Vibhas Deshpande, PhD (*Abstract Co-Author*) Researcher, Siemens AG
Sean A. Woolen, MD, MS (*Presenter*) Research Grant, Siemens AG;Investigator, Siemens AG

### PURPOSE

The healthcare sector significantly impacts the climate crisis, with over half of its carbon footprint stemming from energy use. MRI systems are major energy consumers in the hospital with little known about the energy needed to cool these devices. Our study focuses on evaluating the energy contributions and patterns of dedicated MRI cooling systems.

## METHODS AND MATERIALS

An energy meter (Siemens SEM3) was installed at an outpatient facility where 0.55T (Siemens Magnetom Free.Max) and 3T (Siemens Magnetom Vida) MRI systems were in operation. Current transformers were placed separately on the power distribution units for each of the MRIs and on the chiller units that were providing cooling for the MRI systems. Power data was extracted with a Desigo platform. The chillers were both Filtrine systems and dedicated solely to their MRI. Power draw from each system was continuously monitored with 10s temporal resolution for the period of 1 week. Average power consumption for both the MRI and chillers were evaluated during periods of scanning and idle time. Total energy use of each system over a week was measured. Data were summarized with descriptive statistics and 95% CIs.

## RESULTS

During overnight idle periods, the MRIs exhibited an average power draw of 9.25±0.03 kW (0.55T) and 11.22±0.03 kW (3T). Correspondingly, the chillers used 5.54±6.59 kW (0.55T) and 6.77±7.81 kW (3T). The chillers consistently maintained a characteristic power draw during idle periods, but increased activity during scanning periods due to heightened cooling demands, shifting to shorter cycles and a constant higher power mode. Overall, chillers accounted for 57% of the energy use for the 0.55T and 50% for the 3T MRI systems. Notably, during idle periods, these percentages increased to 60% for both MRI models. Over the course of the week, the MRI systems consumed an average of 239±15 kWh (0.55T) and 399±43 kWh (3T), while the chillers consumed 138±5 kWh (0.55T) and 198±14 kWh (3T). Under constant idle conditions, projected daily energy usage was 222 kWh (0.55T) and 269 kWh (3T) for the MRIs and 125 kWh (0.55T) and 162 kWh (3T) for the chillers. The additional energy associated with scanning was only 17 kWh (0.55T) and 130 kWh (3T) for MRI, and 13 kWh (0.55T) and 36 kWh (3T) for chillers.

## CONCLUSION

Our findings indicate that MRI chillers are responsible for 50-60% of total MRI system energy use, with small additional energy consumed during actual scanning compared to idle periods.

## CLINICAL RELEVANCE/APPLICATION

This study underscores the critical need for strategies that minimize idle energy consumption in cooling systems, enhancing energy efficiency in healthcare. Implementing such energy-efficient practices could significantly lower the carbon footprint of medical imaging facilities.

## M5B-SPNR-1 OPTIMIZING ECHO TIME PARAMETERS IN POINT-RESOLVED SPECTROSCOPY FOR ENHANCED CYSTATHIONINE DETECTION IN GLIOMA PATIENTS: A VALIDATION STUDY

Min Zhou (*Abstract Co-Author*) Nothing to Disclose
Ziqiao Lei, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jie Zhao (*Abstract Co-Author*) Nothing to Disclose
Zhuang Nie (*Presenter*) Nothing to Disclose

### PURPOSE

To optimize the echo time (TE) of point-resolved spectroscopy (PRESS) for cystathionine detection in gliomas, and evaluate the diagnostic accuracy of PRESS for 1p/19q-codeletion identification.

### METHODS AND MATERIALS

The TE of PRESS was optimized with numerical and phantom analysis to better resolve cystathionine from the overlapping aspartate multiplets. The optimized and 97 ms TE PRESS were then applied to 84 prospectively-enrolled patients suspected of glioma or glioma recurrence to examine the influence of aspartate on cystathionine quantification, and diagnostic performance for 1p/19q-codeleted gliomas.

### RESULTS

The TE of PRESS was optimized as (TE1, TE2) = (17 ms, 28 ms). The spectral pattern of cystathionine and aspartate were consistent between calculation and phantom. The mean concentrations of cystathionine in vivo fitting without aspartate were significantly higher than those fitting with full basis-set for 97 ms TE PRESS (1.97 ± 2.01 mM vs. 1.55 ± 1.95 mM, $p < 0.01$), but not significantly different for 45 ms method (0.801 ± 1.217 mM and 0.796 ± 1.217 mM, $p = 0.494$). The cystathionine concentrations of 45 ms approach was better correlated with those of edited-MRS than 97 ms counterparts ($r = 0.68$ vs. 0.49, both $p < 0.01$). The sensitivity and specificity for discriminating 1p/19q-codeleted gliomas were 66.7% and 73.7% for 45 ms method, and 44.4% and 52.5% for 97 ms method, respectively.

### CONCLUSION

The 45 ms TE PRESS yielded more precise cystathionine estimates than the 97 ms method.

### CLINICAL RELEVANCE/APPLICATION

The cystathionine-optimized TE = 45 ms PRESS sequence provides more precise cystathionine measurements, and is anticipated to facilitate noninvasive diagnosis of 1p/19q-codeleted gliomas, and the dynamic monitoring of tumor progression, treatment response, or recurrence in those patients.

## M5B-SPNR-10 CORRELATION BETWEEN GLYMPHATIC SYSTEM FUNCTION AND SEGMENTAL ABNORMALITIES OF WHITE MATTER MICROSTRUCTURE IN MAJOR DEPRESSION DISORDER PATIENTS

Shiyun Tian, MD (*Abstract Co-Author*) Nothing to Disclose
Yan Wei Miao (*Abstract Co-Author*) Nothing to Disclose
Chun Yang (*Presenter*) Nothing to Disclose

### PURPOSE

We aimed to investigate glymphatic system function in major depression disorder (MDD) by performing diffusion tensor imaging analysis along the perivascular space (DTI-ALPS) and to evaluate its association with cerebral white matter abnormalities and neuropsychological scale scores.

### METHODS AND MATERIALS

The preprocessing of 3D-T1WI images was performed using FSL software. Automated Fiber Quantification (AFQ) technology can automatically identify the main 20 fiber bundles in the entire brain. The method for DTI-ALPS calculation is summarized in Fig. 1. Finally, the DTI-ALPS was calculated using the following formula: DTI-ALPS = mean (Dxproj, Dxassoc)/ mean (Dyproj, Dzassoc). We use the average value of two neuro-radiologists for subsequent statistical analysis. SPSS Statistics V26.0. was used to analyze the demographic characteristics (including age, gender, and years of education), HAMD, HAMA, and MoCA. Partial correlation analyses were done to investigate the relationship between DTI-ALPS, AFQ and neuropsychological assessment results, after adjusting age, gender, and years of education.

### RESULTS

Figure 2 summarizes the inclusion process. For the results of mean diffusion differences in tract level, MDD group showed significantly increased AD value (Table 2). For diffusion differences in point-wise level, significant alterations were mainly observed in MD , AD and RD, details were shown in Figure 3 (FWE correction, $p<0.05$). Interobserver agreement was excellent for the ALPS index (ICC, 0.844, 95% CI: 0.750, 0.905). The averaged DTI-ALPS values according to the participant groups were summarized in Table 3 and Figure 4. Partial correlation analysis was conducted mean diffusion differences in tract level of AFQ analysis (Figure 5). For diffusion differences in point-wise level of AFQ analysis, MD value of CB_L were found negatively correlated with DTI-ALPS index (Figure 6). Results for the associations between DTI-ALPS and HAMD Scale, HAMA Scale, and cognitive test results were summarized in Table 4.

### CONCLUSION

In conclusion, we found that the DTI-ALPS index of MDD patients was decreased, which may indicate impaired glymphatic system function. The DTI-ALPS index was associated with retardation and decreased cognitive ability. Our study also revealed associations between impaired DTI-ALPS and white matter microstructural abnormalities. It may be a promising biomarker for the glymphatic system in MDD.

### CLINICAL RELEVANCE/APPLICATION

In this study, we found brain glymphatic activity reduction and white matter damage in patients with MDD. Moreover, impairment of glymphatic function as reflected by DTI-ALPS index was related to white matter damage, retardation, and cognitive impairment in MDD patients. ADDIN EN.REFLIST

## M5B-SPNR-11 IMAGE QUALITY ASSESSMENT AND WHITE MATTER HYPERINTENSITY QUANTIFICATION IN TWO ACCELERATED HIGH-RESOLUTION 3D FLAIR TECHNIQUES: WAVE-CAIPI AND DEEP LEARNING-BASED SPACE

Yangsean P. Choi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ha-Kyung Jung, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the image quality obtained using two accelerated high-resolution 3D FLAIR techniques for the brain—deep learning-reconstruction SPACE (DL-SPACE) and wave-CAIPI FLAIR.

### METHODS AND MATERIALS

A total of 123 participants underwent DL-SPACE and wave-CAIPI FLAIR imaging of the brain were retrospectively reviewed. In a qualitative analysis, two radiologists rated the quality of each image, including the overall image quality, artifacts, sharpness, fine-structure conspicuity, and lesion conspicuity based on Likert scales. In a quantitative analysis, the signal-to-noise ratio (SNR) for the normal-appearing white matter (NAWM) and lesion and the contrast-to-noise ratio (CNR) for a lesion were calculated and compared. Moreover, the volumes of white matter hyperintensities (WMHs) obtained with the two techniques were automatically quantified and compared.

### RESULTS

The DL-SPACE FLAIR technique demonstrated a significantly higher fine-structure conspicuity ($P < 0.001$), lower degree of artifacts ($P < 0.001$), and higher overall image quality ($P = 0.001$). The mean SNR values were significantly higher with the DL-SPACE FLAIR technique (NAWM, 43.95 vs. 31.6; lesion, 31.35 vs. 21.28; all, $P < 0.001$). Additionally, the mean CNR of the WMH was significantly higher with the DL-SPACE FLAIR technique (11.34 vs. 8.22; $P < 0.001$). The periventricular and deep WMH volumes were significantly larger with the DL-SPACE FLAIR technique ($1.91 \pm 4.69$ vs. $1.54 \pm 4.18$; $P < 0.001$ and $0.26 \pm 0.42$ vs. $0.23 \pm 0.38$; $P = 0.002$, respectively).

### CONCLUSION

The DL-SPACE FLAIR technique produced images with superior quality, SNR, and CNR compared to the wave-CAIPI FLAIR technique with the same acquisition time.

### CLINICAL RELEVANCE/APPLICATION

DL-SPACE FLAIR is an accelerated MR technique that provides superior FLAIR image quality of the brain than wave-CAIPI technique in a clinically feasible scan time.

## M5B-SPNR-12 IMPACT OF METHOTREXATE THERAPY ON BRAIN METABOLISM IN PEDIATRIC AND YOUNG ADOLESCENT CANCER SURVIVORS: AN 18F-FDG PET/MRI STUDY

K. Elizabeth Hawk, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lucia Baratto, MD (*Abstract Co-Author*) Nothing to Disclose
Hyun Gi Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Heike E. Daldrup-Link, MD (*Abstract Co-Author*) Managing director, Monasteria Press LLC Research Grant, MegaPro Inc
Tie Liang, PhD (*Abstract Co-Author*) Nothing to Disclose
Zahra Shokri Varniab, MD (*Presenter*) Nothing to Disclose

### PURPOSE

High-dose Methotrexate (HDMTX) chemotherapy has been linked to microglia activation and subsequent oligodendrocyte depletion in pre-clinical studies. However, it is not known if 18F-FDG PET imaging can detect the different phases of brain inflammation and brain damage after HDMTX. To close this gap, we evaluated the brain metabolism of pediatric cancer survivors on [18F] FDG PET/MRI before and after completion of HDMTX therapy. We hypothesized that HDMTX would leads to increased brain metabolism on short term and decreased brain metabolism long term follow up studies.

### METHODS AND MATERIALS

In an IRB approved, retrospective study, we enrolled 19 pediatric patients and young adults (three female and 17 males; age 17.9±4.32 years), with lymphoma (n=13) or osteosarcoma (n=6), who had undergone [18F] FDG PET/MRI at baseline and after completion of HDMTX (>1000 mg/m2). The post-treatment scan was conducted =3 months after the end of HDMTX therapy (group 1, n=12 patients) or more than 3 month after the end of chemotherapy (group 2, n=7 patients). The mean and maximum standardized uptake value (SUVmean and SUVmax) was measured in eleven different brain regions in each patient using PMOD software. Within each group, SUV data of the same region before and after chemotherapy was compared with the Wilcoxon Matched-Pairs Signed-Rank Test.

### RESULTS

Compared to baseline scans, we found increased cortical 18F-FDG signal on short term follow up PET scans, but not long-term follow-up PET scans. In group 1, SUVmean and SUVmax of the entire cortex was significantly increased post treatment (7.40±1.58 and 13.66±3.48) compared to baseline values

(5.29±1.73 and 9.68±3.63, respectively, p<0.001). In group 2, SUVmean and SUVmax of the entire cortex was not significantly different post treatment (5.99±1.39 and 11.06±2.93) compared to baseline values (6.09±1.71 and 11.51±3.50; p=0.1).

**CONCLUSION**

[18F] FDG PET/MRI demonstrated significantly increased cortical metabolism on short term follow up scans after HDMTX, which might indicate microglia activation. By contrast, [18F] FDG PET/MRI scans more than 3 months after end of therapy demonstrated recovered brain metabolism or decreased brain metabolism.

**CLINICAL RELEVANCE/APPLICATION**

Non-invasively identifying brain inflammation with 18F-FDG PET/MRI after HDMTX therapy could enable patient stratification for targeted anti-inflammatory interventions, potentially improving long-term neurological outcomes.

## M5B-SPNR-13 SIMULTANEOUS MULTIPARAMETRIC ESTIMATION OF ARTERIOVENOUS MALFORMATIONS HEMODYNAMICS USING MR FINGERPRINTING ASL (MRF-ASL)

Judy Huang, MD (*Abstract Co-Author*) Nothing to Disclose
Dengrong Jiang (*Abstract Co-Author*) Nothing to Disclose
Dhairya Lakhani, MD (*Abstract Co-Author*) Nothing to Disclose
Wen Shi (*Abstract Co-Author*) Nothing to Disclose
Vivek Yedavalli, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hanzhang Lu, PhD (*Abstract Co-Author*) Nothing to Disclose
Risheng Xu (*Abstract Co-Author*) Nothing to Disclose
Zhiyi Hu (*Presenter*) Nothing to Disclose

**PURPOSE**

Arteriovenous malformations (AVM) are a congenital vascular disease characterized by the direct connection between arteries and veins without a capillary bed. The resulting shunts within the AVM niduses disrupt normal hemodynamics, leading to complications such as hemorrhage or stroke. MR fingerprinting arterial spin labeling (MRF-ASL) enables simultaneous assessment of multiple parameters, including cerebral blood flow (CBF), arterial cerebral blood volume (aCBV), and bolus arrival time (BAT). This study aims to 1) evaluate the effectiveness of MRF-ASL in assessing AVM hemodynamics and 2) compare its sensitivity for AVM detection with CBF measured on single delay pseudo-continuous ASL (pCASL) as graded by the reference standard Spetzler Martin (SM) criteria on digital subtraction angiography (DSA).

**METHODS AND MATERIALS**

Patients with DSA-confirmed AVM were included in this IRB-approved study with SM grades assessed. Derived MRF-ASL parametric maps included: CBF1-compartment, CBF2-compartment, aCBV, BAT, and T1. Single delay 2D pCASL CBF was also acquired for the comparison of AVM detection and characterization. MRF-ASL and pCASL were each acquired within 5 minutes. To quantify MRF-ASL and pCASL parameters, regions-of-interest (ROIs) of AVM nidus and contralateral non-affected tissue were manually drawn based on T2-weighted images. Paired t-test was used to compare the MRF-ASL parameters within the AVM nidus and the same spatial location in the contralateral non-affected side. Associations between SM grades and MRF-ASL parametric values in AVM nidus were evaluated using linear regression.

**RESULTS**

7 AVM patients (5F, age 44.9±13.8 years) were studied. ROI analysis showed that the AVM nidus region had higher CBF1-compartment (P<.0001), CBF2-compartment (P<.0001), aCBV (P=.008), and shorter BAT (P=.005) than the contralateral non-affected side. In contrast, no significant difference in pCASL CBF was found (P=.57). The MRF-ASL aCBV was significantly associated with SM grade (P = .02). No association was found for CBF1-compartment (P=.44), CBF2-compartment (P=.16), or BAT (P=.30).

**CONCLUSION**

MRF-ASL exhibited superior sensitivity in detecting the AVM lesion compared to single delay pCASL. Within the AVM nidus region, we observed elevated CBF1-compartment, CBF2-compartment, aCBV, and shorter BAT values compared to contralateral normal tissue in the same patients. The aCBV values within the nidus were significantly associated with SM grade. In summary, our findings suggest that MRF-ASL holds promise as a useful tool for AVM assessment.

**CLINICAL RELEVANCE/APPLICATION**

Our preliminary analysis demonstrates that the 5-minute multi-parametric MRF-ASL acquisition is a promising technique for AVM detection and characterization.

## M5B-SPNR-14 USE OF MRI IN THE PREDICTION OF DEEP TMS RESPONSE IN OCD

Omer Uysal (*Abstract Co-Author*) Nothing to Disclose
Muhammed Taha Esmeray (*Abstract Co-Author*) Nothing to Disclose
Reyhan Ilhan (*Abstract Co-Author*) Nothing to Disclose
Mehmet Kemal Arikan (*Abstract Co-Author*) Nothing to Disclose
Oznur Kalaba (*Abstract Co-Author*) Nothing to Disclose
Murat Asik (*Presenter*) Nothing to Disclose

**PURPOSE**

Brain morphological biomarkers could contribute to understanding the treatment response in patients with obsessive compulsive disorder (OCD). The present study aims to investigate whether patients responsive to deep Transcranial Magnetic Stimulation (TMS) differ from non-responsive individuals in terms of brain morphology.

**METHODS AND MATERIALS**

This retrospective study included thirty-three OCD patients (14 female and 19 male) aged at 18 - 60 (mean ± SD = 34.52 ± 12.97 years). Based on the 50% reduction in Yale-Brown Obsessive Compulsive Scale (Y-BOCS) scores after treatment, patients were grouped as responders (n=22) and non-responders (n=11). MR imaging in the OCD and control groups was performed by using a 3T MR Scanner.180 sections high-resolution T1-weighted images (magnetization-prepared rapid gradient-echo) were obtained in axial and sagittal planes.The images of all subjects were uploaded to VolBrain which is a fully automatic pipeline for volumetric brain analysis and able to provide accurate volumetric information and segmentation analysis.Brain structure, thickness and general brain measurements were compared among responders, non-responders, and healthy controls. Brain structure and cortical thickness were compared via multivariate analysis of variance by taking gender as fixed factor and age as covariate. The significance level was set at <0.05 for all comparisons.

**RESULTS**

OCD patients who respond to deep TMS treatment had decreased volume in bilateral frontal pole, right basal forebrain, right anterior orbital gyrus, right medial orbital gyrus compared to non-responders and healthy controls. As specific to difference between responders and non-responders, pairwise comparison revealed that there is a statistically significant difference in volumes of bilateral and total frontal pole, total and right basal forebrain, anterior orbital gyrus, and medial orbital gyrus. Responders had decreased volume in comparison to both non-responders and healthy controls.MANOVA indicated there was a statistically significant effect of diagnostic groups on cortical thickness of the entire brain ($p < .0001$) and statistically significant effect of diagnostic groups on overall brain morphology, i.e, white matter and gray matter ( $p < .045$ ).

**CONCLUSION**

Our findings reveal a substantial association between a reduction in anterior orbital gyrus, medial orbital gyrus, frontal pole and, basal forebrain volume and response to deep TMS treatment. Decreased volume in these regions could be the morphological predictor of response to deep TMS in OCD treatment.

**CLINICAL RELEVANCE/APPLICATION**

In brain volumetric MRI examination in patients with OCD, segmentation and volume changes in certain regions support the clinical findings.

## M5B-SPNR-16 A SYSTEMATIC REVIEW OF FUNCTIONAL MRI TRACTOGRAPHY IN GLIOMAS AND PREDICTING OUTCOMES USING ARTIFICIAL INTELLIGENCE

Joe Davids (*Abstract Co-Author*) Nothing to Disclose
Samiullah Dost, MD (*Abstract Co-Author*) Nothing to Disclose
Nishika Bhatt (*Abstract Co-Author*) Nothing to Disclose
Sanchit Aapan (*Abstract Co-Author*) Nothing to Disclose
Nazir Sirajudeen (*Abstract Co-Author*) Nothing to Disclose
Mohammed Blaaza, BSC,MBBS (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this investigation is to undertake an assessment of the application of artificial intelligence (AI) in prognosticating outcomes for glioma patients within the framework of functional magnetic resonance imaging (fMRI) and tractography. These imaging modalities are remarkable for visualising tracts, and gliomas, and their relationship, however, are seldom used in daily diagnostics. Early detection and diagnosis are paramount, and the integration of AI methodologies with anatomical marking holds significant promise in mitigating long-term malignant sequelae.

**METHODS AND MATERIALS**

A systematic search was conducted across PubMed, Ovid MEDLINE, and Web of Science databases. The search query comprised key terms such as "Glioma," "fMRI," "Artificial Intelligence," and "Tractography." A meta-analysis was conducted to quantitatively amalgamate data from various studies. The analyses were completed in line with the PRISMA systematic review guidelines.

**RESULTS**

The search strategy identified 23 relevant papers. After excluding duplicates and ineligible studies, five studies were suitable for meta-analysis, with a total enrolment of 280 patients. The investigation underscored the role of artificial intelligence in prognosticating symptoms based on fMRI and tractography data. Notably, machine learning-based prognostication of motor function exhibited a high sensitivity (0.74) specificity (0.75), and accuracy (0.74), while prediction of aphasia demonstrated a sensitivity of 0.75, specificity of 0.85, and accuracy of 0.81. Furthermore, deep learning models revealed an augmentation in tracked diffusion streamlines by 13% for high-grade gliomas and 9.25% for low-grade gliomas.

**CONCLUSION**

AI methodologies have emerged as highly promising tools in forecasting the occurrence, timing, and severity of symptoms among glioma patients based on fMRI and tractography data. Such insights hold considerable potential to inform clinical decision-making and surgical planning. However, the validation of these preliminary findings warrants further trials and studies to enhance their robustness and reliability.

**CLINICAL RELEVANCE/APPLICATION**

This review aims to provide a comprehensive and reliable summary of the role of artificial intelligence in symptom detection of glioma patients. This summary offers insights into treatment effectiveness, guiding evidence-based decision-making, and ultimately improving patient outcomes.

## M5B-SPNR-17 STRATEGIES FOR PREVENTING BRAIN MRI IMAGE DEGRADATION FOLLOWING FERUMOXYTOL INJECTION AND DETERMINING THE OPTIMAL TIME INTERVAL BETWEEN FERUMOXYTOL ADMINISTRATION AND IMAGING

Thomas J. O'Neill, MD (*Abstract Co-Author*) Nothing to Disclose
Sarah Farooq (*Abstract Co-Author*) Nothing to Disclose
Usman A. Dar, MD (*Abstract Co-Author*) Nothing to Disclose
Seunghong Rhee, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Ferumoxytol, an FDA-approved agent for treating iron deficiency anemia in adults with chronic kidney disease (CKD), is also widely used off-label as a magnetic resonance imaging (MRI) contrast agent. Despite its benefits, the potential for Ferumoxytol to cause unintended degradation of Brain MRI images, particularly in SWI (Susceptibility Weighted Imaging) and GRE (Gradient Recalled Echo) sequences, has been insufficiently addressed. This study aims to investigate the extent of image degradation associated with Ferumoxytol and to establish an optimal time interval between Ferumoxytol administration and MRI to minimize such effects.

**METHODS AND MATERIALS**

This study included 43 patients who received Ferumoxytol and underwent Brain MRI within a 3-month period. We examined the impact of Ferumoxytol on MRI images, focusing on unintended T1 sequence enhancement and degradation of image quality in SWI or GRE sequences. We also measured the time interval between Ferumoxytol administration and MRI scanning. Additional factors considered included the patient's history of dialysis (peritoneal or hemodialysis) and whether the glomerular filtration rate (GFR) was below 60 ml/min at the time of Ferumoxytol administration and imaging.

**RESULTS**

Unintended T1 enhancement was observed in 67.5% of cases, while 62.5% demonstrated image degradation in SWI/GRE sequences. The average time interval between Ferumoxytol administration and Brain MRI was 6.625 days. Among the patients, 70% (no = 28) had a GFR above 60 ml/min, and 10%

had undergone dialysis (no =4). Binary logistic regression analysis revealed a significant correlation between the time interval from Ferumoxytol administration to the observed effects on T1 enhancement and SWI/GRE sequences ($p = 0.007$ for T1 enhancement and $p = 0.008$ for SWI/GRE degradation), while no correlation was found between dialysis or GFR and image quality. A cutoff time interval of 6.5 days yielded an 80% sensitivity and 96% specificity for T1 enhancement effects, whereas a cutoff of 5.5 days provided a 93% sensitivity and 40% specificity for SWI/GRE effects.

**CONCLUSION**

Independent of dialysis status or GFR, a time interval of more than 5 to 6 days between Ferumoxytol administration and Brain MRI is recommended to mitigate image degradation. The study's limitations include a relatively small patient cohort, which restricts the robustness of correlations between dialysis and/or GFR and image degradation.

**CLINICAL RELEVANCE/APPLICATION**

Improving the quality of Brain MRI scans when Ferumoxytol is used as a hematopoietic agent in chronic kidney disease population by identifying a safe window between Ferumoxytol administration and MRI imaging, especially in SWI and GRE sequences.

## M5B-SPNR-19 SUSCEPTIBILITY VALIDATION WITH IRON CONCENTRATION AND TEMPLATE-BASED MULTICHANNEL SPATIAL NORMALIZATION PRECISION FOR OLDER ADULT BRAIN QSM

Md Tahmid Yasar, BSc (*Abstract Co-Author*) Nothing to Disclose
Arnold M. Evia JR, PhD (*Abstract Co-Author*) Nothing to Disclose
Yingjuan Wu, MS,BEng (*Abstract Co-Author*) Nothing to Disclose
Mohammad Rakeen Niaz (*Abstract Co-Author*) Nothing to Disclose
Shengwei Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Abdur Raquib Ridwan, PhD (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Arfanakis, PhD (*Abstract Co-Author*) Nothing to Disclose
Rasheed Abid, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Quantitative susceptibility mapping (QSM) is pivotal for studying iron and calcium homeostasis in brain and age-related pathologies. The newly developed MIITRA-QSM template fills the crucial need for high-resolution QSM imaging of the older adult brain. This work aims to: a) evaluate the average susceptibility of the MIITRA-QSM template against actual iron content in targeted brain regions of older adults, and b) conduct a template-based, multichannel evaluation to assess representativeness and precision in spatial normalization across subjects.

**METHODS AND MATERIALS**

In this study, MIITRA-QSM was first investigated for its correlation with iron concentration, and subsequently, it was compared with two other publicly available templates (HybraPD and MuSus-100), with susceptibility values normalized between 0 and 10000. First, the mean of iron concentration of 308 subjects with non-demented were evaluated for both hemispheres in the inferior-temporal, anterior-cingulate, and middle-frontal cortex. Linear regression was used to investigate the correlation between the median susceptibility of the MIITRA-QSM template with iron concentration in the six selected regions. Next, 3D T1-weighted MPRAGE and multi-echo 3D GRE data from 100 non-demented older adults (aged 67.8-97.2 years) were used for all the templates. Five registration pipelines were used: single-channel registration of susceptibility maps to QSM templates; multichannel registration of T1-weighted images and susceptibility maps to T1-weighted and QSM templates (at 25%, 50%, and 75% weights); and single-channel registration of T1-weighted images to T1-weighted templates. Average log-Jacobian maps of deformations were generated for each participant. Finally, inter-subject pairwise normalized cross-correlation of magnetic susceptibility maps (4950 pairs) was calculated for each registration approach.

**RESULTS**

Regression analysis yielded robust results with an R2 value of 0.892 and a p-value of 0.00453, indicating significant correlation among iron concentration and template susceptibility. Registration to MIITRA-QSM resulted in less deformation compared to other templates across all pipelines. Furthermore, pairwise normalized cross-correlation demonstrated the highest spatial matching for MIITRA-QSM.

**CONCLUSION**

The study underscores that susceptibility in MIITRA-QSM strongly correlates with iron concentrations in targeted regions. Additionally, the MIITRA atlas proved to be highly representative of the older adult brain, demonstrating the highest spatial matching during single-channel susceptibility registration.

**CLINICAL RELEVANCE/APPLICATION**

QSM templates offer insights into age-related changes in brain iron levels.

## M5B-SPNR-2 IMPROVING MICROSTRUCTURE QUANTIFICATION USING SELF-SUPERVISED AND PHYSICS-INFORMED DEEP LEARNING

Qiyuan Tian (*Abstract Co-Author*) Nothing to Disclose
Jialan Zheng (*Abstract Co-Author*) Nothing to Disclose
Ziyu Li (*Abstract Co-Author*) Nothing to Disclose
Yi Jing (*Abstract Co-Author*) Nothing to Disclose
Zihan Li (*Abstract Co-Author*) Nothing to Disclose
Enhao Gong, PhD (*Presenter*) Employee, Subtle Medical, Inc;Stockholder, Subtle Medical, Inc

**PURPOSE**

Diffusion MRI is an important tool for mapping brain tissue microstructure non-invasively. The microstructure properties quantified by diffusion models are critical biomarkers for accurate diagnosis. However, the accurate estimation of diffusion model parameters suffers from intrinsic low-SNR of DWIs. Recently a self-supervised and physics-informed framework for diffusion model optimization entitled DIMOND has been proposed and validated on healthy subjects. This study aims to evaluate DIMOND's efficacy and robustness for diffusion tensor fitting among subjects with anomalies.

**METHODS AND MATERIALS**

This study involved pre-processed diffusion data (18×b=0, 90×b=1000 s/mm2, 1.25 mm iso.) of six subjects with anomalies from Human Connectome Project (HCP). A subset containing the first two b=0 and 15 b=1000 s/mm2 image volumes was extracted for each subject to simulate a clinical acquisition scheme. The anomalies include posterior midline arachnoid cyst, right parietal lobe cyst, right dorsal benign cyst, right lateral ventricle cyst, right frontal white matter atypicality and posterior right cerebellum lesion. The anomalies were labeled manually in reference fractional anisotropy (FA) and axial diffusivity (AD) maps.The training of DIMOND includes three steps: 1) mapping noisy input diffusion data to diffusion model parameter values using NN, 2) modeling diffusion signals by passing NN predictions to forward diffusion models, and 3) optimizing NN's parameter by minimizing the difference between the acquired signals and synthesized signals from step 2. In this study, NN is consisted of one layer of 3×3×3 convolution layers

followed by six fully connected layers. For each subject, reference tensor model parameters were derived from all available diffusion data using ordinary least square regression (OLS) of FSL. DIMOND was trained and applied to the subset of each subject's data and compared with OLS results.

**RESULTS**

Cysts and tumors are distinguishable from the surrounding tissues under both methods. However, DIMOND exhibited denoising effect which enhanced the visibility of anomalies. Quantitatively, DIMOND predicted FA and AD maps with lower MAEs, both throughout the entire brain and in the regions with anomalies.

**CONCLUSION**

DIMOND can recover microstructures accurately and reliably for both normal and abnormal tissues, and outperforms the conventional method.

**CLINICAL RELEVANCE/APPLICATION**

DIMOND's superior performance render it a potential next-generation tool for quantifying microstructural properties in clinical settings, aiding diagnosis and enhancing the AI-based automated diagnostic methods.

## M5B-SPNR-3 ACCELERATED MOTION CORRECTION WITH DEEP LEARNING FOR FUNCTIONAL MRI - A POTENTIAL FOR REAL-TIME FMRI PROCESSING FOR FASTER CLINICAL ASSESSMENT

Saurabh Jain (*Abstract Co-Author*) Nothing to Disclose
Janova Anbarasi (*Abstract Co-Author*) Nothing to Disclose
Akshay Kumaar M (*Abstract Co-Author*) Nothing to Disclose
Sachin Patalasingh (*Abstract Co-Author*) Nothing to Disclose
Shamanth Hampali (*Abstract Co-Author*) Nothing to Disclose
Rimjhim Agrawal, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

While functional MRI (fMRI) offers valuable insights into brain functions, its resolution is lower than that of other techniques making it susceptible to the artefacts caused by head motions, impacting its reliability and interpretability of analyses. Motion correction is a standardised procedure to minimise distortions and inaccuracies caused by movement. However, traditional methods are less efficient and computationally expensive. To address this limitation, we present a novel deep learning framework specially designed for fast and effective motion correction of fMRI.

**METHODS AND MATERIALS**

This study analysed fMRI (N=151) sourced from multiple datasets including the Human Connectome Project, OpenNeuro, and privately acquired datasets. Preprocessing involved slice-time correction and extraction of middle slices from all planes into 2D moving images, each paired with reference volume of the respective subject. A Multi-Head Convolutional Neural Network was trained to predict the 12 affine parameters, utilising the reference and moving images. A subject-level 5-fold cross-validation was employed, with Mean Absolute Error (MAE) to train the framework.

**RESULTS**

We evaluated the network's performance on all 5 evaluation folds using various metrics. It achieved the best results in fold 3, with MAE of 0.03 and a runtime of 0.5, 0.02 seconds on CPU and GPU respectively. The framework was tested for generalizability on unseen data (hold out set, N=17), where the MAE was ~0.06. Further evaluation was done by realigning fMRI data with predicted motion parameters which resulted in significant accuracy improvement, leading to MAE ~0.01, when compared to AFNI with an impressive reduction by 82% in computation.

**CONCLUSION**

In summary, our study utilised diverse fMRI datasets and neural network architectures to predict parameters for motion correction. The model exhibited robust performance leading to efficiency on both CPU and GPU compared to conventional methods which could take hours. This could potentially enable real-time motion correction during scan acquisition. The results solidify the potential of the deep learning framework to significantly improve the reliability and interpretability of fMRI analysis across various datasets and settings.

**CLINICAL RELEVANCE/APPLICATION**

This study highlights the potential for real-time fMRI processing and augmenting quicker decisions in clinical settings like surgeries, neuromodulation, and neurofeedback analysis. This will also ensure results with higher reliability with a lower turnaround time making it apt for diagnosis and prognostic assistance to medical practitioners. This would significantly impact improved patient outcomes by reducing the overall burden by making the process more efficient.

## M5B-SPNR-7 IS IT POSSIBLE TO USE LOW-DOSE DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM FOR BRAIN CT PERFUSION EXAMINATION ON CT ROUTINELY?

Songwei Yue (*Abstract Co-Author*) Nothing to Disclose
Yuhan Zhou, MD (*Abstract Co-Author*) Nothing to Disclose
Zhihao Wang (*Abstract Co-Author*) Nothing to Disclose
Limin Lei (*Presenter*) Nothing to Disclose

**PURPOSE**

Evaluate the performance of deep learning image reconstruction (DLIR) algorithm combined with low-dose protocol in whole brain CT perfusion (CTP) examination.

**METHODS AND MATERIALS**

Retrospective collection involving 112 patients subjected to three CTP dose-modulation scanning protocols (1: 80 kV 150mA, 2: 80 kV and 100mA, 3: 70 kV 150mA). CTP datasets were reconstructed using FBP, ASIR-V40%, 80%, and DLIR L, M, H levels for protocol 1(Group A-F), ASIR-V80% and DLIR-H for protocol 2(Group G, H) and 3(Group I, J). CT values, image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) of each group were compared. Perfusion parameters were evaluated (CBF, CBV, Tmax, MTT, and TTP) according to Abels' scoring system, and compared.

**RESULTS**

The radiation doses of the CTP in protocols 1-3 were 5.70mSv, 3.81mSv, 3.83 mSv, respectively. Within protocols 1, Group F had the highest SNR and CNR. Groups F, E, and C generated higher subjective scores. The perfusion parameters were not changing.Within protocols 2 and 3, the DLIR-H images showed lower SD values than ASIR-V80%, with higher SNR, CNR and subjective scores ($P<0.05$ for Group G vs. H, Group I vs. J).The objective and subjective image quality of DLIR-H images in protocols 2 and 3 were comparable to those of the ASIR-V80% group in protocols 1 ($P>0.05$ for Group C vs.

H vs. J). Groups I and J showed significant differences in perfusion parameters compared to other groups, especially in decreased MTT and increased CBF values in the white matter region. The perfusion parameters were not changing in group G, H.

**CONCLUSION**

Low current with the DLIR-H improves image quality without compromising perfusion parameter accuracy. However, reducing tube voltage to 70kV lowers accuracy, especially for MTT and CBF.

**CLINICAL RELEVANCE/APPLICATION**

TrueFidelity images with reduced tube current holds the potential to design CT acquisition protocols at reduced radiation dose levels without sacrificing image quality, which is particularly attractive in repeat examinations.

## M5B-SPNR-9 EFFECTIVE GLIOBLASTOMA SEGMENTATION THROUGH TRACTOGRAPHY

Shamanth Hampali (*Abstract Co-Author*) Nothing to Disclose
Bhagyasree Kanuparthi (*Abstract Co-Author*) Nothing to Disclose
Akshay Kumaar M (*Abstract Co-Author*) Nothing to Disclose
Aryan Raj Tiwary (*Abstract Co-Author*) Nothing to Disclose
Rimjhim Agrawal, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Traditional imaging techniques for Glioblastoma segmentation rely on multiple structural modalities, often failing to capture the intricate microstructural details necessary for precise delineation of tumor boundaries. This study leverages the unique capabilities of diffusion MRI (dMRI) to track water molecule diffusion, offering a detailed view of white matter tissue connectivity. By employing tractography, we aim to enhance the segmentation accuracy of brain tumour, by evaluating the integrating of white matter structure.

**METHODS AND MATERIALS**

In this study, we propose using dmri image for tractography based segmentation of tumor. Probabilistic tractography was applied to 10 clinical cases (single-shell DWI) of brain tumors, adjusting seed cutoff values to generate scalar map of white matter connectivity. Voxels were scored based on the streamline's seed-cutoff value, with higher scores indicating healthier tissue. T1-weighted imaging combined with CSF segmentation refined these maps, focusing analysis on disrupted white matter tracts. The manually delineated contrast-enhancing tumor regions on preoperative T1 images by two independent expert clinicians served as a standard for evaluating the tractography-based tumor delineation.

**RESULTS**

Initial results show that variable seed cutoff values in tractography effectively isolated areas with reduced or absent white matter connectivity, aligning well with tumor locations. Comparisons between algorithm-based tumor delineation and manual delineations revealed high sensitivity (80%) and specificity (90%), confirming the method's accuracy.

**CONCLUSION**

Integrating variable seed cutoff values in probabilistic tractography offers a promising approach for enhancing tumor boundary delineation in neurosurgical planning. This technique improves the precision of interventions by accurately identifying tumor-affected white matter pathways, potentially leading to better surgical outcomes and patient prognosis.

**CLINICAL RELEVANCE/APPLICATION**

Accurately demarcating tumors supports precise surgical resections and radiation therapy planning, minimizing damage to healthy brain tissue and enhancing overall treatment efficacy. Reduces scan time since multiple structural modalities are not required.

## M5B-SPOB-1 DEEP LEARNING NETWORK BASED ON PET/CT PRIMARY AND METASTATIC LESIONS: PREDICTING PLATINUM RESISTANCE IN OVARIAN CANCER

Wei Qian (*Abstract Co-Author*) Nothing to Disclose
Shouliang Qi (*Abstract Co-Author*) Nothing to Disclose
Beibei Li (*Abstract Co-Author*) Nothing to Disclose
Haoming Zhuang (*Abstract Co-Author*) Nothing to Disclose
Huiwen Luo (*Abstract Co-Author*) Nothing to Disclose
Dianning He, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Clinicians currently use genetic testing to determine platinum drug resistance, but neglect the important information provided by tumor imaging. Given the diverse, specific and heterogeneous nature of ovarian cancer, the present study uses a method of fusing images of primary tumor foci with locoregionally coded metastases to accurately identify whether a patient with high-grade serous ovarian cancer (HGSOC) are resistant to platinum-based drugs.

### METHODS AND MATERIALS

A total of 291 patients with HGSOC, including 97 platinum-resistant and 194 platinum-sensitive patients, are used in this study. Tumors are labeled by a gynecologist with 5 years of experience. In this study, we apply a deep learning model to enhance the traditional platinum resistance prediction method, while using radiomics tools for analysis. In the data pre-processing stage, we accurately localize and encode metastatic foci information, combined with the original lesion image information as the network input. Subsequently, an end-to-end dense convolutional neural network (Densenet) is constructed utilising the squeeze-excitation (SE) module and spatial pyramid pooling (SPP).

### RESULTS

In this study, the accuracy of the Densenet model was 70.7% when fusing primary lesion computed tomography (CT) images, positron emission tomography (PET) images, and metastatic lesion CT images. When primary lesion CT images, PET images, and metastatic lesion PET images were fused, the accuracy based on the Densenet model was 61.5%. However, when only primary lesion CT and PET images were fused, the accuracy based on the Densenet model was 59.9%.

### CONCLUSION

The experimental results demonstrate that the diversity and heterogeneity of metastatic tumors provide a wealth of information, and the fusion of these metastatic data enables the model to capture tumor characteristics in a more comprehensive manner. The proposed deep learning framework, which combines images of the primary lesion with information from metastases, demonstrates superior performance in predicting platinum resistance in patients. This framework has the potential to assist gynecologists in making more appropriate treatment decisions.

### CLINICAL RELEVANCE/APPLICATION

This study makes a significant contribution to the field of medical imaging research by providing insights into the prognostic prediction of platinum resistance. This is of significant clinical value in the development of individualized treatment regimens for each patient.

## M5B-SPOB-2 MULTI-CLASS DEEP LEARNING CLASSIFICATION OF ADNEXAL MASSES ON PELVIC MRI

### PURPOSE

To train a deep convolutional neural network for segmentation and classification of adnexal masses into multiple histopathological entities.

## METHODS AND MATERIALS

141 women (median age 51 years (IQR 38-60)) underwent multiparametric MRI after diagnosis of an indeterminate adnexal mass on transvaginal ultrasound. Axial T2w (used as reference for elastic co-registration and resampling), T1w, T1w fat-saturated, T1w post-contrast, DWI and ADC map calculated from b=0 and b=2000 s/mm2 were used for further analysis. MRI was interpreted by an expert radiologist (Rad) in pelvic MRI who assigned O-RADS category and manually segmented ovaries on all modalities. All patients underwent surgery and histopathology served as gold standard, borderline histopathology was considered as malignant. nnUnet was trained in 5-fold crossvalidation using 23 different histopathological labels. Validation performance with prediction probabilities for each class was recorded and presence of the correct class within the top-1 to top-5 predictions evaluated. While prediction utilized all 23 classes, histopathological subtypes were aggregated for subanalyses.

## RESULTS

The dataset included annotations of 237 adnexal sites. CNN did not detect adnexal mass or tissue in 25 sites (1 malignant, 1 ovarian carcinoma, 17 benign, 1 Brenner tumor, 1 borderline, 2 cystadenofibroma, 1 dermoid, 1 fibroma). The remaining 212 sites included N(Top-1-true positives (TP)/sensitivity/specificity/cluster-adjusted AUC of CNN classification): 50 ovarian carcinomas (40/0.8/0.91/0.91), 3 ovarian metastases (0/0/1.00/0.62), 18 dermoid cysts (14/0.78/0.97/0.94), 23 endometrioma (18/0.78/0.97/0.93), 39 physiologic ovaries (21/0.54/0.91/0.75) , 34 cystadenoma (5/0.24/0.91/0.71). For 8 borderline, 4 corpus luteum cysts, 5 fibroms, 1 fibroplastic tissue, 5 follicles and 1 struma ovarii there were no TP classifications. Overall accuracy was 0.54. Top 2|3|5 TP/sensitivity/specificity was 42/0.84/0.86|44/0.88/0.81|46/0.92/0.74 for ovarian carcinoma, 19/0.83/0.92|21/0.91/0.90|21/0.91/0.85 for endometrioma and 14/0.78/0.91|16/0.89/0.88|16/0.89/0.83 for dermoid.

## CONCLUSION

23-class deep learning using 6 modality mpMRI data achieved best classification performance for ovarian carcinoma, dermoid and endometrioma. Considering the top-5 probable predictions, 92% of ovarian carcinoma is detected, still at specificity of 0.74, with 80% of ovarian carcinomas being correctly classified against the other entities utilizing the top classification.

## CLINICAL RELEVANCE/APPLICATION

Deep learning demonstrates potential for stratification of adnexal masses on multiparametric MRI into multiple histopathological classes.

