co-Author*) Nothing to Disclose
Toshihiro Tanaka (*Abstract Co-Author*) Nothing to Disclose
Nagaaki Marugami (*Abstract Co-Author*) Nothing to Disclose
Ryosuke Taiji, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Congenital heart disease is considered a multifactorial genetic disorder in which cardiac morphogenesis during the embryonic period is caused by fetal genetic abnormalities or maternal environmental factors. Understanding cardiac embryology is very important for diagnosing the morphology of congenital heart disease, understanding the pathogenesis of heart disease. This exhibit aims to: Review congenital heart disease with embryology Discuss how to comprehend the radiological findings of congenital heart disease

### TABLE OF CONTENTS/OUTLINE

l Determination of left-right axis Heterotaxia Right isomerism, asplenia Left isomerism, polysplenia Situs inversus l Development of first heart field Dextrocardia Hypoplastic right ventricle Single ventricle l Development of second heart field Outflow tract Persistent truncus arteriosus (PTA) Double outlet right ventricle (DORV) Tetralogy of Fallot (TOF) Transposition of Great Arteries (TGA) Inflow tract Pulmonary atresia with intact ventricular septum Hypoplastic left heart syndrome (HLHS) l Completion of atrial and ventricular septum Atrial septal defect (ASD) Ventricular septal defect (VSD) Atrio-Ventricular Septal Defect (AVSD)

## CAEE-36 THE ROLE OF CORONARY COMPUTED TOMOGRAPHY ANGIOGRAPHY (CCTA) IN SPONTANEOUS CORONARY ARTERY DISSECTIONS (SCAD): WHAT RADIOLOGISTS NEED TO KNOW

Lojo, MD (*Abstract Co-Author*) Nothing to Disclose
Susana A. Otero Muinelo, MD (*Abstract Co-Author*) Nothing to Disclose
Carla Suarez Silva, MD (*Abstract Co-Author*) Nothing to Disclose
Blanca Perez Perez-Lafuente, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Jose Martinez-Sapina Llanas, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The gold standard for the diagnosis of spontaneous coronary artery dissections (SCAD) is invasive coronariography angiography (ICA). Coronary computed tomography angiography (CCTA) can be the first diagnosis tool in haemodynamically stable patients and it´s very important in the follow-up. To present the role of CCTA in the diagnosis and follow-up of SCAD, with the different types of dissections and the differential diagnosis with other type of coronary occlusion. Also to describe the role of CCTA in the diagnosis of extracoronary arteriopathies related to SCAD.

**TABLE OF CONTENTS/OUTLINE**

SCAD is a cause of myocardial infarction, and it accounts for at least 4% of all acute coronary syndromes. It is more common among young women and pregnant. The clinical presentation is variable, ranging from chest pain to cardiac death, most patients presenting with myocardial injury biomarkers increase. Fibromuscular dysplasia is the most common co-existing condition, also an association with connective diseases has also been reported. SCAD diagnosis is usually made by ICA, but CCTA can be the first diagnostic-tool in haemodynamically stable patients. Although dissection flap occurs in minority of cases, this is the easiest pattern to recognize on CCTA. Most often a stenosis or oclusion occurs and it´s challenging to distinguish between SCAD and other causes of vessel occlusion, so it´s important to observe other findings. Most patients are treated conservatively, unless they have ischaemia or haemodymically instability. Most patients are completely cured in 120 days and up to 30 % present a new SCAD. That is why the main role of CCTA is during follow-up period for assessment of dissection healing, 3/6 months after the SCAD event.