Valeria Pena-Trujillo, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Describe the experience of an academic referral center implementing a free-breathing (FB) abdominal MRI protocol on pediatric patients

### METHODS AND MATERIALS

In this retrospective study, an imaging database of a tertiary academic pediatric center was queried to identify all pediatric patients 0-17 years of age who underwent a clinically indicated abdominal MRI in a 3T scanner (Prisma, Siemens Healthcare) using a FB MRI protocol including a combination of navigator-triggered, radial non-Cartesian and motion robust sequences over a 3 year period. Collected data included patient sociodemographic and clinical characteristics as well as exam-related factors. Indications were classified into four different groups for analysis (non-syndromic oncologic, hereditary cancer syndromes, congenital/other genetic conditions, and non-oncologic abdominal symptoms). Exams performed with or without sedation, as well as those performed with or without intravenous contrast, were compared to evaluate the total scan time in each group based on DICOM sequence time stamps.

### RESULTS

66 cases were analyzed; mean age at imaging was 5.35±3.1 years old. 44 cases (66.7%) were female, 12 cases had MRI without anesthesia (18.2%), and 5 (7.6%) out of 66 were performed without contrast. Overall scanning time was 42.85±7.97 minutes. The most common indication was hereditary cancer syndromes (69.7%), followed by non-syndromic oncologic (25.8%). When comparing patients with anesthesia vs. non-anesthesia, there was no statistically significant difference in terms of the scanning time (42.52±8.23 minutes vs. 44.33±6.74 minutes; p=0.4), gender (females 71.1% vs. 70.0%; p=0.9) nor age (5.28±3.0 vs. 5.67±3.5 p=0.7). Likewise, when comparing patients with MRIs with contrast vs. non-contrast, there was no difference in scanning time (43.05±7.7 minutes vs. 40.40±11.6 minutes; p=0.6).

### CONCLUSION

Implementation of a pediatric FB abdominal MRI protocol in clinical practice showed no significant difference in scan time whether patients were scanned awake or with sedation, making it a valuable and consistent standardized imaging tool for a wide range of challenging patients, including neonates, child life specialists assisted, and anesthetized patients.

### CLINICAL RELEVANCE/APPLICATION

Respiratory motion artifacts are particularly challenging in pediatric abdominal MRI. This is especially relevant in some patients who may be unable to follow breathing instructions due to their young age, sedation, or developmental delays.? Recent advances in MR pulse sequences, such as non-Cartesian radial k-space sampling techniques or navigator-triggered T1-weighted Dixon, have led to improved image quality and decreased motion artifacts during free-breathing abdominal MRI.

## M5B-SPPD-2 THE EFFECT OF BREATH CONTROL ON THE EVALUATION OF HEPATIC SHEAR WAVE ELASTICITY AND DISPERSION IN PEDIATRIC PATIENTS

Chanyoung Rhee, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to assess the impact of breath control on the reliability and accuracy of 2D Shear Wave Elastography (SWE) and Shear Wave Dispersion (SWD) in diagnosing pediatric liver disease, focusing on the optimization of elastography protocols.

### METHODS AND MATERIALS

The study cohort comprised 225 pediatric patients who underwent 2D-SWE and SWD assessments between September 2021 and February 2023, with ultrasound evaluations performed in both gentle free-breath and breath-hold states. Within this group, 30 patients also underwent MR elastography and were subjected to a second ultrasound examination by two radiologists, spaced one week apart. The study assessed correlations between breathing

conditions, compared the Area Under the Curve (AUC) with MRE as the reference standard, and conducted subgroup analyses to evaluate inter-rater agreement and test-retest reliability.

**RESULTS**

Liver stiffness (LS) and liver dispersion (LD) in free-breath and breath-hold states showed a marginally significant difference (5.31 ± 1.28 vs. 5.09 ± 1.27 kPa, p = .08; 12.17 ± 2.04 vs. 11.75 ± 2.01 m/s/kHz, p = .04), with high correlations between each breathing condition (LS, r = .69, P < .001; LD, r = .64, P < .001). The AUC for LS showed no significant difference between free-breath (0.67) and breath-hold (0.71) (p = .175). Inter-rater agreement revealed ICCs of 0.83 (free-breath) and 0.94 (breath-hold) for LS, and 0.70 (free-breath) and 0.85 (breath-hold) for LD, all significant (P < .001). Test-retest reliability for LS was 0.88 in both conditions, while for LD, it was 0.70 in free-breath and 0.74 in breath-hold, all significant (P < .001), underscoring higher but not substantial reliability in breath-hold conditions.

**CONCLUSION**

While maintaining breath-hold during ultrasound elastography slightly increases reliability, the minimal difference from results measured in free-breath conditions renders the latter acceptable, particularly when a breath-hold proves to be difficult.

**CLINICAL RELEVANCE/APPLICATION**

In pediatric patients, where breath control is relatively challenging, breath-holding is not essential for reliably measuring 2D-SWE and SWD.

## M5B-SPPD-3 HIGHER AGE, LOW HOUSEHOLD INCOME, NON-TEACHING HOSPITAL STATUS, AND MIDWEST LOCATION PREDICT INCREASED CT OVER ULTRASOUND UTILIZATION IN CHILDREN WITH APPENDICITIS

Cory Pfeifer, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Samuel Byrne (*Presenter*) Nothing to Disclose

**PURPOSE**

Ultrasound is the first line modality in the radiologic approach to pediatric appendicitis. Ultrasound localization of the appendix requires practice and experience given the propensity for regional bowel gas and dependence on depth of this small structure. Lack of ability to obtain a diagnosis exposes the child to increased cost and radiation associated with CT. This study examines factors associated with increased CT utilization and thus decreased compliance with the ACR Appropriateness Criteria in the United States.

**METHODS AND MATERIALS**

This study utilizes data from the Nationwide Emergency Department Sample. All 2019 emergency department encounters with a diagnosis code for appendicitis (K35.80) and a CPT code for either abdominal ultrasound or CT were assessed. Differential utilization for each modality was evaluated with respect to sex, race, median household income, primary payer, trauma center status, teaching hospital status, and hospital region.

**RESULTS**

291,588 encounters met criteria for the study. Average age for patients receiving CT was 13.91 vs. 10.78 for ultrasound (p<0.001). 33.39% of patients with annual household income below $48,000 received CT vs. 16.68% ultrasound. For annual household income over $82,000, CT utilization was 20.00% vs. 30.60% ultrasound. 38.28% of patients at non-trauma centers were exposed to CT vs. 18.02% US. At level 1 trauma centers, this was reversed at 7.98% CT and 30.47% CT. 40.39% of patients at metropolitan non-teaching centers received CT vs. 14.61% ultrasound. At metropolitan teaching hospitals, this was reversed at 19.55% CT and 27.21% ultrasound. In non-metropolitan hospitals, the rates were 53.05% CT and 10.08% ultrasound. CT utilization was greatest in the Midwest (38.46%) followed by South (31.43%), Northeast (19.48%), and West (17.95%). Ultrasound utilization was 37.01% in the Northeast, 21.69% in the West, 18.91% in the Midwest, and 18.56% in the South. Total ED expense was $15,521 for encounters in which CT was ordered compared to $9,708 in which US was ordered (p<0.001).

**CONCLUSION**

Multiple social determinants of health contribute to increased radiation and cost associated with CT when pediatric appendicitis is suspected in the emergency department.

**CLINICAL RELEVANCE/APPLICATION**

Acute appendicitis is one of the most common abdominal surgical emergencies in children. The use of imaging is a mainstay in diagnosing appendicitis. Because children are more sensitive to CT radiation than adults, it is important to minimize the use of CT when possible.

## M5B-SPPD-4 INFLAMMATORY BOWEL DISEASE AND SACROILIITIS: HOW STRONG IS THIS LIAISON IN PEDIATRIC PATIENTS?

Francesco Causin, MD (*Abstract Co-Author*) Nothing to Disclose
Giulia Fichera, MD (*Abstract Co-Author*) Nothing to Disclose
Chiara Giraudo, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Alice Miotto (*Abstract Co-Author*) Nothing to Disclose
Monica Zuliani, MD (*Abstract Co-Author*) Nothing to Disclose
Lucia Pilati, MD (*Abstract Co-Author*) Nothing to Disclose
Nicole Zizzari, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the occurrence of sacroiliitis in children undergoing abdominal MR for suspected or proven inflammatory bowel disease (IBD).

**METHODS AND MATERIALS**

The electronic database of our tertiary center was searched for children and adolescents (<21 years old) undergoing an abdominal MR for IBD with at least a fluid-sensitive fat-sat and a T1w sequence including the sacroiliac joint in the protocol. For each patient, the sacroiliac joint was subdivided in four quadrants on each side (upper iliac, upper sacral, lower iliac, lower sacral). Then the presence of bone marrow edema (BME), fatty bone marrow replacement, enthesitis, erosions, capsulitis, and ankylosis was assessed. The occurrence of BME, joint effusion, synovitis in the hip was also investigated. The presence of anatomical variants was recorded. If available, follow-ups up to two years were assessed. Descriptive statistics were performed.

**RESULTS**

130 patients (58 female; 17±4 years-old) matched the inclusion criteria. 102 patients were diagnosed with IBD (93 Crohn's, 9 ulcerative colitis), 18 had an indeterminate colitis, and 9 no signs of IBD. Only 3 patients had areas of BME at diagnosis (2.3%), 2 of them affected by Crohn's and 1 without signs of IBD. Therefore, the overall prevalence of BME in IBD at diagnosis was 2%. Only 1 of these 3 patients underwent 2 follow-ups and the BME persisted. Overall, 74 patients underwent a second follow-up and 41 also a third one. At diagnosis, one patient had one single area of BME in the left upper sacrum

which persisted in all 3 MR scans, one had areas of BME in the left upper iliac bone and one in the sacrum and upper and lower iliac bone. During the second MR one patient demonstrated one area of BME in the left upper sacrum which persisted also at the third scan. No other acute or chronic inflammatory changes were detected in the sacroiliac joints nor in the hips. Four patients had a transitional vertebra (two Castellvi type 3a, one type 2b, and one type 2a) without nearby areas of BME.

**CONCLUSION**

Only around 2% of patients with IBD have BME in the sacroiliac joint without any additional sign of inflammation.

**CLINICAL RELEVANCE/APPLICATION**

The occurrence of sacroiliitis seems to be low in pediatric patients with IBD nevertheless when it occurs it tends to persist therefore it should not be overlooked and properly treated.

### PURPOSE

Coronary perivascular fat attenuation index (FAI) from coronary CT angiography (CCTA) imaging is a potential biomarker. Beam hardening from vessel luminal contrast can affect plaque measurements in CT, but its impact on FAI has not been well evaluated. This study examines the influence of contrast on FAI by measuring it in both contrast-enhanced and non-contrast phases within the same CCTA examination.

### METHODS AND MATERIALS

We retrospectively reviewed 88 patients who underwent CCTA for stable chest pain between June 2023 and April 2024. Coronary calcium scoring at 120 kV was followed by CCTA at 100 kV. Cases with extensive calcifications and motion artifacts were excluded due to poor image quality. We collected calcium scores, CAD-RADS classification, heart rate during imaging, and results from additional tests for coronary artery disease with ischemia. Deep learning image reconstruction was used to obtain 0.625mm images in both contrast-enhanced and non-contrast phases. FAI was measured in the right coronary artery from 1 cm distal to its ostium, extending 4 cm. CT values of the right coronary artery lumen in the same region were also measured. We analyzed the correlation between contrast-enhanced and non-contrast FAI using a Bland-Altman plot and performed multivariate analysis to identify factors affecting the difference. Multivariate logistic regression assessed the factors contributing to ischemic coronary artery disease.

### RESULTS

In total, 62 cases were analyzed, 24 of whom were female. The median age was 65 years (IQR 54-74), and the median heart rate was 60 bpm (IQR 56-63). The CAD-RADS scores were: 44 cases with a score below 3, 22 with a score of 3 or above and 14 with coronary artery disease with ischemia. The non-contrast FAI (median -76.0 HU) and contrast-enhanced FAI (median -80.5 HU) were positively correlated ($R = 0.77$, $p < .001$). However, the contrast-enhanced FAI was significantly lower than the non-contrast FAI by -4.7 HU (95% CI, -6.1 to -3.4). Factors affecting this difference included the CT value of the right coronary artery lumen (Stdß = -0.30, $p = .01$) and heart rate during imaging (Stdß = -0.34, $p = .005$). FAI was not significantly related to coronary artery disease with ischemia; only CAD-RADS = 3 showed significance.

### CONCLUSION

FAI in CCTA is significantly lower than non-contrast FAI due to contrast effects in the lumen.

### CLINICAL RELEVANCE/APPLICATION

While FAI in CCTA is a promising imaging biomarker, it's susceptible to variations due to beam hardening from contrast-enhanced RCA lumen. Accurate interpretation and diagnosis require consideration of these factors in the clinical application of FAI in CCTA.

## M5B-SPPH-10 HIGH-FIDELITY CT PHANTOMS FOR ULTRA-HIGH-RESOLUTION IMAGING

Jessica Im, BEng (*Abstract Co-Author*) Nothing to Disclose
Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation
Austin Zhuang (*Abstract Co-Author*) Nothing to Disclose
Michael Geagan (*Abstract Co-Author*) Nothing to Disclose
Ryan Fair, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Ultra-high-resolution (UHR) computed tomography (CT) imaging has become an essential part of clinical routines, driven by the recent introduction of photon-counting CT (PCCT). The increased resolution offers numerous clinical applications, especially in cardiovascular and chest imaging. For evaluating these novel applications, it is necessary to fabricate lifelike phantoms that incorporate UHR features. In this study, we introduce a novel 3D printing technique to generate lifelike UHR phantoms using stereolithography (SLA) printing technology.

**METHODS AND MATERIALS**

Building on our previous 3D printing technology, PixelPrint, designed for fused deposition modeling (FDM), we have developed a novel solution utilizing SLA printing for creating UHR phantoms. An input image, such as a digital phantom or patient data, is converted on a voxel-by-voxel basis into printer instructions by determining the required ratios of polymerized to unpolymerized material for each specific Hounsfield unit (HU). To evaluate the UHR capabilities, a digital version of a Siemens star was used as the input. The phantoms were fabricated using photosensitive resin in an ultra-high resolution 3D printer (microArch S240, Boston Micro Fabrication). The printing parameters were set to a pixel size of 10 µm and a layer thickness of 40 µm. For characterization, the phantoms were scanned using a dual-source PCCT scanner (NAEOTOM Alpha, Siemens Healthineers) with a tube voltage of 120 kVp and an exposure of 1000 mAs. Images were reconstructed in UHR mode with a matrix size of 1024x1024, field of view of 60 mm, and slice thickness of 1 mm. Feature size was evaluated using angular integration profiles at various axial distances from the center of the star.

**RESULTS**

Based on the angular integrals taken, the mean width of spokes measured on the star were as small as 0.16 mm. Feature sizes were still within the standard deviation compared to expected values down to 0.11 mm. Dynamic range of the phantoms was between 115 HU for completely unpolymerized voxels and 220 HU for completely polymerized voxels. A quasi-continuous contrast gradient between these two extrema was also attained in other UHR phantoms.

**CONCLUSION**

The introduced UHR version of PixelPrint, utilizing SLA printing, enables the creation of phantoms with fine features while also accommodating low contrast scenarios, such as in liver and lung imaging. Future studies will be necessary to evaluate the image quality of patient-based phantoms fabricated with this technology.

**CLINICAL RELEVANCE/APPLICATION**

The introduction of high-performance CT phantoms facilitates the evaluation of novel technologies, such as PCCT and AI reconstruction. This advancement helps streamline clinical translation and ultimately enhances patient care.

## M5B-SPPH-2 ASSESSMENT OF LOW CONTRAST DETECTABILITY VIA AN IN-SILICO IMAGING TRIAL COMPARING DEEP LEARNING RECONSTRUCTION TO CONVENTIONAL RECONSTRUCTION ALGORITHMS

Kirsten Lee Boedeker, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Naruomi Akino (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Ilmar Hein, PhD (*Abstract Co-Author*) Nothing to Disclose
Akira Nishikori, MS (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Dylan Mather (*Abstract Co-Author*) Nothing to Disclose
Daniel W. Shin, MS, BS (*Presenter*) Employee, Canon Medical Systems Corporation

**PURPOSE**

Deep learning reconstruction (DLR) algorithms are trained on anatomical images and designed to reduce noise while preserving signal. This study aims to assess the low contrast detectability (LCD) of simulated, controlled test objects in a patient dataset for a prototype DLR vs conventional reconstruction algorithms.

**METHODS AND MATERIALS**

An analytic forward projection model based on the specifications of a wide volume CT scanner (Canon Medical Systems, Aquilion ONE PRISM, Otawara, Japan), including detector, source, and geometry, was used for simulation.. The sinogram of low contrast rods, 5mm in diameter and 35HU in contrast, were simulated and inserted into an existing patient sinogram. A total of 512 test objects were placed into a relatively homogeneous region of the liver across 16 slices of 0.5mm nominal thickness. Simulated dose levels were varied using a noise addition tool. The sinograms were reconstructed with a prototype DLR, Hybrid Iterative Reconstruction (HIR), and Filtered Backprojection (FBP) with a body kernel. Low contrast detectability was evaluated using a non-prewhitening model observer, and the standard error of the estimated detectability value was calculated using a bootstrapping method.

**RESULTS**

At 18.8mGy, DLR had 33% higher detectability (d') compared to HIR and 109% higher detectability compared to FBP. Similarly, at 9.4mGy, DLR showed 24% higher detectability compared to HIR and 131% higher detectability compared to FBP. The p-values for all the comparisons were well below 0.01.

**CONCLUSION**

This in-silico imaging study illustrates significantly improved LCD with DLR compared to conventional reconstruction methods.

**CLINICAL RELEVANCE/APPLICATION**

The improved LCD with DLR demonstrated in Silico provides evidence DLR is likely to increase diagnostic confidence and facilitate dose optimization in acquired patient data.

## M5B-SPPH-3 CHARACTERIZATION OF LUNG LESIONS WITH HYBRID LIFELIKE PHANTOMS IN LOW-DOSE PHOTON-COUNTING DETECTOR CT

Richard Thompson, PhD (*Abstract Co-Author*) Employee, Canon Medical Research, USA
Steven Ross, PhD (*Abstract Co-Author*) Nothing to Disclose
Kai Mei, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate and compare the low-dose performance of photon-counting detector CT (PCDCT) for characterization of lung lesions using a hybrid 3D-printed lifelike phantom.

**METHODS AND MATERIALS**

A hybrid 3D-printed lung phantom (PixelPrint) was created from ultra-high-resolution patient CT images and 3 distinct computational lung lesion models. The lesions were modeled at different sizes (diameter = 13, 17, 27 mm) and levels of spiculations (high, medium, and low). The phantom was placed within the multi-energy CT phantom (Gammex, Sun Nuclear) to simulate a realistic patient size, and scanned using both a conventional energy-integrating detector CT (EIDCT) and a prototype CZT-based PCDCT. The scan protocol (120 kVp; large FOV; small focal spot; CTDIvol of 20.4, 9.8, 4.9, 2.4, and 1.6 mGy; 0.6 pitch (detailed)) was closely matched between the systems. All scans were reconstructed at native resolutions (pixel size/slice thickness of 0.5/0.5 mm for EIDCT and 0.25/0.2 mm for PCDCT) using lung kernel (FC52) and standard strength of iterative denoising. Images were registered to the original patient image dataset (ground truth) used for generating the phantom, using rigid transformations (SimpleITK). Following registration to the original dataset used to generate the phantom, images were resampled using an isotropic voxel size of 0.5 mm. For analysis, ROIs bounding lesions were estimated, and root mean squared error (RMSE) and structural similarity index (SSIM) were computed on all images with respect to the ground truth.

**RESULTS**

Compared to EIDCT, PCDCT was more effective at characterizing lesions, especially at lower doses where PCDCT images were visually sharper without blurring of edges and distortions in lesion shape. For both scanners, RMSE increased and SSIM decreased with reduced dose, with PCDCT performance better than EIDCT at all doses. For PCDCT, relative improvements (mean±SD) over EIDCT for all exposures were found to be 4.9±3.5% and 8.3±4.1% for RMSE and SSIM, respectively, with highest improvements of 7.5% and 11.9% for RMSE and SSIM at lowest dose (1.6 mGy).

**CONCLUSION**

A hybrid lifelike phantom with computational lesions was used to assess the performance of EIDCT and PCDCT for low-dose lung imaging. As indicated by the higher SSIM and lower RMSE compared to EIDCT at all doses, PCDCT images are superior for characterizing lung lesions, especially at lower radiation doses.

**CLINICAL RELEVANCE/APPLICATION**

Accurate visual characterization of morphological and texture features of lesions while reducing patient dose is clinically important for monitoring the severity and progression of lung cancer.

## M5B-SPPH-4 REALISTIC 3D-PRINTED HIGH-RESOLUTION CT PHANTOMS FEATURING COMPUTATIONAL LUNG LESIONS FOR PHOTON-COUNTING COMPUTED TOMOGRAPHY

Naruomi Akino (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Richard Thompson, PhD (*Abstract Co-Author*) Employee, Canon Medical Research, USA
Steven Ross, PhD (*Abstract Co-Author*) Nothing to Disclose
Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation
Zhou Yu, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Leonid Roshkovan, MD (*Abstract Co-Author*) Nothing to Disclose
Shobhit Sharma, PhD (*Abstract Co-Author*) Nothing to Disclose
Kai Mei, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To create a realistic high-resolution 3D-printed lung phantom for characterizing lung lesions using the PixelPrint technology to evaluate photon-counting computed tomography (PCCT).

**METHODS AND MATERIALS**

For this study, 3 computational lung lesions, characterized by distinct features and levels of spiculation (A: highly spiculated, B: moderately spiculated, and C: minimally spiculated), were used. The lesions were scaled (1x-4x) to obtain target sizes of 11-45, 7-30, and 5-20 mm for lesions A, B, and C, respectively. All lesions were 3D-printed as a single phantom at -50 HU attenuation within -700 HU background. To simulate realistic patient sizes, the phantom was inserted in outer ring of Gammex phantom and scanned on a prototype CZT-based PCCT using 120 kVp Large FOV, and S focal spot (0.4x0.5 mm) at 5 dose levels (CTDIvol: 1.6-20 mGy). All scans were reconstructed in ultra high-resolution (UHR) mode (pixel size/slice thickness: 0.25/0.2 mm), using a lung kernel (FC52) and iterative denoising. To assess the phantom for evaluating PCCT, an example radiomics task involving comparison of features amongst doses was selected. For this task, radiomics features were extracted using PyRadiomics from HU-threshold lesion masks and compared against features extracted from largest lesion size at highest dose.

**RESULTS**

All lesions were effectively visualized, with UHR images allowing for distinguishing specific features of each lesion type. Differences in lesions at native sizes (1x) were most difficult to evaluate due to blurring of their characteristic spiculations. For radiomics, variations in dose were found to be inconsequential for relatively larger lesions but caused degradation of accuracy for smaller lesions. For example, volumetric size had errors <1% across all doses for largest lesions (4x) which increased to >6% for smaller lesions (2x) at doses <5 mGy. Similarly, fluctuating errors were observed for smallest (1x) lesions, with errors as high as 15%, making radiomics estimation challenging.

**CONCLUSION**

The study demonstrates that computational lung lesions can be incorporated into PixelPrint phantoms, facilitating the evaluation PCCT UHR imaging. Availability of such phantoms would enable accurate and customized evaluations of this technology by providing access to high-resolution ground-truth information.

**CLINICAL RELEVANCE/APPLICATION**

New medical imaging technologies require task-specific evaluations for effective translation to clinical use. Availability of a high-resolution lung phantom with access to ground-truth would allow for evaluation of PCCT UHR imaging for tasks involving detection and classification of lung nodules.

## M5B-SPPH-5 ASSESSING THE IMPACT OF BREATH HOLDING AND ARM POSITIONING ON 3D CAMERA IMAGING IN CT CHEST EXAMINATIONS

Xinhui Duan, PhD (*Abstract Co-Author*) Nothing to Disclose
Kristina Hallam (*Abstract Co-Author*) Employee, Siemens AG
Suhny Abbara, MD (*Abstract Co-Author*) Royalties, RELX
Lakshmi Ananthakrishnan, MD (*Abstract Co-Author*) Nothing to Disclose
Yin Xi, PhD (*Abstract Co-Author*) Nothing to Disclose
Liqiang Ren, PhD (*Abstract Co-Author*) Nothing to Disclose
Jeffrey B. Guild, PhD (*Abstract Co-Author*) Nothing to Disclose
Afrouz Ataei, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The study aims to assess the influence of breath holding and arm positioning (up/down) on the performance of 3D camera imaging in CT chest examinations.

**METHODS AND MATERIALS**

Authorized by the Institutional Review Board (IRB), 17 patients who underwent chest CT scans were recruited in this study. For each patient, the 3D camera-recommended table height was recorded for three different positions: arms down with no breath holding (G1), arms down with breath holding (G2), and arms up with breath holding (G3). Patients underwent manual positioning by trained radiographers, and the ordered studies performed per standard of care. The recommended table height by the 3D camera for chest scans was compared between G1 and G2 (assessing breath holding) and G2 and G3 (assessing arm position) using Bland-Altman plots. Patient positioning accuracy was quantified through the calculation of the vertical centroid to isocenter (VCI) value, delineating the distance between the gantry isocenter and the patient centroid y-coordinate. Comparison of VCI values (G1 vs. G2; G2 vs. G3) were conducted using Box-and-Whisker plots and Wilcoxon signed-rank-test.

**RESULTS**

The median difference between recommended table heights is -2.9 mm (95% limits-of-agreements (LOAs): [-12.4, 6.7 mm]) for G1 and G2 scans (G1-G2), and -1.7 mm (95% LOAs: [-16.8, 13.4 mm]) for G2 and G3 scans (G2-G3). The median theoretical VCI values, calculated based on the recommend table heights for G1 and G2 scans were -6.4 mm [-8.3, -0.1 mm] and -5.2 mm [-7.1, 1.3 mm] (p=0.055) from gantry isocenter. The median VCI values for G2 and G3 scans were -5.2 mm [-7.1, 1.3 mm] and -2.3 mm [-6.7, 6.3 mm] (p=0.629).

**CONCLUSION**

Breath-holding and arm position (up/down) did not significantly change the 3D camera-recommended table height for our cohort of patients undergoing chest CTs, and all three different positions achieved accurate patient positioning with median differences between patient centroid and gantry isocenter less than 7mm.

**CLINICAL RELEVANCE/APPLICATION**

Accurate patient positioning can be achieved regardless of the status of breath holding and arms position.

## M5B-SPPH-6 IMPROVEMENT OF IMAGE QUALITY IN CT IMAGES USING STOCHASTIC RESONANCE - DUALITY OF IMAGE NOISE IN CT IMAGES

Kengo Igarashi (*Presenter*) Nothing to Disclose

**PURPOSE**

Image noise in Computed Tomography (CT) images is one of the major factors degrading the image quality. Thus, many studies of noise reduction techniques have been conducted. On the contrary, the phenomenon that disproves such traditional thought for noise has been discovered in recent years and is called "stochastic resonance". It is well known that the phenomenon appears by adding noise to non-liner system such as threshold detector and provides the improvement of the system response. We have set out on the following two subjects of study; 1. Verification of stochastic resonance on CT images 2. Effect of stochastic resonance on high and low intensity signals in noise added CT images

**METHODS AND MATERIALS**

We designed the brain phantom that simulates CT imaging findings of acute cerebral infarction. The CT images of the phantom were acquired with a Multi Detector row CT scanner. Two kinds of Gaussian noise were added to the CT images: white Gaussian noise and band limited noise in spatial frequency domain which was generated by passing white Gaussian noise through a band-pass filter (the range of bandwidth from 0.0083 to 0.83 cycle/mm). After adding these noises, the CT images were transformed to 8 bits gray scale images using windowing process which is one of the thresholding techniques window level = 50 HU, window width = 30 HU).

**RESULTS**

The brain sulci and cerebral edema in CT phantom images were employed as the high- and low-intensity signals, respectively. To evaluate the contrast resolution of CT images, the contrast-to-noise ratio (CNR) for each signal was measured. For subjective recognition, when optimal intensity of noise was added, image signals in the noise-added CT images with windowing process can be detected easily. This result indicated that stochastic resonance is induced by adding noises. For quantitative evaluation, regardless of the kind of noise, CNR for the brain sulcus took the maximum value at the added noise intensity of 10 HU, whereas CNR for the cerebral edema decreased as the added noise intensity increased. However, the sharpness of the edema contour was improved by the stochastic synchronization which is one of the stochastic resonances. The results were almost consistent with subjective recognition of these CT images. Thus, appearance of stochastic resonance on CT images was verified quantitatively and found to improve signal detectability.

**CONCLUSION**

Stochastic resonance can be expected to yield the improvement of signal detectability in CT images.

**CLINICAL RELEVANCE/APPLICATION**

It is suggested that the detectability of low-contrast lesions, such as acute cerebral infarction, can be improved by stochastic resonance.

## M5B-SPPH-7 PERFORMANCE EVALUATION OF HIGH-RESOLUTION TYPE DEEP LEARNING RECONSTRUCTION (SPATIAL RESOLUTION, SLICE THICKNESS AND PEAK CT VALUE)

Katsumi Tsujioka, RT (*Presenter*) Researcher, Canon Medical Systems Corporation

**PURPOSE**

In recent years, the deep learning reconstruction (DLR) has emerged as an image reconstruction method that utilizes AI in X-ray CT. However, those were noise reduction type DLRs. The precise IQ engine (PIQE) was developed as a new DLR for high-resolution AI reconstruction. In this report, we present the results of an experiment to improve the spatial resolution in the X-Y plane and Z-axis direction for high-resolution DLR reconstruction.

**METHODS AND MATERIALS**

Two CT machines were used in our study. The conventional CT is Aquilion ONE (Canon Medical Systems, Japan). Conventional reconstruction and PIQE reconstruction were performed on this CT. The other is the Aquilion Precision (Canon Medical Systems, Japan), an ultra-high-resolution CT. A spiral metal wire phantom made of metal wire with a diameter of 0.1 mm was used in the experiment. The MTF in the X-Y plane, the effective slice thickness in the Z-axis direction, and the peak CT value of metal wire were evaluated.

**RESULTS**

As the results of the experiments, the MTF of conventional CT image reconstructed using PIQE was improved compared to conventional image reconstruction, but was slightly inferior to ultra-high-resolution CT. The effective slice thickness was 0.63mm for conventional CT, 0.453mm for PIQE conventional CT, and 0.378mm for ultra-high-resolution CT. The peak CT value was 579.2HU for conventional CT, 893.1HU for PIQE conventional CT, and 1540.0HU for ultra-high-resolution CT.

**CONCLUSION**

Our experiments revealed that high resolution type DLR reconstruction (PIQE) works not only in the X-Y plane but also in the Z-axis direction. It had higher spatial resolution and thinner slice thickness compared to conventional CT. Furthermore, reducing the voxel size had the effect of increasing the CT value of the phantom. It is noteworthy that these phenomena were achieved with DLR without changing the hardware of conventional CT equipment.

**CLINICAL RELEVANCE/APPLICATION**

The increase in peak CT value due to PIQE means that the ability to visualize small blood vessels has improved. In addition, it was found that the spatial resolution improved by PIQE means that even conventional CT equipment has a spatial resolution close to that of ultra-high-resolution CT.

## M5B-SPPH-8 MODEL OBSERVER TASK-BASED ASSESSMENT OF CT METAL ARTIFACT REDUCTION ALGORITHMS: FEASIBILITY STUDY ON HIP ARTHROPLASTY PHANTOM

Brian R. Herts, MD (*Abstract Co-Author*) Grant, Siemens AG
Nancy A. Obuchowski, PhD, MS (*Abstract Co-Author*) Research Consultant, Siemens AG;Research Consultant, IBM Corporation;Research Consultant, Elucid Bioimaging Inc;Research Consultant, Takeda Pharmaceutical Company Limited
Grant Fong, MS (*Abstract Co-Author*) Research Grant, Siemens Healthineers
Wadih Karim, RT (*Abstract Co-Author*) Nothing to Disclose
Steven Izen, PhD (*Abstract Co-Author*) Nothing to Disclose
Andrew Primak, PhD (*Abstract Co-Author*) Employee, Siemens AG
Naveen Subhas, MD, MPH (*Presenter*) Research support, Siemens AG

**PURPOSE**

Recently published USFDA framework for task-based assessment of CT metal artifact reduction (MAR) algorithms using channelized Hotelling observers (CHO) was performed in a mathematical phantom. This method provided a standardizable approach but has not been validated in a physical phantom. The present study investigates the feasibility of assessing lesion detectability using CHO in a hip arthroplasty phantom and compares the performance to that of human observers.

**METHODS AND MATERIALS**

A phantom simulating a human pelvis was designed with rotatable hip inserts containing cobalt-chromium spheres connected to titanium rods surrounded by 16 unique spherical lesions embedded in bone and soft tissue. This phantom was scanned 100 times on a CT (Somatom Force, Siemens Healthineers) at standard-dose and half-dose protocols (140 kVp, 300 and 150 quality reference mAs) with inserts rotated in four orientations to provide lesion present/absent pairings for CHO lesion detectability (d') calculations. d' was optimized by testing different channel selections (Gabor and Laguerre-Gauss) and image transformation techniques on images reconstructed with and without iterative MAR (iMAR, Siemens Healthineers) at both dose protocols. Differences in d' were assessed using linear regression and compared to previously published human observer detectability and confidence scores using Spearman's correlation.

**RESULTS**

Accurate CHO d' required image masking and thresholding to isolate lesion signal and minimize background differences. d' measurements using Laguerre-Gauss channels were less sensitive to artifacts and therefore selected for testing. Pooling across all lesions, d' of half-dose iMAR images were significantly greater than standard-dose filtered back projection images ($p=0.010$) and not significantly different from standard-dose iMAR images ($p=0.358$). d' results showed a significant, positive correlation with human observer detectability ($?=0.723$, $p<0.001$) and confidence scores ($?=0.727$, $p<0.001$).

**CONCLUSION**

Using CHO for lesion detectability assessment of CT MAR algorithms is feasible and correlates well with human observers but requires appropriate channel selection and artifact reduction techniques.

**CLINICAL RELEVANCE/APPLICATION**

The use of model observers for task-based evaluations can provide a objective assessment of how well MARs perform in clinical scenarios.

## M5B-SPPH-9 IMPACT OF DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM ON IMAGE QUALITY AND LUNG FUNCTION MEASUREMENTS IN LOW-DOSE CHEST CT IMAGING FOR DIAGNOSING CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Suping Chen (*Abstract Co-Author*) Nothing to Disclose
Yuanfen Liu (*Abstract Co-Author*) Nothing to Disclose
Wanyi Zheng (*Abstract Co-Author*) Nothing to Disclose
Ye Xiongxin (*Abstract Co-Author*) Nothing to Disclose
Borong Tang (*Abstract Co-Author*) Nothing to Disclose
Xiaoyong Zhang (*Abstract Co-Author*) Nothing to Disclose
Liwei Xue, BS (*Presenter*) Nothing to Disclose

## PURPOSE

To explore the Impact of deep learning image reconstruction algorithm on image quality and lung function measurements in low-dose chest CT imaging for diagnosing chronic obstructive pulmonary disease (COPD).

## METHODS AND MATERIALS

We prospectively collected 38 suspected COPD patients who underwent low-dose biphasic chest CT scans. The CT data were reconstructed by four algorithms: filtered back projection (FBP), adaptive statistical iterative reconstruction-Veo with weights of 40% and 80% (ASIR-V40%, ASIR-V80%), and high-level deep learning image reconstruction (DLIR-H). We collected and compared the objective image quality parameters (SD, signal-to-noise ratio [SNR] and contrast-to-noise ratio [CNR]), the parameters related to the emphysema and the small airways on the three-grouped CT images. The differences in CT quantitative parameters on different algorithm-reconstructed images were analyzed using the Friedman test.

## RESULTS

Our study included 28 (73.7%) COPD patients. The DLP was 71.80±30.34 mGy*cm. Comparison in the percentage of voxel volume with CT values below -950 HU on the inspiratory phase (LAAisp-950%): FBP > ASIR-V40% >ASIR-V80% > DLIR-H ($P < 0.05$), while there was no statistical difference in comparisons of other emphysema-related parameters ($P < 0.05$). For all small airway-related quantifications including lumen area, wall area, and wall thickness on upper-right, lower-right, and lower-left bronchia showed no statistical difference among the four grouped images (all $P > 0.05$). Muscle SD was significantly different on the images of the four groups and was lowest on DLIR-H images (FBP > ASIR-V40% >ASIR-V80% > DLIR-H , $P < 0.05$); in the main bronchial SNR and CNR comparisons, (DLIR-H > ASIR-V80% >ASIR-V40% > FBP, $P < 0.05$ for both).

## CONCLUSION

In low-dose chest CT imaging, the deep learning image reconstruction algorithm improves image quality and reduces LAAisp-950% measurements without affecting small airway measurements.

## CLINICAL RELEVANCE/APPLICATION

In COPD diagnosis, deep learning image reconstruction algorithms improve low-dose chest CT image quality and have high clinical value.

## M5B-SPRO-1 DUAL-ENERGY CT PARAMETERS AND QUANTITATIVE ASSESSMENT OF EXTRACELLULAR VOLUME FRACTION IN GRADING INVASIVE PULMONARY ADENOCARCINOMA

Yinghui Ge (*Abstract Co-Author*) Nothing to Disclose
Xiaojing Kan (*Abstract Co-Author*) Nothing to Disclose
Bin Nan (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the value of various Dual-Energy Computed Tomography (DECT) parameters and Extracellular Volume Fraction (ECV) in grading the differentiation of invasive pulmonary adenocarcinoma.

### METHODS AND MATERIALS

A retrospective collection of invasive pulmonary adenocarcinoma patients who underwent preoperative DECT enhancement scans at our institution from June 2018 to December 2023 was conducted. Based on pathological results, patients were divided into a moderate/high differentiation group (21 cases) and a low differentiation group (19 cases). Measurements of lesion iodine concentration and effective atomic number during arterial and venous phases, as well as ECV, normalized iodine concentration, and normalized effective atomic number, were taken. The ?2 test was used to analyze categorical parameter differences between the two groups, including patient gender, lesion location, and mediastinal lymph node metastasis presence. An independent sample t-test compared differences in patient age, BMI, hematocrit, maximum lesion diameter, micropapillary structure proportion, and various imaging quantitative parameters across phases. Receiver Operating Characteristic (ROC) curves evaluated statistically significant parameters for distinguishing adenocarcinoma differentiation grades.

### RESULTS

The arterial phase ECV, arterial phase normalized effective atomic number, and venous phase ECV, iodine concentration, normalized iodine concentration, and normalized effective atomic number were significantly higher in the moderate/high differentiation group than in the low differentiation group ($t=2.166\sim4.195$, $P<0.05$). The lesion diameter and micropapillary structure content were smaller in the moderate/high differentiation group, with significant differences ($P<0.05$). ROC curve analysis of arterial phase ECV, arterial phase normalized effective atomic number, and venous phase ECV, iodine concentration, normalized iodine concentration, and normalized effective atomic number yielded AUCs of 0.714, 0.662, 0.820, 0.749, 0.807, 0.799, respectively, with venous phase ECV diagnosis having the highest AUC, sensitivity, and specificity of 76.2% and 78.9%, respectively.

### CONCLUSION

DECT parameters can provide additional information for preoperative assessment of pulmonary adenocarcinoma differentiation, offering significant clinical value, with venous phase ECV demonstrating the highest diagnostic efficacy.

### CLINICAL RELEVANCE/APPLICATION

The potential for ECV to contribute to more accurate tumor differentiation and patient management is cautiously optimistic, pending further validation from broader studies.

## M5B-SPVA-1 DYNAMIC RADIAL MR IMAGING FOR ENDOLEAK SURVEILLANCE AFTER ENDOVASCULAR REPAIR OF ABDOMINAL AORTIC ANEURYSMS WITH INCONCLUSIVE CT ANGIOGRAPHY: A PROSPECTIVE STUDY

Sven S. Walter, MD (*Abstract Co-Author*) Nothing to Disclose
Gerd Groezinger (*Abstract Co-Author*) Nothing to Disclose
Haidara Al Mansour, MD, MEng (*Presenter*) Nothing to Disclose

### PURPOSE

To assess free-breathing, dynamic radial magnetic resonance angiography (MRA) for detecting endoleaks post-endovascular aortic repair (EVAR) in cases with inconclusive computed tomography angiography (CTA).

### METHODS AND MATERIALS

This prospective single-center study included participants who underwent dynamic radial MRI (Golden-angle RAdial Sparse Parallel-Volumetric interpolated breath-hold, GRASP-VIBE) after inconclusive multiphasic CT for the presence of endoleaks during the follow-up of EVAR-treated abdominal aortic aneurysms. CT and MRI datasets were independently assessed by two radiologists for image quality, diagnostic confidence, and the presence/type of endoleak. Statistical analyses included interrater and intermethod agreement, and diagnostic performance (sensitivity, specificity, area under the curve (AUC)).

### RESULTS

A total of 17 participants (mean age, 70±9 years; 13 males) were included. Subjective image analysis demonstrated good image quality and interrater agreement (k=0.6) for both modalities, while diagnostic confidence was significantly higher in MRA (P=.03). There was significantly improved accuracy for detecting type II endoleaks on MRA (AUC 0.97 [95% CI:0.87, 1.0]) compared to CTA (AUC 0.66 [95% CI:0.41, 0.91]; P=.03). Although MRA demonstrated higher values for sensitivity, specificity, AUC, and interrater agreement, none of the other types nor the overall detection rate for endoleaks showed difference in the diagnostic performance over CT (p=0.12). CTA and MRA revealed slight to moderate intermethod concordance in endoleak detection (k=0.3 - 0.64).

### CONCLUSION

The GRASP-VIBE MRA characterized by high spatial and temporal resolution, demonstrates clinical feasibility with good image quality and superior diagnostic confidence. It notably enhances diagnostic performance in detecting and classifying endoleaks, particularly type II, compared to traditional multiphase CTA with inconclusive findings.

### CLINICAL RELEVANCE/APPLICATION

Enhanced surveillance for endoleaks post-EVAR could be attained through the utilization of radial MR imaging. This method not only enhances endoleak detection but also enables precise classification of endoleak types, thereby impacting clinical management strategies.

## M5B-SPVA-2 PREVALENCE OF UNRUPTURED INTRACRANIAL ANEURYSMS IN HEALTHY VIETNAMESE COMMUNITY:AN ANALYSIS BASED ON BRAIN EXAMINATION BY 3-TESLA MR-ANGIOGRAPHY

Quoc-Anh Nguyen-Duong, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to assess the detection rate, imaging features, and some risk factors of unruptured intracranial aneurysms (UIA) using 3 Tesla MRI and MR angiography (MRA).

### METHODS AND MATERIALS

A brain examination using 3 Tesla MRI/ MRA was scanned in 2962 healthy adults 18 years or older (mean age [± SD] 53.9 ± 12.1 years; 48.7% women) in the South of Vietnam between March 2021 and June 2023. Exclusion criteria were saccular aneurysm type protrusions with a maximum diameter < 1.5 mm and non-diagnostic imaging in cases of suspected aneurysms. The cases with a confirmed aneurysm diagnosis were analyzed in the aneurysm group. PHASES Score and the relationship between aneurysm occurrence and risk factors (age, sex, smoking history, alcohol use, hypertension, hyperlipidemia, medical symptom of headache, familial medical history of stroke, unruptured intracranial aneurysm) were investigated by the authors.

## RESULTS

276 aneurysms were confirmed in 237 individuals (detection rate 8%). Aneurysm incidence trended upward with increasing age. The average age in the aneurysm group was 56,9±11,3. The detection rate for women was significantly higher than for men (p < 0.001). The highest detection rate was 32.9% for people in their 50s. Of the patients with aneurysms, 33 (13.9%) had multiple cerebral aneurysms. By location, the internal carotid artery (ICA) was the most common aneurysm position, with 233 (85.6%) occurrences. Within the ICA, following the Boulithier classification, C1- C5 was the site of 56 aneurysms (20.6%); C6, 165 (60.6%); and C7, 12 (4.4%). Regarding aneurysm size, 2.0-2.9 mm was the most common size range, with 96 occurrences (35.3%), followed by 3.0-3.9 mm (24.3%). The largest aneurysm was 40 mm. The PHASES score was = 2 in 83.1% of the cases. Multivariate logistic regression analysis showed that familial medical history of UIA (p = 0.039, OR 1.91, 95% CI 1.02- 3.57), age (p < 0.001, OR 2.3, 95% CI 1.3-4.1), and female sex (p < 0.001, OR1.74, 95% CI 1.32-2.28), were statistically significant risk factors for aneurysm occurrence, whereas alcohol use was not a significant risk factor (p = 0,012, OR 0,7, Cl 95%: 0,53 - 0,92).

## CONCLUSION

The aneurysm detection rate was high in this study. Familial medical history of UIA, female sex, and older age were associated with an increased aneurysm detection rate, whereas alcohol use was not associated with an increased detection rate.

## CLINICAL RELEVANCE/APPLICATION

This retrospective analysis supports the necessity to screen and manage cerebral aneurysms in the community by utilizing 3 Tesla MRI imaging.

# M5B-SPVA-3 EVALUATION OF 4D FLOW MRI TO THE HEMODYNAMIC CHANGES OF THE CAROTID ARTERIES IN PATIENTS WITH HYPERLIPIDEMIA

Shuangqi Fu (*Abstract Co-Author*) Nothing to Disclose
Yang Li (*Abstract Co-Author*) Nothing to Disclose
Xiang Yong (*Abstract Co-Author*) Nothing to Disclose
Weiling Wang (*Presenter*) Nothing to Disclose

## PURPOSE

To obtain various hemodynamic parameters of carotid artery in patients with hyperlipidemia through 4D Flow MRI technology, and to explore the correlation between blood lipids and hemodynamic parameters.

## METHODS AND MATERIALS

This study prospectively enrolled 109 participants (46 females, 63 males, mean age 37 years) under 55 years of age. According to the serum triacylglycerol (TAG) value on the day of examination or within three days, they were further divided into normal group,elevated group and severely elevated group,normal group and elevated group according to serum total cholesterol (TC) value, and normal group and high-risk group according to serum high-density lipoprotein (HLD) value.All subjects underwent 4D Flow MR examination of the neck, and the total volume, peak blood flow velocity, mean axial Wall Shear Stress(WSS), mean circumferential WSS, WWSmax and WWSmean of bilateral common carotid artery (CCA) and internal carotid artery (ICC) were obtained by CVI post-processing software.The test for between-group differences was performed using Man-Whitney-Turst and Kruskal-Wallisha-Turst..A multiple linear regression model was established to evaluate the effects of age, sex, TG, TC and HLD on hemodynamic parameters.

## RESULTS

There were significant differences in WWSmax between the TAG-severely elevated group with the TAG-elevated group (p=0.00059) and the TAG-normal group (p=0.00000) (P<0.001), but there was no statistically significant difference between the TAG-elevated group and TAG-normal group (P=0.94).There were significant differences in WWSmean between the TAG-severely elevated group with the TAG-elevated group (p=0.0027) and the TAG-normal group (p=0.00033) (P<0.05), but there was no significant difference between the TAG-elevated group and the TAG-normal group (P=0.88).There were significant differences in WWSmax between the abnormal HDL group and the normal group (P=0.023) and between the abnormal TC group and the normal group (P=0.036), and there was no significant difference in WWSmean between the abnormal TC group and the normal group (P=0.039), but there was no significant difference between the abnormal HDL group and the normal group (P=0.13).There were no statistically significant differences in the remaining hemodynamic parameters.The TAG mixed model (F=10.025, p<0.001; F=3.881, p=0.011302) could significantly predict WWSmax and WWSmean.

## CONCLUSION

Abnormal changes in the three blood lipid indexes (TG,TC,HDL) can cause an increase in Wall Shear Stress, especially when TAG is severely elevated.

## CLINICAL RELEVANCE/APPLICATION

By measuring the changes of carotid artery 4D Flow MRI blood flow parameters, it can guide the clinical treatment control range of patients with hyperlipidemia.

## R2-SPBR-1 PREDICTORS OF LOCAL RECURRENCE IN EARLY-STAGE BREAST CANCER: PREOPERATIVE IMAGING AND CLINICOPATHOLOGIC FACTORS FOLLOWING ABBREVIATED BREAST MRI

Eun Ju Son, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Na Lae Eun, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to investigate preoperative MRI and clinicopathologic features associated with local-regional recurrence (LRR) in early-stage breast cancer patients who underwent postoperative abbreviated MRI following breast and axillary surgery.

### METHODS AND MATERIALS

A retrospective analysis was conducted on 1170 patients (mean age, 54.2 years; range, 24-90 years) with stage I or II breast cancer between January 2013 and December 2017. Patients underwent preoperative MRI, surgery, and postoperative abbreviated MRI. Preoperative imaging features, including the Breast Imaging Reporting and Data System (BI-RADS) lexicon of mammographic density and MRI, and clinicopathologic characteristics were analyzed using logistic regression to identify factors independently associated with LRR at abbreviated breast MRI screening.

### RESULTS

Among the patients, 57 (4.9%) experienced LRR at a median follow-up of 77.8 months. In multivariable analysis, dense breast tissue on mammography (OR = 4.208; 95% CI: 0.998, 17.748; P = 0.05), absence of heterogeneous enhancement on preoperative MRI (OR = 0.403; 95% CI: 0.192, 0.846; P = 0.016), high nuclear grade (OR = 2.104; 95% CI: 1.079, 4.106; P = 0.03), and presence of lymphovascular invasion (OR = 2.021; 95% CI: 1.076, 3.798; P = 0.03) were significantly associated with LRR at abbreviated breast MRI screening.

### CONCLUSION

Dense breast tissue, absence of heterogeneous enhancement on preoperative MRI, high nuclear grade, and presence of lymphovascular invasion are associated with increased risk of LRR in early-stage breast cancer patients undergoing postoperative abbreviated MRI surveillance.

### CLINICAL RELEVANCE/APPLICATION

Incorporating dense breast tissue, absence of heterogeneous enhancement on preoperative MRI, high nuclear grade, and presence of lymphovascular invasion into clinical practice may aid in tailoring follow-up strategies for early-stage breast cancer patients undergoing postoperative abbreviated MRI surveillance.

## R2-SPBR-10 PATIENT PERCEPTION OF ARTIFICIAL INTELLIGENCE IN BREAST IMAGING

Laurie R. Margolies, MD (*Abstract Co-Author*) Stock options, Nuevozen Corporation Medical Advisory Board, Screenpoint Medical
Nikki Mehran, MD (*Abstract Co-Author*) Nothing to Disclose
Sarah Ameri, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Artificial intelligence (AI) has the potential to improve diagnostic accuracy and efficiency in breast imaging. Though radiologists appreciate the benefits and limitations of AI, little information exists regarding patients' receptiveness and understanding of the use of AI in their individual breast imaging analysis. The goal of the study is to investigate patients' preferences about and perceptions of AI and its role in breast imaging interpretation.

### METHODS AND MATERIALS

Surveys were distributed to all patients presenting for imaging or biopsies within the breast radiology department at six facilities within an urban hospital system between September 2023 and March 2024 to evaluate their subjective understanding of AI, their perception of its use in ultrasound and mammography, and their potential concerns or interest in incorporating AI into their imaging analysis and reporting. Data was analyzed using Pearson's Chi squared test and $p<0.05$.

### RESULTS

Among 130 survey respondents, 66 (48%) supported the use of AI in breast radiology if they benefited from an earlier and more accurate diagnosis, which was independent of age, sex, race/ethnicity, level of education, and subjective understanding of AI. The majority of patients (64%) would feel more comfortable with doctors using AI, if they better understood how AI was used to create a diagnosis. The most frequently cited concern about the use of AI in breast radiology was loss of the relationship between patient and doctor (43%), followed by concern of doctors losing their skills (28%) and AI making

too many mistakes (23%). A minority of patients (16%) would want AI to be used in their imaging analysis if an additional cost was required for its use. There was no correlation between using social media platforms or technological applications for healthcare information and support of AI in breast imaging (p = 0.9). A majority of patients (60%) would like their study primarily read by a physician with a second physician consulted for questions, rather than AI. This was not correlated with having a personal or familial history of breast cancer (p=0.7) or every having had a biopsy (p=0.8).

**CONCLUSION**

Patients have variable understanding, perceptions and preferences regarding the use of AI in breast imaging. Educational measures to increase transparency and improve patients' understanding of AI in radiology can suggest a synergistic relationship between AI and providers as well as increase patient trust in their personal healthcare experience.

**CLINICAL RELEVANCE/APPLICATION**

Patients have variable understanding, perceptions and preferences regarding the use of AI in breast imaging. Increased communication and education about AI may help improve patient comfort with this increasingly prevalent diagnostic aid.

## R2-SPBR-3 MOBILE SCREENING MAMMOGRAPHY AT A MAJOR COMPREHENSIVE CANCER CENTER: HOW THE COVID-19 PANDEMIC AFFECTED COMPLIANCE WITH IMAGING FOLLOW-UP AFTER ABNORMAL SCREENING MAMMOGRAM

Jia Sun (*Abstract Co-Author*) Nothing to Disclose
Elliana Young (*Abstract Co-Author*) Nothing to Disclose
Ethan O. Cohen, MD (*Abstract Co-Author*) Spouse, Consultant, Boehringer Ingelheim GmbH;Spouse, Consultant, Novo Nordisk AS;Spouse, Consultant, Eli Lilly and Company
Gary J. Whitman, MD (*Abstract Co-Author*) Consultant, Siemens AG;Editor, Wolters Kluwer nv
Charisma DeSai, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Our mobile screening mammography program serves mostly underserved, uninsured patients (insured patients are occasionally imaged), and covid-19 forced a temporary shutdown of this program during 2020. The study goal was to determine how covid-19 affected compliance with follow-up after an abnormal screening mammogram.

**METHODS AND MATERIALS**

We retrospectively reviewed all screening mammograms (mobile and non-mobile) from the following time periods: Pre-pandemic (01/01/17-03/06/20), covid shutdown (03/07/20-07/07/20, when our mobile mammography program was inoperative), subacute pandemic (07/08/20-12/31/20), and chronic pandemic (01/01/21-12/31/22). Demographics and imaging follow-up data were recorded. Statistical analysis included Fisher's Exact and the Kruskall-Wallis tests.

**RESULTS**

The underserved mobile screening mammography population was predominantly Hispanic (81.6-93.2% across time periods), uninsured (100% across time periods), and resided in postal codes below the U.S. national median income (59.3-60% across time periods). The reverse was true for insured mobile screening mammography patients and non-mobile screening mammography patients (all $p<0.001$). Compliance with follow-up after an abnormal screening mammogram was 87.8-90% across all time periods for non-mobile screening mammography patients, while the compliance rates for the underserved and insured mobile screening patients were 76.2% and 67.2%, 59.7% and 30%, 53.7% and 42.9% during the pre-pandemic, subacute pandemic, and chronic pandemic time periods, respectively (all overall $p<0.001$). Median screening to diagnostic interval for non-mobile screening patients was 19, 12, and 11 days during the pre-pandemic, subacute pandemic, and chronic pandemic time periods, respectively ($p<0.001$). In comparison, the median screening to diagnostic interval for the underserved and insured mobile screening patients were 41 and 29 days, 57 and 40 days, 49 and 19 days during the pre-pandemic, subacute pandemic, and chronic pandemic time periods, respectively (all overall $p<0.001$).

**CONCLUSION**

Compared with before the covid-19 pandemic, our mobile screening mammography program's underserved population, which is predominantly Hispanic, uninsured, and of lower income, has had reduced compliance with follow-up after an abnormal screening mammogram. By the end of 2022, the screening to diagnostic interval remained worse than pre-pandemic levels.

**CLINICAL RELEVANCE/APPLICATION**

Our underserved mobile screening mammography population has been negatively impacted by the covid-19 pandemic. Additional efforts to improve follow-up after an abnormal screening mammogram are needed.

## R2-SPBR-4 ABBREVIATED MRI PROTOCOLS IN HIGH RISK BREAST SCREENING PROGRAMMES: ARE WE READY TO GO?

Linda Metaxa, MD (*Abstract Co-Author*) Nothing to Disclose
Shefali Dani (*Abstract Co-Author*) Nothing to Disclose
Nithya Vidyaprakash, FRCR, MBBS (*Abstract Co-Author*) Nothing to Disclose
Vasiliki Papalouka, MBBS, MSc (*Abstract Co-Author*) Nothing to Disclose
Sookyeen Lee, MBChB (*Abstract Co-Author*) Nothing to Disclose
Tamara Suaris, MBBS, FRCR (*Presenter*) Nothing to Disclose

**PURPOSE**

Abbreviated MRI protocols ( AbbMRI) aim to provide a cost-effective study without compromising diagnostic accuracy. We aim to assess the diagnostic performance of AbbMRI in high-risk breast cancer screening.

**METHODS AND MATERIALS**

Four experienced breast radiologists retrospectively reviewed the AbbMRI protocol in 236 MRI breast studies performed for very high-risk women between January 2018 - 2020. The protocol consisted of six sequences: pre-contrast T1W, T2W axial, two dynamic postcontrast, subtracted axial sequences and MIP reconstruction. Readers were blinded to history, and patient outcomes. Prior MRI imaging was reviewed when available in AbbMRI format. Results were compared with existing reports of the full protocol (19 sequences). The studies were double read both in the AbbMRI and full protocol and in cases of discrepancies, a 3rd read followed. Descriptive Statistics, sensitivity, specificity, and predictive values were calculated and compared.

**RESULTS**

From the 236 MRI studies, four invasive malignancies and one B3 lesion (radial scar) were identified. The average time to read the AbbMRI was 69 seconds (range: 28 to 240 seconds; 95% CI: 63, 74 seconds). The inter-rater rate (IRR) between the readers in Abb MRI was 90.7%, while between the abbreviated and full protocol reading was 94.3%. The recall rate for AbbMRI was 5.1%, and 6.1% for full protocol (p=0.9). Sensitivity achieved by AbbMRI (100%) was equal to the full protocol (no cancers were missed). NPV were high for both reading sessions (100%). There was no statistically significant difference between the specificity of the abbreviated MRI (95.7%) and the full protocol (95.5%) (p=0.9, a=0.05), as well as the PPV (16.7 vs 16, p>0.05).

**CONCLUSION**

Abbreviated MRI is feasible in screening MRI of high risk patients, with sensitivity and cancer detection rate comparable to the full MRI protocol. Abbreviated breast MRI can be considered as a safe alternative to conventional MR studies in UK very high-risk screening programme , reducing MR waiting times/backlog. Limitations: This is a small retrospective study with only 4 cancers identified in our study sample.

**CLINICAL RELEVANCE/APPLICATION**

The use of AbbMRI protocols appear to have potential in High risk screening programmes, helping to improve MRI efficiency, reduce radiology reading time without compromising recall rates and cancer detection rates.

## R2-SPBR-6 SOCIOECONOMIC DEMOGRAPHICS OF BREAST IMAGING PATIENTS STRATIFIED BY EXAMINATION DAY AND START TIME

Habib Tannir, MS (*Abstract Co-Author*) Nothing to Disclose
Olga Lukyanchenko (*Abstract Co-Author*) Nothing to Disclose
Elaine Hwang (*Abstract Co-Author*) Nothing to Disclose
Jia Sun (*Abstract Co-Author*) Nothing to Disclose
Taylor Stutz (*Abstract Co-Author*) Nothing to Disclose
Ethan O. Cohen, MD (*Presenter*) Spouse, Consultant, Boehringer Ingelheim GmbH;Spouse, Consultant, Novo Nordisk AS;Spouse, Consultant, Eli Lilly and Company

**PURPOSE**

With ongoing concerns over the disparities in access to breast imaging, we compared breast imaging patient demographics based on their imaging appointment time and day.

**METHODS AND MATERIALS**

Screening mammography, diagnostic mammography, breast ultrasound, and breast MRI patients during 01/01/2016-01/30/2022 were retrospectively reviewed. Patient race, ethnicity, age, insurance status, and income were assessed.

**RESULTS**

304,029 examinations were included. Appointments for Asians, African Americans, younger patients, and patients with wealthier zip codes were more common on Fridays and Saturdays than Monday-Thursdays (all p<0.001; Asians: 9.5% and 13.5% of Friday and Saturday appointments versus 7.7-8.6% for Monday-Thursdays, African Americans: 15.2% and 21.9% of Friday and Saturday appointments versus 13.1-13.9% for Monday-Thursdays, median age: 57 and 54 years for Friday and Saturday appointments versus 58-59 years for Monday-Thursdays, wealthier zip codes: 56.9% and 68.2% of Friday and Saturday appointments versus 55.0-56.9% for Monday-Thursdays) and more common in the late afternoon and evening than other times of day (all p<0.001; Asians: 10.2% and 11.2% of late afternoon and evening appointments versus 8.3-8.5% for other times, African Americans: 14.7% and 15.2% of late afternoon and evening appointments versus 13.5-14.3% for other times, median age: 57 and 52 years for late afternoon and evening appointments versus 58 years for other times, wealthier zip codes: 59.7% and 57.0% of late afternoon and evening appointments versus 54.7-56.2% for other times). Similar trends were not seen for Hispanics. Self-pay patient appointments were more common on Saturdays and in the evening (2.0% of Saturday appointments versus 1.7% for Monday-Fridays, p<0.001; 3.1% of evening appointments versus 1.6-1.9% for other times, p=0.001).

**CONCLUSION**

Breast Imaging patient demographics differ based on appointment day and examination time. Asian, African American, younger, and wealthier patients were more commonly scheduled later in the day and on Fridays or Saturdays. Self-pay patients were more commonly scheduled in the evening or on Saturdays.

**CLINICAL RELEVANCE/APPLICATION**

Greater availability of Friday, Saturday, and later afternoon-evening appointments could improve disparities in access to breast imaging services.

## R2-SPBR-7 EARLY PREDICTION OF NEOADJUVANT CHEMOTHERAPY RESPONSE: A COMPREHENSIVE RADIOMICS ANALYSIS OF TUMOR AND BREAST TISSUE

Haoxin Zheng (*Abstract Co-Author*) Nothing to Disclose
Kyunghyun Sung, PhD (*Abstract Co-Author*) Nothing to Disclose
Ran Yan (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate prediction of neoadjuvant chemotherapy (NAC) response in breast cancer is pivotal for optimizing treatment plans and surgical approaches. This study aims to evaluate the predictive potential of combining radiomics features from tumor, peritumoral region, and background parenchymal enhancement (BPE) with clinical data for early complete response prediction following NAC.

**METHODS AND MATERIALS**

A total of 191 patients from ten clinical trial sites in the BMMR2 challenge data as a subset of the ACRIN6698 trial were included in this study. Each patient included DCE MRIs before (T0) and at an early stage (T1) of NAC. The peritumor region is segmented outward from the tumor for 8mm. The fibroglandular tissue is segmented by a previously developed neural network to extract BPE radiomics. Radiomics features were extracted from the tumor, peritumoral region, and BPE across three DCE image phases (pre-contrast, early post-contrast, and late post-contrast). Features of time points T0, T1, and delta radiomics features reflecting dynamic changes between T0 and T1 were included.We pruned features for redundancy using the variance inflation factor (VIF) and the correlation matrix and eliminated low-performing features via logistic regression. Our final selection of radiomics features was refined using the lasso model. Prediction models were developed using multivariable logistic regression, SVM, and XGBoost based on different combinations of

radiomics features with clinical features. The AUC, specific sensitivity, and specificity values at the Youden index were used to evaluate the performance of prediction models.

**RESULTS**

Data were divided into training (117) and testing (74) datasets. The tumor region alone exhibited the highest performance (AUC [95% CI]: 0.780 [0.729-0.831], sensitivity: 92.2%, specificity: 51.5%) among single region models, with further enhancement upon incorporating BPE radiomics (AUC [95% CI]: 0.806 [0.711-0.923], sensitivity: 81.6%, specificity: 70.7%). However, combining all three regions did not yield superior predictive power (AUC [95% CI]: 0.720 [0.651-0.793], sensitivity: 65.3%, specificity: 72.7%). Notably, the combination of tumor and BPE radiomics excelled in predicting response in hormone receptor-positive subtypes and high-grade tumors.

**CONCLUSION**

Integrating tumor radiomics with clinical data from DCE-MRI enables robust early prediction of NAC response in breast cancer. The addition of BPE radiomics further refines prediction accuracy.

**CLINICAL RELEVANCE/APPLICATION**

The inclusion of BPE radiomics features augments the efficacy of early NAC response prediction, suggesting its potential to reflect underlying cancer pathophysiological responses to treatment.

## R2-SPBR-8 INTRA- AND PERITUMORAL RADIOMICS BASED ON MULTIPARAMETRIC MRI FOR PREOPERATIVE PREDICTION OF AXILLARY LYMPH NODE BURDEN AND DISEASE-FREE SURVIVAL IN INVASIVE BREAST CANCER

Tingting Liu (*Abstract Co-Author*) Nothing to Disclose
Yanni Jiang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Jialu Lin (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate a radiomics signature based on intratumoral and peritumoral multiparametric MRI for preoperative prediction of axillary lymph node (ALN) burden and assessment of individualized disease-free survival (DFS) in invasive breast cancer.

**METHODS AND MATERIALS**

A total of 410 patients with pathologically confirmed invasive breast cancer (training dataset: n = 287; validation dataset: n = 123) from January 2018 and December 2019 who underwent breast MRI before treatment were retrospectively recruited. Pathological axillary lymph node metastases =3 or >3 were used to differentiate between low and high ALN burden groups. Based on five distinct MRI sequences, including T2 turbo inversion recovery magnitude (TIRM) of the fat compression sequence, diffusion-weighted imaging (DWI), apparent diffusion coefficient (ADC) map, and the second and fourth phases of dynamic contrast-enhanced (DCE) MRI, radiomics features related to ALN burden were selected in three specific regions (intratumor, peritumour, and intratumour + peritumour). Subsequently, the Support Vector Machine (SVM) was utilized to construct the three radiomics models and calculate the radiomics signature (Radscore) for each region. Univariate and multivariate logistic regression analyses were applied to identify clinical features associated with ALN burden, which were then incorporated into the radiomics nomogram. Kaplan-Meier survival curves based on the radiomics and nomogram models were used to estimate DFS.

**RESULTS**

All three Radscores showed good performance for ALN burden prediction, with the combined regional Radscore (Com-Radscore) performing the best, yielding AUCs of 0.909 in the training dataset and 0.808 in the validation dataset. The established radiomics nomogram, incorporating the combined radiomics features and MRI-reported peritumoral edema and lesion enhancement pattern, demonstrated satisfactory calibration and discrimination in both the training and validation datasets, with AUCs of 0.907 (95% CI: 0.873-0.942) and 0.832 (95% CI: 0.759-0.906), respectively. DFS was significantly shorter in the higher-risk groups defined by the combined radiomics model and nomogram (both $p < .05$). Higher Com-Radscore was independently associated with worse DFS in the entire cohort ($p < .05$).

**CONCLUSION**

The combined regional radiomics model and radiomics nomogram based on multiparametric MRI provided satisfactory preoperative prediction of ALN burden and DFS in patients with invasive breast cancer.

**CLINICAL RELEVANCE/APPLICATION**

The new model aids in providing opportunities for precision axillary management and subsequent follow-up by effectively predicting preoperative ALN burden and prognosis among patients with invasive breast cancer.

## R2-SPBR-9 A NOMOGRAM BASED ON APPARENT DIFFUSION COEFFICIENT DERIVED FROM DIFFUSION-WEIGHTED IMAGING (DWI) FOR PREDICTING AXILLARY LYMPH NODE METASTASIS IN BREAST CANCER

Huifang Chen (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study was to construct a nomogram based on apparent diffusion coefficient (ADC) to accurately preoperative evaluate ALN metastasis before treatment and the ALN metastasis after neoadjuvant chemotherapy (NAC) and avoid unnecessary axillary surgery in patients with breast cancer.

**METHODS AND MATERIALS**

In this retrospective cohort study, we conducted an analysis of 778 breast cancer patients from two hospitals. These patients were enrolled from the training cohort (427 patients) and the external validation cohort 1 (351 patients). Uni- and multivariable logistic regression was performed to identify independent predictors of ALN metastasis. The nomogram was constructed based on the significant factors associated with ALN metastasis before treatment (task 1) and ALN metastasis after NAC (task 2), respectively. Model performance was assessed by area under the curve (AUC), accuracy, sensitivity, and specificity. The clinical benefit of these models was revealed by decision curve analysis (DCA). The predictive performance was validated using external validation cohort.

**RESULTS**

The ADC values for ALN metastasis before treatment and ALN metastasis after NAC were significantly lower than that for ALN non-metastasis before treatment and ALN non-metastasis after NAC between the two cohorts (all $P < 0.05$). The nomogram model combined ADC value and clinical data exhibited the best performance. The nomogram demonstrated satisfactory predictive performance in the training cohort (task 1: AUC 0.879, task 2: AUC 0.761), and external validation cohort 1 (task 1: AUC 0.837, task 2: AUC 0.805).

## CONCLUSION

The nomogram, a noninvasive, preoperative prediction tool that incorporates a combination of ADC and clinical data, showed favorable predictive efficacy for the status of ALN metastasis before treatment and ALN metastasis after NAC. Validation of the external cohort achieved good predictive performance. Therefore, the nomogram potential to serve as a noninvasive approach to assist personalized treatment decisions, guide ALN management, avoiding unnecessary ALND.

## CLINICAL RELEVANCE/APPLICATION

ADC is a non-invasive, acceptable, and widely used in clinical MRIs screening method. The nomogram based on ADC to differentiate ALN metastasis before treatment and the ALN metastasis after NAC, and help to avoid unnecessary axillary surgery.

## R2-SPCA-1 A CARDIAC MAGNETIC RESONANCE 4D FLOW STUDY ON MITRAL ANNULOPLASTY (MAP): IMPACT ON LEFT VENTRICULAR FLOW DYNAMICS AND FUNCTIONAL CORRELATIONS WITH DIFFERENT TYPES OF DEVICES

Letizia Ruoli, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate functional and fluidodynamic modifications after MAP with different types of annuloplasty prosthetics using 4D-flow techniques and analysis of left atrial strain in CMR.

### METHODS AND MATERIALS

We enrolled 12 patients treated with MAP - 6 with a semi-rigid ring with an open anterior segment and 6 with a flexible band - and had them undergo CMR at least 12 months after the procedure. The protocol included cineMR and 4D-Flow sequences covering the entire heart. We quantified Total Flow Volume (TFV), Peak Velocity (Vmax), and Wall Shear Stress (WSS) with their respective locations. We analyzed left atrial volumes and strain obtaining Reservoir, Conduit, and Booster-Pump values. We ultimately compared patients with 30 healthy controls matched for age and sex, including 10 with 4D-flow sequences

### RESULTS

Patients who underwent MAP had lower ejection fraction (49.3±4.2% vs. 62.34±6.3%; $p < 0.001$), reduced TFV (52.3±7.8ml vs. 69.6±9.7; $p = 0.014$), and higher WSS (0.7±0.2Pa vs. 0.4±0.2Pa; $p < 0.001$) compared to controls; the WSS appeared also higher in the first group (semi-rigid ring) compared to the flexible band. As per the vortex flow patterns analysis, both interventricular and beneath the mitral valve during the whole cardiac cycle, there were no significant changes among the two different groups of MAP compared with controls.MAP patients also exhibited decreased Reservoir (20.6±20.1% vs. 22.9±2.5%; $p = 0.033$), lower Conduit (9.1±3.48% vs. 12.7±1.8%; $p = 0.005$), and increased Booster Pump strain (12.4±1.8% vs. 8.9±2.3%; $p = 0.001$) compared to controls. The time since the intervention inversely correlated with trans-mitral TVF (r: -0.95; $p = 0.041$) but did not affect valvular WSS. In MAP patients, left atrial Booster Pump strain inversely correlated with transvalvular Vmax (r: -0.95; $p = 0.046$).

### CONCLUSION

Patients who underwent MAP showed a decrease in TFV and an increase in transvalvular WSS with the highest values found along the prosthetic edge due to an increase in annular rigidity, especially in the semi-rigid ring compared to the flexible ring. However, the flow patterns remained similar to the control group, indicating a good resolution post-procedure for both prosthetics. Ultimately, the left atrium appears to compensate functionally by increasing active contraction after MAP, showing higher values of booster pump strain.

### CLINICAL RELEVANCE/APPLICATION

We aim to provide new parameters for post-MAP functional assessment to improve patient selection and personalize prosthetic type for each patient, aiming for an increasingly personalized approach.

### PURPOSE

Cardiac CT has significant potential for accurate 3D imaging of complex mitral valve (MV) anatomy before valve repair surgery. However, evaluating the thin and floppy MV in 3D volume-rendered (3DVR) images is challenging. We hypothesized that a deep-learning (DL) based post-processing denoising technique could improve image quality, contributing to the creation of more diagnostic 3DVR images without projection data.

### METHODS AND MATERIALS

We retrospectively reviewed 50 cardiac CTs from 2023 patients with severe mitral regurgitation preparing for MV repair. We use a dual-source CT scanner to scan all heart phases through contrast bolus tracking in the left atrium (LA). A radiologist chose the stationary MV phase during systole for further evaluation. Iterative reconstruction was used to obtain original images. And the images denoised using a post hoc method using the residual dense network. In image analysis, we compared the original image with the denoised image. We measured CT values and standard deviations in the LA cavity using circular ROIs and the MV leaflet using linear ROIs. We created 3DVR images using a 3D workstation, adjusting to the surgeon's view and blood chamber transparency to display LA walls and valve leaflets. CT values for LA and leaflet were thresholded at the 75th percentile using opacity curves. We used a 10-point scoring system to evaluate images for LA cavity transparency and MV leaflet depiction. We evaluated diagnostic confidence for prolapse leaflets using eight-valve leaflet segments: A1-3, P1-3, AC, and PC. Image noise and qualitative scores were compared with the Wilcoxon sign-rank test between original and denoised images. Surgical outcomes were used as a reference to assess the diagnostic ability of 3DVR images via ROC curves with generalized estimating equations.

### RESULTS

In 50 cases (median age 64 [IQR 55-74] years, 20 female, average heart rate at scan 67±2 bpm), the denoising method resulted in a significant reduction in image noise, from 28 [21-30] HU to 16 [13-17] HU ($P < .001$). The 3DVR image evaluation showed improved uniformity in LA cavity transparency (from 4.5 [3-6] to 9 [7.8-9.3]) and significantly enhanced depiction of valve leaflets (from 8 [6-8.3] to 9 [8-10]) ($P < .001$ for all). The area under the curve for the ROC showed a substantial increase with denoised images (0.940, 95% CI 0.906-0.976) compared to the original (0.906, 95% CI 0.868-0.945) ($P = .009$).

### CONCLUSION

DL-based post hoc denoising significantly improves 3DVR imaging and its diagnostic performance of the MV in cardiac CT.

### CLINICAL RELEVANCE/APPLICATION

Advanced 3D Cardiac CT imaging can improve surgical outcomes and patient satisfaction by aiding surgeons in planning repair procedures and helping patients understand their condition.

## R2-SPCA-2 PHOTON-COUNTING DETECTOR COMPUTED TOMOGRAPHY QUANTIFICATION OF WHOLE-BODY EXTRACELLULAR VOLUME TO ASSESS FLUID VOLUME STATUS

Pal Maurovich Horvat, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Martin Ugander, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nora M. Kerkovits (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a method and healthy normal values for quantification of whole body extracellular volume (ECV) using photon-counting computed tomography (PCCT).

### METHODS AND MATERIALS

Consecutive healthy subjects provided written informed consent and underwent PCCT (Naeotom Alpha, Siemens) urography as part of their evaluation as potential living kidney donors. ECV (ml) was calculated as ECV = ([I]CA x VCA - IMbladder) x (1-hematocrit) / [I]blood, incorporating known injected iodinated contrast concentration ([I]CA, mg/ml) and volume (VCA, ml), measured blood iodine concentration ([I]blood, mg/ml), and urinary bladder total excreted iodine mass (IMbladder, mg) quantified on iodine maps with a region of interest in the inferior vena cava and regions of interest in all images covering the whole urinary bladder acquired at one time point 6-10 minutes after intravenous iodinated contrast administration (iomeprol or iopromide, 300±26 mg/kg injected iodine dose), and hematocrit measured from venous blood sampling.

### RESULTS

In healthy subjects (n=51, age 47±9 years, 55% female, body mass index 26.9±5.3 kg/m2) unindexed whole body ECV was greater in males compared to females (9.7±2.0 vs 7.8±1.6 L, $p<0.001$), but did not differ when indexed to body weight (112±14 vs 112±18 ml/kg, $p=0.91$, combined normal range 112±15, 95% limits 82-142 ml/kg), and was independent of age ($p=0.83$), contrast agent type ($p=0.79$), and scan delay time after contrast injection ($p=0.29$).

### CONCLUSION

Iodine mapping with PCCT is an effective and robust method for measuring whole body ECV, enabling the objective quantification of fluid volume status, and normal values are presented.

### CLINICAL RELEVANCE/APPLICATION

Single timepoint late phase post-contrast PCCT iodine mapping as part of routine CT urography can quantify whole body extracellular fluid volume for applications in conditions characterized by volume overload such as heart failure or chronic kidney disease. This simple and novel method holds promise as an objective measure of fluid volume status for diagnosis, risk stratification, and assessing and managing therapy response.

## R2-SPCA-3 CARDIAC PSEUDOANEURYSMS: CLINICAL PATTERNS AND PREDICTORS OF OUTCOMES

Mangun Randhawa, MD (*Abstract Co-Author*) Nothing to Disclose
Sandeep S. Hedgire, MD (*Abstract Co-Author*) Nothing to Disclose
Vinit Baliyan, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Andre Lupp Mota, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Brian B. Ghoshhajra, MD, MBA (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Koninklijke Philips NV;Consultant, Siemens AG
Amine El Kandoussi (*Abstract Co-Author*) Nothing to Disclose
Azin Ghamari (*Presenter*) Nothing to Disclose

**PURPOSE**

Cardiac pseudoaneurysms (PSA), characterized by a contained rupture and covered by pericardium, thrombus, or scar, pose significant diagnostic and management challenges due to their high risk of fatal rupture. This study, leveraging the diagnostic strengths of CT imaging, expands the examination of PSAs beyond the ventricular subtypes commonly resulting from myocardial infarction to include various locations and etiologies. It aims to identify clinical profiles, imaging characteristics, and patterns that may predict patient outcomes.

**METHODS AND MATERIALS**

This IRB-approved, retrospective study analyzed cardiac PSA imaging characteristics (location, size, multiplicity) from cardiothoracic CTs performed between April 2014 and April 2024. Data on demographics, comorbidities, risk factors, major adverse cardiac events (MACE), and surgical intervention were extracted from electronic health records. Statistical analysis was performed using JASP (an open-source statistical software).

**RESULTS**

This study included 82 patients (mean age 59.5 years, 57 males) with 96 PSAs. The most common etiologies were infection (80.5%), myocardial infarction (12.2%), and iatrogenic causes (7.3%). The most prevalent location was the aortic valve (56.2%), with an average size of 3.21 ± 2.69 cm.Complications included new heart block (54.8%), valvular dysfunction (51.2%), and heart failure (36.5%). Surgical intervention occurred in 54.5% of cases, with a mean time to intervention of 70 ± 178.53 days from diagnosis. Follow-up until the date of the last recorded encounter revealed MACE in 47.6% of patients, primarily from cardiovascular death (12.2%) and stroke (10.4%).Logistic regression revealed that predictors of MACE included age ($p=0.024$), smoking ($p=0.016$), and prior infective endocarditis ($p=0.037$). Predictors of surgical intervention were age ($p=0.007$), hypertension ($p=0.019$), alcohol intake ($p=0.039$), intravenous drug use ($p=0.005$), and new heart block ($p=0.041$).

**CONCLUSION**

Age, smoking status, prior infective endocarditis, hypertension, alcohol intake, intravenous drug use, and new heart block significantly predict MACE and surgical outcomes in PSA patients.

**CLINICAL RELEVANCE/APPLICATION**

This study enhances the understanding of cardiac pseudoaneurysms by detailing their diverse etiologies and locations, aiding in more accurate prognosis assessments.

## R2-SPCA-4 EVALUATING THE STATUS OF CARDIAC IMAGING TRAINING IN RADIOLOGY RESIDENCY PROGRAMS IN THE UNITED STATES

Diana Litmanovich, MD (*Abstract Co-Author*) Nothing to Disclose
Tami J. Bang, MD (*Abstract Co-Author*) Nothing to Disclose
Aurelija Liubauske (*Abstract Co-Author*) Nothing to Disclose
Ivan Diogo Queiros, MD,MMed (*Abstract Co-Author*) Nothing to Disclose

Jennifer M. Cutts, MD (*Abstract Co-Author*) Nothing to Disclose
Jonathan Revels, DO (*Abstract Co-Author*) Nothing to Disclose
Yuval Liberman, MD, MMedSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Cardiac imaging holds significant importance in contemporary diagnostic radiology and constitutes a portion of the Radiology Core examination. Consequently, ensuring comprehensive training in this domain is imperative for radiology residency programs. This study aims to assess the present status of cardiac imaging training across radiology residency programs in the United States.

**METHODS AND MATERIALS**

Utilizing the Research Electronic Data Capture (REDCap) platform, survey questionnaires were distributed to heads of cardiac/cardiothoracic sections in all eligible US radiology residency programs.

**RESULTS**

Out of 163 questionnaires dispatched, 70 responses were received, with a completion rate of 82.9%. The findings revealed that 85.9% of programs offered a dedicated cardiac imaging rotation, with 58.8% spanning four weeks, primarily conducted in a single block. Moreover, 31.4% of programs provided an extended cardiac experience ranging from 6 to 12 weeks. A designated individual responsible for cardiac imaging was reported by 90.7% of programs, with 68.5% being radiologists and 22.2% representing combined radiologist and cardiologist roles. Regarding reporting responsibilities, 40.7% assigned cardiac CT interpretations to radiologists alone, while 59.3% involved combined radiologist and cardiologist assessments. For cardiac MRI studies, 69.0% shared reporting duties, either through alternate coverage days or with radiologists focusing on non-cardiac findings. Furthermore, 65.5% of programs conducted over six cardiac case conferences annually, and 75.9% offered more than six cardiac lectures. Among the surveyed programs, 65.6% provided cardiothoracic fellowships, with 87.2% allocating over three months to cardiac imaging training. However, only 18.6% offered dedicated cardiovascular fellowships.

**CONCLUSION**

This study provides valuable insights into the current landscape of cardiac imaging education and practice within radiology residency programs. These findings can inform professional societies in developing guidelines to establish a more standardized and comprehensive approach to cardiac imaging education.

**CLINICAL RELEVANCE/APPLICATION**

Assess the present status of cardiac imaging training across radiology residency programs in the United States.

## R2-SPCA-5 INCIDENCE OF DEVICE-RELATED THROMBOSIS FOLLOWING LEFT ATRIAL APPENDAGE OCCLUSION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Wei Li (*Abstract Co-Author*) Nothing to Disclose
Hamid Chalian, MD (*Abstract Co-Author*) Nothing to Disclose
Mehrad Rokni, MD (*Abstract Co-Author*) Nothing to Disclose
Tannaz Rajabi (*Abstract Co-Author*) Nothing to Disclose
Seyedali Nabipoorashrafi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Device-related thrombus (DRT) is one of the most important complications of left atrial appendage occlusion (LAAO). However, existing literature on the incidence and timing of DRT post-LAAO contains mixed findings, and there are currently no standardized timelines for follow-up imaging to ensure prompt detection of DRT. This study conducted a meta-analysis to calculate the incidence of DRT at various time points post-LAAO to aid in understanding the over-time trend of DRT incidence.

**METHODS AND MATERIALS**

The PubMed, Cochrane Library, and Embase databases were searched from inception to May 2023 for articles that reported on DRT following LAAO. References were then hand-searched according to PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) to identify studies meeting the following inclusion criteria: clinical trials or observational studies that include at least 20 patients who received an LAAO device, and which specify the follow-up imaging protocol and time of DRT diagnosis. The data were collected and stratified into six timepoints based on the time to diagnosis from procedure via TEE or CTA: 30, 45, 60, 90, 180, and more than 180 days (the longest follow-up reported). Statistical analysis was subsequently performed using a random effects model to calculate the cumulative DRT incidence with 95% confidence intervals (CI) at each timepoint.

**RESULTS**

2181 records were obtained from the initial database search. After review, 97 relevant articles were identified with a total DRT incidence of 706/33,245 (2.12%). The mean cumulative incidence at day 30 was 0.83% (15/996, CI: 0.23% - 2.98%, I2 = 0.00%); day 45 was 1.24% (156/10,909, CI: 0.90% - 1.70%, I2 = 37.30%); day 60 was 1.91% (25/1,347, CI: 1.10% - 3.29%, I2 = 34.10%); day 90 was 2.14% (120/4,559, CI: 1.41% - 3.25%, I2 = 36.90%); day 180 was 2.06 (159/8,088, CI: 1.45% - 2.92%, I2 = 62.50%); and day >180 was 2.9% (231/7,346, CI: 2.07% - 4.06%, I2 = 70.60%).

**CONCLUSION**

Our results reveal the incidence of DRT over time following LAAO. The trend of cumulative incidence changes was not uniform across different time points. The cumulative incidence rises rapidly within the first 90 days, then plateaus by 180 days post LAAO, increasing marginally thereafter. This pattern underscores the need for vigilant monitoring during the early post-procedural period. At the same time, it demonstrates that additional follow-up imaging is required beyond this time period.

**CLINICAL RELEVANCE/APPLICATION**

Our results show the incidence of DRT over time post LAAO. Understanding how the incidence of DRT changes over time will help guide post-LAAO follow-up protocols, enhance the safety of LAAO devices, and potentially improve patient outcomes.

## R2-SPCA-6 THE INVESTIGATION OF LEFT ATRIAL STRAIN ANALYSIS USING CARDIAC COMPUTED TOMOGRAPHY IMAGING IN PATIENTS WITH ATRIAL FIBRILLATION

Takuya Matsuda (*Abstract Co-Author*) Nothing to Disclose
Yusuke Kobayashi (*Abstract Co-Author*) Nothing to Disclose
Teruhito Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
SHUN SAWADA (*Abstract Co-Author*) Nothing to Disclose
Yuki Tanabe (*Abstract Co-Author*) Nothing to Disclose
Tomoro Morikawa, MD (*Abstract Co-Author*) Nothing to Disclose
Hiroshi Suekuni (*Presenter*) Nothing to Disclose

**PURPOSE**

Atrial fibrillation (AF) is one of the most frequent tachyarrhythmias, and it increases the risk of intracardiac thrombus causing cerebral infarction and other embolisms. Catheter ablation (CA) is currently used as a treatment for AF, but the relatively high recurrence rate after treatment is an issue. Previous studies have reported that left atrial strain could have evaluated for LA function than conventional morphological indices such as left atrial volume index (LAVI). This study aimed to examine the feasibility of CT-derived LA strain (CT-LAS) analysis for LA function assessment in patients with AF.

**METHODS AND MATERIALS**

A total of 406 patients with AF (paroxysmal AF, 56%; persistent AF, 43%), who underwent cardiac CT to acquire the navigation data for CA, were included. CT-LAS was calculated by dividing the difference between the maximum and the minimum circumference by the minimum, and the average values of two and four chamber view were used. The maximum and minimum LA volume index (LAVImax and LAVImin) were also calculated with CT. The correlations between CT-LAS and both LAVIs were assessed by Spearman's rank correlation coefficient. Additionally, The correlations between CT-LAS and the types of AF(paroxysmal or persistent) were assessed by Mann-Whitney U test.

**RESULTS**

There were significant correlations between CT-LAS and LAVImax (r: 0.45, p <0.0001) or LAVImin (r: 0.68, p <0.0001). CT-LAS in patients with paroxysmal and persistent AF were 20.6 (14.8-25.9) % and 8.5 (7.0-11.2) %. LAVImax in patients with paroxysmal and persistent AF was 49.5 (41.5-60.3) and 63.7 (545.0-77.6) mL/m2. LAVImin in patients with paroxysmal and persistent AF was 28.9 (22.3-36.8) and 52.2 (41.5-67.0) mL/m2. There were significant differences in CT-LAS, LAVImax and LAVImin between patients with paroxysmal and persistent AF (p <0.0001 in each).

**CONCLUSION**

CT-LAS analysis is feasible for LA function assessment in patients with AF.

**CLINICAL RELEVANCE/APPLICATION**

CT-LAS is as useful as or more than conventional morphologic indices in assessing LA function in patients with AF. CT-LAS can provide an incremental value of LA function to cardiac CT imaging that is performed as a navigation tool for catheter ablation.

## R2-SPCA-7 LEFT ATRIAL VOLUME INDEX DERIVED FROM COMPUTED TOMOGRAPHY CAN BE A POWERFUL PREDICTOR OF ATRIAL FIBRILLATION RECURRENCE AFTER INITIAL CATHETER ABLATION

SHUN SAWADA (*Abstract Co-Author*) Nothing to Disclose
Takuya Matsuda (*Abstract Co-Author*) Nothing to Disclose
Teruhito Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hiroshi Suekuni (*Abstract Co-Author*) Nothing to Disclose
Yuki Tanabe (*Abstract Co-Author*) Nothing to Disclose
Tomoro Morikawa, MD (*Abstract Co-Author*) Nothing to Disclose
Yusuke Kobayashi (*Presenter*) Nothing to Disclose

### PURPOSE

Catheter ablation (CA) for atrial fibrillation (AF) has been established, but the recurrence is still common. Left atrial volume index derived from echocardiography (US-LAVI) is one of powerful predictors for AF recurrence, but several challenges exist in US-LAVI analysis due to deep attenuation, limited acoustic window, and so on. The aim of this study was to propose LAVI derived from computed tomography (CT-LAVI) as an alternative parameter to US-LAVI and to determine the relationship between CT-LAVI and AF recurrence after initial CA.

### METHODS AND MATERIALS

This retrospective study included 304 patients who underwent cardiac CT and echocardiography before the initial CA for AF. CT- and US-LAVI were defined as the maximum LA volume divided by the body surface area. The correlation between CT-LAVI and US-LAVI was evaluated by Spearman's rank correlation coefficient and Bland-Altman analysis. CT-LAVI and US-LAVI were compared by Wilcoxon signed-rank test. Cox proportional hazard model was used to calculate hazard ratios (HR) of predictors for AF recurrence. AF recurrence curves were constructed by Kaplan-Meier method.

### RESULTS

Of 304 patients, 275 patients (paroxysmal AF, 51%; persistent AF, 49%) were enrolled excluding 1 patient for poor contrast enhancement in cardiac CT and 28 patients for poor LA visualization in echocardiography. CT-LAVI was significantly correlated with US-LAVI ($r=0.74$, $p <0.001$). Bland-Altman analysis revealed that the mean difference with 95 % confidence interval (CI) between CT-LAVI and US-LAVI were 24.1 (95%CI, 22.6 to 25.7) ml/m2, and the proportional bias was observed. The median CT-LAVI was 58.5 (46.7-72.5) ml/m2, which was significantly greater than that of US-LAVI [34.2 (26.7-43.1) ml/m2] ($p <0.001$). After a median-follow-up of 19 (9-36) months, 92 of 275 patients (33%) had AF recurrence. In a univariable Cox regression analysis, AF phenotype, US-LAVI above the mean (36.7 ml/m2), and CT-LAVI above the mean (60.9 ml/m2) were associated with AF recurrence. In a multivariable Cox regression analysis, AF phenotype (HR, 2.3 [95%CI, 1.4-3.7]; $p =0.0009$) and CT-LAVI (HR, 1.8 [95%CI, 1.1-3.0]; $p =0.031$) were identified as independent predictors, but US-LAVI was not. At Kaplan-Meier analysis, AF recurrence frequency after 5 years was significantly higher in patients with CT-LAVI above the mean than that in patients with CT-LAVI below the mean (65% vs. 43%, $p =0.001$).

### CONCLUSION

CT-LAVI was an independent predictor for AF recurrence after CA superior to US-LAVI.

### CLINICAL RELEVANCE/APPLICATION

Cardiac CT is feasible not only for preoperative-navigation image of CA, but also for LA function assessment and postoperative AF recurrence prediction.

## R2-SPCA-8 RELIABILITY OF POST-CONTRAST DL-BASED HIGHLY-ACCELERATED CARDIAC CINE MRI FOR THE ASSESSMENT OF VENTRICULAR FUNCTION

Tsuyoshi Sugawara (*Abstract Co-Author*) Nothing to Disclose
Kunihiro Yoshioka, MD (*Abstract Co-Author*) Nothing to Disclose
Makoto Orii (*Presenter*) Nothing to Disclose

### PURPOSE

The total exam time can be reduced if high-quality 2D cine images can be collected post-contrast to minimize non-scanning time prior to late gadolinium enhancement imaging. This study aimed to assess the hypothesis that the diagnostic performance of deep learning-based highly-accelerated cardiac cine imaging (DL cine) can be equivalent pre- and post-contrast injection, by evaluating the cine image quality and quantification accuracy of biventricular volumes and functions.

### METHODS AND MATERIALS

Thirty patients (20 men, mean age 53.7 ± 17.8 years) underwent cardiac magnetic resonance (CMR) using a 1.5 T scanner (SIGNA Artist, GE HealthCare) for clinical indications, and pre- and post-contrast DL cine images were acquired on the short-axis view. The image quality scores was scored with three main criteria: blood-to-myocardial contrast, endocardial edge delineation, and presence of motion artifacts throughout the cardiac cycle. Biventricular end-diastolic volume (EDV), end-systolic volume (ESV), stroke volume (SV), ejection fraction (EF), and left ventricular mass (LVM) were analyzed. These measurements were compared between pre- and post-contrast DL cine images.

### RESULTS

The median actual time of acquisition of DL cine was 38.4 ± 9.1 s. There were no significant differences about the image quality scores between pre- and post-contrast injection ($p > 0.05$). The two sequences demonstrated no significant difference in terms of biventricular EDV, ESV, SV, EF, and LVM ($p > 0.05$). Moreover, the linear regression yielded good agreement between the two techniques ($r = 0.82$).

### CONCLUSION

The diagnostic performance of 2D DL cine is equivalent pre- and post-contrast injection for the assessment of image quality and ventricular function. Hence, the use of post-contrast 2D DL cine would contribute the shorter scan time while preserving image quality of CMR in the clinical setting.

### CLINICAL RELEVANCE/APPLICATION

With the use of deep learning-based highly-accelerated technique, 2D cine imaging can be performed after contrast injection during a waiting time for late gadolinium enhancement imaging.

## R2-SPCA-9 INCREASING THE RATE OF DATASETS AMENABLE FOR $CT_{FFR}$ AND QUANTITATIVE PLAQUE ANALYSIS: VALUE OF SOFTWARE FOR REDUCING STAIR-STEP ARTIFACTS

Thomas G. Flohr, PhD (*Abstract Co-Author*) Employee, Siemens AG
Matthias Eberhard, MD (*Abstract Co-Author*) Nothing to Disclose
Hatem Alkadhi, MD (*Abstract Co-Author*) Nothing to Disclose
Victor Mergen, MD (*Abstract Co-Author*) Nothing to Disclose
Costanza Lisi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the value of a new algorithm for reducing the prevalence and extent of stair-step artifacts for CTFFR and quantitative coronary plaque analyses in patients undergoing sequential mode coronary CT angiography (CCTA).

## METHODS AND MATERIALS

Forty patients (6 females, mean age 66 ± 17 years) undergoing sequential mode CCTA with dual-source photon-counting detector CT were included, who had at least one stair-step artifact in a coronary segment >1.5 mm diameter. Twenty patients (14 males; mean age, 57 ± 17 years) without coronary atherosclerosis constituted the population for CTFFR analysis (45 coronary segments with stairstep artifact). Twenty patients (20 males; mean age, 74 ± 13 years) had stair-step artifacts crossing an atherosclerotic plaque and constituted the population for quantitative coronary plaque analysis (22 coronary segments). Artifacts were graded and CTFFR and quantitative coronary plaque analyses were performed using advanced post-processing software in standard reconstructions and in those reconstructed with a new algorithm (ZeeFree algorithm). Wilcoxon tests were used to compare ordinal and continuous variables. Paired samples t test served to compare means. Statistical significance was assumed at a two-tailed P-value below 0.05.

## RESULTS

Stair-step artifacts grade was significantly reduced in ZeeFree compared to standard reconstructions ($p<0.05$). In standard reconstructions, CTFFR analyses were not feasible in 3/45 (7%) segments, while they were feasible in ZeeFree reconstructions in all segments (100%). In 9/45 (20%) segments without atherosclerosis, the ZeeFree algorithm led to a change of CTFFR values from pathologic (<0.80) in standard to physiologic (>0.80) values in ZeeFree reconstructions. In one segment (1/22, 5%), quantitative plaque analysis was not feasible in standard but in Zee Free reconstructions. The mean overall plaque volume (111 ± 60 mm3), the calcific (77 ± 47 mm3), fibrotic (31 ± 28 mm3), and lipidic plaque volume (4 ± 3 mm3) were higher in standard than in ZeeFree reconstructions (overall plaque volume 75 ± 50 mm3, $p<0.001$; calcific 51 ± 42mm3, $p<0.001$; fibrotic 22 ± 19 mm3, $p<0.05$; lipidic 3 ± 3 mm3, $p=0.055$).

## CONCLUSION

Preliminary evidence indicates that an algorithm for reducing the prevalence and extent of stair-step artifacts in sequential mode CCTA increases the rate and quality of datasets amenable to CTFFR and quantitative coronary plaque analysis.

## CLINICAL RELEVANCE/APPLICATION

Our study indicates that the occurrence of a commonly encountered problem in sequential mode CCTA, i.e. stair-step artifacts, can be considerably reduced when using a novel algorithm for image processing (ZeeFree), with improved results for both CTFFR and plaque analysis.

# Abstract Archives of the RSNA, 2024

R2-SPCH

**Chest Imaging Thursday Morning Poster Discussions**

Thursday, Dec. 5 9:00AM - 9:30AM Room: LEARNING CENTER

**Sub-Events**

## R2-SPCH-1 ULTRA-LOW-DOSE VS. LOW-DOSE HIGH-RESOLUTION CHEST CT SCANS IN ADULTS WITH CYSTIC FIBROSIS ON THE PHOTON-COUNTING DETECTOR CT: A RADIATION DOSE AND IMAGE QUALITY STUDY

Halil Ibrahim Tazeoglu, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Regular disease monitoring with low-dose high-resolution chest CT scans is necessary for the clinical management of pwCF. The risk of induced malignancy increases with the radiation dose. Different CT protocols result in different radiation dose and image quality. The aim of this study was to compare the radiation dose and image quality of LD-HR and ULD-HR CT protocols for PCCT in pwCF.

### METHODS AND MATERIALS

This retrospective study included 60 pwCF, of which 30 received a LD-HR chest CT protocol and 30 received an ULD-HR chest CT protocol using a PCCT detector. Radiation dose and image quality was compared. The study measured the dose-length product (DLP), volumetric CT dose index (CTDIvol), effective dose and signal-to-noise radio (SNR). Three blinded radiologists assessed the overall image quality, image sharpness, image noise and the assessability of bronchiectasis, bronchial wall thickening, and mucoid impaction using a 5-point Likert scale ranging from 1 (poor) to 5 (excellent).

### RESULTS

ULD-HR PCCT used approximately 63% less radiation than LD-HR PCCT (median effective dose: 0.20 vs. 0.54 mSv, CTDIvol: 0.27 vs. 0.81 mGy; DLP: 10.15 vs. 31.15 mGy·cm; $p<0.0001$). There was no significant difference between the ULD-HR and LD-HR protocols for the subjective assessment of overall image quality, image sharpness, and image noise ($p<0.0001$) or the clinical parameters of bronchiectasis, bronchial wall thickening, and mucoid impaction ($p<0.0001$). The mean lung parenchyma SNR was lower with ULD-HR PCCT compared to LD-HR PCCT ($p<0.0001$).

### CONCLUSION

ULD-HR chest CT protocols for PCCT scans provide equivalent image quality, with significantly reduced radiation dose compared to LD-HR in pwCF.

### CLINICAL RELEVANCE/APPLICATION

Regular disease monitoring with CT scans is necessary for the clinical management of people with cystic fibrosis (pwCF). This is associated with an increased radiation dose and an increased risk of malignancy. Therefore, new technologies such as photon-counting CT (PCCT) are approaches to reduce the radiation dose in this patient cohort. Ultra-low-dose high-resolution (ULD-HR) CT protocols result in good image quality with reduced radiation dose in comparison to low-dose high-resolution (LD-HR) CT protocols.

## R2-SPCH-3 ENHANCED CHEST TOMOSYTHESIS THROUGH DEEP LEARNING

Manuel Desco-Menendez, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Monica Abella, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

One limitation of plain radiography compared to computed tomography (CT), which is impractical for routine use due to cost and high radiation dose, is its lower sensitivity for detecting lung lesions. Tomosynthesis can substantially improve the radiological diagnostic accuracy in plain radiology systems, providing pseudo-tomographic information at a much lower dose. The incorporation of AI techniques in tomosynthesis image reconstruction could address the major limitation of tomosynthesis, namely, the lack of quantitative information. Attempts to enhance the quality of tomosynthesis images by incorporating a Deep-learning (DL) still fall short of achieving the quantitative precision characteristic of CT scans.

### METHODS AND MATERIALS

We present a DL multi-step approach that applies a first postprocessing step on the sagittal view of a preliminary FDK reconstruction, followed by second postprocessing step in the coronal view. The DL model is based on a modified version of the U-Net architecture implemented using Pytorch. Training was done for 50 epochs to minimize the mean squared error, using Adam as the optimizer, a weight decay equal to 10-3, with learning rate initialized to 10-3 and divided by 2 when the train loss function has reached a plateau.The database consisted of 75 chest CT studies, from which we generated tomosynthesis projections based on a standard chest tomosynthesis protocol with 61 projections, a source-to-detector distance of 1800 mm and a vertical source displacement of 960 mm.

**RESULTS**

The proposed method manages to recover details as nodules and ground glass texture that are neither seen in the planar radiography, nor in the conventional tomosynthesis reconstruction.

**CONCLUSION**

The pseudo-tomographic quality attained from tomosynthesis data suggests the potential of the proposed strategy to replace CT scans in applications where the radiation dose is critical such as lung screening.

**CLINICAL RELEVANCE/APPLICATION**

A low-dose and highly available pseudo-tomographic image would represent a paradigm shift in radiological examinations of the chest, potentially replacing the use of planar radiology for lung cancer screening, where plain radiography has demonstrated low sensitivity. This would also have a significant impact on cases such as patients arriving at the emergency department with an infection after a transplant, where avoiding false negatives is crucial for the patient's survival.

## R2-SPCH-4 INFLUENCE OF FOREIGN BODIES ON DARK-FIELD CHEST RADIOGRAPHS: FIRST EXPERIENCES

Lisa Steinhelfer (*Abstract Co-Author*) Nothing to Disclose
Florian T. Gassert, MD (*Abstract Co-Author*) Nothing to Disclose
Marcus R. Makowski (*Abstract Co-Author*) Nothing to Disclose
Daniela Pfeiffer, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Franz Pfeiffer (*Abstract Co-Author*) Nothing to Disclose
Theresa Urban, MSc (*Abstract Co-Author*) Nothing to Disclose
Alexander W. Marka, MD (*Abstract Co-Author*) Nothing to Disclose
Henriette Klein, MD (*Abstract Co-Author*) Nothing to Disclose
Lennard Kaster, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

X-ray dark-field imaging visualizes the condition of the lungs' alveolar structure by measuring the ultra-small-angle scattering of X-rays. In this study, we investigate the effects and artifacts caused by foreign bodies on both dark-field and conventional radiographs using the first human dark-field chest radiography system.

**METHODS AND MATERIALS**

Written informed consent was obtained from all participants. Subjects were selected from clinical studies conducted between 2018 and 2021, focusing on emphysema and COVID-19 cases. Images of study participants were obtained by using our in-house developed and commissioned clinical x-ray dark-field prototype, yielding both the conventional and dark-field radiographs simultaneously. Blinded readers independently assessed these images to evaluate the impact of various foreign bodies on image quality and artifacts.

**RESULTS**

Our investigation revealed distinct behavior based on the microstructure of foreign bodies. Those lacking microstructural features exhibited either a diminished dark-field signal or no recognizable signal. A similar pattern emerged for osseous structures overlaying lung areas. While conventional radiographs showed radiopaque signals from these structures due to X-ray attenuation, the dark-field radiographs remained devoid of discernible signals owing to their lack of microstructure. Conversely, materials with microstructure yielded an additional dark-field signal. Strongly attenuating foreign bodies (such as pacemakers) produced a dark-field signal, albeit not due to ultra-small-angle scattering, but as an artifact. Adjacent areas were unaffected by foreign bodies.

**CONCLUSION**

Our findings demonstrate that dark-field radiography enhances the overlay-free assessment of pulmonary tissue compared to conventional radiography. We observed reduced overlapping radiopaque artifacts within the investigated regions through minimized interfering signals. This improvement positively impacts image quality and interpretability, addressing the projection-related limitations of radiography compared to computed tomography (CT).

**CLINICAL RELEVANCE/APPLICATION**

Foreign bodies produce fewer signals and artifacts in dark-field radiographs, resulting in better image quality and interpretability. Dark-field radiography enhances an overlay-free assessment of pulmonary tissue compared to conventional radiography.

## R2-SPCH-5 ASSESSING THE IMAGE QUALITY OF DIGITALLY RECONSTRUCTED RADIOGRAPHS FOR CHEST CT

Hildo J. Lamb, MD, PhD (*Abstract Co-Author*) Consultant, Koninklijke Philips NV
Merlijn Sevenster (*Abstract Co-Author*) Nothing to Disclose
Olivier Paalvast, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate different Digitally Reconstructed Radiograph (DRR) construction methods qualitatively and quantitatively for DRRs constructed from ultra-low-dose chest (ULD) CT.

**METHODS AND MATERIALS**

A cohort of 200 patients who underwent an ULDCT and a chest X-Ray (CXR) on the same day, spanning from January 2016 to December 2017, was retrospectively included. DRRs were constructed for all patient cases using four methods identified in literature. A deep learning CXR disease classification network was used as a quantitative analysis tool to compare DRRs to the CXRs using the radiological report as ground truth. A subset of the DRRs was used in the qualitative evaluation, where six radiologists were recruited to score the DRRs on the diagnostic image quality of specified anatomic regions and to rank them with regards to the CXR of the same patient case.

**RESULTS**

The Area under the curve (AUC) for the disease classification network were 0.80, 0.81, 0.75, 0.82 and 0.82 for the original CXR, Method 1, Method 2, Method 3 and Method 4 respectively. In the qualitative evaluation Method 3 scored best overall in terms of diagnostic image quality and was chosen out of four DRRs as the best representation of a CXR 18 our 36 times.

### CONCLUSION

The 'softMip' method (Method 3) was found to the be preferred DRR construction method. DRRs are equivalent with regards to disease classification network performance and end-users generally appreciate their diagnostic potential, identifying potential improvements in the level of noise, the resolution and the look-and-feel.

### CLINICAL RELEVANCE/APPLICATION

DRRs constructed from chest CT can represent similar information visually when compared to chest X-Rays and may serve a role as an intermediary in the interpretation of chest CT scans.

## R2-SPCH-6 DEEP LEARNING-BASED VIRTUAL CONTRAST-ENHANCED CHEST CT FROM NON-CONTRAST CT: IMAGE QUALITY ASSESSMENT OF MEDIASTINAL LYMPH NODES

Motohiko Yamazaki, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Contrast-enhanced CT is generally superior to non-contrast CT in lesion visibility, but the use of contrast agents is limited in patients with iodine allergies. The purpose of this study was to develop a deep-learning model that generates contrast-enhanced chest CT images from non-contrast CT images and to investigate if the model helped improve the image contrast of mediastinal lymph nodes.

### METHODS AND MATERIALS

We used 504 chest CT examinations as training data and 100 chest CT examinations performed using a scanner of a different manufacturer as test data. Paired images of non-contrast and contrast CTs were trained using pix2pix, a deep learning architecture, with an input image size of 512×512×8, a batch size of 1, and 10 epochs. The similarity between the generated and true-contrast CT images were evaluated using structural similarity (SSIM). The image quality of mediastinal lymph nodes on the non-contrast and generated contrast CT images was quantitatively and qualitatively compared using signal-to-noise ratio (SNR), contrast-to-noise ratio between the lymph nodes and mediastinal fat (CNRLnFat), CNR between the lymph nodes and aorta (CNRLnAo), and a visual 3-point scale (better, almost equal, or worse, compared to non-contrast CT images).

### RESULTS

SSIM (mean±standard deviation) was high in both the training data (0.958±0.018) and the test data (0.910±0.025). In the test data, SNR and CNRs were significantly higher in generated contrast CT than in non-contrast CT (SNR, 9.123±3.366 vs. 2.987±1.270; CNRLnFat, 16.211±5.466 vs. 9.731±2.999; CNRLnAo, 4.851±1.797 vs. 0.951±0.722) (all $P < 0.001$). Two board certificated radiologists considered all generated contrast CT images of the test data to have better contrast of lymph nodes than the non-contrast CT.

### CONCLUSION

Deep-learning model that generates contrast-enhanced chest CT from non-contrast CT improved the image quality of the mediastinal lymph nodes compared with the original non-contrast CT.

### CLINICAL RELEVANCE/APPLICATION

Our deep-learning model that generates contrast-enhanced chest CT from non-contrast CT may contribute to improving lesion visibility in patients that cannot receive a contrast agent.

## R2-SPCH-7 COMPARISON BETWEEN PHOTON-COUNTING-DETECTOR CT AND MICRO-CT USING CADAVERIC HUMAN LUNGS: AIRSPACE, INTERLOBULAR SEPTA, AND GROUND-GLASS OPACITY

Keisuke Ninomiya (*Abstract Co-Author*) Nothing to Disclose
Masahiro Yanagawa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuriko Yoshida (*Abstract Co-Author*) Nothing to Disclose
Yukiko Tokuda, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shuhei Doi, MD (*Abstract Co-Author*) Nothing to Disclose
Ryo Ogawa, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Shigeyoshi Saito (*Abstract Co-Author*) Nothing to Disclose
Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kazuki Yamagata, MD (*Abstract Co-Author*) Nothing to Disclose
Daiki Nishigaki, PhD (*Abstract Co-Author*) Nothing to Disclose
Akinori Hata, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the performance of photon-counting-detector CT (PCD-CT) and energy-integrating-detector CT (EID-CT) to depict small airspace, normal interlobular septa (ILS), and internal texture of ground-glass opacity (GGO) using cadaveric human lungs compared with micro-CT.

### METHODS AND MATERIALS

Image data of 20 cadaveric lungs were acquired by EID-CT and PCD-CT at low radiation dose (CTDIvol 1.2mGy) and high dose (CTDIvol 9.0mGy). EID-CT images were reconstructed with 512 matrix, 350-mm filed-of-view (FOV), and 0.6-mm thickness. PCD-CT images were reconstructed with 1024 matrix, 100-mm FOV, and 0.2-mm thickness. A specimen per lung was obtained and scanned by a micro-CT system for small animals. The micro-CT images was acquired with 20μm (0.02 mm) of spatial resolution. The EID-CT and PCD-CT images were evaluated by a radiologist for airspace with emphysema on a 5-point scale (5=Granular structures on EID-CT/PCD-CT are consistent with normal alveolar ducts on micro-CT, 4=Dilated alveolar ducts can be identified, 3=Rough morphology of emphysematous lesions less than 5mm in size can be delineated, 2=Emphysematous lesions smaller than 5mm can be identified, but the morphology is not consistent with micro-CT, 1=Airspace consistent with micro-CT cannot be identified) and for normal ILS and GGO on a 3-point scale (ILS: 3=Clearly detectable, 2=Barely detectable, 1=Not detectable; GGO: 3=Septal structures inside the GGO are depicted, 2=GGO is detectable, but internal texture is not depicted, 1=GGO is not detectable). Airspace and ILS were evaluated at up to three regions per specimen; GGO was evaluated for the entire specimen. The Wilcoxon signed-rank test with Bonferroni correction was used for statistical analyses.

### RESULTS

Twenty-five regions of airspace, 24 ILSs, and 11 GGOs were evaluated. PCD-CT at high dose showed significantly better scores than others in the airspace and ILS evaluation ($p<0.005$). PCD-CT at low dose showed significantly better scores for the airspace evaluation than EID-CTs (<0.001). Normal interlobular septa were often detectable, especially on PCD-CT at high dose. There was no significant difference in the GGO evaluation. Normal alveolar ducts and septal structures inside the GGO were not depicted on all CTs.

### CONCLUSION

PCD-CT has a better potential to depict small structures of emphysema and interlobular septa than EID-CT.

### CLINICAL RELEVANCE/APPLICATION

Interlobular septa without thickening may be detectable on PCD-CT, which suggests that different practices may be required on PCD-CT compared with EID-CT. Further spatial resolution improvement is needed to differentiate interstitial and airspace lesions in GGO.

## R2-SPCH-8 CHEST CT-BASED AUTOMATED DETECTION OF SCOLIOSIS AND ITS APPLICATION IN COPD

Punam K. Saha, PhD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth A. Regan, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Alejandro Comellas, MD (*Abstract Co-Author*) Nothing to Disclose
Patrick Carry (*Abstract Co-Author*) Nothing to Disclose
Syed Ahmed Nadeem, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Scoliosis is an abnormal rotational deformity of the spine affecting 2-3 percent of the population. It can worsen with age causing chronic pain, impaired mobility, respiratory problems, and cardiac compression. We present a chest CT-based automated method for thoracic scoliosis detection and examine the association of scoliosis with chronic obstructive pulmonary disease (COPD).

### METHODS AND MATERIALS

The image computational method involves the following steps (Figure 1): (1) segmentation and labelling of twelve thoracic and first lumbar vertebrae using a hybrid deep segmentation algorithm; (2) computation of spine centerline and lateral angles between every pair of vertebral endplate locations on the centerline; (3) scoliosis likelihood assessment using a fully-connected neural network (NN) classifier and 78 lateral angles between 13 vertebrae; and (4) optimization of likelihood threshold for scoliosis detection using receiver operating characteristic (ROC) curve analysis. The method was applied on inspiratory chest CT scans from the multi-site Genetic Epidemiology of COPD (COPDGene) study at baseline visits (N = 2,911; # of sites = 15). Expert manual grading of no scoliosis (n = 2,311), scoliosis (189), and no consensus (411) were used as the ground truth for both training (n = 450) and performance evaluation (2,461). Equal distribution across scoliosis grading was applied in partitioning training and performance evaluation datasets.

### RESULTS

The method was successfully applied on chest CT data of 2,911 participants (age (mean±standard deviation): 59.1±9.0 years; 1,422 (48.8%) females). The optimum value of 0.3 was determined for the scoliosis likelihood threshold a from the ROC curve corresponding to accuracy, sensitivity, and specificity of 92.0, 91.0, and 96.1%, respectively (Figure 1(c)). Application of the optimized method to the unseen data from 2,461 participants delivered the accuracy, sensitivity, and specificity of 91.1, 90.5, and 94.2%, respectively. Among the 2,911 participants examined in this study, it was observed that 5.6, 5.6, 7.4, and 8.0% of participants with preserved lung function, mild, moderate, and severe COPD, respectively, had scoliosis.

### CONCLUSION

An automated chest CT-based method for scoliosis detection has been developed and evaluated. The method is applicable to inspiratory chest CT scans and offers high accuracy, sensitivity, and specificity.

### CLINICAL RELEVANCE/APPLICATION

Observed performance and automation of the chest CT-based method demonstrate its feasibility for application to population-based thoracic studies investigating mechanistic interactions of spinal deformities with respective disease comorbidities, progression, and clinical outcomes.

## R2-SPER-1 SENSITIVITY AND SPECIFICITY OF ARTIFICIAL INTELLIGENCE SOFTWARE IN THE DETECTION OF FRACTURES IN EMERGENCY DEPARTMENTS COMPARED WITH CT SCANS

Djamel Dabli (*Abstract Co-Author*) Nothing to Disclose
Julien FRANDON (*Abstract Co-Author*) Nothing to Disclose
Jean-Paul Beregi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Joel Greffier, PhD (*Abstract Co-Author*) Nothing to Disclose
Fabien De Oliveira (*Abstract Co-Author*) Nothing to Disclose
Maxime PASTOR (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the diagnostic performance of artificial intelligence software in standard radiography for the detection of fractures of the pelvis, proximal femurs or extremities in emergency trauma situations in adults, compared with standard-dose CT examinations, as a gold standard.

### METHODS AND MATERIALS

The study was conducted in a sub-group of patients from the multicentric survey ULD-Traumato (4 french centres including adult patients with suspected traumatic fractures between January 2022 and August 2023 investigated by standard dose CT, Ultra-Low Dose CT and radiographs of the pelvis and/or hip and extremities). In this sub-group, artificial Intelligence software (AI, Rayvolve, AZmed, France) was used retrospectively on the radiographs with analysis of the results (suspected fracture yes/no and location of suspected fracture for all radiographs). The results were compared with the standard-dose CT scan interpretation performed by the senior radiologist.

### RESULTS

A total of 94 patients (63 women, mean age 56.4 ± 22.5 years) were included. 47 patients had at least one fracture and a total of 71 fractures were detected (26 hand/wrist, 16 pelvis, 29 foot/ankle) on CT scan. The sensitivity of the AZmed software was 81.6%, with 58 true positives and 13 false negatives (4 hand/wrist, 1 pelvis, 8 foot/ankle). The specificity of the AZmed software was 68.8%, with 33 true negatives and 15 false positives (5 hand/wrist, 1 pelvis, 9 foot/ankle).

### CONCLUSION

This study showed that the AI solution was highly sensitivity in detecting fractures, although some false positives were corrected by the radiologists. However, the presence of false negatives calls into question the use of this solution in triage.

### CLINICAL RELEVANCE/APPLICATION

AI software in the emergency department for the detection of fractures, could help improve patient management, but requires radiologist supervision, given the presence of false negatives.

## R2-SPGI-12 EVALUATING APPARENT DIFFUSION COEFFICIENT (ADC) AS A PROGNOSTIC INDICATOR FOR SURVIVAL, PATHOLOGICAL RESPONSE, TUMOR GRADE IN PANCREATIC CANCER PATIENTS UNDERGOING NEOADJUVANT THERAPY

Cheng Hung Liao, MD, BA (*Presenter*) Nothing to Disclose

### PURPOSE

To assess ADC as prognostic indicators for survival, pathological response, and tumor grade in pancreatic cancer patients undergoing neoadjuvant therapy.

### METHODS AND MATERIALS

This retrospective study included 98 pancreatic cancer patients (52 males, 46 females, mean age 61) treated from December 2019 to July 2023. 19 had distant metastases at diagnosis, with 3 resectable, 29 borderline resectable, and 47 unresectable tumors, requiring neoadjuvant therapy. Mean ADC values were evaluated using pre-treatment and follow-up MRIs, typically 3 months apart, by a resident radiologist. Tumor resectability followed NCCN 2019 criteria. Inter-rater reliability was assessed via repeated measurements by another experienced radiologist, using the intraclass correlation coefficient(ICC). Spearman correlation tests examined relationships between ADC changes and CA19-9 or CEA levels. Statistical analyses, including the Wilcoxon rank-sum test and Cox regression analysis, assessed differences in ADC and patient survival, with significance set at $p<0.05$, using STATA 14.0.

### RESULTS

Surgery succeeded for 25 (26%) patients meeting resection criteria: no hepatic metastasis, normal CA19-9, and stable/reduced tumor size 4-6 months post-neoadjuvant treatment. Median follow-up: 923 days. ICC shows good to excellent reliability in baseline ADC (CI: 0.898-0.954) and follow-up ADC (CI: 0.943-0.977). A significant negative correlation emerged between baseline CA19-9 and ADC ($p<0.01$), while a borderline negative significance was observed between relative CA19-9 change and ADC relative changes ($p=0.08$). Patients with distant metastases had lower follow-up ADC ($p<0.01$) and relative changes ($p=0.02$). Grade 3 tumors had lower follow-up ADC values ($p<0.01$) and relative changes ($p<0.01$). Regarding OS, distant metastases correlated with worse outcomes (HR=2.02, $p=0.04$), while successful surgery correlated with improved OS (HR=0.16, $p<0.01$). Larger follow-up size (HR=1.45, $p<0.01$), higher size changes (HR=3.44, $p=0.02$), higher baseline CA19-9 ($p=0.01$), follow-up CA19-9 ($p<0.01$), and baseline CEA (HR=1.04, $p=0.02$) were associated with worse OS. No significant differences in OS were found for baseline/follow-up ADC or changes in ADC.

### CONCLUSION

Reliable ADC measurements highlight their potential as prognostic indicators, offering insights into tumor characteristics during neoadjuvant chemotherapy. They predict tumor grade and differences in metastatic disease but didn't show significant differences in OS. Further research is needed to explore their clinical utility in treatment decisions.

### CLINICAL RELEVANCE/APPLICATION

ADC measurement in advanced pancreatic cancer is reliable and may reveal the underlying nature of the disease status.

## R2-SPGI-4 PREDICTORS OF MORTALITY IN PATIENTS HOSPITALIZED FOR ALCOHOLIC HEPATITIS

Francisco Restrepo, PhD (*Abstract Co-Author*) Nothing to Disclose
Gene Im (*Abstract Co-Author*) Nothing to Disclose
Bachir Taouli, MD (*Abstract Co-Author*) Research Grant, Bayer AG;Research Grant, Takeda Pharmaceutical Company Limited;Consultant, Bayer AG;Consultant, Guerbet SA;Research Grant, Regeneron Pharmaceuticals, Inc

Andrew Kirsner, MS, MD (*Abstract Co-Author*) Nothing to Disclose
Deborah Feldman, MD (*Abstract Co-Author*) Nothing to Disclose
Kazuya Yasokawa, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The role of radiographic imaging in AH is not well defined. To identify clinical and imaging predictors of mortality in patients hospitalized for alcoholic hepatitis (AH).

### METHODS AND MATERIALS

This is a single center retrospective study of a cohort of 104 patients (M/F: 47/57, mean age: 44.8y) hospitalized for AH with definite or probable AH by National Institute on Alcohol Abuse and Alcoholism Alcoholic Hepatitis Consortia criteria who had CT (n=96) or MRI (n=8) within 3 months of diagnosis of AH and blood tests within 2 weeks of imaging. The following parameters were measured: liver (whole liver, right and left lobes) and spleen volumes; subcutaneous fat cross-sectional area, visceral adipose tissue area and both psoas muscle cross-sectional areas at the level of L3; liver, spleen and psoas muscle density on unenhanced images. Qualitative imaging evaluation included: cirrhosis, ascites, portal hypertension score, liver enhancement, steatosis, periportal edema, and lymphadenopathy. Demographics, blood tests and imaging variables were compared between patients who died vs those alive within 90 days.

### RESULTS

36 (35%) patients died within 90 days. 86 (83%) patients had cirrhosis on imaging. There were no differences in sex, age and cirrhosis between the 2 groups (p>0.12). The top performing parameters for predicting mortality were: psoas muscle density (AUC=0.71, P=0.006: Table.1), MELD (AUC=0.70, P=0.001), serum Cr (AUC=0.69, P=0.002), MELD-Na (AUC=0.67, P=0.004), T-Bili (AUC=0.66, P=0.01), ascites (AUC=0.66, P=0.004), visceral adipose tissue area (AUC=0.63, P=0.033), and subcutaneous fat cross-sectional area (AUC=0.62, P=0.049). Liver, spleen volumes/density, psoas muscle cross-sectional areas, and FIB-4 had no predictive value (P>0.07). Combination models for predicting death within 90 days were MELD+psoas muscle density+ascites (AUC=0.83, P<0.001; Fig.1).

### CONCLUSION

Blood tests and sarcopenia predict 90-day mortality in patients hospitalized for AH.

### CLINICAL RELEVANCE/APPLICATION

Sarcopenia measured on CT in addition to blood tests can have prognostic value in patients with alcoholic hepatitis.

## R2-SPGI-5 RACIAL DISPARITY IN CLINICAL FEATURES AND SURVIVAL OF GASTROINTESTINAL TUMORS (GISTS)

Francesco Alessandrino, MD (*Abstract Co-Author*) Nothing to Disclose
Haleh Amirian (*Abstract Co-Author*) Nothing to Disclose
Akash P. Naidu, MD (*Abstract Co-Author*) Nothing to Disclose
Emily Jonczak (*Abstract Co-Author*) Nothing to Disclose
Julie Grossman (*Abstract Co-Author*) Nothing to Disclose
Ty K. Subhawong, MD (*Abstract Co-Author*) Research Consultant, Arog Pharmaceuticals, Inc;Stockholder, AbbVie Inc;Stockholder, AstraZeneca PLC;Stockholder, Johnson & Johnson;Stockholder, Pfizer Inc ;Stockholder, F. Hoffmann-La Roche Ltd;Stockholder, Teva Pharmaceutical Industries Ltd
Adrian Parra, BS (*Presenter*) Nothing to Disclose

### PURPOSE

GISTs are the most common mesenchymal tumors of the gastrointestinal tract. There is limited data on how racial and ethnic groups are affected by these tumors. We sought to evaluate clinical and imaging features, as well as overall survival (OS) and recurrence-free survival (RFS) among racial/ethnic groups in a diverse cohort of GIST patients.

### METHODS AND MATERIALS

A local cancer registry database of patients with diagnosis of GIST between January 2011 and December 2021 was queried for clinical, survival and demographic data. CT scans at diagnosis and during follow-up were retrospectively reviewed by a radiologist for evidence of metastases through PACS system. OS using Kaplan-Meier log-rank estimates was stratified by racial/ethnic groups.

### RESULTS

Of a total of 285 GISTs with available demographic and survival data, 57% were non-Hispanic White (NHW), 14% non-Hispanic Black, and 29% were Hispanic (H). Stomach was the most common primary site in all 3 groups, however, was significantly more common in NHB (86% vs. 56% NHW vs. 53% H, P=0.01). Recurrence occurred in 27% of patients and was significantly lower in Hispanics (16% vs. 34% NHW vs. 32% NHB; P=0.01). Peritoneal recurrence occurred in 13% of NHBs and 10% of NHW whereas only 1% of Hispanics (P=0.03). Sllightly more than half of patients (54%) had metastases which was significantly higher in NHWs (64% vs. 51% in NHB vs. 47% in H; P=0.03). Peritoneal metastases were observed more commonly in NHB and NHW compared to Hispanics (38% vs. 35% vs. 18% respectively; P=0.02). OS was not significantly different between NHW, NHB, and H (median OS 11 vs. 7 vs. 11 years respectively; P=0.23). However, RFS was significantly lower in NHB (1 vs. 4 NHW vs. 6 years in H; P=0.001).

### CONCLUSION

In our diverse cohort of patients with GISTs, we have found different clinical and imaging features as well as a gap in RFS among racial/ethnic groups with GIST. Our findings call for prospective studies to understand the etiology of these disparities and to close the gap among these populations.

### CLINICAL RELEVANCE/APPLICATION

As the most common mesenchymal tumor of GI tract, limited data is available on clinical features and imagingfindings of GISTs in different racial/ethnic groups. Knowing these information could be helpful while reviewing images on these patientpopulations. Additionally, understanding the racial/ethnic disparities in GIST patients could lead to further prospective studies on the underlyingfactors.

## R2-SPGI-7 PROGNOSTICATION OF POSTOPERATIVE OUTCOMES IN PANCREATIC DUCTAL ADENOCARCINOMA USING DYNAMIC CONTRAST-ENHANCED COMPUTED TOMOGRAPHY DERIVED EXTRACELLULAR VOLUME FRACTION

**PURPOSE**

Pancreatic ductal adenocarcinoma (PDAC) is associated with poor prognosis and presents challenges in postoperative outcome prediction. This study evaluates the prognostic value of the extracellular volume fraction (fECV), derived from contrast-enhanced CT (CE-CT), in predicting recurrence-free survival (RFS) and overall survival (OS) after PDAC surgery.

**METHODS AND MATERIALS**

This study included 71 consecutive patients who underwent CE-CT with precontrast and equilibrium phases before neoadjuvant chemotherapy and were diagnosed with PDAC post-surgery (35 males and 36 females; mean age, 70.3 years; 95% CI, 68.1-72.6; SD, 9.8; age range, 45-89 years). Pancreatic parenchyma in non-cancerous areas and pancreatic tumors were automatically segmented from the subtraction images of unenhanced and equilibrium-phase scans, excluding focal lesions, major vascular branches, and ducts, using a workstation application, and mean CT values for them were calculated respectively. The enhancement degree of the aorta (?Aorta) was also measured. The fECV was calculated using the equation: fECV = (100 - hematocrit) * (?Pancreas / ?Aorta). Univariate and multivariate analyses using the Cox proportional hazards model assessed fECV in the pancreatic parenchyma in non-cancerous area and tumor against variables such as age, gender, chemotherapy regimen, tumor marker, tumor location, tumor size, stage, and histological type, as well as RFS and OS. Time-dependent receiver operating characteristic curves were constructed to determine the optimal fECV cutoff values for predicting RFS and OS. The Kaplan-Meier method with the log-rank test was used to assess RFS and OS for patients with fECV rates above and below the derived cutoff values.

**RESULTS**

Multivariate analysis identified the adjuvant chemotherapy regimen, poorly differentiated adenocarcinoma, and fECV of pancreatic parenchyma in non-cancerous areas as independent predictors of OS ($P < 0.001$, $P = 0.045$, and $P = 0.019$, respectively), and the neoadjuvant gemcitabine and S-1 combination therapy, and TNM stage (IB) as independent predictors of RFS ($P = 0.019$ and $P < 0.01$, respectively). Patients with higher fECV in pancreatic parenchyma in non-cancerous areas had inferior RFS and OS compared to those with lower fECV based on optimal cutoffs of 40.3% for RFS and 43.6% for OS (RFS, $P = 0.036$; OS, $P < 0.001$). No significant disparity in RFS and OS was observed for tumor fECV.

**CONCLUSION**

fECV of pancreatic parenchyma in non-cancerous areas from CE-CT emerges as a significant predictor of survival outcomes in PDAC, with distinct cutoff values for RFS and OS.

**CLINICAL RELEVANCE/APPLICATION**

Incorporating fECV into postoperative evaluation may improve prognostic accuracy and inform treatment decisions for PDAC patients.

## R2-SPGI-9 PREDICTORS FOR DIAGNOSTIC INACCURACY OF PANCREATIC BIOPSY IN FOCAL PANREATIC LESIONS: A NESTED CASE-CONTROL STUDY

Weilu Chai (*Presenter*) Nothing to Disclose

**PURPOSE**

The study aimed to evaluate the effectiveness of pancreatic biopsy in diagnosing focal pancreatic lesions using ultrasound-guided techniques and to identify key factors that could contribute to diagnostic inaccuracies.

**METHODS AND MATERIALS**

The study included 1611 consecutive patients with 1674 cases who underwent ultrasound-guided core-needle biopsy (US-CNB) for focal pancreatic lesions from January 2017 to June 2023, with follow-up until December 2023. The study evaluated the diagnostic performance, technical success rate, and adverse events of US-CNB. Additionally, a nested case-control study was conducted to identify risk factors associated with inaccurate diagnoses of focal pancreatic lesions using US-CNB. The case group consisted of patients with inaccurate diagnoses of pancreatic biopsy, while controls with accurate diagnoses were matched. Conditional logistic regression was used to identify the independent factors associated with inaccurate diagnosis of pancreatic biopsy.

**RESULTS**

The study cohort included 1674 pancreatic biopsy procedures using US-CNB on 1611 patients, with a technical success rate of 99.8% (1670/1674). Out of the successful biopsies, US-CNB demonstrated a diagnostic accuracy of 96.3% (1609/1670), sensitivity of 96.2% (1545/1606), and specificity of 100% (64/64). In the analysis of 122 procedures using a nested case-control design, with 61 cases of inaccurate diagnosis and 61 accurately diagnosed controls, the median age was 64.0 years (interquartile range [IQR] 14.3), median BMI was 21.0 kg/m2 (IQR 4.2), and 62.3% (76/122) were male. The study found that tumor size (odds ratio [OR], 0.651; 95% CI: 0.454, 0.933; p=0.019) and exophytic and backward growth morphology (OR, 0.184; 95% CI: 0.041, 0.833; p=0.028) were independent predictors for inaccurate diagnosis of pancreatic biopsy by US-CNB.

**CONCLUSION**

In conclusion, US-CNB demonstrates excellent diagnostic performance and safety for focal pancreatic lesions. The size and morphology of the targeted pancreatic lesions were associated with inaccurate diagnosis of pancreatic biopsy by US-CNB.

**CLINICAL RELEVANCE/APPLICATION**

Ultrasound-guided pancreatic biopsy was a highly effective and safe method for diagnosing focal pancreatic lesions. It is important to note that the accuracy of the diagnosis was affected by the size and morphology of the targeted pancreatic lesions.

## R2-SPGU-2 REDUCED BEAM HARDENING IN UROGENITAL IMAGING - A COMPARISON BETWEEN PHOTON COUNTING CT AND ENERGY INTEGRATING CT

Felix C. Muller, MD (*Abstract Co-Author*) Employee, Siemens AG
Yousef W. Nielsen, PhD (*Abstract Co-Author*) Nothing to Disclose
Erik Brandt, MD (*Abstract Co-Author*) Nothing to Disclose
Michael B. Andersen, MD, PhD (*Presenter*) Speaker, Koninklijke Philips NV;Speaker, Boehringer Ingelheim GmbH

### PURPOSE

To investigate if photon counting CT (PCCT) improves image quality in the lower pelvis and on the level of the kidneys, traditionally areas affected by beam hardening artifacts, in comparison to energy integrating CT (EID-CT).

### METHODS AND MATERIALS

We retrospectively identified 35 patients scanned on both EID-CT (Philips IQon or Siemens Force) and PCCT (Siemens Naeotom Alpha) in the period from October 2021 until December 2023, who had undergone a portal venous phase CT under suspicion for malignancy. Intravenous contrast (Iomeron 350mg/mL) were administered according to patient weight (1.5 mL/kg). Scans were reconstructed with BR44 Kernel and with 1.5 mm slice thickness and 1.5 mm increment.. Image quality was evaluated by four consultant radiologists in onco- or abdominal radiology, blinded to the CT scanner used in 2 sessions with a 4-week washout period. Scans were read in a random order between both sessions and readers. Image quality in the medial perirenal fat and the urinary bladder was rated on a 5-point Likert-scale (from 1=non-diagnostic with severe beam hardening To 5=no beam hardening), in both a standard abdominal W/L setting and a specialized W/L setting (i.e. C-100/W100 for the perirenal fat and C30/W100 for the urinary bladder). In addition, a single reader measured image noise (SD of HU measurements) in the medial perirenal fat and in the posterior urinary bladder and recorded the dose length product. All data analysis was performed with RStudio, version 2022.07.1. Continuous variables were compared with a paired t-test and mean image quality ratings with a Wilcoxon signed rank test.

### RESULTS

Image quality ratings were significantly higher for all readers and mean readers in PCCT compared to EID-CT, both in the perirenal fat and the lower pelvis. Mean scores for the perirenal fat were 4.45 (SD 0.378) vs 3.36 (SD 0.383), p<.001 and for the lower pelvis 4.45 (SD 0.933) vs 2.95 (SD 0.611), p<.001. Image noise was significantly lower in PCCT scans compared to EID-CT scans (Posterior Bladder 15.6HU vs 22.5HU, p <.001 Perirenal Fat 12.3HU vs 19.9HU, p<.001). Mean DLP was significantly lower in the PCCT scans with a dose reduction of reduction 21.5% (735.5 mGy*cm vs 936.8 mGy*cm, p <.001).

### CONCLUSION

Image quality in the portal venous phase in lower pelvis and perirenal areas was rated significantly higher, and image noise significantly lower, in PCCT compared to EID-CT scans at significantly reduced radiation doses.

### CLINICAL RELEVANCE/APPLICATION

EID-CT scans are often limited in the assessment of the lower pelvis, due to beam hardening and other artifacts. PCCT improves the image quality and potentially leads to better assessment of the upper and lower urinary tract.

## R2-SPGU-3 SURVIVAL PREDICTION OF BLADDER CANCER PATIENTS AFTER SURGERY BASED ON MACHINE LEARNING MODELS WITH RADIOMICS AND GENOMIC DESCRIPTORS

**PURPOSE**

To study the feasibility of predicting the 2-year survival of bladder cancer patients after surgery by machine learning models using radiomics and genomic descriptors.

**METHODS AND MATERIALS**

With IRB approval, we retrospectively collected pre-surgical CT urography (CTU) exams from 2019 to 2021 for 85 patients with bladder cancer. The patients underwent procedures including primarily cystectomy and transurethral resection of a bladder tumor (TURBT) in the same timeframe, from which tissue samples were collected for genomic analysis. 2-year survival status was obtained as ground truth. We split the data into three sets: training (46 cases: 30 alive (A); 16 deceased (D)); validation (4 cases: 2 A; 2 D); and test (35 cases: 22 A; 13 D). We used our AI-CALS algorithm to segment the cancers. A total of 92 radiomics features (RF) including morphology, texture, and intensity-based features were extracted from the segmented cancers. 32 genomic markers (GEN) were obtained from the collected tissue samples for the same subjects. GEN markers associated with different cell types including luminal, basal, and EMT/Claudin were identified. A random forest classifier was used to generate 3 models: radiomics model (RFM), genomic model (GENM) and combined radiomics-genomics model (RF-GENM). The area under the ROC curve (AUC) was assessed for each model to estimate its performance in predicting 2-year post-surgery survival. Kaplan-Meier analysis was used to evaluate the classification performance on the held-out test set.

**RESULTS**

The test AUC for 2-year survival prediction was 0.63±0.10 for RFM and 0.69±0.10 for GENM. The AUC increased to 0.74±0.09 for the combined RF-GENM. The median survival times by Kaplan-Meier analysis for the two classes (deceased or alive) were 1.25 and 2 years ($p=0.014$) as estimated by the RFM, 0.195 and 2 years ($p<0.001$) as estimated by GENM, and 0.205 and 2 years ($p<0.001$) as estimated by RF-GENM. The useful radiomics biomarkers included 3 heterogeneity features, 1 gray level feature, and 4 contrast features. The useful genomic markers included ZEB2 (EMT/Claudin), DES, ZEB1 (EMT/Claudin), and FOXA1 (Luminal) based on selection by the random forest classifier. ZEB1 and ZEB2 are transcription factors that strongly correlate with metastasis invasion and decreased survival.

**CONCLUSION**

The machine learning techniques are promising in selecting useful radiomics and genomic biomarkers. Predictive models that merge these biomarkers may further enhance their effectiveness in providing decision support for bladder cancer survival prediction.

**CLINICAL RELEVANCE/APPLICATION**

An objective decision support tool that merges radiomic and genomic biomarkers in a predictive model may assist clinicians in making more accurate cancer survival prediction.

## R2-SPGU-5 THE PREDICTIVE VALUE OF MRI-BASED RADIOMICS FOR KIDNEY FUNCTION AND RENAL FIBROSIS IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Chaogang C. Wei III, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate the predictive value of radiomics models based on native T1 mapping and diffusion-weighted imaging (DWI) for identifying the kidney function (KF) and renal fibrosis (RF) in patients with chronic kidney disease (CKD).

**METHODS AND MATERIALS**

In this prospective, single-center study, 122 patients with CKD underwent renal magnetic resonance imaging (MRI) examination and pathological confirmation by renal biopsy from October 2021 to December 2023. They were randomly assigned in a 7:3 ratio to 85 cases in the training cohort and 37 cases in the validation cohort. Patients were divided into three subgroups according to the CKD stages for KF (KF 1, normal KF; KF 2, mildly impaired KF; KF 3, moderately to severely impaired KF) and histopathological results for RF (RF 1, normal RF; RF 2, mild RF; RF 3, moderate to severe RF). 122 parenchyma ROIs of the right kidney were manually delineated slice by slice after setting imaging thresholds. Least absolute shrinkage and selection operator (LASSO) logistic regression was used for feature selection and developing radiomics models. The persistence and degree of KF (KF 1 vs. KF 2 and KF 3; KF 2 vs. KF 3) and RF (RF 1 vs. RF 2 and RF 3; RF 2 vs. RF 3) were analyzed. The diagnostic performance was assessed by receiver operating characteristic (ROC) curve in both the training and validation cohorts. The calibration curve and decision curve analysis were used to internally validate the goodness of fit and clinical effectiveness.

**RESULTS**

For KF 1 versus KF 2 and KF 3, the combined model achieved the best diagnostic performance with the highest AUC (training: 0.908; validation: 0.818), surpassing that of the native T1 mapping model (0.884, 0.815) and the ADC model (0.813, 0.792). For KF 2 versus KF 3, the combined model also reached the highest AUC (training: 0.923; validation: 0.880). Similarly, for RF 1 versus RF 2 and RF 3, the radiomic model had the highest AUC (training: 0.923, validation: 0.898), higher than that of the native T1 mapping model (0.897, 0.849), and the ADC model (0.785, 0.753). For RF 2 versus RF 3, the combined model with the highest AUC (training: 0.933, validation: 0.870). The combined model had favorable predictive abilities and satisfactory clinical benefits for the internal validation.

**CONCLUSION**

Both the native T1 mapping- and ADC-based radiomics models could better identify KF and RF in patients with CKD.

**CLINICAL RELEVANCE/APPLICATION**

The radiomics combined model exhibited robust and satisfactory diagnostic performance for the assessment of kidney function and renal fibrosis in patients with CKD, thus providing more information for CKD management and clinical decision-making.

## R2-SPGU-6 RENAL SHEAR WAVE ELASTOGRAPHY IN PEDIATRIC NEPHROTIC SYNDROME: CAN IT PREDICT THE CLINICAL OUTCOME?

Amita Malik, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Nephrotic syndrome is a common type of kidney disease seen in children. Imaging, to date, has not played a significant role in predicting the clinical outcome of pediatric patients with nephrotic syndrome. We performed this study for evaluation of ElastPQ renal shear modulus in pediatric patients with nephrotic syndrome and correlated it with the clinical subtype of the disease.

**METHODS AND MATERIALS**

This cross-sectional study consisted of 60 cases of nephrotic syndrome in the age group less than 12 years along with 60 age-matched controls. The cases were clinically classified as steroid responsive, steroid resistant, steroid dependent, frequent relapsing and infrequent relapsing. Grey scale ultrasound and Shear wave elastography of both kidneys was performed for all children. The mean values of the shear modulus of both kidneys were compared among the two groups. Among the cases, the mean shear wave modulus was correlated with the clinical status. p value <0.05 was considered as statistically significant.

**RESULTS**

The mean shear modulus of kidneys in cases was found to be higher than that in controls (5.31 vs 2.57 kPa, p<0.001). Mean shear modulus in steroid resistant, steroid dependant, frequent relapsing, infrequent relapsing and steroid responsive nephrotic patients was 7.44, 6.08, 4.93, 4.65 and 3.79 kPa, respectively. The shear modulus was found to be highest in steroid resistant patients. Maximum diagnostic accuracy of shear modulus for diagnosing steroid resistance was at 5.85 kPa (93 % sensitivity and 83.48 % specificity).

**CONCLUSION**

Shear-wave elastography is a promising ultrasound technique in predicting the clinical outcome in pediatric patients with Nephrotic syndrome.

**CLINICAL RELEVANCE/APPLICATION**

Prediction of response to steroid treatment in pediatric nephrotic syndrome and early institution of alternative therapy can induce remission or halt its progression to chronic renal failure.

## R2-SPGU-9 STANDARDIZATION OF BODY COMPOSITION STATUS IN PATIENTS WITH ADVANCED UROTHELIAL TUMORS: THE ROLE OF A CT-BASED AI-POWERED SOFTWARE FOR THE ASSESSMENT OF SARCOPENIA AND PATIENT OUTCOME CORRELATION

Carlo Catalano, MD (*Abstract Co-Author*) Nothing to Disclose
Giuseppe Martina (*Abstract Co-Author*) Nothing to Disclose
Martina Pecoraro, MD (*Abstract Co-Author*) Nothing to Disclose
Valeria Panebianco, MD (*Abstract Co-Author*) Nothing to Disclose
Ludovica Laschena, MD (*Abstract Co-Author*) Nothing to Disclose
Antonella Borrelli, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Sarcopenia is a well know prognostic factor in oncology, influencing patients' quality of life and survival. We aimed to investigate the role of sarcopenia, assessed by a Computed Tomography (CT)-based artificial intelligence (AI)-powered-software Quantib Body Composition® , as a predictor of objective clinical benefit in advanced urothelial tumors and its correlations with oncological outcomes.

**METHODS AND MATERIALS**

We retrospectively searched patients with advanced urothelial tumors, treated with systemic platinum-based chemotherapy and an available total body CT, performed before and after therapy. An AI-powered software was applied to CT to obtain the Skeletal Muscle Index (SMI-L3), derived from the area of the psoas, long spine, and abdominal muscles, at the level of L3 on CT axial images. Logistic and Cox-regression modeling was implemented to explore the association of sarcopenic status and anthropometric features to the clinical benefit rate and survival endpoints.

**RESULTS**

97 patients were included, 66 with bladder cancer and 31 with upper-tract urothelial carcinoma. Clinical benefit outcomes showed a linear positive association with all the observed body composition variables variations. The chances of not experiencing disease progression were positively associated with ?_SMI-L3, ?_psoas, and ?_long spine muscle when they ranged from ~10-20% up to ~45-55%. Greater survival chances were matched by patients achieving a wider ?_SMI-L3, ?_abdominal and ?_long spine muscle.

**CONCLUSION**

A CT-based AI-powered software body composition and sarcopenia analysis provide prognostic assessments for objective clinical benefits and oncological outcomes

**CLINICAL RELEVANCE/APPLICATION**

An AI-driven software that utilizes CT scans has the capability to automatically segment body composition and diagnose sarcopenia. Our research indicates that combining standardized radiological staging methods with sarcopenia analysis could assist in identifying patients who may benefit from customized nutritional therapies, ultimately resulting in improved outcomes and quality of life. The AI tool can represent a means to increase the clinical value of CT imaging reports and to promote the implementation of precision medicine.

## R2-SPHN-1 MAGNETIC RESONANCE IMAGING-BASED PREDICTION MODELS FOR TUMOR STAGE AND CERVICAL LYMPH NODEMETASTASIS OF TONGUE SQUAMOUS CELL CARCINOMA

Simona Marzi (*Abstract Co-Author*) Nothing to Disclose
Vincenzo Dolcetti (*Abstract Co-Author*) Nothing to Disclose
Antonello Vidiri, MD (*Abstract Co-Author*) Nothing to Disclose
Francesca Piludu, MD (*Abstract Co-Author*) Nothing to Disclose
Raul Pellini (*Abstract Co-Author*) Nothing to Disclose
Sonia Lucchese, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the ability of preoperative MRI-based measurements to predict the pathological T (pT) stage and the cervical lymph node (LN) metastasis, by machine learning (ML)-driven models trained in squamous cell carcinoma of the tongue (OTSCC).

### METHODS AND MATERIALS

108 patients with a new diagnosis of OTSCC were enrolled in the present retrospective study. Preoperative MRI study including post contrast high resolution T1-weighted images were acquired in all patients. The entire dataset was randomly divided into a training set and a validation set. Different types of ML algorithms were trained on our dataset and compared in terms of accuracy.

### RESULTS

MRI-based depth of invasion (DOI) and tumor dimension, together with several shape-based and intensity based features, significantly discriminated the pT stage and LN status. The overall accuracy of the model for predicting the pT stage was 0.86 [95%CI, 0.78-0.92] and 0.81 [0.64-0.91] in the training and validation sets, respectively. When including also shape-based and intensity-based signature, no improvement in the model performance was observed. The proposed models for predicting the LN status had a fair to good accuracy, which was between 0.68-0.75 and 0.67-0.69 in the training and validation sets, respectively. The MRI-based radiomics has led to an improvement in the model sensitivity.

### CONCLUSION

MRI-based models, driven by ML algorithms, provided a good ability to stratify patients with OTSCC according to the pT stages and a fair ability to predict cervical LN metastasis.

### CLINICAL RELEVANCE/APPLICATION

We did not explore the correlation among MRI-based measurements, clinicopathological factors, and treatment outcomes, i.e.,locoregional control and disease-specific survival, which willbe the topic of future investigations.

## R2-SPHN-2 STEPWISE DECISION TREE MODEL IN DIFFERENTIAL DIAGNOSIS OF HEAD AND NECKKIMURA'S DISEASE

Yingwei Wu, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To distinguish Kimura's disease (KD) with Sjogren's syndrome with mucosa-associated lymphoma (SS with MALT lymphoma), neurofibromatosis (NF) and lymphoma in head and neck by using stepwise decision tree model.

### METHODS AND MATERIALS

202 patients diagnosed with KD, SS with MALT lymphoma, NF and lymphoma were collected from 2009 to 2024. Preoperative head and neck MR with diffusion weighted imaging (DWI) and dynamic contrast-enhanced imaging (DCE-MRI) were performed. Demographic data and MR variables were collected. Quantitative MR variables such as apparent diffusion coefficient (ADC), time to peak (TTP) and wash-in rate were measured and recorded. Chi-square test, Mann-Whitney U and Kruskal-Wallis H test were used to analyse categorical and continuous variables, respectively. A stepwise decision tree model was developed to distinguish KD and other three diseases and the differential diagnostic accuracy was assessed.

### RESULTS

Males(92%),skin thickening(72%) and lymphadenopathy(83%) were the most frequent characteristics involved in KD. Well-defined nodular and ill-defined infiltrative lesions can coexist in KD. Locations, lymphadenopathy, skin thickening and ADCs were the most predicable variables for distinguishing above four diseases. For the training and test set, the stepwise decision tree model achieved excellent accuracy of 97.6% and 95.2%, respectively, in

predicting the above four diseases individually. Moreover in the test set, the diagnostic accuracy of KD was 83.3%, and the other three confounding diseases were diagnosed correctly. 2 cases of KD were misdiagnosed as lymphoma and SS with MALT lymphoma.

**CONCLUSION**

KD had morphological as well as functional characteristics on MR. The decision tree model based on demographic and MR features yielded reliable accuracy in preoperative differential diagnosis of KD.

**CLINICAL RELEVANCE/APPLICATION**

The decision tree model enhances the precision of diagnosing Kimura's disease before surgery, offering guidance in crafting tailored clinical management plans for affected patients.l KD is characterized by male gender, skin thickening and lymphadenopathy.l ADCs and TICs patterns were distinguishable in differentiating KD, SS with MALT lymphoma, NF and lymphoma inhead and neck. l The stepwise decision tree model using demographic and MR features accessed great differential diagnosis on KD and other head and neck diseases.

## R2-SPHN-3 THE USEFULNESS OF HYPERPOLARIZED $^{13}$C-MRI IN ASSESSING LYMPH NODE METASTASES IN THE PATIENTS WITH HEAD AND NECK CANCERS

Kuan-Ying Lu, MS (*Abstract Co-Author*) Nothing to Disclose
Ching-Yi Hsieh, PhD (*Abstract Co-Author*) Nothing to Disclose
Gigin Lin, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ying-Chieh Lai (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the application of hyperpolarized (HP) 13C-MRI in identifying lymph node metastases in the patients with head and neck cancers

**METHODS AND MATERIALS**

This prospective phase II clinical trial was approved by IRB. Patients with histopathologic proved head and neck cancers and having lymph node metastases on 18F-FDG-PET/CT were included. The patients underwent HP 13C-MRI using [1-13C]pyruvate as probe before treatment. The probe was hyperpolarized using a clinical polarizer, SPINlab, for 2-3 hours to reach a polarization level of 20%-40%. The solution, comprising the hyperpolarized probe, underwent meticulous quality control measures and was subsequently transported to an MRI scanner for administration in human subjects. The 13C signal was acquired using slice-selective pulse-and-acquire sequence followed by model-based imaging (IDEAL spiral CSI) and generic MRSI. The 13C data was analyzed through kinetic modeling (pyruvate-to-lactate conversion rates, kPL) and metabolite ratios (area under the curve [AUC] ratios).

**RESULTS**

Two patients were included (Patient 1: 60 years-old male having postcricoid hypopharyngeal cancer, cT1N3bM0; Patient 2: 54-year-old male having bilateral tongue cancers, cT4aN3bM0). Both patients underwent HP 13C-MRI targeted at their lymph node metastases at left neck level IV. Within the imaged lymph nodes, the downstream metabolites including [1-13C]lactate, [1-13C]alanine, and [1-13C]bicarbonate were detected. The kPL were 1.9 × 10-2 s-1 and 1.1 × 10-2 s-1 for patient 1 and 2, respectively. The metabolites-to-total carbon AUC ratios were 42.8 and 30.1 for lactate, 5.7 and 6.7 for alanine, and 2.3 and 4.2 for bicarbonate. Notably, the necrotic core of the lymph node in patients 2 did not display metabolite signal.

**CONCLUSION**

Hyperpolarized 13C-MRI has the potential to detect lymph node metastases for patients with head and neck cancer.

**CLINICAL RELEVANCE/APPLICATION**

MRI is a standard-of-care exam for evaluation of head and neck cancer. However, detecting lymph node metastasis has been a drawback of MRI. HP 13C-MRI can be integrated into the conventional MRI protocol to enhance the accuracy of MRI in detected lymph node metastasis.

## R2-SPHN-5 ENHANCED COCHLEAR IMPLANT EVALUATION: PRECISION ANALYSIS WITH PHOTON-COUNTING CT

Jan P. Grunz, MD (*Abstract Co-Author*) Research Consultant, Siemens AG
Henner Huflage, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Cochlear duct length (CDL) measurement plays a key role in the context of individualized cochlear implant (CI) surgery regarding an individualized selection and implantation of the CI electrode carrier and an efficient postoperative anatomic fitting process. The level of detail of the preoperative temporal bone CT scan depends on the imaging modality with major impact on CDL measurement and CI electrode contact position determination. The aim of this study was to evaluate the accuracy of perioperative CDL measurement and electrode contact determination in photon-counting CT (PCCT).

**METHODS AND MATERIALS**

Ten human petrous bone specimens were examined with a first-generation PCCT. A clinically applicable radiation dose of 27.1 mGy was used. Scans were acquired before and after CI insertion. Postoperative measurement of the CDL was performed with an otological planning software and 3D-curved multiplanar reconstruction. Investigation of electrode contact position was performed by two different observers. Measurements were compared to a conventional multislice CT and to a high-resolution flat-panel volume CT with secondary reconstructions.

**RESULTS**

Pre- and postoperative CDL measurements in PCCT images showed no significant difference to high-resolution flat-panel volume CT. Postoperative CI electrode contact determination was also as precise as the flat panel CT-based assessment. PCCT and flat-panel volume CT were equivalent concerning interobserver variability.

**CONCLUSION**

Cochlear duct length measurement with PCCT was equivalent to flat-panel volume CT. PCCT enabled highly precise postoperative CI electrode contact determination with substantial advantages over conventional multislice CT scanners.

**CLINICAL RELEVANCE/APPLICATION**

Photon-Counting CT matches High-Resolution Flat-Panel Volume CT in precise pre- and postoperative Cochlear Duct Length measurements and electrode contact determination for Cochlear Implant evaluation

## R2-SPIN-1 DEBIASING FOR MULTIPLE CONFOUNDING ATTRIBUTES USING GRADIENT REVERSAL

Ramon Correa-Medero, BS (*Abstract Co-Author*) Nothing to Disclose
Bhavik N. Patel, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*) Consultant, Softbrew Digital LTD
Vedant Joshi (*Abstract Co-Author*) Nothing to Disclose
Imon Banerjee, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Deployment of AI models is limited by the impact biases formed from spurious correlations can have on patient populations. For minority groups, biased models would further existing health disparities. Debiasing techniques are training techniques to develop fair models. However, are only applied to one spurious feature, whereas multiple spurious correlations may exist. We introduce a debiasing technique alongside a loss balancing technique to tackle the issue of multiple biasing attributes.

### METHODS AND MATERIALS

We modify a convolutional neural network ( CNN) to use three auxiliary classifiers predicting confounding attributes: age, race, and presence of support devices(SD). The model is trained in two steps; during the first forward pass, the backbone and primary classifier are trained to predict the presence of 4 radiological findings ( No Finding, Pleural Effusion, Edema, and Lung Opacity). The auxiliary classifies one of the three confounding attributes. Their updates do not influence the backbone. During the second forward step, the auxiliary classifiers are updated, and the updates of the auxiliary classifiers are sent toward the backbone after its gradient direction has been flipped by the gradient reversal layer. The model backbone unlearns features related to the confounding attributes. Each confounding attribute classifier had its loss term weighted by a dynamic weight based on the loss value. The dynamic weight allowed the three confounding attributes to be equally weighted despite the differences in loss magnitudes. The model was trained using the Chexpert dataset; 190K images were randomly split into training validation tests by patient ID. The model was evaluated on MIMIC and Emory data containing 296K and 498K image. A model comp without debiased served as baseline. Bias was evaluated using the intersectional identity of patients across race(Asian, Black, White ), age ( lt 40,40-60,60+), and SD producing 18 demographic groups. True positive rate disparity(TPR) ratio was measured by comparing each group's TPR to the majority; values exceeding 0.8-1.2 were found to be biased.

### RESULTS

AUC on the Chexpert averaged 0.82 and 0.81 for the baseline and debiased models. Performance on MIMIC had an average AUC of 0.81 for both models. Both models averaged AUC of 0.79 on Emory. No finding bias decreased 11 to 7 groups in Chexpert. Mimic bias decreased from 13 to 3. Emory saw no disparity change for No Finding.

### CONCLUSION

Our proposed technique produces comparable average AUC across the three datasets, with noticeable reductions in prediction disparities across groups.

### CLINICAL RELEVANCE/APPLICATION

We present a debiasing technique that reduces the effects of multiple confounding attributes without significantly degrading model performance.

## R2-SPIN-2 EVALUATION OF A LONGITUDINAL AI MODEL FOR AUTOMATIC REPORT GENERATION FROM CHEST X-RAYS

Joseph N. Stember, MD, PhD (*Abstract Co-Author*) Founder, Authera, LLC;Patent holder, Authera, LLC
Sarah Eskreis-Winkler, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Dipit Vasdev (*Abstract Co-Author*) Nothing to Disclose
Nathaniel Swinburne, MD (*Abstract Co-Author*) Nothing to Disclose
Chinmay Hegde (*Abstract Co-Author*) Nothing to Disclose
Etay Ziv, MD,PhD (*Abstract Co-Author*) Research Grant, Johnson & Johnson;Research Grant, Novartis AG
Krishna Nand Keshava Murthy, PhD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Automatic generation of medical reports has the potential to lighten the workload of radiologists, aid accurate and timely diagnosis, and lower reporting errors. While several AI models can generate reports from images, few account for patient longitudinal information. We train and evaluate an existing large scale multi-modal AI model that incorporates prior chest X-ray (CXR)/report to generate findings from CXRs.

### METHODS AND MATERIALS

CXR-report pairs from the MIMIC CXR data set were extracted excluding patients with single visits, resulting in 26625 unique patients. Ordered by study date, 94169 pairs of current and prior CXR-report samples from consecutive visits were extracted into training (26156 patients; 92374 samples), validation (203 patients; 737 samples), and test (266 patients; 2,058 samples) sets. The longitudinal MIMIC CXR model based on the transformer architecture with cross attention and memory based decoder was trained to take current CXR, previous CXR/findings as input and generate current findings as output. BLUE, METEOR, ROUGE and CIDEr metrics were used to evaluate generation performance. Results on the test set were compared against zero-shot inference on the well established Large Language and Vision Assistant (LLaVA), CXR LLaVA models which don't account for longitudinal information.

### RESULTS

The longitudinal model was superior to CXR LLaVA and LLaVA with 300% and 700% improvement in BLUE-4, 8% and 20% improvement in METEOR, 92% and 89% improvement in ROUGE, and 550% and 900% improvement in CIDE scores respectively. Interestingly, excluding previous visit-CXR and/or report during inference for current CXR resulted in only marginal decrease in scores (up to 1%), whereas using random text/image as input resulted in legible (though inaccurate) text across models.

### CONCLUSION

The longitudinal model performs better than zero-shot large vision-language models that ignore prior information. The surprising behavior with missing prior/random input highlights the need for elaborate testing and appropriate metrics to understand model failures critical for clinical consumption.

### CLINICAL RELEVANCE/APPLICATION

Demonstrating the importance of incorporating longitudinal information and the need for understanding failure modes of large generative AI models are necessary steps to show usefulness in the clinic.

## R2-SPIN-3 MULTILINGUAL CLINICAL INFORMATION EXTRACTION FOR CHEST CT SCANNING AND POSTPROCESSING WORKFLOW AUTOMATION

### PURPOSE

To validate multilingual clinical context-based chest CT scanning and postprocessing workflow automation ("protocol refinement") for simplifying exam workflow and obtaining patient-tailored suggestions for improving the quality and consistency of results.

### METHODS AND MATERIALS

We built and tested a prototype (Siemens Healthineers) based on 376 rules/guidelines that takes clinical context in natural language (reasons for ordering CT and prior CT reports) to extract relevant information for selecting the best scan protocol, acquisition and reconstruction factors, and auto-image-processing with multiple AI models. We used an LLM (GPT-4) to extract and structure input information from multilingual clinical contexts in English, German, Persian, Spanish, Portuguese, and Mandarin Chinese from 214 chest CTs representing multiple scan protocols. The reports were split into development (n=49) and validation datasets (n=165). The system was developed using the English development dataset. Notably, no adaptations were made for other languages; the LLM prompts remained in English and contained no instructions that acknowledge other languages. The prototype outputs were compared to ground truth by one radiologist and one CT technologist. We estimated accuracy, precision, and recall (as applicable) for all languages and workflow steps.

### RESULTS

For English, the prototype had 91.5% accuracy (151/165), 95.2% (157/165), 93.9% (155/165) and 86.7% (143/165) for selecting the scan protocol, windowing, scan range, and image reformations. The corresponding values for other languages were 90.9%, 95.2%, 93.3%, 78.8% (German), 77.0%, 87.3%, 78.2%, 78.2% (Persian), 89.7%, 95.2%, 90.3%, 82.4% (Spanish), 89.7%, 95.2%, 92.1%, 84.2% (Portuguese), and 89.1%, 95.2%, 91.5%, 85.5% (Mandarin). The observed precision and recall for downstream AI tasks were 75.5%/76.4% (English), 76.0%/76.3% (German), 72.6%/75.7% (Persian), 75.4%/76.0% (Spanish), 75.3%/76.4% (Portuguese), and 74.8%/76.5% (Mandarin).

### CONCLUSION

Our multilingual clinical context-based scanning and postprocessing workflow automation prototype can automate the selection of scan protocol, acquisition and reconstruction factors, and postprocessing.

### CLINICAL RELEVANCE/APPLICATION

Multilingual rule-based solutions with LLMs can extend benefits of automation beyond the English-speaking world, potentially with negligible localization efforts for well-represented languages.

## R2-SPIN-4 DEVELOPMENT OF AN ARTIFICIAL INTELLIGENCE MODEL FOR PREDICTING ANESTHESIA REQUIREMENTS IN PEDIATRIC MAGNETIC RESONANCE IMAGING PROCEDURES

Claudio Silva, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Ricardo Castillo (*Abstract Co-Author*) Nothing to Disclose

Gonzalo Araya, MSc, MBA (*Abstract Co-Author*) Nothing to Disclose
Maria Victoria Rojas (*Presenter*) Nothing to Disclose

**PURPOSE**

Performing MRIs without anesthesia is challenging for children up to 8 years old due to the need for stillness and other complicating factors. Currently, pediatric patients at our institution are scheduled without anesthesia based on experiential criteria, leading to uncertainties and potential rescheduling. Our research aims to develop an AI model to predict anesthesia needs for patients from infancy to 8 years old.

**METHODS AND MATERIALS**

The methodology utilized for this project was: 1.- Data Preparation 2.-Variable SelectionC3.- Initial Model Building, various machine learning models were evaluated (logistic regression, decision trees, and random forests, among others)4.- Model Optimization5.- Evaluation of the Optimized ModelThe materials that were used, they were as follows: • Database built from our institution's Agfa Healthcare PACS.• Python programming language.• Google Colab to be able to write the code • Power BI for data visualization.

**RESULTS**

The research utilized a database of 304 pediatric patients aged 0 to 10, spanning from 2018 to 2021, with 13 variables. Key analyses identified AGE, FASTING, COMPANION, PROTOCOL, CONTRAST MEDIA (MDC), PAIN, DIAGNOSTIC HYPOTHESIS, and ORIGIN as critical predictors for anesthesia needs in MRI procedures. Patients older than 8, typically not requiring anesthesia, were excluded to prevent model bias, leaving 155 for training. The Random Forest model, selected for its superior performance with an accuracy of 93.75%, underwent hyperparameter optimization. It notably excelled with an AUC of 0.987, demonstrating excellent discriminatory power. Key influential variables included Fasting, Companion, Use of contrast medium, and Age.

**CONCLUSION**

Following a comprehensive data science approach, we developed an AI-based predictive model to forecast anesthesia use in pediatric patients up to 8 years old. The optimized Random Forest model emerged as the top performer, achieving 94% accuracy. It offers balanced precision and recall, excels in managing imbalanced classes, and is robust against overfitting. Key influential variables identified include Fasting, Companion, Use of contrast medium, and Age.

**CLINICAL RELEVANCE/APPLICATION**

The study's importance is demonstrated by the predictive model's utility in optimizing MRI exam scheduling, reducing pediatric patient stress by forecasting anesthesia needs, enhancing resource use, and improving model robustness with ongoing data training.

## R2-SPIN-5 PATIENT-FRIENDLY OR POTENTIALLY MISLEADING? QUALITATIVE AND QUANTITATIVE EVALUATIONS OF LLM-GENERATED SUMMARY FOR RADIOLOGY REPORT IMPRESSIONS

Brian A. Xavier, MD (*Abstract Co-Author*) Nothing to Disclose
Samer Albahra (*Abstract Co-Author*) Nothing to Disclose
Michael A. Bergen, MD (*Abstract Co-Author*) Nothing to Disclose
Scott Robertson (*Abstract Co-Author*) Nothing to Disclose

Chintan Shah, MD, MS (*Abstract Co-Author*) Spouse, Employee, Merck & Co, Inc
Po-Hao Chen, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Nancy A. Obuchowski, PhD, MS (*Abstract Co-Author*) Research Consultant, Siemens AG;Research Consultant, IBM Corporation;Research Consultant, Elucid Bioimaging Inc;Research Consultant, Takeda Pharmaceutical Company Limited
Namita S. Gandhi, MD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

1. To evaluate patient-friendly large language model (LLM) generated summary of radiology report impressions, for clarity, missing information, and hallucinations. 2. To evaluate the potential of using calculated metrics as a scalable replacement for human expert evaluation for radiology reports

**METHODS AND MATERIALS**

Single-institution, multi-site, retrospective study of 401 consecutive CT abdomen report impressions. WizardLM, a LLM based on the LLaMA 2 architecture with 70 billion parameters in 8-bit quantization, was instructed to generate a summary of the report impression at grade 8 reading level. Radiologists evaluated the report impression for complexity, the LLM-generated summary for clarity, missing information, and hallucinations. Content similarity scores like BERT Scores, Recall-Oriented Understudy for Gisting Evaluation (ROGUE), and Bilingual Evaluation Understudy (BLEU) were calculated.Spearman's rank correlation coefficients were used to assess correlation between complexity of the impression and LLM clarity and to assess correlation between LLM clarity and BERT scores, ROUGE, and BLEU. Logistic regression models were used to test for complexity of the interpretation as a predictor of LLM missing information and hallucinations at a significance level of 0.05Paired t-tests were used to compare Flesch Kincaid (FK) grade level and reading ease scores of LLM summaries with the original reports.

**RESULTS**

LLM provided a clear impression summary in 81%. The LLM summaries were missing key information in 3.5%, hallucinations were present in 10%. 1.3% of summaries were both missing information and contained hallucinations. There was no significant association between report complexity and clarity or hallucinations, but there was an association between complexity and missing key information (low scores :1%, high scores: 6.3%; p=0.004). There was a significant reduction in grade level ($p<0.001$) and a significant increase in reading ease ($p<0.001$) for the LLM summaries.LLM clarity score was not significantly associated with BERT Scores: Cosine Similarity ($r=0.07$, $p=0.168$), F1 ($r=0.09$, $p=0.071$), P ($r=0.02$, $p=0.629$, R($r=0.09$, $p=0.059$) nor with BLEU ($r=0.05$, $p=0.309$) or ROUGE ($r=0.08$, $p=0.133$).

**CONCLUSION**

LLM-generated summary is clear in the majority and provides improved reading ease and lower grade level of readability. However, in a minority of reports it misses key findings and introduces hallucinations. None of the calculated summarization metrics could replicate the results of human expert-assigned quality score.

**CLINICAL RELEVANCE/APPLICATION**

LLM generated reports can be significantly easier for patients to comprehend, but a human-in-the-loop workflow may be necessary to avoid inaccuracies.

## R2-SPIN-6 LEVERAGING LARGE LANGUAGE MODELS FOR AUTOMATIC CALCULATION OF O-RADS RISK STRATIFICATION SCORE FROM MRI REPORTS

Satheesh Krishna, MD (*Abstract Co-Author*) Nothing to Disclose
Masoom A. Haider, MD (*Abstract Co-Author*) Nothing to Disclose
Ankush Jajodia, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Tanya P. Chawla, MBBS (*Abstract Co-Author*) Nothing to Disclose
Genevieve Bouchard-Fortier (*Abstract Co-Author*) Nothing to Disclose
Yangqing Deng (*Abstract Co-Author*) Nothing to Disclose
Rajesh Bhayana, MD, FRCPC (*Presenter*) Nothing to Disclose

**PURPOSE**

O-RADS MRI helps facilitate management by stratifying malignancy risk and improving communication. But radiologist adoption is inconsistent. The purpose of this study was to evaluate large language models (LLMs) for automatically calculating O-RADS MRI scores from existing report descriptions.

**METHODS AND MATERIALS**

In this IRB-approved retrospective study, 144 consecutive gadolinium-enhanced MRI pelvis reports from July 2021 to October 2023 with at least one assigned MRI O-RADS score were included (189 masses). 10 random reports (16 masses) were used to create the applications, leaving 134 reports (173 lesions with 158 O-RADS assigned; test set 1). Since reports with O-RADS scores more likely use standard O-RADS descriptors, 140 additional consecutive reports (183 masses) from January 2018 to October 2019, before O-RADS MRI was established, were used for additional validation (test set 2). Reference standard O-RADS scores were determined by two radiologists interpreting reports after scores were redacted, with disagreements handled by an O-RADS expert radiologist. Two Auto-O-RADS application strategies were evaluated. The first involved few-shot learning with GPT-4 (version 0613), instructed to categorize masses using provided O-RADS MRI rules ("LLM-Only"). The second was a hybrid strategy that leveraged GPT-4 to classify key features (i.e. solid enhancing tissue, etc), and then applied a deterministic formula to calculate the score ("Hybrid"). Performance of each application was evaluated compared to the reference standard.

**RESULTS**

Of the 173 masses (test set 1), 40.5% were O-RADS 1/2 (n=70), 30.1% O-RADS 3 (n=52), and 29.5% O-RADS 4/5 (n=51) according to reference standard. For assigning O-RADS MRI scores, the Hybrid model (97%, 168 of 173) outperformed LLM-only (90%, 155 of 173; p=0.006). For lesions with an O-RADS score in the original report, the Hybrid model's accuracy exceeded the reporting radiologist (97 vs 88%, 153 and 139 of 158, p=0.004). For reports issued prior to O-RADS MRI implementation (test set 2), the hybrid model outperformed the LLM-only model (93 vs 86%, 170 and 158 of 183; p=0.04). Hybrid model performance was not different on reports prior to and after O-RADS implementation (93 vs 97%, p=0.12).

**CONCLUSION**

A hybrid LLM-based application, fusing LLM feature classification with deterministic elements, enabled high accuracy for calculating O-RADS MRI scores from report descriptions, exceeding an LLM-only strategy and the reporting radiologist in accuracy.

**CLINICAL RELEVANCE/APPLICATION**

Accurate automated calculation of O-RADS MRI scores from report descriptions could widely increase adoption of O-RADS MRI and improve the accuracy of assigned scores.

## R2-SPIN-7 AI DRIVEN SCREENING MAMMOGRAPHY OUTREACH PROGRAM IMPROVES 15-MONTH COMPLIANCE AND REDUCES THE GAP FOR UNDERSERVED POPULATIONS

Rishi Deshpande, BEng, MS (*Abstract Co-Author*) Nothing to Disclose
Aasim Ansari (*Abstract Co-Author*) Nothing to Disclose
Vaibhav Mathur (*Abstract Co-Author*) Nothing to Disclose
Hemlata Malav (*Presenter*) Nothing to Disclose

**PURPOSE**

Breast cancer screening provides early detection and more favorable outcomes only with compliance to regular screening intervals as guidelines recommend. Lack of compliance is more common in underserved populations, leading to delayed diagnosis, poorer outcomes and greater health disparities. The goal of this work is to study if an AI-based targeted outreach program can significantly increase compliance rates of breast cancer screening and reduce the historical gap between the majority and underserved populations.

**METHODS AND MATERIALS**

An AI driven outreach program for patients to schedule screening mammograms was started in Oct 2019 at 272 imaging clinics. The program determines outreach cadence based on an AI-generated score and conducts outreach over 3 months via multiple channels (e.g. text, voice call, or voicemail), starting 2 weeks before the annual mammogram due date. Data was collected from 6,629,027 patients (White 43.7%, Black/African American 23.2%, Asian 5.9%, Hispanic 12%, Others 15.2%) (<51yo 25.6%, 51-60yo 30.7%, 61-70yo 27.0%, >71yo 16.6%) over 9,185,808 visits before and after the outreach program (from Oct 2015 to Sept 2023). The compliance rate was calculated by determining the % of patients that returned for another mammogram within 15 months of their previous screening mammogram.

**RESULTS**

For the entire patient base we observed 8.0% increase in compliance over 4 years compared to the year before outreach started, with a particularly large increase in Black/African American women and younger age groups. Historically there had been a gap of 6.6% between White and Black/African American in the compliance which was brought down to 2.4% by the outreach program. Compliance was significantly improved across race (Black/African American +11.9%; Hispanic +4.9%; Asian +7.7%; White +7.7%; p<0.001) and age (<50yo +9.9%; 51-60yo +8.5%; 61-70yo +7.1%; >71yo +4.9%; p=0.002). The largest increase in compliance was seen among Black patients less than 60 years old (+13.3%; p=0.008), who are at particularly high risk for poor outcome and have multiple known barriers to screening attendance as compared to the white population.

**CONCLUSION**

Our study demonstrated a significant increase in compliance with an AI-based outreach program that reduced the health disparities across patient groups. The largest improvements were noted in groups who traditionally have lower compliance rates at screening such as Black women under 60.

**CLINICAL RELEVANCE/APPLICATION**

Increased compliance rate increases the chances of catching cancer at an early stage. This study demonstrated that an outreach program can be used to sustainably increase screening mammography rates, including in underserved populations, and may be a useful tool in reducing health disparities.

## R2-SPIR-1 ROLE OF PERCUTANEOUS TRANSHEPATIC CHOLECYSTO CHOLANGIOGRAPHY (PTCC) IN PRE OPERATIVE EVALUATION OF INFANTS WITH SUSPECTED EXTRAHEPATIC BILIARY ATRESIA (EHBA)

Kushaljit S. Sodhi, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Anmol Bhatia, MD (*Abstract Co-Author*) Nothing to Disclose
Vivek Garg (*Abstract Co-Author*) Nothing to Disclose
Sadhna Lal (*Abstract Co-Author*) Nothing to Disclose
Ravi Kanojia, MBBS (*Abstract Co-Author*) Nothing to Disclose
Akshay K. Saxena, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the role of percutaneous transhepatic cholecysto cholangiography (PTCC) in pre operative evaluation of infants with suspected extrahepatic biliary atresia (EHBA)

### METHODS AND MATERIALS

This was an ethics committee approved prospective study conducted in a tertiary care level teaching hospital. 22 infants with suspected EHBA were enrolled in the study after obtaining informed written consent from the parent/guardian. The children were excluded if there was refusal of consent, coagulopathy or non visualization of gallbladder on diagnostic sonography even after 4 hours fasting. PTCC was performed under ultrasound guidance by a consultant having more than 5 years of experience in Pediatric Interventional Radiology procedures. The diagnosis of EHBA was considered as excluded if there was opacification of right and left hepatic ducts, common hepatic duct and common bile duct with passage of contrast into the duodenum. In remaining patients PTCC was considered suggestive of EHBA and patient was subjected to intraoperative cholangiogram (IOC).

### RESULTS

PTCC was attempted in 21/22 patients where gall bladder was visualized and was technically successful in 20/21 patients. The mean age for performing PTCC in our study was 71.47 days ±17.06 days (range 40 days to 103 days). Diagnosis of EHBA was excluded in 2/20 patients which avoided negative laparotomy in these cases. Amongst the 18/20 patients where PTCC was suggestive of EHBA, a successful IOC was performed in 13 patients. The mean gap between the PTCC and IOC was 3.85days ± 2.48 days (range 0 days to 8 days). PTCC had sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) of 100%, 50%, 86.6% and 100% respectively in our study. Mild peritoneal leak of contrast was seen during PTCC in 7/20 (35%) patients. None of these patients had any hemodynamic instability after the PTCC procedure. The mean duration of hospital stay before confirmation (or exclusion) of diagnosis of EHBA in our study was 8.63 days ±3.99 days (range 2 to 17 days).

### CONCLUSION

PTCC is a minimally invasive simple procedure with a low rate of technical failure and haemodynamically significant complications. It can be performed successfully even in small babies. It can bring down the rates of negative laparotomies in patients suspected to have EHBA. However, the diagnosis of EHBA at PTCC is not infallible and IOC should continue as the gold standard investigation for the diagnosis of EHBA.

### CLINICAL RELEVANCE/APPLICATION

Pre operative PTCC is a safe minimally invasive radiological tool for establishing, or excluding, diagnosis of EHBA with potential for reducing the frequency of negative laparotomies.

## R2-SPIR-2 INITIAL EXPERIENCE WITH CT-GUIDED LOCALIZATION OF ENDOPHYTIC RENAL MASSES USING ADJACENT MICROCOIL IMPLANTATION PRIOR TO LAPAROSCOPIC PARTIAL NEPHRECTOMY: A FEASIBILITY AND DESCRIPTIVE STUDY

Tianhao Su, MD (*Abstract Co-Author*) Nothing to Disclose
Jin Long (*Abstract Co-Author*) Nothing to Disclose
Zhiyuan Zhang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To describe and assess computer tomography (CT)-guided percutaneous microcoil localization for guiding laparoscopic partial nephrectomy (LPN) for the treatment of totally endophytic renal masses.

### METHODS AND MATERIALS

Eleven patients with totally endophytic renal tumors were retrospectively enrolled from March 2021 to March 2023. Microcoils were placed next to the renal masses under CT guidance prior to LPN. The head of the microcoil was pinpointed adjacent to the target endophytic renal mass, and its end tail remained outside the renal surface. The outcomes assessed included the localization success rate, operative time, margin status, and complications.

### RESULTS

Eleven patients(57.0 [43.0, 64.0] years, 7males) with eleven lesions were included. Percutaneous microcoil localization was successful for eleven (11/11, 100.0%) lesions within 1 cm of the masses without dislodgement. The median duration of the preoperative CT-guided microcoil localization procedure was 30 [23.0, 37.0] minutes, and no major or minor complications related to the procedure were observed. The median time interval between CT-guided microcoil insertion and the initiation of the surgical procedure was 17.0 [15.0, 19.0] hours. All patients had negative surgical margins, with no intraoperative complications. At discharge, the median decrease in Hgb was 1.1 g/dl. No recurrences were observed at the 1-year follow-up. The median percent decrease in the eGFR at discharge was 13% (5-31%), and the 1-year decrease in the eGFR was 11.9% (1.0-19.1%).

### CONCLUSION

Percutaneous microcoil localization is a viable and safe technique for the precise localization of totally endophytic renal masses, facilitating LPN without the need for intraoperative imaging.

### CLINICAL RELEVANCE/APPLICATION

The management of completely endophytic renal tumors presents a notably intricate challenge. These tumors evade direct observation or palpation from the kidney's surface, rendering accurate localization primarily reliant on preoperative imaging. We recently introduced a novel method for precise preoperative localization of completely endophytic renal tumors prior to partial nephrectomy. This method addresses the limitations associated with previous percutaneous hookwire localization of abdominal masses. Localization with the microcoil is applicable not only for laparoscopic partial nephrectomy but also for robot-assisted partial nephrectomy. By employing CT-guided microcoil localization for the preoperative marking of completely endophytic renal tumors, we can achieve precise and expeditious tumor excision during laparoscopic partial nephrectomy, as evidenced by our preliminary results.

## R2-SPIR-3 DEFINING THE IDEAL PATIENT EXPERIENCE IN INTERVENTIONAL RADIOLOGY: EXPLORING INFLUENTIAL FACTORS FOR HIGH PATIENT SATISFACTION SCORES

Mina S. Makary, MD (*Abstract Co-Author*) Nothing to Disclose
Esha Chadha, BA (*Presenter*) Nothing to Disclose

### PURPOSE

The focus on patient satisfaction has increased, leading to more use of online platforms for rating doctor experiences. These platforms provide insights into a physician’s care quality, including interventional radiologists, capturing positive and negative feedback. The purpose of this study was to evaluate study patients' online feedback about interventional radiologists, seeking insights into factors shaping patient experiences and satisfaction.

### METHODS AND MATERIALS

Patient satisfaction data on 300 randomly selected interventional radiologists from the Society of Interventional Radiology (SIR) website listing were examined. Public online patient satisfaction repositories utilized included US Health News, Share Care, Vitals, WebMD, and Google Reviews. Variables including rating, wait time, insurances accepted, patient satisfaction, cultural competency, procedural outcomes, and physician demographics were analyzed. Additional data on dissatisfaction reasons, such as procedural outcomes, bedside manner, and patient education, were collected for physicians rated below 5 stars.

### RESULTS

The study analyzed 1964 five-star reviews. Procedural patients accounted for 52% (2061), while nonprocedural patients contributed 48% (1903). Conversely, 139 less than five-star reviews encompassed 241 negative comments, with procedural patients providing 72% (174) and nonprocedural patients 28% (63). A chi-square test ($?^2 = 204.09$, $df = 1$, $p < 0.001$) revealed a significant association, indicating that patient type, whether procedural or nonprocedural, affects review ratings. Positive clinical comments mainly focused on medical explanations, while negative feedback often highlighted procedural outcomes (78%) and inadequate patient education (13%). Positive nonclinical remarks lauded good bedside manner (82%) and culturally sensitive care (78%), while negative comments frequently criticized poor bedside manner (92%) and long wait times (59%).

### CONCLUSION

Physicians excelling in communication, positive outcomes, and cultural competence receive high patient ratings. Conversely, shortcomings in procedural outcomes, patient education, and bedside manner contribute to negative feedback. Addressing these aspects can enhance patient experience and overall healthcare quality in Interventional Radiology.

### CLINICAL RELEVANCE/APPLICATION

In the setting of limited patient satisfaction data in Interventional Radiology, this work investigated predictors of high patient satisfaction scores to provide insights for interventionalists for optimal healthcare delivery.

## R2-SPIR-4 COMPUTED TOMOGRAPHY ASSESSMENT WITH TOTAL ABDOMINAL MUSCLES IN OUTCOMES OF PATIENTS WITH INTERMEDIATE TO ADVANCED HEPATOCELLULAR CARCINOMA UNDERGOING HEPATIC ARTERIAL INFUSION CHEMOTHERAPY

Chih-Horng Wu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jing-Wei Kang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In patients with liver cirrhosis and hepatocellular carcinoma (HCC), sarcopenia has been demonstrated as an independent predictor for poor prognosis. Computed tomography (CT)-based evaluation of sarcopenia provides a standardized method to assess abdominal skeletal muscle. Among total abdominal muscle (TAM), psoas muscle (PM) and paraspinal muscle (PS), which is an index muscle for sarcopenia remains unclear. Therefore, we investigated whether CT-based sarcopenia can serve as a prognostic factor for patients with intermediate to advanced HCC after hepatic arterial infusion chemotherapy (HAIC).

### METHODS AND MATERIALS

In this retrospective study, we enrolled patients who underwent HAIC for intermediate to advanced stage HCC between January 2012 and December 2019. Before HAIC treatment, the TAM, PM, and PS areas were evaluated using a single CT slice at the level of third lumbar vertebra. Sarcopenia was determined using the TAM, PS, PM indices divided by the square of the body height. Finally, we analyzed each muscle-defined sarcopenia to decide whether it can serve as a prognostic factor for overall survival (OS) in patients who underwent HAIC.

### RESULTS

We analyzed 75 (65 men and 10 women) patients with intermediate to advanced HCC and all patients underwent HAIC treatment. All types of muscle areas (TAM, PM, and PS) of men were significantly higher than those of women (all $p<0.001$). The patients with TAM-defined sarcopenia had significantly poorer OS than those without sarcopenia (median OS 14.4 vs. 8.6 months, $p=0.038$). There was no significantly difference in OS between sarcopenia and non-sarcopenia groups when defined by the PM or PS. In multivariate analysis, TAM-defined sarcopenia remained an independent predictor for the poor OS after adjustment for up-to-11 criteria, main portal vein thrombosis, treatment response.

### CONCLUSION

CT-based sarcopenia defined by TAM can be an independent prognostic factor for the poor prognosis of intermediate to advanced HCC after HAIC treatment.

### CLINICAL RELEVANCE/APPLICATION

Cancer related cachexia has been associated with poor cancer prognosis, but the diagnosis of cachexia is complicated. Sarcopenia can be measured easily by using CT scan, which is a common diagnostic tool for HCC and routinely used for cancer staging. Previous studies showed that sarcopenia was associated with postoperative complications, longer hospital stays, and poorer prognosis after liver transplantation, resection and radioembolization. Therefore, identifying patients with sarcopenia before HAIC is crucial. Further studies should investigate whether perioperative nutritional therapy and strength training to increase muscle mass can increase survival in patients undergoing HAIC treatment.

### PURPOSE

To teach interventional radiology (IR) procedures to medical students or residents, we first train them on our IR simulator using a virtual reality system (VR-IR). We examined the effectiveness of this teaching method.

### METHODS AND MATERIALS

Ninety-nine fifth-year medical students who trained IR treatment for hepatocellular carcinoma transarterial chemoembolization in a 120-minute class from April 2022 to March 2023 were included in this study. We randomly divided them into a VR-IR simulator group (55 students) and a conventional classroom lecture group (44 students). Two students were subsequently excluded from the simulator group due to illness or equipment failure. After the VR-IR simulator or the lecture, the VIST® G5 (image-guided augmented rearity [AR-IR] simulator, Mentice, Gothenburg, Sweden) was used as a simulated patient. The total procedure time, amount of contrast media, fluoroscopic time, and patient peak skin dose for each group of the simulated patients using VIST® G5, were compared. An interventional radiologist also evaluated technical achievement level of students.The interventional radiologist evaluated items related to the procedure technique, each item were rated on a 1-5 (Likert scale), with a total score of 50 points. Results are shown as median [25% / 75% interquartile range] and statistical test to investigate difference between the 2 groups were performed using the Mann-Whitney's U test.

### RESULTS

The results of VR-IR simulator group and conventional group were total procedure time: 13.5 [11.8/14.5] vs.14.3 [12.3/16.8] minutes ($p = 0.11$), amount of contrast media : 28.0 [21.0/36.2] vs. 40.0 [32.3/50.9] mL ($p < 0.01$), fluoroscopic time: 10.1 [8.5/13.0] vs. 11.0 [8.6/13.7] minutes ($p = 0.31$), patient peak skin dose: 276 [243/373] vs. 303 [239/395] mGy ($p = 0.57$), and technical achievement score: 36 [34/44] vs. 31 [29/32] ($p < 0.01$), respectively. There was a significant difference between the two groups for amount of contrast media and evaluation technical score by IR specialists

### CONCLUSION

VR-IR simulator could reduce amount of contrast media in interventional procedures and improve technical achievement score of students. VR-IR simulator may contribute to the improvement education of interventional radiology procedures for medical students.

### CLINICAL RELEVANCE/APPLICATION

Our virtual reality-based simulator can be effective in education of interventional radiology procedures for medical students.

## R2-SPIR-7 ENHANCED VISUALIZATION OF VASCULAR STENT FRACTURE: A COMPARATIVE PHANTOM STUDY ON PHOTON COUNTING AND CONVENTIONAL CT

Reinoud Bokkers (*Abstract Co-Author*) Nothing to Disclose
Yiheng Tan (*Abstract Co-Author*) Nothing to Disclose
Marcel Greuter, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Vascular stents are widely used in endovascular therapy to treat both stenotic and dilating vascular diseases. Stent fractures are associated with adverse events such as stenosis and thrombosis but are difficult to detect. Photon counting computed tomography (PCCT) is a new technology that enables higher spatial resolution compared to conventional CT (CCT), energy resolved imaging and spectral post-processing. The aim of this study was to assess the visibility of vascular stent fractures on PCCT in comparison to CCT.

**METHODS AND MATERIALS**

In an abdominal phantom (QRM-20118) a total of 5 BeGraft peripheral balloon-expandable covered stents (Bentley InnoMed GmbH, Hechingen, Germany) with diameters of 7 mm were utilized. Scans were made on PCCT (Naeotom Alpha, Siemens Healthineers) in standard-resolution (SR) and ultra-high-resolution (UHR) mode. Two CCT scanners were used for comparison (Somatom AS and Force, Siemens Healthineers). Acquisition parameters were based on clinical abdominal CTA protocols. All images were reconstructed using median kernel. In addition, sharp kernel was used in PCCT. Five vascular stents were sequentially fractured from Type 1 to Type 4 and scanned individually (Type1: single strut fracture; Type2: multiple single fractures; Type3: complete transverse linear fracture without stent displacement; Type4: complete transverse linear fracture with stent displacement). Quantitative assessment was performed with an automatic algorithm on strut sharpness, blooming, and noise.

**RESULTS**

PCCT showed smaller blooming and better overall image quality than CCT. Type 1 and 2 fractures can be detected better on PCCT in UHR than in SR mode. Strut sharpness was significantly higher on PCCT UHR mode (?HU 4505±166) and SR mode (?HU 3009±140). Blooming and noise were significantly lower in PCCT UHR mode than on CCT. PCCT SR mode showed significantly less noise than CCT (all $p<0.01$), and smaller blooming than Force (0.39±0.01 to 0.43±0.01, $p<0.01$). On PCCT strut sharpness was significantly higher, and blooming was significantly lower with Br72 kernel than Br56 (all $p<0.05$). Noise was significantly higher with Br72 kernel in both resolution modes (all $p<0.01$). Br72 kernel improved fracture visibility in PCCT UHR mode but reduced in SR mode.

**CONCLUSION**

PCCT can visualize single-strut stent fractures that remain undetectable by CCT. Utilizing UHR mode and sharp kernel in PCCT further enhances the visibility of fractures. Additionally, PCCT offers significant improvement in strut sharpness, reduced blooming, and noise.

**CLINICAL RELEVANCE/APPLICATION**

PCCT can improve follow-up imaging capabilities for patients with post-endovascular therapy, enabling to distinguish clinically relevant stent fractures that need reintervention.

## R2-SPIR-8 REDUCTION OF RADIATION DOSE AND CONTRAST MEDIUM IN CATHETER-BASED INTERVENTIONS OF PERIPHERAL ARTERY DISEASE USING DIGITAL VARIANCE ANGIOGRAPHY

Thomas Zeller (*Abstract Co-Author*) Consultant, sanofi-aventis Group;Speaker, sanofi-aventis Group;Consultant, C.R. Bard;Speaker, C.R. Christopher L. Schlett, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Dr. Elias Noory (*Abstract Co-Author*) Nothing to Disclose
Till Schurmann (*Presenter*) Nothing to Disclose

**PURPOSE**

Digital variance angiography (DVA) represents a pioneering image processing technique, which exhibits promising prospects in the reduction of radiation exposure and iodinated contrast medium (ICM) of digital subtraction angiography (DSA). This study aimed to determine the reduction in both radiation dose and ICM concentration in different regions of lower limb interventions.

**METHODS AND MATERIALS**

A software prototype for DVA (Kinepict Health Ltd., Budapest, Hungary) was utilized for patients undergoing percutaneous transluminal angioplasty (PTA). DSA normal dose (DSA-ND) protocols were revised from 1.20 µGy/frame and 0.81 µGy/frame to DVA low dose (DVA-LD) protocols with 0.36 µGy/frame and occasionally 0.24 µGy/frame based on specific examination requirements. In parallel, ICM concentration was systematically reduced by 80%. The cumulative dose area product (DAP) was evaluated retrospectively. Contrast-to-noise ratio (CNR) was measured pairwise for summated DVA-LD acquisitions and compared to DSA-LD at the subjective highest contrast for each individual image of the DSA series. CNR was calculated by defined ROIs on vessels and background, which were equally distributed from large (>3mm ?) to small vessels (<1mm ?).

**RESULTS**

Evaluation included 370 DSA-ND and 62 DVA-LD interventions of three lower limb regions (mean age: 72.8±10.9 years, 66.9% male). DVA-LD reduced DAP of DSA-ND significantly by 62.0%, 53.8%, and 59.4%, respectively. DAP decreased from 3238.6 [962.5-27538.8] to 1230.4 [528.9-11.675.4] cGy·cm² in pelvic regions ($p<0.005$), from 1190.9 [226.8-10393.7] to 550.8 [97.5-3739.1] cGy·cm² in femoral and popliteal regions ($p<0.0001$), and from 827.6 [197.5-4091.1] to 336.0 [69.8-1013.9] cGy·cm² in cruro-pedal regions ($p<0.0005$). With a total of 1644 ROIs in 66 acquisitions for CNR measurements, DVA-LD images exhibited enhanced contrast and decreased noise compared to DSA-LD in all regions. CNR increased from 8.8 [1.5-32.6] to 14.4 [2.1-128.0] in pelvic regions ($p<0.0001$), from 6.9 [0.6-43.2] to 17.8 [1.8-134.7] in femoral and popliteal regions ($p<0.0001$), and from 7.8 [0.6-36.1] to 17.3 [2.0-152.4] in cruro-pedal regions ($p<0.0001$).

**CONCLUSION**

DVA reveals significant dose reduction in lower limb PTA when applying 20% ICM of the standard concentration and enhances image contrast while decreasing noise, thereby ensuring adequate clinical image quality.

## CLINICAL RELEVANCE/APPLICATION

DVA can significantly reduce (stochastic) health risks of radiation exposure for both patients and angiologists. Furthermore, drastic reduction of ICM decreases the risk of iodine-induced adverse effects for patients and enables interventions, which could not be conducted previously due to higher ICM concentrations.

## R2-SPMK-1 IMPLEMENTATION OF A NEW CLASSIFICATION AND STRATIFICATION SYSTEM FOR SOLITARY BONE TUMOR: OSSEOUS TUMOR RADIOLOGICAL AND INTERPRETATION AND MANAGEMENT SYSTEM (OT-RIMS)

Lin Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Jiachun Zhuang (*Abstract Co-Author*) Nothing to Disclose
Yingyi Zhu (*Abstract Co-Author*) Nothing to Disclose
Haijun Wu, MD,PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Due to the abundance and relative rarity of histological subtypes of bone tumors, an accurate histological diagnosis of bone tumors must be interpreted by an experienced bone tumor pathologist in collaboration with a musculoskeletal radiologist and discussed in a multidisciplinary team. Even for radiologists, achieving a pathologically consistent diagnosis is still a challenging task for the radiographic heterogeneity and morphological overlap of bone tumors. Therefore, a new radiological classification system oriented by tumor biological behavior and patient management, OT-RIMS, has been proposed to streamline the radiological evaluation of bone tumors and consolidate key radiological features into ordinal severity categories that would inform corresponding patient management actions.

### METHODS AND MATERIALS

This retrospective study between January 2015 and August 2022 evaluated patients with solitary bone tumors confirmed by pathology and imaging follow-up received two or three imaging modalities of radiographs, CT, or MRI. Three radiologists independently assessed radiological features, categorized bone lesions based on OT-RIMS criteria, and reached a consensus. Kappa statistics and observed agreement were calculated.

### RESULTS

A total of 341 patients (mean age, 26.0 years;159 women) were included, with 102 malignant, 177 benign, and 62 intermediate or low-grade malignant bone lesions. Sensitivity and specificity of readers 1, 2, and 3, respectively, in the identification of malignant tumors into OT-RIMS 4 were 93.1% (95 of 102) and 93.3% (223 of 239), 96.1% (98 of 102) and 91.6% (219 of 239), 92.2% (94 of 102) and 89.5% (214 of 239). Inter-reader agreement of OT-RIMS category for three readers was considered excellent (Kendall's W=0.924, $p<0.001$) with a kappa value of reproducibility in categories 12, 3, and 4 of 0.764, 0.528, and 0.930, respectively.

### CONCLUSION

The OT-RIMS category demonstrated excellent reproducibility despite the reader's expertise level in categorizing the risk stratification of bone tumors and informing patient management, with histological grades used as the reference standard.

### CLINICAL RELEVANCE/APPLICATION

This study confirmed that OT-RIMS categories demonstrated excellent diagnostic performance and reproducibility regardless of the professional experience of readers in the classification of bone tumor risk stratification and informing patient management. This work could promote a more standardized and streamlined evaluation of bone tumors and standardize patient management.

## R2-SPMK-2 ON THE FEASIBILITY OF DETECTING SPINAL STENOSIS USING DEEP LEARNING IN RADIOGRAPHY

Joon-Yong Jung, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Changmin Ryu (*Abstract Co-Author*) Nothing to Disclose
Sungwon Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Keum San Chun, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Magnetic resonance imaging (MRI) is considered the gold standard for diagnosing spinal stenosis for its capabilities in obtaining detailed information at tissue level. However, MRI requires longer scanning times and incurs higher costs compared to radiography. This study aims to explore the feasibility of using deep learning (DL) to automatically detect spinal stenosis in radiographs. To this end, we trained and validated a DL model using radiographs and corresponding labels obtained from MRI images.

### METHODS AND MATERIALS

Radiography and MRI images from 4,075 patients across five independent hospitals in South Korea were collected to develop a DL model for detecting spinal stenosis. Each radiographic data included anteroposterior (AP) and lateral (LAT) view images. From these images, three image segments were extracted for each vertebral joint, covering the range from the twelfth thoracic vertebra (T12) to the first sacral vertebra (S1). The three segments, each

representing a vertebral joint in the AP view and the LAT view, and a foramen in the LAT view, are designed to comprehensively capture crucial information for spinal stenosis. Collectively, the three segments constituted a single sample, and a total of 17,621 samples were obtained. Each sample was assigned a binary value based on the diagnosis derived from the accompanying MRI image. Each of the three segment images was processed using contrast limited adaptive histogram equalization before being input to a pre-trained ResNet50 model. The intermediate outputs from each of the three ResNet50 models were then passed through a linear layer to generate the final probability of spinal stenosis. The overall performance was assessed using a 10-fold cross-validation (CV), with performance reported in positive predictive value (PPV), sensitivity, and F1 score.

**RESULTS**

From 10-fold CV, the PPV, sensitivity and F1 scores were 75%, 69% and 72%, respectively. And the area under the curve (AUC) for the receiver-operating curve (ROC) was 79%, and the AUC for the precision-recall curve was 78%.

**CONCLUSION**

This study offers initial findings on DL-based automated spinal stenosis detection. The evaluation of the preliminary model demonstrates encouraging outcomes, suggesting the potential of the DL model as a supportive tool in diagnosing spinal stenosis, albeit the need for improved classification performance before clinical deployment. With improved classification accuracy, we envision this algorithm serving as a valuable tool for rapid and precise spinal stenosis diagnosis.

**CLINICAL RELEVANCE/APPLICATION**

Automated detection of spinal stenosis in radiography using DL can improve the diagnostic speed and accuracy while lowering the medical cost.

## R2-SPMK-3 VASCULAR DAMAGE RISK ASSESSMENT IN LUMBAR PEDICLE SCREW FIXATION

Giovanni Ambrogi (*Abstract Co-Author*) Nothing to Disclose
Greta Recchia (*Abstract Co-Author*) Nothing to Disclose
Carlo Catalano, MD (*Abstract Co-Author*) Nothing to Disclose
Stefano Perotti SR, MD (*Abstract Co-Author*) Nothing to Disclose
Alessandro Napoli, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Alessandra Valenti, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to evaluate the distribution of vessels running anterior to the lumbar spine with a distance <5 mm and >5 mm in front of the vertebral bodies from D12 to L5 to determine the risk of vessel damage in lumbar pedicle screw fixation.

**METHODS AND MATERIALS**

This is a single-center retrospective study. During January-August 2023, 60 random abdomen CT scans with contrast were evaluated by an experienced MSK radiologist. The upper third of the vertebral bodies were divided into 4 equal sections (in the axial plane: right lateral, right median, left median, left lateral). We classified the vessels into major vessels (aorta, inferior vena cava and common iliac artery/vein) and minor vessels (considering vessels that had a diameter >4mm) and assessed the number of vessels with a distance of less than 5 mm from the bony cortical (cut-off chosen to correspond to the screw pitch used in our center) and at rooms greater than 5 mm from the bony cortical. Patients with previous vertebral procedures or scoliosis (Cobb's angle >10) and patients with tumor lesions of the vertebral soma were excluded. There were 60 patients including 30 males (50%) and 30 females (50%) ranging in age from 75 years to ±10.58. Measurements were measured by orienting the plane according to the angle of the vertebral soma . The quadrants of the vertebral soma were chosen considering the position and angle of the screws that is usually chosen during surgery.

**RESULTS**

The risk of causing damage to a major vessel has a minimum-average probability risk (0-10%) in all sections except: the left lateral sections of D12 and left median of L2 that have a high probability risk (10-12%) for arteries and the right lateral sections of L3 to L5 and right median of L3 and L4 have a high probability risk (11-24%) for veins. The risk of causing damage to a minor vessel has a minimum-medium probability (0-7%) in all sections except L5, which has a high risk (11-17%) in all sections.

**CONCLUSION**

This study may help surgeons to predict the risk of hemorrhage due to vessel injury during fixation of screws that may go beyond the alterior cortical of the vertebral soma.

**CLINICAL RELEVANCE/APPLICATION**

This study may help surgeons predict the severity of the complication based on the type of vessel injured, whether major vessel or minor vessel, which is more likely to be found at a given level of the lumbar spine and in a given quadrant of the vertebral soma undergoing surgical treatment.

## R2-SPMK-4 PREDICTION OF PATHOLOGICAL RESPONSE AND PROGNOSIS IN PATIENTS WITH BONE SARCOMA WHO RECEIVED NEOADJUVANT CHEMOTHERAPY USING IMAGING-BASED TISSUE ANALYSIS METHOD

Meltem Kursun, MD (*Abstract Co-Author*) Nothing to Disclose
Onur Bugdayci, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of our study is to reveal the correlation between the pathological response after neoadjuvant chemotherapy (NACT) and MRI-based texture analysis method in primary bone sarcomas and to evaluate of this method in predicting overall-disease free survival.

**METHODS AND MATERIALS**

Our study included 116 patients who were diagnosed with Osteosarcoma or Ewing sarcoma after trucut biopsy and were operated after NACT. Treatment response was evaluated in four groups based on the postoperative pathology specimens.T1,T2-weighted and contrast enhanced sequences of the lesions were obtained from pre and post treatment MRI and texture analysis of the lesions was performed.

**RESULTS**

Among 116 lesions included in the study, 54 of them (% 46,5) had a good pathological response to treatment. A significant relationship was found between texture parameters AngScMom (p=0,01), InvDfMom (p=0,006), Entropy (p=0,02), DifEntrp (p=0,04) GLevNonU (p=0,03), LngREmph (p=0,004), ShrtREmp (p=0,007), Fraction values (p=0,005) - delta texture analysis parameters SumAverg (p=0,04), DifVarnc (p=0,03), LngREmph (p=0,04) values obtained from contrast enhanced images and NACT response. DifVarnc, LngREmph and SumEntrp parameters obtained from pre-treatment T2-weighted images showed statistically significant difference in predicting overall and event-free survival (p<0,05).In chondroblastic type

osteosarcoma, GLevNonU value obtained from pre-treatment T2-weighted images was significantly lower than the other type osteosarcomas statistically (p=0,03).

**CONCLUSION**

As a result, when pre- and post-treatment MRI examinations are evaluated together with pathology data obtained at diagnosis in patients with primary bone sarcoma, the tissue analysis method provides significant contributions beyond existing qualitative methods in predicting NACT response.

**CLINICAL RELEVANCE/APPLICATION**

We believe that pre-treatment T2A-based parameters can be utilized as prognostic markers. The successful prediction of necrosis rates using data obtained from post-treatment contrast-enhanced series raises hopes for earlier prediction of this response through interim evaluations during treatment.

## R2-SPMK-5 REDEFINING FRONTIERS IN CHONDROSARCOMA: A STUDY BASED ON DEMOGRAPHIC, RADIOLOGIC AND PATHOLOGY CHARACTERISTICS OF THE CASE SERIES FROM A SARCOMA REFERENCE CENTER

Ana M. Crespo, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Maria J. Moreno Casado (*Abstract Co-Author*) Nothing to Disclose
Juan Arrazola (*Abstract Co-Author*) Nothing to Disclose
Maria Guerrero Martin (*Abstract Co-Author*) Nothing to Disclose
Sara Gomez Pena, MD (*Abstract Co-Author*) Nothing to Disclose
Alvaro Rueda-de-Eusebio, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Ų To describe the characteristics of the series of chondrosarcomas treated and followed up in our Sarcoma Reference Center. Ų To establish the criteria in radiography, CT and MRI to differentiate between low grade chondrosarcomas (atypical cartilaginous tumors and grade I chondrosarcoma) and high grade chondrosarcomas (grade II- III). Ų To determine radiological characteristics that differentiate grade I chondrosarcomas in the axial skeleton from atypical cartilaginous tumors of the appendicular skeleton, indistinguishable from the anatomopathological point of view, but with different prognosis. Ų To assess the influence of all the above on the follow-up and survival rate of these patients.

**METHODS AND MATERIALS**

We reviewed the PACS of our institution, as well as the archive of our Sarcoma Reference Center to identify all patients under follow-up for chondrosarcoma at our institution from 2003 to 2023. Different demographic, anatomopathology and radiology variables were collected. Tumor histology was classified according to the updated WHO classification of 2020, with special emphasis on the differentiation between atypical cartilaginous tumors (ACT) and grade I chondrosarcomas located in the axial skeleton. For the comparison between different groups, the t-test, Mann-Whitney test and the chi-square test were used where applicable. Kaplan-Meier test was used for survival analysis.

**RESULTS**

59 chondosarcomas were included in this study. Distinguishing features of high-grade chondrosarcoma (II-III) included endosteal scalloping greater than two-thirds of the cortical thickness (83% in high-grade, 26% in low-grade), extension of endosteal scalloping greater than two-thirds of the lesion length (50% in high-grade, 0% in low-grade), size ($p<0.001$), soft tissue mass and soft tissue edema ($p<0.05$). Regarding the distinction between axial grade I chondrosarcomas and ACTs, cortical destruction (62.5% vs. 20%, $p<0.05$) and soft tissue mass (62.5% vs. 6.7%, $p<0.01$) stood out. Fifty-six patients received surgical treatment, of which 18.6% recurred. 20.3% of the patients developed pulmonary metastases. 14 patients died during follow-up, with a median time to death of 20 months.

**CONCLUSION**

Given the difficulty in clinicopathologic classification of chondroid tumors, imaging findings are helpful in decision making by the multidisciplinary sarcoma committee.

**CLINICAL RELEVANCE/APPLICATION**

Our findings are consistent with the previously published regarding the differentiation between low-grade chondrosarcomas and high-grade chondrosarcomas. Given the recent implementation of the WHO 2020 classification, our work is the first to address the differentiation between ACT and grade I axial chondrosarcoma.

## R2-SPMK-6 DIAGNOSTIC PERFORMANCE AND REPRODUCIBILITY OF ACR BONE-RADS FOR THE RADIOGRAPHIC EVALUATION OF POTENTIALLY NEOPLASTIC BONE LESIONS

Domenico Albano (*Abstract Co-Author*) Nothing to Disclose
Luca Maria Sconfienza, MD, PhD (*Abstract Co-Author*) Travel support, Bracco Group;Travel support, Esaote SpA;Speakers Bureau, Esaote SpA;Travel support, ABIOGEN PHARMA SpA;Speakers Bureau, P&R Holding;Speakers Bureau, Pfizer Inc ;Speaker, Novartis AG;Speaker, Merck KGaA;Speaker, MSDF
Carmelo Messina, MD (*Abstract Co-Author*) Nothing to Disclose
Salvatore Gitto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Stefano Fusco, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance and the reproducibility of the recently introduced American College of Radiology (ACR) Bone-RADS score for the radiographic evaluation of potentially neoplastic bone lesions.

**METHODS AND MATERIALS**

Patients who underwent a bone biopsy for a focal bone lesion in their extremities were retrospectively enrolled, with a requirement for a radiograph conducted within three months before the biopsy. All radiographs were evaluated using the ACR Bone-RADS scoring system by two radiologists: one musculoskeletal radiologist with three years of experience in bone tumors, and one general radiologist with less than six months of musculoskeletal imaging training during residency. Interobserver agreement was determined for all the assessment categories of the ACR Bone-RADS using percent agreement and Cohen’s kappa coefficient (with 95% confidence intervals). The score's diagnostic performance was assessed using a ROC curve. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the score were calculated using histological results as the reference standard.

**RESULTS**

The study included 143 patients (80 males, 63 females), with atypical cartilaginous tumor being the most common histological diagnosis (33/143; 23.1%). Interobserver agreement was good for almost all ACR Bone-RADS categories, except for the "endosteal scalloping" category. Substantial

agreement was also observed for the final Bone-RADS score value (K = 0.806). The score demonstrated good diagnostic performance in distinguishing between benign and potentially aggressive lesions (AUC = 0.81). However, using a cutoff of Bone-RADS = 3 (intermediate risk lesions) resulted in suboptimal sensitivity and NPV. Exclusion of cases of atypical cartilaginous tumors significantly enhanced diagnostic performance, with an AUC of 0.93.

**CONCLUSION**

The ACR Bone-RADS score provides a standardized approach for reporting bone lesions based on radiographic features. It exhibited high reproducibility and accuracy in identifying benign lesions, offering valuable assistance to radiologists in patient care and management. The score may underestimate the risk of low-grade cartilaginous tumors, suggesting the consideration of advanced imaging instead of radiographic surveillance for low-risk chondroid lesions (Bone-RADS = 2).

**CLINICAL RELEVANCE/APPLICATION**

ACR Bone-RADS score offers a standardized framework for reporting bone lesions, helping radiologists in choosing the appropriate management for the patient.

## R2-SPMS-1 DEEP LEARNING FOR AUTOMATED SEGMENTATION AND QUANTIFICATION OF COMPONENTS IN PERIPHERAL LYMPHEDEMA USING CT SCANS

Bushra Urooj (*Abstract Co-Author*) Nothing to Disclose
Kyung Won Kim, MD (*Abstract Co-Author*) CEO, Trial Informatics Company
Sejin Choi, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Computed tomography (CT) images provide specific imaging features and structural details of peripheral lymphedema, reflecting the clinical staging guidelines by the Consensus Document of the International Society of Lymphology. However, its application in clinical practice is limited due to the time-consuming process required to segment the tissue components. We aimed to develop a deep learning algorithm (DLA) for the automated segmentation of lower extremity components, enabling quantification and distribution analysis of tissue components using CT scans.

### METHODS AND MATERIALS

A DLA for lower extremity segmentation was trained using a development dataset of CT venography images from 118 patients. Of these, 102 CT scans covered three levels of the lower extremity (i.e., mid-thigh, knee, and mid-calf), and 16 scans provided full slices of the lower extremity, ranging from the ischial tuberosity to the talar dome. Segmentation maps of subcutaneous fat, muscle, and bone—manually drawn—as well as fibrotic tissue extracted based on attenuation, were created to serve as ground truth data. The performance of the DLA was evaluated using the Dice similarity coefficient (DSC) and volumetric similarity (VS) on both internal and external validation datasets, which included 10 CT scans from 10 subjects at our institution and an outside institution.

### RESULTS

The mean DSC for subcutaneous fat, muscle, and fluid-fibrosis components was high for both the internal (0.94, 0.97, 0.99, respectively) and external validation datasets (0.95, 0.96, 0.99, respectively). Volumetric measurements of each component also demonstrated high performance in both internal and external validatiMaon datasets, with a VS greater than 0.97 for all components in both datasets. The DLA exhibited high segmentation performance for both normal and diseased limbs, which varied in tissue composition and volume, achieving DSC of 0.97 for normal limbs and 0.96 for diseased limbs.

### CONCLUSION

The DLA demonstrated high performance and accuracy in the automatic segmentation and volumetric measurement of lower extremity components on CT images.

### CLINICAL RELEVANCE/APPLICATION

Automatic segmentation of CT images enhances the convenience and accessibility of lymphedema assessments, making easier to track and manage the condition.

## R2-SPNMMI-1 FIBRONECTIN-TARGETING RADIOTHERAPY SENSITIZERS TO INDUCE PYROPTOSIS OF BREAST CANCER BY DUAL-ENERGY CT IMAGING-GUIDED CHEMO-RADIOTHERAPY

Dengbin Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Yanhong Chen (*Abstract Co-Author*) Nothing to Disclose
Defan Yao (*Abstract Co-Author*) Nothing to Disclose
Yuelin Huang (*Presenter*) Nothing to Disclose

### PURPOSE

Precise localization is the most important factor for successful radiotherapy. Dual-energy CT, with its ability to produce images at lower photon energies, has demonstrated the advantages of improving contrast resolution and precise localization. However, conventional iodinated contrast agents cannot meet the needs of dual-energy imaging at high keV. To improve the efficacy of radiotherapy, fibronectin-targeting radiotherapy sensitizers were designed to induce pyroptosis of breast cancer by dual-energy CT imaging-guided chemo-radiotherapy.

### METHODS AND MATERIALS

The fibronectin-targeting radiotherapy sensitizers, DAC@KBiF4 nanoclusters, were synthesized by a one-pot synthesis protocol and chemotherapy drug decitabine (DAC) loading into KBiF4 nanoparticles. DAC@KBiF4 nanoclusters were further modified with Cys-Arg-Glu-Lys-Ala (CREKA) peptide to target fibronectin for better biosafety.

### RESULTS

DAC@KBiF4 is an integrated diagnostic and therapeutic probe to localize tumors by CT imaging before radiotherapy. At the same time, the Bi ions were utilized to eliminate glutathione (GSH) and increase reactive oxygen species (ROS) levels through low-dose radiation irradiation. Subsequently, the chemotherapeutic agent decitabine was released to up-regulate GSDME, further inducing pyroptosis to achieve an anti-tumor immune response.

### CONCLUSION

In summary, we developed a GSH-responsive low-dose radiotherapy sensitizer DAC@KBiF4 targeting fibronectin to induce pyroptosis of breast cancer under the guidance of CT imaging. The results show that DAC@KBiF4 has a better localization ability in dual-energy CT. It can achieve anti-tumor immunity to effectively inhibit tumor growth under the synergy of chemotherapy and radiotherapy, which helps to improve the localization accuracy and efficacy of radiotherapy.

### CLINICAL RELEVANCE/APPLICATION

None.

## R2-SPNR-1 EFFECT OF DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM ON CT ANGIOGRAPHY OF CAROTID ARTERY ENTERING SKULL BASE

Yanhong Zhao, MMed,MMed (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the effect of deep learning image reconstruction (DLIR) on the image quality of CT angiography of carotid artery entering skull by comparing with FBP and hybrid iterative reconstruction algorithm (ASIR-V).

### METHODS AND MATERIALS

30 patients with suspected head and neck vascular diseases were selected. The head and neck CTA imaging was performed with revolution apex CT, The tube voltage was 100kV. Three groups of images were reconstructed by filtered back projection reconstruction (group A), 40% ASIR-V reconstruction (group B) and high level of DLIR (DLIR-H, Group C). The CT values and SD in petrosal bone segment, cavernous sinus segment, superior clinoid process segment and muscles at the same level of internal carotid artery were measured, and SNR and CNR were calculated, The subjective image quality was evaluated by two doctors with more than 5 years of diagnostic experience. The CT value, SD, SNR, CNR and subjective image quality of the carotid artery entering the skull base of the three groups were compared.

### RESULTS

There was no significant difference in the CT values of the three groups ($P > 0.05$). The noise of FBP, 40%ASIR-V, and DLIR-H images entering the internal carotid artery of the skull base were 24.52±3.18, 21.72±9.78, 16.61±3.67, respectively, and the differences were statistically significant ($P<0.05$). The noise of DLIR-H reconstruction algorithm is 32.26% lower than that of FBP, and 23.53% lower than that of 40% ASIR-V. There are statistically significant differences in the signal-to-noise ratio and contrast-to-noise ratio of the three groups of images (all $P<0.05$). The signal-to-noise ratio and contrast-to-noise ratio of DLIR-H reconstruction algorithm are higher than FBP and 40% ASIR-V. The subjective scores of FBP, 40%ASIR-V, and DLIR-H images were 3.60±0.50, 4.13±0.43, and 4.40±0.50, respectively. The subjective image quality score of DLIR-H was higher than that of FBP and 40%ASIR-V (P values are $<0.05$).

### CONCLUSION

DLIR-H reconstruction algorithm can reduce the image noise of CT angiography of carotid artery entering the skull base and improve the image quality of SNR, CNR and subjective image.

### CLINICAL RELEVANCE/APPLICATION

CT angiography of carotid artery entering the skull base is vulnerable to image noise. DLIR-H reconstruction algorithm can reduce the image noise of CT angiography of carotid artery entering the skull base and improve the image quality of SNR, CNR and subjective image.

## R2-SPNR-12 ADVANCING DIAGNOSTIC CAPABILITIES: DEEP LEARNING-BASED TOOL FOR ENHANCED DISCRIMINATION OF MULTIPLE SCLEROSIS AND SMALL VESSEL DISEASE ON ROUTINE NON-ENHANCED BRAIN MAGNETIC RESONANCE IMAGING

Melika Boroomand-Saboor, MD (*Abstract Co-Author*) Nothing to Disclose
Masoumeh Gity, MD (*Abstract Co-Author*) Nothing to Disclose
Arash Azhideh, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Mehran Arabahmadi, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

The diagnosis of Multiple Sclerosis (MS) primarily relies on clinical examination, supported by magnetic resonance imaging (MRI) interpreted by experienced radiologists. However, typical imaging features of MS can mimic other central nervous system diseases. Cerebral Small Vessel Disease (SVD) is one such pathology that may pose challenges for the radiologist in making a definitive diagnosis. Differential diagnosis is often difficult at the onset of the disease when the manifestations and symptoms are not yet spatially and temporally extensive. The aim of this study is to develop and evaluate a Computer-Aided Diagnosis (CAD) system based on brain MRI images using a robust deep neural network, to differentiate the diagnosis of MS from SVD in MRI images.

### METHODS AND MATERIALS

Brain MRI images obtained from a 3 Tesla scanner of patients with a definite diagnosis of multiple sclerosis (MS) in both stages, acute attack and clinically silent phase, as well as patients who underwent brain MRI for other reasons at the imaging center and were diagnosed with SVD by a radiologist based on their medical history of risk factors for cardiovascular diseases and imaging findings, were evaluated. The MRI images with FLAIR, T1 without contrast, and T2 without contrast sequences were enrolled. The white matter lesions were reported by an expert neuroradiologist with at least ten years of experience and then segmented via the pre-designed artificial intelligence software. Afterward, 80 percent of data used for training, 10 percent for validation, and 10 percent for the test. Finally, the results were evaluated by a neuroradiologist based on each patient diagnosis. The diagnostic performance of the artificial intelligence method was compared with the current gold standard (combination of clinical and imaging criteria).

### RESULTS

A total of 80 patients with multiple sclerosis (MS) including , 265 brain lesions, as well as 67 patients with cerebral small vessels disease (SVD) and 218 SVD lesions, were examined. The results of this study showed that the artificial intelligence tool had a sensitivity of 78.57% and specificity of 93.33% (P-value<0.05), with a positive predictive value (PPV) of 91.67, negative predictive value (NPV) of 82.35, balanced accuracy of 85.95, and area under the curve (AUC) of 78.71 (90.48-102.2).

### CONCLUSION

Artificial intelligence has the ability to differentiate between MRI images of patients with MS and those with SVD solely based on single MRI studies routine sequences.

### CLINICAL RELEVANCE/APPLICATION

The application of artificial intelligence in distinguishing MS and SVD brain lesions has the potential to revolutionize clinical practice by enhancing diagnostic accuracy and streamlining patient care for these neurological conditions.

## R2-SPNR-13 PERFORMANCE AND VALIDATION OF A MACHINE LEARNING-BASED ANEURYSM DETECTION TOOL IN THE CLINICAL SETTING

Ichiro Yuki (*Abstract Co-Author*) Research Grant, Siemens AG
Daniel S. Chow, MD (*Abstract Co-Author*) Stockholder, Avicenna.ai Medical Imaging ;Consultant, Canon Medical Systems Corporation;Grant, Canon Medical Systems Corporation;Consultant, Cullen & Grandy;Grant, NovoCure Ltd
Stephanie Shieh, RN, MS (*Abstract Co-Author*) Nothing to Disclose
Jennifer E. Soun, MD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Joseph Carbone, MD (*Abstract Co-Author*) Nothing to Disclose
Jacob Schlossman (*Presenter*) Nothing to Disclose

### PURPOSE

Cerebral aneurysm detection on CT angiography (CTA) is essential to prevent subarachnoid hemorrhage due to ruptured aneurysm. This study evaluated the performance of a commercially available CTA aneurysm detection tool in a real-life setting.

### METHODS AND MATERIALS

This was a retrospective, single center study using CTA Head scans performed at a quarternary medical center from 07/01/2023 to 12/31/2023. All scans were processed by Viz Aneurysm, an automated machine learning algorithm for the detection and triage of cerebral aneurysms = 4 mm in size. Ground truth was established by the original radiology report, which was written by a board-certified neuroradiologist and included the Viz Aneurysm performance assessment in its template . Overall performance was evaluated as well as subset analyses based on aneurysm location and size.

### RESULTS

703 CTA Head scans were included in this study, comprising 645 (91.7%) negative and 58 (8.3%) positive aneurysm scans. Viz Aneurysm demonstrated a sensitivity of 96.6%, specificity of 98.1%, and accuracy of 98.0%. Positive predictive value (PPV) was 82.4% and negative predictive value (NPV) was 99.7% percent. Viz Aneurysm detected 8 cases with multiple aneurysms and 21 cases with aneurysms < 4 mm in size. 56 anterior circulation and 9 posterior circulation aneurysms were detected. Missed cases included one case with a 4 mm aneurysm and another with multiple aneurysms.

### CONCLUSION

Viz Aneurysm successfully detected most of the aneurysms in our clinical dataset. This performance was consistent across subset analyses. This tool can augment the radiologist’s diagnostic accuracy in aneurysm detection, potentially allowing for improvements in triage for follow-up care.

### CLINICAL RELEVANCE/APPLICATION

This is one of the first studies to evaluate the performance of a machine learning-based aneurysm detection tool directly in the clinical setting. Future analyses will assess the follow up management of Viz Aneurysm detected cases and provide a cost effective analysis of the tool’s implementation.

## R2-SPNR-14 ARTIFICIAL INTELLIGENCE-ASSISTED VOLUME ISOTROPIC SIMULTANEOUS INTERLEAVED BRIGHT- AND BLACK-BLOOD EXAMINATION FOR BRAIN METASTASES

Kousei Ishigami, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Osamu Togao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kazufumi Kikuchi, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to verify the effectiveness of artificial intelligence-assisted volume isotropic simultaneous interleaved bright-/black-blood examination (AI-VISIBLE) in diagnosing brain metastases.

### METHODS AND MATERIALS

This retrospective study included 20 patients with brain metastases and 20 patients without brain metastases. Seven independent observers (three radiology residents and four neuroradiologists) participated in two reading sessions: in the first session, brain metastases were detected using VISIBLE only; in the second session, the results of the first session were evaluated by adding AI-VISIBLE information. Sensitivity, diagnostic performance, and false-positives/case were evaluated. The diagnostic performance was assessed using figure of merit (FOM) calculated based on jackknife free-response receiver operating characteristics. Sensitivity and false-positives/case were evaluated using McNemar and paired t-tests, respectively.

### RESULTS

The McNemar test revealed a significant difference between AI-VISIBLE and VISIBLE ($p < 0.0001$). Averaged additional reading time with AI session was 95 sec. Significantly higher sensitivity (94.9% ± 1.7% vs. 88.3% ± 5.1%, $p = 0.0028$) and FOM (0.983 ± 0.009 vs. 0.972 ± 0.013, $p = 0.0063$) were achieved using AI-VISIBLE than using VISIBLE only. No significant difference in false-positives/case was observed between with and without AI information (0.23 ± 0.19 vs. 0.18 ± 0.15, $p = 0.250$). With AI assistance, radiology residents were comparable to neuroradiologists in terms of sensitivity and FOM (without AI information: sensitivity, 85.9% ± 3.4% vs. 90.0% ± 5.9%; FOM, 0.969 ± 0.016 vs. 0.974 ± 0.012; with AI information: sensitivity, 94.8% ± 1.3% vs. 95.0% ± 2.1%; FOM, 0.977 ± 0.010 vs. 0.988 ± 0.005).

### CONCLUSION

AI-VISIBLE improved the sensitivity and performance for diagnosing brain metastases.

### CLINICAL RELEVANCE/APPLICATION

Radiologists can identify brain metastases more accurately using AI-VISIBLE. This technology can easily detect brain metastases and thus facilitate prompt treatment.

## R2-SPNR-15 ROBUST MRI BRAIN TUMOR CLASSIFICATION: MITIGATING MOTION ARTIFACTS WITH PHYSICS-BASED AUGMENTATIONS

Beliz Gunel (*Abstract Co-Author*) Nothing to Disclose
Kristen W. Yeom, MD (*Abstract Co-Author*) Nothing to Disclose
Batuhan Sozer (*Abstract Co-Author*) Nothing to Disclose
Peter Chang, MD (*Abstract Co-Author*) Co-founder, Avicenna.ai;Stockholder, Avicenna.ai;Research Grant, Canon Medical Systems Corporation;Speakers Bureau, Canon Medical Systems Corporation;Research Grant, General Electric Company
Kerem Nernekli, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to compare two deep learning (DL) classification models trained using different augmentation techniques: 1) traditional image-based augmentation and 2) physics-based augmentation that takes MRI physics into account. When trained solely on artifact-free data, DL models may become less robust to the challenges encountered in clinical settings, such as motion artifacts. Our goal is to determine whether physics-based augmentation, which simulates motion artifacts by perturbing k-space, produces more robust models and leads to more effective classification under real-world conditions.

### METHODS AND MATERIALS

We used the fastMRI+ dataset, which includes fully sampled k-space data and label annotations for patients. Patients were included if their scans showed either a brain mass or appeared normal; our final study cohort consisted of 51 patients (1187 T1-weighted MRI scans). This cohort was divided into training, validation, and testing sets following a 60-20-20 split. We employed a MONAI 2D ResNet50 architecture for binary prediction of tumor vs non-tumor. The experiment compared two training groups with a single test group. The first training group used image-based augmentation with random rotations. The second group utilized physics-based augmentation, simulating motion artifacts in k-space using the TorchIO library's RandomMotion transform function (number of transforms = 5). Our balanced test set included MRIs with and without motion artifacts. We used five-fold cross-validation to develop five separate models. The PyTorch and frameworks on Python 3.9 were used for model training.

### RESULTS

We assessed the performance of all models using the receiver operating characteristic (ROC) curve. The average area under the ROC curve (AUC) from five-fold cross-validation demonstrated superior performance with physics-based augmentations (AUC of 0.94) compared to image-based augmentations (AUC of 0.82). The model with image-based augmentations achieved an accuracy of 0.63, sensitivity of 0.60, specificity of 0.66, and an F1 score of 0.51. In contrast, the model with physics-based augmentations demonstrated significantly enhanced results: accuracy of 0.92, sensitivity of 0.93, specificity of 0.92, and an F1 score of 0.90.

### CONCLUSION

We demonstrated that physics-based augmentations are superior to traditional image-based augmentations for the classification of brain tumors from MRI scans when motion artifacts are present.

### CLINICAL RELEVANCE/APPLICATION

Training DL models with physics-based augmentation techniques can lead to models that are more robust to common challenges, such as motion artifacts in MRI scans. This, in turn, could pave the way for the wider adoption of DL models in clinical settings.

## R2-SPNR-18 WHITE MATTER HYPERINTENSITIES PREFERENTIALLY ACCUMULATE WITHIN THE BORDER ZONES REGIONS OF THE BRAIN IN HEALTHY INDIVIDUALS

Kevin Whittingstall (*Abstract Co-Author*) Nothing to Disclose
Davy Vanderweyen, MD (*Presenter*) Nothing to Disclose

### PURPOSE

White matter hyperintensities (WMHs) are a common incidental finding on brain MRI, which is often associated with cerebral small vessel disease (CSVD) and tends to increase in severity with age. It is known that they preferentially accumulate in the periventricular white matter, but a more precise topology and chronology of their deposition with age is unknown. We hypothesized that CSVD would preferentially involve brain regions containing mostly microvasculature and with reduced perfusion, such as border zone regions (BZRs).

### METHODS AND MATERIALS

The arterial tree was segmented into anterior (ACA), middle (MCA), and posterior cerebral arteries (PCA) branches using an in-house automatic approach on 3T time-of-flight magnetic resonance angiography from 258 pathology-free cognitively intact participants (OASIS-3 database). BZRs were defined as voxel planes equidistant from two arteries based on distance maps. WMHs were segmented using an automated method. The intersection between WMHs and BZRs was computed and compared to WMHs outside BZRs.

### RESULTS

Mean patient age was 70.8 years old (range 42.7-92.3; SD=8.35). Across subjects, 70% of WMHs were located within 1 cm of the 3D border zone plane. As expected, WMHs burden increased significantly with age, with an average volume of 5.3 mL of WMH for patients <70 years and 14.6 mL for patients >70 years (p=2.6e-18). However, the fraction of WMHs within 1cm of the border zone decreased with age, with 71.1% of WMHs within the BZRs in patients <70 years and 67.6% in patients >70 years (p=0.002).

### CONCLUSION

In healthy subjects, WMHs initially accumulate in BZRs and spread to non BZRs as the disease progresses, pointing to an underlying vascular vulnerability of these regions to chronic ischemic insults. This data can be interpreted as an increased susceptibility of BRZs to CSVD compared to the rest of brain parenchyma, and this may be due to their location at the farthest point from main arteries and its reliance strictly on small vessels for nutrient delivery.

### CLINICAL RELEVANCE/APPLICATION

These insights into this common disease's localization may better explain the spatial distribution of incidental WMHs on brain imaging and provide the radiologist with a more accurate understanding of the distribution and chronology of WMHs. This could allow us to categorize these findings into “typical” disease where WMHs predominates in the BZRs and is more likely caused by CSVD, and “atypical” disease where there are more WMHs outside of the border zones, which could hint to a different etiology responsible for these WMHs, such as multiple microembolic events, which could alter patient treatment. This may also guide future research on WMHs pathophysiology.

## R2-SPNR-2 REDUCING BOTH RADIATION AND CONTRAST DOSES IN 80-KV HEAD AND NECK CT ANGIOGRAPHY WITH VARIOUS STRENGTH DEEP LEARNING IMAGE RECONSTRUCTION: COMPARISON WITH 100-KV CT ANGIOGRAPHY

Yu Chen, MD (*Abstract Co-Author*) Nothing to Disclose
Min Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Jian Wang (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose
Tong Su, MD (*Abstract Co-Author*) Nothing to Disclose
Xinyue Zhang (*Abstract Co-Author*) Nothing to Disclose
Yun Wang (*Abstract Co-Author*) Nothing to Disclose
Jiajing Tong (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the use of 80-kV tube voltage combined with various strengths of deep learning image reconstruction (DLR) in head and neck CT angiography to reduce both radiation and contrast doses, by comparing with 100-kV regular protocol using hybrid iterative reconstruction (HIR).

### METHODS AND MATERIALS

Sixty-six patients were prospectively enrolled and divided into two groups randomly: low-dose group (n=33) with 80-kV, 25ml iodinated contrast agent, noise index (NI) of 15, reconstructed with HIR and DLR at low-, medium- and high-strength (DLR-L, DLR-M, and DLR-H). Regular-dose group (n=33) with 100-kV, 40ml contrast agent, NI of 10, and reconstructed with HIR. The CT attenuation, image noise, signal-to-noise ratio (SNR) of aorta, intracranial and extracranial arteries, brainstem and back muscle, the contrast-to-noise ratio (CNR) of vessels were calculated and compared between two groups. The subjective image quality was evaluated by two radiologists using a 5-point scale.

### RESULTS

Low-dose group significantly reduced contrast dose (37.5% reduction) and radiation exposure (0.41±0.08 mSv VS 1.18±0.12 mSv, P<0.01, 65% reduction) compared to regular-dose group. Compared with HIR of regular-dose group, DLR-H and DLR-M of low-dose group provided significantly lower image noise and significantly higher SNR in vessels (all P<0.05). The CNR of vessels was superior in DLR-H of low-dose group (all P<0.001), equivalent in DLR-M, when compared to HIR of regular-dose group. Subjective image quality score of low-dose group was increase with the improvement of strength and all scores were reach 3 point (DLR-H VS HIR of regular-dose: 3.70±0.81 VS 3.94±0.24, P=0.04) .

### CONCLUSION

The application of DLR in head and neck CTA acquired with 80kV tube voltage and 37.5% lower contrast dose maintained diagnostic image quality while exhibited lower image noise and higher CNR compared to regular-dose with HIR.

### CLINICAL RELEVANCE/APPLICATION

The DLR (especially DLR-H) has great potential to reduce radiation dose and improving image quality in head and neck CTA with 80-kV tube voltage.

## R2-SPNR-4 DETERMINATION OF PATIENT PROGNOSIS BASED ON UNRUPTURED BASILAR ARTERY ANEURYSM MORPHOLOGY BY A NOVEL DYNAMIC PREDICTION MODEL

Wenjun Yao, MD,MD (*Abstract Co-Author*) Nothing to Disclose
Yifan Fu (*Abstract Co-Author*) Nothing to Disclose

Wenxin Wang, PhD (*Abstract Co-Author*) Nothing to Disclose
Wei Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to createan assessment system for predicting the survival of patients with basilar artery aneurysms undergoing endovascular embolization by examiningthe morphological parameters of the aneurysms and surrounding vessels.

**METHODS AND MATERIALS**

A total of 100 consecutive patients who underwent brain computed tomography angiography in the North District of the First Affiliated Hospital of Anhui Medical University from 2019 to 2022 were included in this study, with 42 being exclusion. The retrospective analysis focused on fifty-eight patients who underwent endovascular embolization for basilar artery aneurysm. The survival rate of these patients at three months, six months, and one year after surgery was observed through long-term follow-up. An online dynamic column chart utilizinga proportional hazards regression model (COX model) was developed to predict the survival outcomes of patients with basilar artery aneurysm who underwent interventional embolization. The model's discrimination ability was assessed using the consistency index (C-index) and receiver operating characteristic (ROC) analysis.. Internal validation was performed through bootstrap resampling, and calibration curves were generated. Decision curve analysis (DCA) was employed to evaluate the clinical applicability of the model.

**RESULTS**

Cox regression analysis identified the basilar artery diameter (BA) and the neck of basilar artery aneurysm as significant risk factors impacting the survival following interventional embolization of the basilar artery aneurysm ($P<0.05$). The area under the ROC for BA was 0.745 (95% confidence interval [CI], 1.01-4.45), and that for the neck of basilar artery aneurysm was 0.823 (95% CI, 1.04-6.23). The C-index of the model was 0.805. Furthermore, the DCA curves indicated that the model provided greater net benefit compared to operating on all or none of patients, across a range of threshold probabilities from 0 to100%

**CONCLUSION**

The online dynamic columnar mapping based on basilar artery aneurysm morphology can reliably predict survival in patients undergoing interventional embolization for basilar artery aneurysm.

**CLINICAL RELEVANCE/APPLICATION**

Previous studies have highlighted significant differences in the MCA, internal carotid artery, and BA between patients with and without aneurysms.Vascular morphology, hemodynamics, hypertension, gender, age, smoking, and alcohol abuse are known risk factors in the development and progression of aneurysms. Among these factors, vascular morphological characteristics play an important role in the initiation, formation, and rupture of aneurysms.

## R2-SPNR-5 MYELIN IMAGING IN THE HUMAN BRAIN USING A 3D DOUBLE ADIABATIC INVERSION RECOVERY PREPARED ULTRASHORT ECHO TIME (3D DIR-UTE) SEQUENCE IN MULTIPLE SCLEROSIS

Jiang Du, PhD (*Abstract Co-Author*) Nothing to Disclose
Yajun Ma (*Abstract Co-Author*) Nothing to Disclose
Mahyar Daskareh, MD (*Abstract Co-Author*) Nothing to Disclose
Jiyo Athertya (*Abstract Co-Author*) Nothing to Disclose
Eric Y. Chang, MD (*Abstract Co-Author*) Nothing to Disclose
Soo Hyun Shin (*Abstract Co-Author*) Nothing to Disclose
James Lo (*Presenter*) Nothing to Disclose

**PURPOSE**

This study uses a novel 3D double adiabatic inversion recovery prepared ultrashort echo time (3D DIR-UTE) sequence to map myelin proton fraction (MPF) in patients with multiple sclerosis (MS).

**METHODS AND MATERIALS**

The DIR-UTE sequence utilizes two identical adiabatic full passage (AFP) pulses with carrier frequencies centered on the water peak to invert long T2 magnetization. TI1 is defined by the time between the centers of two AFP pulses, while TI2 is defined as the period from center of second AFP pulse to the center of multispoke acquisition. Three patients with MS diagnosis (54±15 years old, 2 females) and five healthy control participants (31±4 years old, 2 females) were scanned on a 3T clinical scanner (MR750, GE) using an eight-channel head coil. To estimate the MPF, a proton density-weighted UTE (PD-UTE) sequence was scanned in conjunction with DIR-UTE. For the in vivo subject scan, the parameters were as follows: (i) DIR-UTE: TR/TI1/TI2=200/100/47ms, echo time (TE)=0.032ms, flip angle (FA)=20°, number of spokes (Nsp)=5, field-of-view (FOV)=24×24×14.4cm3, matrix=108×108×24, and scan time=20min; (ii) PD-UTE: TR/TE=7/0.032ms, FA=1°, FOV=24×24×14.4cm3, matrix=108×108×24, and scan time=40sec. Regions of interest (ROIs) were manually delineated in eight white matter (WM) regions(the left and right centrum semiovale, periventricular regions, subcortical WM, the splenium and genu of the corpus callosum). Additional ROIs were drawn in lesions which were identified and localized on T2-FLAIR images. An independent t-test was conducted to compare MPF between NWM vs. NAWM, NAWM vs. lesions, and NWM vs. lesions. P values <0.05 were considered significant.

**RESULTS**

Representative images from DIR-UTE and PD-UTE images as well as MPF maps from a healthy control (32-year-old male) and a patient with MS (37-year-old female) are presented. A clinical T2-FLAIR image of the patient is included which shows confluent white matter plaques due to chronic demyelinating disease in the right centrum semiovale. There is an apparent signal loss in this interested region on the corresponding DIR-UTE images, consistent with demyelination. MPF of the normal white matter (NWM) in control brain is 5.42%, which is significantly higher than both NAWM (4.83%) and plaques (2.33%) in MS patients.

**CONCLUSION**

The 3D DIR-UTE sequence provided sufficient long T2 water signal suppression for selectivel myelin imaging in the brain and showed marked MPF reduction in MS lesions and a smaller reduction in NAWM compared with the NWM in volunteers.

**CLINICAL RELEVANCE/APPLICATION**

The proposed 3D DIR-UTE technique enables sufficient long T2 suppression for selective myelin imaging in the human brain. The measured MPF can be a useful biomarker for assessing various demyelinating diseases.

## R2-SPNR-7 AUTOMATED REFORMAT ALGORITHM IMPROVES BRAIN ALIGNMENT TO ENHANCE RADIOLOGIST AND RADIOGRAPHER WORKFLOW EFFICIENCY

Ludovic Sibille (*Abstract Co-Author*) Nothing to Disclose
Ronny Elor (*Abstract Co-Author*) Nothing to Disclose
Joel M. Stein, MD, PhD (*Abstract Co-Author*) Research Grant, Hyperfine Research, Inc;Consultant, Centaur Diagnostics, Inc
Ajit Shankaranarayanan (*Abstract Co-Author*) Employee, Subtle Medical, Inc
Praveen Gulaka, PhD (*Abstract Co-Author*) Employee, Subtle Medical, Inc
Thomas C. Arnold, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Growing demand for radiology services combined with workforce shortages has resulted in increased pressure on radiologists and radiographers for efficiency. Consistent, symmetric image orientation facilitates disease diagnosis and tracking. Poor image alignment necessitates manual realignment, causing workflow disruptions and frustration. Here we introduce an automated machine-learning-based brain alignment algorithm the was recently FDA cleared (K233699) and validate its performance using a diverse dataset.

**METHODS AND MATERIALS**

We analyzed 373 3D brain MRI scans, encompassing T1, T1+Gad, T2, and T2-FLAIR sequences from over 20 centers. Two neuroimaging experts (TCA and PG: 10 17 years experience, respectively) independently labeled four anatomical points (anterior/posterior commissures, left/right eye centers). A third-party neuroradiologist (JMS: 17 years experience) adjudicated cases where labels differed beyond a predetermined threshold (pitch<5°, roll<3°, or yaw<3°). We applied the image reformatting algorithm and compared its output with ground truth alignment to assess pitch, roll, and yaw error.

**RESULTS**

Raters exhibited high consistency, with pitch differing by <2° and both roll and yaw by <0.5°. Input image absolute errors averaged 10.46° ± 7.22° for pitch (-35° to 24°), 2.44° ± 2.10° for roll (-9° to 9°), and 2.95° ± 2.64° for yaw (-17° to 14°). The algorithm reduced absolute error by 77.9% for pitch (to 2.31°), 64.4% for roll (to 0.87°), and 78.1% for yaw (to 0.65°). Summed absolute error improved in 96.8% of subjects by an average of 8.2°. We assessed the impact of large anatomical anomalies on algorithm performance for 3 pathology subgroups: brain tumors (N=24, avg. 34cc, max 129cc), tumor resections (N=24, avg. 37cc, max 81cc), and neurodegenerative disorders (N=90). Pathology groups demonstrated stable performance (pitch: 2.28°, 2.49°, 2.01°, roll: 1.10°, 0.88°, 1.07°, yaw: 0.91°, 0.54°, 0.70°, respectively). Two pediatric subgroups (age 5-11: N=30, age 12-21: N=30) also showed similar performance (pitch: 2.11° 2.83°, roll: 0.73° 0.83°, yaw: 0.73° 0.64°).

**CONCLUSION**

Radiographer and radiologist workflows are frequently disrupted by poor image alignment, which impairs assessments of bilateral symmetry. We presented an algorithm that improved alignment in 96.8% of subjects with an average improvement of 8.2°. The algorithm can preprocess images prior to PACS display, thus eliminating manual reorientation and streamlining radiology workflows.

**CLINICAL RELEVANCE/APPLICATION**

Machine learning algorithms can automate brain alignment to preserve bilateral symmetry, thus eliminating manual reorientation and improving radiographer and neuroradiologist workflows.

## R2-SPNR-8 COMPACTNESS ANALYSIS FROM MAGNETIC RESONANCE RADIOMICS CORRELATES WITH SEIZURE ACTIVITY IN BRAIN ARTERIOVENOUS MALFORMATIONS

Chung-Jung Lin, MD (*Abstract Co-Author*) Nothing to Disclose
Chia-Feng Lu, PhD (*Abstract Co-Author*) Research support, Ministry of Science and Technology
Yong-Sin Hu, MD (*Abstract Co-Author*) Nothing to Disclose
Kang-Lung Lee, MD (*Abstract Co-Author*) Nothing to Disclose
JIH YUAN LIN (*Presenter*) Nothing to Disclose

**PURPOSE**

The assessment of brain arteriovenous malformations through angioarchitectural analysis is inherently subjective. This research aimed to objectively quantify the morphology and signal alterations in both the nidal and perinidal regions using MR radiomics. Additionally, it sought to evaluate the effectiveness of MR radiomics compared to angioarchitectural analysis in identifying epileptic BAVMs.

**METHODS AND MATERIALS**

Between 2010 and 2020, a retrospective study encompassed 111 patients diagnosed with supratentorial BAVMs, categorized based on their initial seizure presentation. Analysis of patients' angiograms and MR imaging aimed to delineate the corresponding angioarchitecture. The BAVM nidus was outlined using time-of-flight MR angiography, while the perinidal brain parenchyma was delineated on T2-weighted images, followed by radiomic analysis. Logistic regression analysis was conducted to identify independent seizure risk factors. Comparative analyses, including ROC curve analysis, decision and curve analysis (DCA), were performed to assess the diagnostic efficacy of angioarchitecture-based and radiomics-based models in detecting epileptic BAVMs.

**RESULTS**

In multivariate analyses, low compactness (OR: 2.27x104, p = .03) and angiogenesis (OR: 5.30, p = .01) were independently associated with a high risk of seizure after adjustment for age, sex, temporal location, and nidal volume. Intraobserver reliability and interobserver reliability of compactness were both 0.94. The AUC for the angioarchitecture-based and MR radiomics-based models was 0.672 and 0.783, respectively. DCA confirmed the clinical utility of the MR radiomics-based model.

**CONCLUSION**

Low nidal compactness and angiogenesis were linked to heightened seizure vulnerability in individuals diagnosed with BAVMs. Utilizing MR radiomics-derived tools offers a noninvasive and objective approach to assess the risk of seizures attributable to BAVMs.

**CLINICAL RELEVANCE/APPLICATION**

A correlation was found between low nidal compactness and elevated seizure susceptibility in individuals with brain arteriovenous malformations. Utilizing MR radiomics presents a promising avenue for noninvasive and objective assessment of seizure risk in BAVM patients.

## R2-SPNR-9 WIDENING THE TREATMENT OF SHALLOW INTRACRANIAL ANEURYSMS WITH INTRASACCULAR FLOW DISRUPTION: PRELIMINARY EXPERIENCE WITH THE FLAT WEB

Francesco G. Garaci, MD (*Abstract Co-Author*) Nothing to Disclose
Noemi Pucci (*Abstract Co-Author*) Nothing to Disclose

Francesca Di Giuliano, MD (*Abstract Co-Author*) Nothing to Disclose
Valerio Da Ros (*Presenter*) Nothing to Disclose

**PURPOSE**

Endovascular treatment of intracranial shallow wide-necked aneurysms remains an endovascular challenge. Among intrasaccular devices, the Woven EndoBridge (WEB) effectiveness and safety have been thoroughly assessed in several clinical practice trials and recently new dimensions (6-2 and 7-2 mm) are available on the market. We describe our preliminary experience with the use of the new "flat" WEBs for the treatment of shallow intracranial aneurysms

**METHODS AND MATERIALS**

We retrospectively analyzed data from all patients with intracranial unruptured and ruptured aneurysms treated with 6- and 7-2 mm flat WEB in two institutions between November 2023 and April 2024. Technical success, complications with early clinical and imaging follow-up were assessed

**RESULTS**

7 patients with 7 wide-necked aneurysms were included; one aneurysm was ruptured. All aneurysms involved the anterior circulation. Technical success of embolization was accomplished and no intraprocedural complications occurred. At early follow-up, adequate occlusion was obtained for all treated aneurysms.

**CONCLUSION**

Broad-based aneurysms with unfavorable height and aspect ratio are suitable for endovascular treatment using WEB intrasaccular flow disruption with good safety and feasibility profile. Larger series are needed to confirm their long-term efficacy.

**CLINICAL RELEVANCE/APPLICATION**

This is a preliminary experience with the new generation of intrasaccular device for broad based shallow intracranial aneurysms.

Matthias W. Wagner, MD (*Abstract Co-Author*) Nothing to Disclose
Sara Ketabi, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Detecting the genetic markers of pediatric low-grade glioma (pLGG), the most common brain tumor in children, is crucial for targeted treatment planning. Despite the significant performance of convolutional neural networks (CNNs) in diagnosing these genetic markers from brain magnetic resonance imaging (MRI), these models are not widely used in clinical settings mainly due to the lack of explainability. In other words, the features influencing a model's prediction are not typically understandable to radiologists. Radiology reports can be integrated with MR images to improve CNN explainability. In this study, we propose a multimodal framework to minimize the distance between the MRI and the corresponding report representations and maximize the distance between the mismatched MRI and reports. The learnt MRI representations can then be applied to improve the explainability and performance of pLGG genetic marker classification.

### METHODS AND MATERIALS

The dataset for this REB-approved retrospective study contains 341 FLAIR MR images for pLGG cases aged between 5 and 18, and associated radiology reports. To encode the whole MRI and reports, we apply 3D Residual Network (ResNet), initialized with a set of pretrained weights named “MedicalNet”, and a transformer called Clinical Longformer, respectively. The encoded representations are then compared based on the cosine similarity to adjust their distance. Consequently, similar MRI and report representations would be close to each other, while dissimilar pairs would be far apart. Next, we initialize ResNet with the weights extracted from this framework and fine-tune it on the genetic marker classification task using a subset of 204 MRIs. This subset relates to the two most important pLGG genetic markers, i.e., BRAF fusion and BRAF V600E mutation.

### RESULTS

Using a 5-fold cross validation, we calculated the area under the ROC curve (AUC) and Dice score between the model’s attention maps and manual tumor segmentation masks. The ResNet model initialized with the proposed weights outperforms a baseline classification model trained from scratch, achieving an AUC of 0.877 +/- 0.072 versus 0.748 +/- 0.083. Furthermore, this initialization increases the attention maps Dice score from 2% to 15.8%.

### CONCLUSION

Applying the proposed multimodal framework to the pLGG genetic marker classification significantly outperforms the baseline model, i.e., a 17.2% increase in the AUC. It also boosts the Dice score between the model attention maps and manual segmentation masks by a factor of six, enhancing model explainability.

### CLINICAL RELEVANCE/APPLICATION

The improved performance and explainability of pLGG genetic marker classification will aid in non-invasive tumor prognosis and efficient targeted treatment planning.

## R2-SPPD-2 EXPLORING THE IMPACT OF RADIOLOGY REPORTS ON MRI-BASED CLASSIFICATION OF PEDIATRIC BRAIN TUMOR GENETIC MARKERS

Birgit B. Ertl-Wagner, MD, PhD (*Abstract Co-Author*) Spouse, Employee, Siemens AG
Uri Tabori (*Abstract Co-Author*) Nothing to Disclose
Cynthia Hawkins (*Abstract Co-Author*) Nothing to Disclose
Matthias W. Wagner, MD (*Abstract Co-Author*) Nothing to Disclose
Farzad Khalvati, PhD, MSc (*Abstract Co-Author*) Board of Directors, MESH Scheduling Inc
Sara Ketabi, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Pediatric Low-grade Glioma (pLGG) is the most common brain tumor in children. Detecting pLGG genetic markers can assist in tumor prognosis and targeted treatment planning. The current gold standard for this task is biopsy, which is an invasive procedure. To mitigate the risks associated with

biopsies, convolutional neural networks (CNNs) have been proposed to detect genetic markers from MRI data noninvasively. Nonetheless, the impact of the integration of MR images with radiology reports, as invaluable information sources derived from radiologists' knowledge, on the CNNs prediction performance has yet to be explored. Thus, we concatenate radiology reports with MRI in a multimodal learning framework for diagnosing pLGG genetic markers and compare the predictive performance with that of MRI-based alone CNNs.

**METHODS AND MATERIALS**

Our dataset for this REB-approved retrospective study is related to pLGG cases aged between 5 and 18, containing 3D brain FLAIR MR images, corresponding radiology reports, and genetic marker labels. We used only the cases associated with the two most prevalent genetic marker labels, namely BRAF Fusion and BRAF V600E Mutation, resulting in a total of 204 datapoints. To examine the predictive performance of MR images alone, we trained a 3D ResNet model, initialized with a set of pretrained weights called "MedicalNet", along with a fully-connected (FC) classification layer. Subsequently, we concatenated report representation obtained from a transformer named Clinical Longformer, with image representation extracted from 3D ResNet. Two FC layers were applied on top of the fused representations to map them onto a joint space and perform the classification.

**RESULTS**

Area under the ROC curve (AUC) was used to compare the performance of the two models. Our results indicate that the AUC of the image-based model is 0.79 (±0.101). Applying the proposed multimodal learning framework (MRI and report) improves the classification performance by 0.073, achieving an AUC of 0.863 (±0.114). This demonstrates the significant effect of radiology reports and the interactions between image and text representations on the classification task.

**CONCLUSION**

We developed a multimodal learning framework for classifying pLGG genetic markers, as an important procedure for targeted treatment planning. We trained two separate models on MRI and MRI-report combination and showed that the latter notably enhanced the classification performance, revealing considerable correspondence between the two modalities.

**CLINICAL RELEVANCE/APPLICATION**

Our multimodal framework can serve as a helping hand to radiologists by providing high-performing pLGG genetic marker diagnosis, reducing the need for invasive biopsy and leading to efficient treatment planning.

## R2-SPPH-1 REDUCING RADIATION DOSE AND IMPROVING SPATIAL RESOLUTION USING SUPER-RESOLUTION DEEP-LEARNING-BASED RECONSTRUCTION FOR ABDOMINAL CT: PHANTOM STUDY

Toshinori Hirai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yasunori Nagayama, MD (*Abstract Co-Author*) Nothing to Disclose
Daisuke Sakabe, MS (*Abstract Co-Author*) Nothing to Disclose
Takashi Tsutsumi (*Abstract Co-Author*) Nothing to Disclose
Yutaka Chiba (*Abstract Co-Author*) Nothing to Disclose
Yoshinori Funama, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Super-resolution deep-learning-based reconstruction (SR-DLR) image for the dedicated abdominal region is newly developed and expects the improvement of spatial resolution for lower contrast while reducing radiation dose. This study aimed to examine the image quality of SR-DLR images compared with hybrid iterative reconstruction (HIR) and normal-resolution deep-learning-based DLR (NR-DLR) images at various radiation doses and field of view (FOV) sizes based on the data of the phantom study.

### METHODS AND MATERIALS

A Catphan phantom with an external body ring was utilized and scanned with 320-row multidetector CT (Aquilion ONE GENESIS; Canon Medical Systems, Tokyo, Japan). The CTDIvol for CT scanning was set at 7.9 and 11.0 mGy. All images were reconstructed with filtered back-projection (FBP) and HIR, NR-DLR, and SR-DLR with three noise reduction strengths: mild, standard, and strong at various FOVs. Noise power spectrum (NPS) was computed from all images using a uniform portion of the phantom. The noise magnitude ratio (NMR) and central frequency ratio (CFR) were determined from HIR, NR-DLR, and SR-DLR images relative to FBP images employing NPS. CFR indicates the degree of lower frequency shift for NPS. Task-based transfer function (TTF) with 50 HU contrast was also assessed from all CT images.

### RESULTS

NMR for SR-DLR, HIR, and NR-DLR with mild levels were 0.29 to 0.36, 0.40 to 0.44, and 0.27 to 0.31 at 7.9 mGy and 0.35 to 0.45, 0.46 to 0.76, and 0.32 to 0.39 at 11.0 mGy, respectively. SR-DLR obtained substantial noise reduction compared to HIR and the same level as NR-DLR regardless of noise reduction strengths. The CFR for SR-DLR was reduced with decreasing NMR and a similar tendency to that for NR-DLR. The TTF10% for SR-DLR, HIR, and NR-DLR with mild levels was 0.72 to 0.81 mm-1, 0.66 to 0.72 mm-1, and 0.65 to 0.76 mm-1 at 7.9 mGy and 0.78 to 0.98 mm-1, 0.69 to 0.76 mm-1, and 0.69 to 0.81 mm-1 at 11.0 mGy. The same tendency was achieved at standard and strong levels. Spatial resolution for SR-DLR was superior to HIR and NR-DLR.

### CONCLUSION

SR-DLR images for the dedicated abdomen demonstrate substantial noise reduction while improving spatial resolution, particularly beneficial for smaller FOV.

### CLINICAL RELEVANCE/APPLICATION

SR-DLR images for dedicated abdomen are expected to benefit not only adults but also pediatric patients in particular due to substantial radiation dose reduction and improvement of spatial resolution.

## R2-SPPH-11 IMPACT OF THE COVID-19 PANDEMIC ON RADIATION EXPOSURE OF EMERGENCY PATIENTS

Clemens C. Cyran, MD (*Abstract Co-Author*) Nothing to Disclose
Matthias Klein (*Abstract Co-Author*) Nothing to Disclose
Katharina Schmidt (*Abstract Co-Author*) Nothing to Disclose
Sabine Woellert (*Abstract Co-Author*) Nothing to Disclose
Enrico Schulz (*Abstract Co-Author*) Nothing to Disclose
Jens Ricke, MD, PhD (*Abstract Co-Author*) Research Grant, Sirtex Medical Ltd;Research Grant, Bayer AG;Research Grant, Terumo Corporation;Research Grant, Boston Scientific Corporation
Maria Steinberger (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the impact of the COVID-19 pandemic on the number of emergency CT scans and the resulting radiation exposure of ER patients assessed via the average effective dose.

### METHODS AND MATERIALS

A total of n = 374,694 ER patients were included in this retrospective study. The study cohort was split into two age-related groups: 18-59 years (n = 227,010) and = 60 years (n = 147,684). The study period was divided into 3 phases: pre-pandemic (01/2018-02/2020), pandemic (03/2020-12/2022), post-pandemic (01/2023-12/2023). A total of n = 122,161 ER CT scans were performed during the study period. Radiation exposure was assessed via effective dose calculated as a risk-weighted average of organ doses. The use of a dose management system allowed matching patient data (patient ID, sex, age) and exam data (study ID, date, protocol, effective dose) and focusing on CT scans for selected COVID-19-related suspected diagnoses (stroke, pulmonary embolism (PE)). Differences among groups were assessed via Post-hoc Dunn-Test and effect size via Cohen's d. Index 1 refers to the comparison pre vs pandemic, 2 to pandemic vs post, 3 to pre vs post.

### RESULTS

In the pandemic and post-pandemic phase a significant increase of CT scans per day (n = 54.5 [pre] vs 54.1 [pandemic] vs 63.2 [post], P2,3 < 0.001, 0.5 = d2,3 < 0.8) was observed, with a particular, significant increase in stroke (n = 5.4 vs 5.6 vs 7.5, P2,3 < 0.001) and PE protocols (n = 2.0 vs 2.6 vs 3.7, P1,2,3 < 0.001). The number of CT scans per 100 ER patients increased significantly (n = 31.4 vs 33.3 vs 33.1, P1,3 < 0.001), especially for patients over 60 years (n = 47.1 vs 48.6 vs 49.2, P1,2,3 < 0.001). For stroke (n = 3.1 vs 3.4 vs 3.9, P1,2,3 < 0.001) and PE scans (n = 1.1 vs 1.6 vs 1.9, P1,2,3 < 0.001), a particular, significant increase was observed. The mean effective dose per ER patient due to CT scans showed a significant increase (E = 1.22 mSv vs 1.55 mSv vs 1.56 mSv, P1,3 < 0.001, d1,3 = 0.8) especially for patients over 60 years (E = 2.12 mSv vs 2.51 mSv vs 2.50 mSv, P1,3 < 0.001).

### CONCLUSION

Compared to the pre-pandemic phase, a significant increase of CT scans in ER patients was observed in the pandemic and post-pandemic phase, especially in stroke and PE protocols and for patients over 60 years. This increase was paralleled by a significant increase of mean effective dose per ER patient.

### CLINICAL RELEVANCE/APPLICATION

In the pandemic and post-pandemic phase, a significant increase of CT scans and radiation exposure per ER patient was observed. This finding was particularly significant for stroke and PE protocols, most likely due to the thromboembolic complication profile of COVID-19. In the post-pandemic phase, no significant reduction of ER CT scans was observed so far. An unchanged implicit bias of radiologists and ER physicians may be an influencing factor.

## R2-SPPH-3 INFLUENCE OF RADIATION DOSE REDUCTION AND RECONSTRUCTION ALGORITHMS TO QUANTITATIVE COPD EVALUATIONS ON HIGH-DEFINITION CT WITH SUPER-HIGH-RESOLUTION MODE IN SMOKERS

Yoshiharu Ohno, MD, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

### PURPOSE

High-definition CT (HDCT) with energy integrated detector is clinically available and can provide higher spatial resolution images by high-resolution (HR: 0.5 mm×80 rows/1792 channels) and super-high-resolution (SHR: 0.25 mm×160 rows/1792 channels) modes as compared with conventional multi detector row CTs. The purpose of this study was to determine the influence of radiation dose and reconstruction algorithms to quantitative chronic obstructive pulmonary disease (COPD) evaluation on HDCT with SHR mode in smokers.

### METHODS AND MATERIALS

49 smokers underwent HDCT with SHR mode at standard- (CTDIvol: 9.0±1.8mGy), reduced- (1.7±0.2mGy) and ultra-low-dose (0.8±0.1mGy) levels. All HDCT data were reconstructed with hybrid-type iterative reconstruction (IR), model-based IR and deep learning reconstruction (DLR). Standard protocol in this study was standard-dose HDCT with hybrid-type IR. According to pulmonary function test results, all smokers were divided into five groups as follows: 'non-COPD', 'GOLD I', 'GOLD II', 'GOLD III' and 'GOLD IV' groups. In each smoker, percentages of low attenuation volume within lung (%LAV) and wall area at sixth level bronchi (%WA) were automatically measured by means of our proprietary software. To determine the influence of radiation dose reduction and reconstruction algorithm to quantitative COPD evaluation, each index was correlated between each HDCT and standard protocols by Pearson's correlation. Moreover, paired t-test was performed to compare each index between each HDCT and standard protocols. Furthermore, both indexes on each HDCT protocol were compared among all groups by Tukey's HSD test.

### RESULTS

%LAV (0.97=r, p<0.0001) and %WA (0.92=r, p<0.0001) had excellent correlations between each HDCT and standard protocols, although no significant differences of both indexes were determined. At each HDCT protocol, both indexes of 'non-COPD' and 'GOLD I' groups had significant differences with those of others (p<0.05). Moreover, both indexes of 'GOLD II' group had significant difference with that of 'GOLD III' or 'GOLD IV' groups (p<0.05).

### CONCLUSION

HDCT has little influence of radiation dose reduction and reconstruction algorithm to quantitative CT evaluation of COPD on HDCT with SHR mode in smokers.

### CLINICAL RELEVANCE/APPLICATION

Quantitatively assessed HDCT has little influence of radiation dose reduction and reconstruction algorithm to COPD evaluation in smokers.

## R2-SPPH-5 HOW DOSE METRICS IN COMPUTED TOMOGRAPHY COMPARE TO RADIATION RISK IN BEIR VII

Christiane S. Burton, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Dose metrics in computed tomography (CT) are used to optimize patient exams and justify patient dose. However, these common dose metrics may not consider radiation risk based on age, gender or tissue type. This study compares dose metrics in CT to radiation risk in BEIR Report VII across 18 different CT scanners and 30 protocols.

**METHODS AND MATERIALS**

This study included 200 CT abdomen/pelvis and chest examinations from 30 protocols with techniques listed in Table 1. The 14 scanners' make and model were included in Table 2. Radimetrics (Bayer) was used to calculate organ doses for stomach, colon, liver, lung, breast, bladder. The following dose metrics were considered: relative effective dose (RED), organ dose-based effective dose (ICRP 103), volume computed tomography dose index (CTDIvol), dose-length product (DLP), size specific dose estimate (SSDE) calculated using the effective diameter (ED) and water-equivalent diameter (WED), and organ dose (OD). A linear regression (R2) was applied to compare the dose metrics to the lifetime attributable risk (LAR). The results were characterized in terms of risk sensitivity index (RSI) and risk differentiability index (RDI).

**RESULTS**

The R2 correlation between RED and LAR was 1.0 for all organs analyzed. RED also showed the best correlation in terms of RSI and RDI. The RSI ranged from 0.02 for CTDIvol and 1.0 (RED). RDI ranged between 0.00 (RED) and 0.92 (CTDIvol) cancers × 105patients/100 mGy. For patients of the same gender, similar age, and similar girth, the CTDIvol could differ by a factor of 4 between scanners.

**CONCLUSION**

The dose metrics attributed to risk of a population may lead to different characterizations. RED demonstrated the strongest correlation and differentiability between populations, whereas common dose metrics such as CTDIvol, DLP, and SSDE did not. When justifying dose or optimizing CT protocol, there should be more caution when attributing the radiation risk dose metrics that are unrepresentative of risk.

**CLINICAL RELEVANCE/APPLICATION**

Medical physicists and radiologists should be cautious about attributing dose metrics to radiation risk in order to justify and optimize protocols.

## R2-SPPH-6 RADIATION DOSE MANAGEMENT IN PEDIATRIC HEAD CT AT A DEDICATED CHILDREN'S HOSPITAL AND REGIONAL GENERAL HOSPITALS

Elena Tonkopi, MS (*Abstract Co-Author*) Nothing to Disclose
Jessica Kimber (*Abstract Co-Author*) Nothing to Disclose
Tahani M. Ahmad, MD (*Abstract Co-Author*) Nothing to Disclose
Catherine Gunn, MBA, RT (*Abstract Co-Author*) Nothing to Disclose
Yulia Kotlyarova (*Abstract Co-Author*) Nothing to Disclose
Megan Iwaskow, BSc, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare radiation doses and image quality from pediatric head CT examinations performed at a children’s hospital and general regional hospitals in Nova Scotia, Canada, and to establish provincial diagnostic reference levels (DRLs).

**METHODS AND MATERIALS**

Data were collected from five scanners in three hospitals including a pediatric facility. For comparison with published data, the patients were grouped by age: <1, 1-5, 6-10, and 11-15 years old. Most examinations were from 2020-2023 with some studies dating back to 2016 due to insufficient number of pediatric cases from general hospitals. The sample size from each scanner included 4-30 patients under 1 year and 13-30 cases in other age groups. Volume CT dose index (CTDIvol) and dose-length product (DLP) were retrospectively extracted from PACS. Provincial DRLs were established as the 75th percentile of the dose distributions and modeled as a continuous function of patients’ AP thickness using quantile regression for the 75th percentile. To evaluate image quality, samples of 25 studies from each scanner were randomized and blinded for review by a pediatric neuro-radiologist. Images were graded using a 4-point Likert scale (excellent, good, suboptimal, non-diagnostic) in 7 categories including GM-WM differentiation in the posterior fossa and supratentorial regions, bony detail, sharpness of subarachnoid spaces, reduction of image noise and reduction of artifact. Differences in the scores and radiation doses between scanners were assessed using the Kruskal-Wallis test with $p<0.05$ denoting statistical significance. Ordinary Least Squares (OLS) regression with robust standard errors was used to determine the effect of DLP values on total quality scores.

**RESULTS**

Dose survey included 358 studies, 125 of which were assessed for image quality. Provincial DRLs were established as discrete quantities in each age group and modeled as $DLP=142.3 \bullet e0.093 \bullet AP$. Differences in dose indices between scanners were statistically significant for all age categories, and median dose values obtained from the pediatric hospital were highest in the province for patients <1 year and 1-5 years old. Results of image quality evaluation demonstrated significant differences in distributions of total scores between all scanners; however, the OLS regression indicated that the impact of DLP on total score is insignificant for each scanner, showing joint p-value=0.783.

**CONCLUSION**

The study determined provincial DRLs in pediatric head CT and demonstrated potential for dose optimization without affecting image quality.

**CLINICAL RELEVANCE/APPLICATION**

The increased vulnerability to stochastic effects of radiation in children emphasizes the clinical need for pediatric-specific DRLs to inform dose-optimized CT imaging.

## R2-SPPH-7 BODY CT EXAMINATIONS IN ONCOLOGIC PATIENTS: THE IMPACT OF SUBSPECIALTY RADIOLOGY ON RADIATION EXPOSURE IN THE CLINICAL PRACTICE. A QUALITY CARE STUDY

MATTEO MERLI (*Abstract Co-Author*) Nothing to Disclose
Andrea D'Ermo (*Abstract Co-Author*) Nothing to Disclose
Luca Bellesi, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The primary objective of this retrospective study was to assess whether the CT dose delivered to oncologic patients was different in a subspecialty radiology department, compared to a general radiology department. The secondary explorative objective was to assess whether the objective image quality of CT examinations was different in the two settings.

**METHODS AND MATERIALS**

Chest and abdomen CT scans performed for oncologic indications were selected from a general radiology department and a subspecialty radiology department. By using a radiation dose management platform, we extracted and compared CT dose index (CTDIvol) and dose length product (DLP) both for each phase and for the entire CT exams. For objective image quality evaluation, we calculated the signal-to-noise ratio (SNR) and the contrast-to-noise ratio (CNR) at the level of the liver and of the aorta. A P-value $< 0.05$ was considered significant.

**RESULTS**

A total of 7098 CT examinations were included. CTDIvol was evaluated in 12,804 phases; DLP in 10,713 phases and in 6714 examinations. The CTDIvol and DLP overall were significantly lower in the subspecialty radiology department compared to the general radiology department CTDI median (IQR) 5.19 (3.91-7.00) and 5.51 (4.17-7.72), DLP median and IQR of 490.0 (342.4-710.6) and 503.4 (359.9-728.8), $p < 0.001$ and $p = 0.01$, respectively. The objective image quality showed no significant difference in the general and subspecialty radiology departments, with median and IQR of 4.03 (2.82-5.51) and 3.84 (3.09-4.94) for SNRLiv ($p = 0.58$); 4.81 (2.70-7.62) and 4.34 (3.05-6.25) for SNRAo ($p = 0.30$); 0.83 (0.20-1.89) and 1.00 (0.35-1.57) for CNRLiv ($p = 0.99$); 2.23 (0.09-3.83) and 1.01 (0.15-2.84) for CNRAo ($p = 0.24$) with SNRLiv ($p = 0.58$), SNRAo ($p = 0.30$), CNRLiv ($p = 0.99$) and CNRAo ($p = 0.24$).

**CONCLUSION**

In a subspecialty radiology department, CT protocols are optimized compared to a general radiology department leading to lower doses to oncologic patients without significant objective image quality degradation.

**CLINICAL RELEVANCE/APPLICATION**

The Ri-organization of subspecialty radiology give the opportunity to compare the CT doses and image quality delivered to patients enabling reductions of the amount in ionizing radiation to patients while improving image quality.

## R2-SPPH-8 ASSESSMENT OF ORGAN DOSE THROUGH MONTE CARLO SIMULATION IN CT AUTOMATIC TUBE CURRENT MODULATION

Yoshinori Funama, PhD (*Abstract Co-Author*) Nothing to Disclose
Hiroyuki Ikenaga, RT (*Abstract Co-Author*) Nothing to Disclose
Hiroyasu Sanai, RT (*Abstract Co-Author*) Nothing to Disclose
Tsutomu Tamada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Takanori Masuda, PhD (*Abstract Co-Author*) Nothing to Disclose
Ryo Moriwake, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Monte Carlo simulation are commonly used for estimating organ doses in computed tomography (CT) examinations, however the precision of such as the calculated values remains uncertain. Therefore, we competed the radiation dose between organ dose characteristics derived from dose control simulation system and the actual measured values obtained through calculation with a fluorescent glass dosimeter inserted into a RANDO phantom.

**METHODS AND MATERIALS**

An Aquilion Prime SP (Canon Medical Systems) X-ray CT system was used in this study. The radiation dose was compared based on the calculated values from the simulation software of Radimetrics (Bayer Yakuhin) and the measured values from 65 GD-352M fluorescent glass dosimeters (AGC Techno Glass) inserted at each organ location (23 sites) in the RANDO phantom (The Phantom Laboratory). The measurement conditions were as follows: tube voltage 120 kV, X-ray beam width 0.5 x 80 mm, S-FOV 50 cm, and imaging slice thickness 5 mm. The scan range was 625 mm from the chest to the pelvis. The scan method was the helical scan, and 10 consecutive scans were taken using automatic tube current modulation. Image noise (standard deviation: SD) was performed at 8. The measurement process was repeated thrice, and the resulting values were averaged to obtain the final average value.

**RESULTS**

The simulated organ doses ranged from 0.33 to 27.42 mSv, while the measured doses ranged from 0.49 to 48.20 mSv, with mean values of 18.82 mSv. The relative error of the simulation compared to the measured values was -10.17%, with an absolute value of 20.66%.

**CONCLUSION**

When comparing the simulation-based organ doses with the measured values, we found a relative error of -10.17%. However, the absolute value of the relative error was larger, at 20.66%.

**CLINICAL RELEVANCE/APPLICATION**

In this study, we employed an 80-row MDCT, a novel addition not previously explored in similar research, alongside a Radimetrics dose management system. Furthermore, we expanded the scope to include 23 target organs, encompassing the entire trunk of the body. This approach provided valuable insights into the disparities between simulation software predictions and actual measured values. Armed with this understanding of the associated errors, simulation software can be utilized to assess organ doses for individual patients and effectively manage doses based on accumulated data.

## R2-SPRO-1 OPTIMIZING MR IMAGING IN HEAD AND NECK RADIATION THERAPY: A COMPARATIVE STUDY OF A NEW FLEXIBLE COIL SET-UP FOR IMPROVED SIGNAL-TO-NOISE RATIO

Evy Nostvold (*Abstract Co-Author*) Nothing to Disclose
Helge Aurdal (*Presenter*) Nothing to Disclose

### PURPOSE

High precision modern radiation techniques require precise target definition to fully realize their potential for improving radiation therapy outcomes. In head and neck (HN) cancer, MRI provides superior soft tissue contrast, thereby increasing target definition. However, MRI in the context of radiation therapy for HN cancer is challenging. HN coils are typically heavy, non-flexible and cannot be placed directly onto the patient's radiation therapy mask. The standard set-up is to place the coil in a holder above the patient, which creates a distance from the coil elements to the patient and lowers the signal-to-noise ratio (SNR). The new coil set-up in this study uses a lightweight, flexible coil that can be fitted to the patient's mask. This should result in images with higher SNR. This study aimed to compare the SNR between a standard set-up with the coil above the mask and a new flexible coil set-up fitted to the mask.

### METHODS AND MATERIALS

In a clinical 3T MRI system, T2w images were acquired on a phantom and a volunteer using the standard set-up with the coil above the mask, and the new coil set-up with the flexible coil fitted to the mask. T2w offers the best soft tissue contrast for anatomy and thin 3D slices are well suited for image fusion with CT, therefore we selected an axial spin echo 3D T2w sequence with 1 mm isotropic resolution. The 3D spin echo sequence utilizes parallel imaging. Thus, we measured the SNR using the subtraction method described by Goerner and Clarke (2011). The subtraction images and measurements were conducted using a clinical standard tool in PACS (Sectra). The measurements were done in vertebra C4.

### RESULTS

Visual inspection of the MR images, both on the phantom and the volunteer, demonstrated a higher signal when using the new coil set-up. Furthermore, the subtraction images showed a lower noise level than the standard set-up. In the phantom, the new coil set-up achieved a 2.1 times higher SNR than the standard coil set-up. Similarly, in the volunteer, the new coil set-up achieved a 2.0 times higher SNR than the standard coil set-up.

### CONCLUSION

The new flexible HN coil set-up improves the SNR by a factor of two compared to the standard coil set-up.

### CLINICAL RELEVANCE/APPLICATION

Improved SNR can be translated to shorter scan times or higher image resolution. The MRI procedure, which requires the patients to wear a mask with a coil on top, is uncomfortable and claustrophobic. Therefore, a scan time as short as possible is highly desirable. However, development towards more conformal radiation therapy, such as stereotactic radiotherapy and proton therapy, require increasingly more accurate tumor delineation. With improved SNR, better image resolution is feasible without increasing the scan time.

## R2-SPVA-2 GOLDEN-ANGLE RADIAL SPARSE PARALLEL (GRASP) MR ANGIOGRAPHY FOR ENDOLEAK EVALUATION AFTER ENDOVASCULAR REPAIR OF THE AORTA: A PROSPECTIVE COMPARISON TO CONVENTIONAL TIME-RESOLVED MRA

Ulrich Grosse, MD (*Abstract Co-Author*) Nothing to Disclose
Haidara Al Mansour, MD, MEng (*Abstract Co-Author*) Nothing to Disclose
Christoph P. Artzner (*Abstract Co-Author*) Nothing to Disclose
Gerd Groezinger (*Abstract Co-Author*) Nothing to Disclose
Sven S. Walter, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Keyhole sampling of the k-space may mask smaller vessels particularly in peripheral anatomic regions. The purpose was to assess the feasibility of radial GRASP sequence (Golden-angle RAdial Sparse Parallel) in patients with inconclusive post-endovascular aortic repair (EVAR) endoleak status compared to the conventional TWIST (Time-Resolved angiography With Interleaved Stochastic Trajectories) MRA.

### METHODS AND MATERIALS

The prospective study enrolled adults with inconclusive findings regarding endoleak presence in multiphasic CT following EVAR for abdominal aortic aneurysm. Participants underwent contrast enhanced MRA with dynamic TWIST and GRASP sequences. Two independent radiologists assessed for image quality, diagnostic confidence, and the presence and type of endoleak. One reader performed quantitative assessment for signal-to-noise ratios (SNR) and contrast-to-noise ratios (CNR) in both sequences. Statistical analyses included interrater and intermethod agreement, and diagnostic performance testing.

### RESULTS

Twenty participants (mean, 72±9 years; 13 males) were included. Overall image quality was significantly better for GRASP than TWIST sequences (median: 1 [IQR: 1, 2], 2 [IQR: 2, 3]; P<.001) with predominantly absent motion artifacts (median: 1 [IQR: 1, 2], 3 [IQR: 3, 4]; P<.001) and very good interreader agreement (k=0.82 [95% CI:0.57, 1.0]). Diagnostic performance significantly improved for detecting type II endoleak with GRASP compared to TWIST (AUC: 0.96 vs 0.73; P=.04). Although diagnostic accuracy improved with GRASP for overall endoleak detection (AUC: 0.94 vs. 0.79) and endoleak type I detection (AUC: 1.0 vs. 0.90), the results were not significant (P=.08). Sequences performed the same for type III endoleaks (P=1.0). Interrater agreements for endoleaks in general, type I and type II endoleaks were higher for GRASP (k=0.89) than TWIST (k=63). TWIST sequences had significantly higher SNR for measurements in the clotted aneurysm sac (P=.01). However, measurements in the aorta and, if present, in the perfused aneurysm sac did not show significant differences (P=n.s.).

### CONCLUSION

Compressed sensing dynamic GRASP sequence provides superior subjective image quality and diagnostic confidence. It also outperformed the conventional dynamic TWIST sequence in detecting type II endoleaks. Furthermore, our results suggest that the GRASP sequence improves diagnostic accuracy for endoleaks in general and type I endoleaks.

### CLINICAL RELEVANCE/APPLICATION

Clinical precision of post-EVAR endoleak surveillance can be enhanced by utilizing GRASP MRA, providing detailed images with excellent image quality and blood flow dynamics around the stent graft. Thus, aiding in accurate detection and management of endoleaks.

## R5A-SPBR-1 ENHANCING RADIOLOGY RESIDENT TRAINING IN MAMMOGRAM INTERPRETATION: LEVERAGING GLOBAL MAMMOGRAPHIC RADIOMIC FEATURES TO IDENTIFY DIFFICULT CASES

Patrick C. Brennan, BS, PhD (*Abstract Co-Author*) Director, DetectED-X
Ziba Gandomkar (*Abstract Co-Author*) Nothing to Disclose
Somphone Siviengphanom (*Abstract Co-Author*) Nothing to Disclose
Sarah J. Lewis, PhD, MEd (*Abstract Co-Author*) Nothing to Disclose
Phuong Dung Trieu, PhD (*Abstract Co-Author*) Nothing to Disclose
Moayyad E. Suleiman, PhD (*Presenter*) CTO, DetectED-X

### PURPOSE

Radiology residents (RRs) have limited capability for global image processing. To accelerate and enhance trainee learning, identifying global image features in an image that make a normal case difficult to interpret for a trainee is of significant interest to radiology educators. This study therefore investigates whether difficult-to-interpret normal, cancer-free cases for RRs can be distinguished from easy-to-interpret cases using global mammographic radiomic features (GMRFs).

### METHODS AND MATERIALS

A set of retrospective de-identified reading data consisting of 280 normal screening mammographic cases from 137 RRs was utilized. These cases were categorized into difficult- vs. easy-to-interpret normal cases (70 cases each) based on the 75th and 25th percentiles of the cases containing the respective highest and lowest difficulty scores (i.e., percentage of incorrect reports per case). Thirty-four quantitative global radiomic features of images, extracted from a previous study, were investigated for the 140 difficult- and easy-to-interpret categories of normal cases. The GMRFs were then used to build a random forest machine learning classifier for predicting difficult- from easy-to-interpret normal cases of radiology trainees. The model was trained and validated using leave-one-out-cross-validation approach. The performance of the model was assessed using the area under the receiver operating characteristic curve (AUC).

### RESULTS

The model achieved an AUC of 0.75 (95% CI: 0.67-0.83), indicating the effectiveness of GMRFs in distinguishing difficult from easy-to-interpret cases for RRs. Significant differences in 15 out of 34 features were observed, with cluster prominence and range emerging as key predictors.

### CONCLUSION

GMRFs show promise in improving and accelerating RRs' interpretation skills and facilitating personalized training programs for mammogram interpretation. This approach may reduce false positive errors and enhance RRs' expertise in breast cancer screening.

### CLINICAL RELEVANCE/APPLICATION

Global mammographic radiomic features offer a valuable tool for facilitating the tailoring radiology resident’s education and help build required global image processing skills.

## R5A-SPBR-10 A PRELIMINARY STUDY USING DIGITAL BREAST TOMOSYNTHESIS (DBT) RADIOMICS COMBINED WITH CLINICAL INFORMATION IN PREDICTING BENIGN AND MALIGNANT BREAST MASSES

Huizhi Cao (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the predictive value of digital breast tomosynthesis (DBT) radiomics combined with clinical data for preoperative differentiation of benign and malignant breast masses.

### METHODS AND MATERIALS

A retrospective analysis included 381 patients with single breast mass-type lesions enrolled between March 15, 2023, and November 15, 2023. Clinical and imaging features were collected, followed by univariate and multivariate logistic analyses. Radiomics features were extracted from synthesized 2D and DBT images of CC and MLO views. Features were standardized, and model selection algorithms identified stable and optimal features for constructing different prediction models: a synthetic 2D imaging omics model (Model 1), a DBT-based imaging omics model (Model 2), and a combined DBT + clinical factors model (Model 3). Model performance was assessed using AUC, decision curve analysis, and calibration curves.

**RESULTS**

AUCs for Models 1, 2, and 3 were 0.75 (95% CI: 0.63-0.87), 0.83 (95% CI: 0.75-0.92), and 0.94 (95% CI: 0.88-0.99), respectively. Model 3 exhibited significantly better diagnostic performance than Models 1 and 2 (P < 0.05). Model 2 demonstrated higher AUC, accuracy, sensitivity, and specificity compared to Model 1. Calibration curves indicated good agreement between predicted and actual outcomes for all models, and decision curves demonstrated high clinical utility for predicting benign and malignant breast masses.

**CONCLUSION**

DBT-based radiomics models outperformed synthetic 2D models in predicting benign and malignant breast masses. The combined DBT imaging features with age and mass morphology yielded the highest performance, with superior AUC, accuracy, sensitivity, and specificity. These findings offer valuable insights for preoperative prediction of breast mass pathology.

**CLINICAL RELEVANCE/APPLICATION**

DBT-based radiomics combined with clinical information can provide clinical value for predicting benign and malignant breast mass before clinical operation.

## R5A-SPBR-3 PREVALENCE OF BREAST ARTERIAL CALCIFICATIONS VARIES BASED ON ETHNICITY AND BREAST DENSITY

Alyssa T. Watanabe, MD (*Presenter*) Officer, CureMetrix, Inc;Stockholder, CureMetrix, Inc

**PURPOSE**

We examine the prevalence of BAC and its dependency on age, breast density and ethnicity, using an artificial intelligence (AI) based device for detection and localization of BAC ion mammograms.

**METHODS AND MATERIALS**

A retrospective study analyzed a dataset of 20,029 mammograms collected from four sites in various geographic locations from 2005 to 2019. Patients' ages ranged from 40 to 89, (median age,56). The AI device (cmAngio, San Diego, CA) assessed the prevalence of BAC. Data extraction from clinical reports utilized the generative AI model, LLAMA. Two-sided proportion tests evaluated the statistical significance of BAC prevalence differences across age, ethnicity, and density groups, while one-sided pairwise proportion tests examined specific comparisons between these groups.

**RESULTS**

The BAC prevalence rate was 19.8%. breast density and ethnicity. BAC prevalence ranged 15.4% to 28.8% across sites, increasing significantly across age groups (8% in 40-49, up to 67% for patients aged 80-89). Compared with dense breasts, patients with non-dense breasts had significantly higher BAC prevalence 24.2% vs 12.2%, p<0.01). BAC prevalence was lowest in Asians (16.7%), highest in African Americans (23.2%), followed by non-white hispanics (22.5%) and whites (20.1%) (p for comparison <0.001). Variations in BAC prevalence across ethnicities could be linked to differences in average breast density among these groups. There were notable ethnic differences in breast density: proportion of dense breasts in Asians (64%), African Americans (27.6%), non-white Hispanics (38%) and whites (44%).

**CONCLUSION**

BAC prevalence increases with age, BAC varies significantly between ethnic populations with highest BAC in African American and non-white Hispanics. Given established ethnic disparities in cardiovascular disease, assessment of BAC in different ethnic groups may have additive value as a personalized risk marker for future CVD. BAC prevalence is lower with high tissue density which could be due to many potential variables.

**CLINICAL RELEVANCE/APPLICATION**

Disproportionately high CVD event rates are seen in certain ethnic minority subgroups who may have limited access to healthcare. Reporting BAC presence on screening mammograms provides an opportunity for earlier identification of at-risk patients, patient education, and consideration of lifestyle modifications.

## R5A-SPBR-4 HABITAT-BASED ANALYSIS OF MRI INTRA-TUMORAL PERFUSION HETEROGENEITY PREDICTS HER2-ZERO, -LOW, AND -POSITIVE TERNARY EXPRESSION STATUS IN BREAST CANCER

Xiaowen Liu (*Abstract Co-Author*) Nothing to Disclose
Shuxing Wang (*Abstract Co-Author*) Nothing to Disclose
Jingshan Gong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The novel HER2-directed antibody-drug conjugate (ADC) had showed significant improve outcomes of patients with HER2-low metastatic breast cancers, which made it is necessary to discriminate HER2-zero, HER2-low, and HER2-positive breast cancers. The aim of this study was to explore whether radiomics models derived from imaging habitat to address intra-tumoral perfusion heterogeneity of dynamic contrasted enhanced (DCE) MRI could differentiate these three categories.

**METHODS AND MATERIALS**

This retrospective study included a total of 955 women with breast cancer who underwent MRI at three different centers (Centre A, B, C) between October 2017 and February 2024. Construction of voxel vectors based on three perfusion imaging parameters of dynamic contrast-enhanced MRI wash-in, wash-out and wash-out ratio map. Voxels with similar tumor perfusion imaging vectors were clustered into one group using the K-means method and three habitats were determined. Habitat radiomics features were then extracted for each of the three sub-regions and integrated to develop Habitat model, and a whole tumor model was constructed on the basis of radiomics features derived from the entail tumor. Patients from Center A were used as the training cohort (n=564), while patients from Center B (n=222) and C (n=169) were used as the two external test cohorts, respectively. Habitat and whole tumor models were developed for ternary classification regarding HER2 expression status, respectively. The area under the receiver operating characteristic curve (AUC) was used to evaluate the performance of the models.

**RESULTS**

The Habitat model archived AUC of 0.800 (95% CI: 0.740,0.861)for predicting HER2-zero, 0.760 (95% CI: 0.693,0.827)for HER2-low, and 0.770 0.770(95% CI: 0.695,0.845)for HER2-positive in the center B external test cohort, respectively. AUCs of the ternary prediction of the whole tumor model were 0.703(95% CI: 0.735,0.772), 0.663(95% CI: 0.590,0.735), and 0.712(95% CI: 0.633,0.790), respectively. In the Center C external test cohort, AUCs for the HER2-zero, -low, and -positive were 0.802 (95% CI: 0.731,0.873)vs. 0.656(95% CI: 0.571,0.741), 0.739 (95% CI: 0.661,0.817)vs. 0.652(95% CI: 0.566,0.737), and 0.775 (95% CI: 0.694,0.857)vs 0.711(95% CI: 0.627,0.796), respectively.

**CONCLUSION**

A radiomics model based on Habitat analysis of intra-tumoral perfusion heterogeneity could predict the ternary expression status of breast cancer accurately.

**CLINICAL RELEVANCE/APPLICATION**

Harnessing the intra-tumor heterogeneity, Habitat model could archive accurately ternary classifications of HER2 expression status of breast cancer to provide guide for state-of-art HER2-directed therapy.

## R5A-SPBR-5 THE MQSA NATIONAL STATISTIC TRENDS AND WHAT THE FUTURE ENTAILS

Miriam Sklair-Levy, MD, MD (*Abstract Co-Author*) Nothing to Disclose
Eyal Klang, MD (*Abstract Co-Author*) Nothing to Disclose
Larisa Gorenstein, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

In a landmark move for public health, the Mammography Quality Standards Act (MQSA) was established as law on October 27, 1992. The Congress aimed at guaranteeing universal access to high-quality mammography service, to facilitate early detection of breast cancer, thereby improving treatment outcomes by identifying the disease in its most manageable stages. Our objective was to assess the MQSA's national statistics and provide insights.

**METHODS AND MATERIALS**

We accessed the MQSA National Statistics, publicly available on the FDA website (https://www.fda.gov/radiation-emitting-products/mammography-information-patients/mqsa-national-statistics). Available data from 2002 to 2024 was collected. The site was accessed on 04/04/2024, and the data is current to 04/01/2024. We also used state population projections of the CDC, publicly available (https://wonder.cdc.gov/population-projections.html).

**RESULTS**

An average of 382,646,076 mammography procedures were performed between 2004-2023 in an average of 8,752 certified facilities. There was an 8.2% increase in mammography procedures in the last decade, while the projected growth in the number of women in the ages of 40-74 at this period was 11.4%. The maximal number of accredited facilities was 9,306 in 2002 vs 8,834 facilities in 2024. Digital breast tomosynthesis units were first listed in 2016, with an average of 3,711 units, with a steady rise to 12,061 units in 2024, an increase of 325%. The average percent of inspections with no violation ranged between 64.2% and 88.9%, most of the violations were level 2.

**CONCLUSION**

We observed a higher growth rate of women eligible for mammography screening compared to the rate of expansion of mammography units and MQSA-approved facilities. Given these findings, there is a pressing need to prioritize regulatory resources towards the establishment of additional facilities and units.

**CLINICAL RELEVANCE/APPLICATION**

The allocation of regulatory resources towards increasing the number of accredited mammography facilities should be considered.

## R5A-SPBR-6 JOINT BREAST CANCER & CARDIOVASCULAR SCREENING: BEACON STUDY TO ASSESS OPPORTUNISTIC CARDIOVASCULAR SCREENING USING BREAST ARTERIAL CALCIFICATION ON MAMMOGRAPHY

Jean M. Seely, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Elsie Nguyen, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Kaitlin M. Zaki-Metias, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Kate Hanneman, MD, MPH (*Abstract Co-Author*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Vivianne Freitas, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Paula Harvey (*Abstract Co-Author*) Nothing to Disclose
Sandeep Ghai, MD (*Abstract Co-Author*) Nothing to Disclose
Charlotte J. Yong-Hing, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Hayley McKee, MSc, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Breast arterial calcifications (BAC) are incidental findings that are not routinely reported on mammography. Our study aimed to assess the utility of BAC for identifying coronary artery calcium (CAC) on cardiac computed tomography scans in asymptomatic participants undergoing mammography.

**METHODS AND MATERIALS**

Participants undergoing mammography at a single centre were prospectively recruited over 12 months. BAC were qualitatively scored (none/mild/moderate/severe) by two independent breast radiologists. All participants had non-contrast cardiac CT for CAC scoring by the Agatston method within 6 months of mammography. Cardiovascular risk factor data was collected on baseline questionnaires.

**RESULTS**

286 participants were included (median age 61±10). Overall prevalence of BAC was 13% (38/286). For BAC: 248 had none (87%), 18 (6%) had mild, 16 (5%) moderate, and 4 (1%) severe. 180 (62%) had CAC of 0, 70 (24%) had CAC score between 1-99 (mild), 28 (10%) had CAC score between 100-399 (moderate), and 8 (3%) had CAC score >400 (severe). For diagnosis of any CAC, presence of any BAC had high specificity (92%,166/180), low sensitivity (23%,24/106) and moderate positive predictive value (63%,24/38). 59% (14/24) of participants with positive BAC and CAC did not believe they were at higher risk of heart disease and only 8% (2/24) were on lipid-lowering agents.

**CONCLUSION**

We demonstrate low prevalence of BAC that may limit its utility for comprehensive cardiovascular screening during mammography. Though not common, BAC reporting can prompt cardiovascular risk factor assessment and appropriate investigations such as calcium score CT scans. Additionally, interventions such as lifestyle modifications and medical management can be implemented.

**CLINICAL RELEVANCE/APPLICATION**

Few participants with both CAC and BAC were on lipid lowering agents. BAC should be reported on mammography as an opportunistic cardiovascular screening tool given its high specificity to identify those who may benefit from optimal medical management and lifestyle modifications that may help

reduce future cardiovascular events.

## R5A-SPBR-7 ASSESSING THE AVAILABILITY OF MULTILINGUAL & ACCESIBLE MAMMOGRAM INFORMATION IN NORTH AMERICA

Charlotte J. Yong-Hing, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Sonali Sharma, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

Breast cancer screening is crucial for early detection and improved outcomes, and inadequate access to screening information in one's native language not only impedes understanding but also reduces screening participation. This study aimed to assess the availability of multilingual and accessible mammography guidelines on websites across Canadian provinces and territories, and American states.

### METHODS AND MATERIALS

Mammography screening guideline websites in each Canadian province and territory and each American state were evaluated for the availability of information in multiple languages and the presence of accessibility features such as the ability to increase text size, dyslexia-friendly formatting and the use of images/infographics.

### RESULTS

In the evaluation of 200 websites, our analysis highlighted that a significant portion, 58 websites (29%), provided content exclusively in English. Comparatively fewer websites offered multilingual support, with 86 websites (43%) including French or Spanish translations and 94 websites (47%) capable of offering translations into more than four languages. In terms of accessibility, only 42 websites (21%) featured enhancements such as increased text size and dyslexia-friendly formats. A statistical analysis was performed to determine the significance of these variations in translation and accessibility options among the websites. We found statistically significant disparities ($p < 0.05$), indicating that private practice websites are less likely to implement extensive language translation and accessibility features compared to academic websites.

### CONCLUSION

The study highlights a significant need for linguistic inclusivity and accessibility in mammography breast cancer screening. These findings emphasize the need for private practices to enhance their website's accessibility and language support to improve service delivery and patient engagement, which is essential for empowering individuals to understand and participate in breast cancer screening.

### CLINICAL RELEVANCE/APPLICATION

Information that is not accessible or available in a patient's first language can contribute to reduced screening participation, which is a critical factor in detecting breast cancer at an early stage. By prioritizing the translation and accessibility of mammogram information, potentially low screening attendance can be mitigated, leading to improved patient outcomes.

## R5A-SPBR-9 MULTICENTER RADIO-MULTIOMIC ANALYSIS FOR PREDICTING BREAST CANCER OUTCOME AND UNRAVELLING IMAGING-BIOLOGICAL CONNECTION

Weijun Peng, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Jiayin Zhou (*Abstract Co-Author*) Nothing to Disclose
Yajia Gu (*Abstract Co-Author*) Nothing to Disclose
Xu Zhang (*Abstract Co-Author*) Nothing to Disclose
Shiyun Sun (*Abstract Co-Author*) Nothing to Disclose
Chao You, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Radiomics offers a noninvasive avenue for predicting clinicopathological factors. However, thorough investigations into a robust breast cancer outcome-predicting model and its biological significance remain limited. This study develops a robust radiomic model for prognosis prediction, and further excavates its biological foundation and transferring prediction performance.

### METHODS AND MATERIALS

Three breast cancer patient cohorts comprising preoperative dynamic contrast-enhanced MRI were retrospectively collected. In Cohort 1 ($n = 466$), Lasso was used to select features correlated with patient prognosis and multivariate Cox regression was utilized to integrate these features and build the radiomic risk model, while multiomic analysis was conducted to investigate the model's biological implications. Cohort 2 ($n = 619$) and Cohort 3 ($n = 128$) were used to test the performance of the radiomic signature in outcome prediction.

### RESULTS

A thirteen-feature radiomic signature was identified in the Cohort 1 training set and validated in the Cohort 1 testing set, Cohort 2 and Cohort 3 for predicting relapse-free survival (RFS) and overall survival (OS) (RFS: $p = 0.013$, $p = 0.024$ and $p = 0.035$; OS: $p = 0.036$, $p = 0.005$ and $p = 0.027$ in the three cohorts). Multiomic analysis uncovered metabolic dysregulation underlying the radiomic signature (ATP metabolic process: NES = 1.84, $p = 0.02$; cholesterol biosynthesis: NES = 1.79, $p = 0.01$). Regarding the therapeutic implications, the radiomic signature exhibited value when combining clinical factors for predicting the treatment response (Cohort 2, AUC = 0.72; Cohort 3, AUC = 0.73).

### CONCLUSION

A breast cancer outcome-predicting radiomic signature was identified in a multicenter radio-multiomic study, along with its biological significance in prognostic risk assessment, laying the groundwork for future prospective clinical trials in personalized risk stratification and precision therapy.

### CLINICAL RELEVANCE/APPLICATION

Our study presents a robust radiomic model for non-invasively predicting breast cancer outcomes, enhancing the personalization of treatment plans and improving prognostic stratification. By revealing differences in metabolic pathways between high- and low-risk tumor groups, our research suggests potential therapeutic targets, advancing the application of precision medicine in oncology. Additionally, our model showcased its potential for broader clinical implementation by effectively predicting the response to neoadjuvant chemotherapy through the synergistic integration of radiomic risk score and clinical factors.

## R5A-SPCA-1 THE IMPACT OF MATRIX SIZE ON SPATIAL RESOLUTION IN CARDIAC CT WITH ULTRA-HIGH-RESOLUTION PHOTON COUNTING CT

Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation
Audrey Rich, MD (*Abstract Co-Author*) Nothing to Disclose
Friedrich D. Knollmann, MD, PhD (*Abstract Co-Author*) Editor, Reed Elsevier
Harold I. Litt, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV
Peter Makhoul, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Photon counting CT (PCCT) has demonstrated multiple benefits over conventional CT imaging such as decreased radiation dose and higher spatial resolution, including "ultra-high" resolution (UHR) mode with 0.2 mm slice thickness. Coronary CT angiography is an established method for diagnosing coronary artery disease. The use of PCCT for the evaluation of coronary arteries and plaque characterization is currently of interest, though optimal image reconstruction parameters are not fully established. While conventional CT typically uses 512 x 512 matrices, UHR-CT can use higher matrix sizes, including 1024 x 1024 matrices. This study examines the effects of increasing matrix size on spatial resolution under cardiac motion conditions.

### METHODS AND MATERIALS

A cardiac motion simulator (phantom) with a mobile wire was used to replicate a moving coronary artery. Images were taken on a PCCT (NAEOTOM Alpha, Siemens Healthineers) using 512 x 512 and 1024 x 1024 matrices at rest, 75 bpm, and 88 bpm using UHR mode (0.2 mm slices). Parameters included a tube voltage of 120 kVp, field of view of 80 mm, and convolution filter of Bv44u. Images were reconstructed at 10% intervals. A square region of interest was drawn around the wire to include all image artifact and extract the pixel attenuation values. Areas at half maximum attenuation of the point spread function were determined for each reconstruction as a metric of spatial resolution, called dynamic spatial resolution (DSR), and these values were compared after adjusting for pixel size.

### RESULTS

For the non-moving phantom, the DSR was similar for both matrices at 0.974 mm2. At a heart rate of 75 bpm, the DSR was overall similar for both matrices but degenerated to different degrees at different times of the simulated cardiac cycle. Optimal DSR was obtained at a reconstruction of 60%, with a DSR of 1.211 mm2 for both the 512 and 1024 matrices. At a heart rate of 88 bpm, the DSR was also similar for both matrices with varying degeneration across the cardiac cycle. Optimal DSR was obtained at a reconstruction of 50%, with a DSR of 1.766 mm2 for the 1024 matrix and a DSR of 1.817 mm2 for the 512 matrix.

### CONCLUSION

For the imaging parameters and phantom model used, there was no significant difference in optimal dynamic spatial resolution at rest, 75 bpm, or 88 bpm between the 512 and 1024 matrices. There was therefore no benefit to spatial resolution by using the higher matrix size under these conditions.

### CLINICAL RELEVANCE/APPLICATION

Additional investigations are warranted to determine optimal imaging parameters, including matrix size, for coronary artery evaluation with photon counting CT.

## R5A-SPCA-4 FIRST IN VIVO USE OF 1000 FPS HIGH-SPEED ANGIOGRAPHY IN A SWINE MODEL OF CORONARY ARTERY DISEASE

Daniel Bednarek, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Vijay Iyer (*Abstract Co-Author*) Nothing to Disclose
Brian Weil (*Abstract Co-Author*) Nothing to Disclose
Stephen Rudin, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Ciprian N. Ionita, PhD (*Abstract Co-Author*) CEO, QAS.AI;Grant, Canon Medical Systems Corporation
Emily Vanderbilt (*Abstract Co-Author*) Nothing to Disclose
Venkat Keshav Chivukula (*Abstract Co-Author*) Nothing to Disclose
Swetadri Vasan Setlur Nagesh, MS, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the application of 1000 fps high-speed x-ray angiography (HSAngio) to measure dynamic flow through a coronary artery stenosis in swine.

### METHODS AND MATERIALS

A high speed x-ray detector, Aries from Varex Corporation, featuring a 7 cm x 5 cm field of view and 100 µm pixels, capable of 1000 fps acquisition rate, was mounted on a mechanical changer attached to the frontal c-arm of a Canon Medical Infinix biplane system. The detector automatically moves into the FOV for HSAngio imaging when a preprogrammed switch on the c-arm console is engaged. The system's x-ray tube and generator were unmodified. A 125 lbs. swine with chronic stenoses in the proximal left circumflex and left anterior descending arteries each was administered standard doses of heparin and sedated under general anesthesia. A 5F catheter was guided into the left main coronary artery using conventional 10 fps imaging. Subsequently, 1000 fps HSAngio images capturing flow of iodine contrast agent through the left circumflex artery stenosis were acquired. Contrast was injected at 120 ml/min for 0.5 seconds using a MEDRAD injector. Flow velocities were immediately calculated from the HSAngio images using optical flow methods and were made available to the operator performing the procedure.

### RESULTS

The HSAngio images clearly show that, during diastole, a contrast bolus is propelled through the stenotic section in a narrow jet. At the bifurcation, most of the flow divides between the two descending arteries, while a smaller fraction recirculates back toward the stenosis at a reduced pace, creating a disturbance similar to an eddy current. This can significantly affect shear forces on the blood and vessel wall, potentially inducing thrombus formation. Additionally, the velocity profile from the HSAngio images reveals higher velocities up to 40 cm/s within and beyond the stenotic region, as expected.

### CONCLUSION

The results highlight the utility of 1000 fps HSAngio imaging in cardiovascular procedures. The images clearly reveal detailed flow patterns in and around the stenotic region. From these images, velocity profiles distal and proximal to the stenosis are obtainable. These quantitative data can help determine the impact of stenoses on blood flow. Further such research will expand our understanding of HSAngio's applications in both cardiovascular research and clinical practice.

### CLINICAL RELEVANCE/APPLICATION

High-speed angiography at 1000 frames per second captures detailed flow patterns in stenotic coronary arteries, allowing immediate extraction of quantitative data such as flow velocities. This data can potentially aid in assessing the functional impact of a stenosis and diagnosing flow-affecting vascular pathologies such as Coronary Artery Disease (CAD).

## R5A-SPCA-5 INVESTIGATING THE DIAGNOSTIC PERFORMANCES OF CARDIOVASCULAR MAGNETIC RESONANCE IMAGING (CMR) PARAMETERS UTILIZED IN THE MODIFIED LAKE LOUISE CRITERIA FOR DIAGNOSING MYOCARDITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF INDIVIDUAL AND COMBINED CMR PARAMETERS

Latika Giri (*Abstract Co-Author*) Nothing to Disclose
Muhammad Umair, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

This systematic review and meta-analysis aimed to investigate the diagnostic performances of individual and combined quantitative CMR parameters within the framework of the 2018 LLC for myocarditis diagnosis.

### METHODS AND MATERIALS

We included original articles published within the last 10 years utilizing parametric mapping techniques for diagnosis of myocarditis from PubMed. We included data on sensitivity, specificity, and the area under the receiver operating characteristic curve. The data extraction and quality assessment using the Quality Assessment of Diagnostic Accuracy Studies-2 (QUADAS-2) tool were conducted independently by two reviewers. The study protocol was registered in the PROSPERO with registration number: CRD42023484275.

### RESULTS

A total of 11 studies were included in the review, with a total of 788 patients from 11 cohorts. The Native T1 mapping had a sensitivity of 83% (95% Confidence Interval [CI] :78-83), specificity 86% (95% CI: 75-93), DOR 39(95% CI: 21.83 - 72.635) and AUC of 0.91. The T2 mapping had sensitivity 81% (95% CI:73-87), specificity 86% (95% CI: 76-92), DOR 25 (95% CI: 15.11-43.21) and AUC was 0.89. The sensitivity 71 % (95% CI: 62-79), specificity 81% (95% CI: 74-86), DOR 13 (95% CI: 7.39- 19.31) and AUC was 0.83 for ECV. The Native T1 mapping had higher diagnostic accuracy across all index tests. Subgroup analyses with meta regression showed no significant difference in diagnostic odds ratio based on reference standard as either myocardial biopsy or Clinical criteria for native T1 and T2 mapping, and ECV.

### CONCLUSION

The utilization of parametric CMR tests emerges as the optimal strategy for diagnosing myocarditis. The current meta-analysis has defined optimal cut points for ECV for the diagnosis of myocarditis and has shown that sensitivity and specificity is improved by using quantitative mapping techniques, and potentially test combinations.

### CLINICAL RELEVANCE/APPLICATION

Although parametric mapping is widely studied, there is vast heterogeneity in technical parameters, and patient population, hence a meta-analysis is important to combine these results to improve the combined evidence and help guide clinical decision making.

## R5A-SPCA-6 IMPACT OF PHOTON-COUNTING COMPUTED TOMOGRAPHY-BASED VIRTUAL MONOENERGETIC IMAGING ON DETECTING MYOCARDIAL LATE IODINE ENHANCEMENT COMPARED TO CARDIAC MRI

**PURPOSE**

To investigate the image quality and diagnostic performance of photon-counting detector (PCD)-CT-based late iodine enhancement (LIE) at different virtual monoenergetic imaging (VMI) levels in detecting and characterizing myocardial scars, using late gadolinium enhancement (LGE)-MRI as reference.

**METHODS AND MATERIALS**

Patients with various cardiomyopathies who underwent LGE-MRI and same-day research LIE-CT on a PCD-CT system between July 2021 and January 2022 were included in this prospective study. LIE-CT scans were reconstructed at different VMI levels (40, 45, 50, 60, 70, and 90 keV). Two blinded readers evaluated subjective and objective image quality, presence, and pattern of scar on a per-segment level. Measures of diagnostic performance were calculated, and agreement with MRI in scar detection and pattern identification was evaluated with Cohen's ? statistics.

**RESULTS**

The LIE-CT scans of 27 patients (27% male, 52.9±17.2 years) who underwent same-day cardiac MRI were analyzed. VMI at 50 keV demonstrated an adequate trade-off between objective and subjective image quality and exhibited the highest sensitivity, specificity, and accuracy in scar detection, both in per-patient (100%, 93.3%, and 96.3%) and per-segment (87.4%, 97.8% and 95.9%, respectively) analyses, with a strong agreement with MRI in both cases (?= 0.93 and 0.86, respectively). These reconstructions also showed the highest concordance in discriminating different scar patterns. Notably, subepicardial scars and patchy fibrosis had excellent detection rates (100%).

**CONCLUSION**

PCD-CT LIE scans at 50 keV allow for an accurate evaluation of myocardial viability, not only in detecting the scar but also in characterizing different scar patterns.

**CLINICAL RELEVANCE/APPLICATION**

PCD-CCTA combined with LIE-CT holds the potential for becoming an increasingly utilized, noninvasive tool for comprehensive, simultaneous assessment of coronary artery and myocardial disease.

## R5A-SPCA-7 MODIFIED CT TECHNIQUE IMPROVES IMAGE QUALITY AND DIAGNOSTIC ACCURACY IN CARDIAC CONDUCTION DEVICE LEAD PERFORATION

**PURPOSE**

Metallic artifact near the lead tip of cardiac conduction devices (CCD) can limit CT evaluation for lead perforation. This study aims to assess a novel CT technique for improved detection of CCD lead tip perforation.

**METHODS AND MATERIALS**

In this single-center retrospective cohort study, patients who underwent cardiac CT for suspected CCD lead perforation were evaluated, including both standard and modified techniques. The modified technique involved decubitus patient positioning and angulation of the CT gantry to shift metallic artifact away from the lead tip. Three fellowship trained radiologists blinded to identifying information independently reviewed the CTs to determine if the lead had perforated through the right ventricular myocardium and rated image quality and level of confidence on a five-point Likert scale. Diagnostic accuracy for identification of perforation was compared against a reference standard determined by 2 other fellowship-trained readers (18 and 15 years of experience) and all available clinical information. Chi-square tests, Mann-Whitney U tests were performed and inter-rater reliability using Fleiss' Kappa were calculated between the three reviewers for the modified technique compared to standard CT technique from an age-matched control group.

**RESULTS**

Twenty-two patients were included with modified (n=11, 6/11 male, 60.2±10.2 years) and standard CT techniques (n=11, 7/11 male, 60.5±13.0 years). Overall, lead tips were perforated in 14 (8 modified and 6 standard) and non-perforated in 8 (3 modified and 5 standard) patients. Image quality was higher for the modified versus standard technique (3.12±0.29 vs. 2.21±0.47, p<0.001) with moderate agreement among raters (?=0.67). Diagnostic confidence was higher with the modified versus standard technique (4.52±0.34 vs. 3.45±0.57, p<0.001) with good agreement (?=0.75). Diagnostic accuracy was higher with the modified technique (82% accuracy versus 52% for the standard technique, p=0.009).

**CONCLUSION**

With careful manipulation of the patient position to optimize lead position in the gantry as well as adjustment of the gantry angle, we were able to improve image quality and more confidently and accurately identify CCD lead tip perforation.

**CLINICAL RELEVANCE/APPLICATION**

Our modified CT technique can be integrated into routine clinical practice to enhance imaging of CCD lead perforation and improve diagnostic accuracy.

## R5A-SPCA-8 IMPACT OF DEEP LEARNING-BASED NOISE REDUCTION ON LOW-DOSE CORONARY CT ANGIOGRAPHY IMAGE QUALITY AND CORONARY ARTERY DISEASE REPORTING AND DATA SYSTEM ASSESSMENT

Yuki Tanabe (*Abstract Co-Author*) Nothing to Disclose
Tomoro Morikawa, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the effect of deep learning (DL)-based, post hoc noise reduction on image quality, CAD-RADS category assessment, and diagnostic performance in quarter-dose coronary CT angiography (CCTA), using full-dose images as the reference.

**METHODS AND MATERIALS**

In this IRB-approved retrospective study, forty patients (mean age: 71±7 years; 24 males; mean heart rate: 67±10 bpm) underwent ECG-gated CCTA using a third-generation dual-source CT scanner. Depending on the patient's heart rate, CCTA was performed at full dose during either the systolic or diastolic phase, while the alternate phase received a quarter dose. We acquired motion-free coronary images in both phases using an iterative reconstruction method. Additionally, a residual dense network, trained on external datasets, was utilized to denoise the quarter-dose images. Image analyses were conducted to compare the original and denoised quarter-dose images. Firstly, the quality of both the original and denoised quarter-dose images was assessed by comparing noise levels and contrast-to-noise ratios (CNR) in the aorta and coronary arteries using Tukey's test. Furthermore, excluding the myocardial bridge coronary segment, a segment-based evaluation was performed. CAD-RADS classification and diagnostic serial confidence levels were recorded. The consistency of the CAD-RADS classifications, relative to full-dose images, was assessed using Cohen's kappa. The diagnostic performance for identifying significant stenosis, using full-dose images as the reference, was evaluated by comparing the area under the ROC curves (AUC) with the DeLong test.

**RESULTS**

The denoising model reduced noise levels in quarter dose CCTA from 37 to 18HU (P <.001) achieving noise levels comparable to full-dose images (22HU). CNRs were significantly improved (P <.001 for all). Among total 523 segments, denoised images showed better CAD-RADS classification consistency (0.78 [95% CI, 0.72-0.83]) compared to original quarter-dose images (0.64 [95% CI, 0.58-0.70]). Furthermore, denoised images demonstrated superior diagnostic performance in detecting significant stenosis, with a higher AUC (0.97, [95% CI: 0.94-1.00]) compared to original quarter-dose images (0.93, [95% CI: 0.89-0.98]) (P=.03).

**CONCLUSION**

DL-based, post hoc denoising for quarter-dose CCTA significantly reduced image noise, and improved CAD-RADS agreement and diagnostic performance for significant stenosis detection.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning-based post-hoc denoising markedly enhanced image quality and diagnostic accuracy in quarter-dose CCTA. Our method showed promise in reducing radiation exposure without compromising CCTA outcomes.

## R5A-SPCA-9 IMPACT OF DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM ON (80-KV) MYOCARDIAL EXTRACELLULAR VOLUME FRACTIONS CALCULATION

Yuegui Jiang (*Abstract Co-Author*) Nothing to Disclose
Yunlei