## CAEE-37 MYOCARDIAL T1 MAPPING FOR CHARACTERIZING MYOCARDIAL DISEASES: STATE OF THE ART

Priya Jagia, MD (*Abstract Co-Author*) Nothing to Disclose
Niraj N. Pandey, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Sanjeev Kumar, MBBS,MD (*Abstract Co-Author*) Nothing to Disclose
Vineeta Ojha, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. T1 mapping is a robust tool for evaluating myocardial diseases by quantifying changes in myocardial tissue composition.2. T1 mapping complements late gadolinium enhancement (LGE) imaging by detecting diffuse interstitial fibrosis, which LGE might miss.3. The utility of T1 mapping spans a diverse spectrum of cardiac conditions that influence both therapeutic strategies and clinical outcomes.After going through the exhibit, the reader will be able to explain the physics and principles behind T1 mapping, acquisition and interpretation, and applications of T1 and ECV mapping for diagnosis, prognostication, treatment and follow-up for various myocardial pathologies.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction2. Principles of T1 Mapping: Acquisition, post processing and interpretation3. Overview of T1 mapping indices and histological correlates: native T1, post contrast T1, and Extracellular Volume (ECV) Fraction4. Normal ranges5. T1-Mapping Techniquesa. Inversion Recovery-Based Techniquesb. Saturation Recovery-Based Techniquesc. Other techniques6. T1 Mapping in Ischemic Heart Diseasea. Acute Myocardial Infarctionb. Chronic Myocardial Infarction7. T1 Mapping in Non-Ischemic Cardiomyopathya. Non-Ischemic Dilated Cardiomyopathy (NIDCM)b. Takotsubo Cardiomyopathyc. Genetic Cardiomyopathies i. Hypertrophic Cardiomyopathy ii. Arrhythmogenic Right Ventricular Cardiomyopathy iii. Left Ventricular Noncompactiond. Post heart transplant e. Miscellaneous 8. Inflammatory Cardiomyopathiesa. Acute myocarditisb. Cardiac Sarcoidosis9. Infiltrative Cardiomyopathiesa. Cardiac Amyloidosisb. Anderson-Fabry Diseasec. Cardiac Siderosis10. Valvular Heart Disease11. Conclusions

## CAEE-38 ADVANTAGES OF DUAL-SOURCE PHOTON-COUNTING DETECTOR CT FOR MYOCARDIAL EXTRACELLULAR VOLUME QUANTIFICATION

Akio Hiwatashi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Misugi Urano, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kazuya Ohashi, PhD, RT (*Abstract Co-Author*) Nothing to Disclose
Toshihide Itoh, PhD (*Abstract Co-Author*) Employee, Siemens AG

Shibuki Matsui (*Abstract Co-Author*) Nothing to Disclose
Tatsuya Kawai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nobuo Kitera, RT, MSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Non-invasive quantification of the extracellular volume (ECV) is a method for the evaluation of focal and diffuse myocardial fibrosis, potentially obviating the need for invasive endomyocardial biopsy. 2. Quantification of ECV is an established method in MRI. However, quantification of ECV using CT (CT-ECV) is lower-cost, more accessible and faster than that of ECV using MRI (MR-ECV), and is also available even for patients where MRI is contraindicated. 3. Dual-source photon-counting detector CT (DS-PCD-CT) always provides spectral information. Moreover, this information can be obtained by ECG-gated scan mode and high-pitch spiral scan mode, which is unavailable with energy-integrating detector dual-source CT. 4. The new DS-PCD-CT option allow for more accurate CT-ECV quantification, which remains robust to variability of heart rate without the need for increased radiation dose.

**TABLE OF CONTENTS/OUTLINE**

1. Utility of ECV for cardiac diseases 2. Non-invasive quantification of ECV-CT in comparison to ECV-MRI 3. Advantages of DS PCD-CT in cardiac imaging 4. Validation of the accuracy of data acquisition method specific to DS-PCD-CT 5. Advantages and disadvantages of CT-ECV and development with DS-PCD-CT

## CAEE-39 SUPRA-AORTIC TENDON: AN ENIGMA ON CARDIAC IMAGING RESEMBLING AORTIC DISSECTION

Satinder P. Singh, MD (*Abstract Co-Author*) Nothing to Disclose
Mostafa Abozeed, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Mohamed Ibrahim, MD (*Abstract Co-Author*) Nothing to Disclose
Inayat Grewal (*Abstract Co-Author*) Nothing to Disclose
Naga Sai Rasagna Mareddy, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

; Understand the embryological basis and origin of the supra-aortic tendon; Gain insight into the challenges of diagnosing this rare entity on cardiac imaging and become familiar with its mimics; Identify the clinical significance and limitations of conventional cardiac imaging modalities in assessing for this entity.; Describe the imaging features of supra-aortic tendon that help to distinguish it from type A aortic dissection

**TABLE OF CONTENTS/OUTLINE**

; Overview of embryological development of supra-aortic tendon; Explanation of how to diagnose supra-aortic tendon on cardiac imaging:a) Understanding the limited role of echocardiogram and non-gated cardiac CTA to differentiate the two entities.b) Discussion of importance of gated Cardiac CT to better evaluate the aortic root.c) Discussion of impact of accurate diagnosis of this condition on patient management; Identification of specific imaging features found in patients with type A aortic dissection to better understand the similarities and differences in both conditions on imaging; Strategies for Radiologists who encounter similar cases in their practice.
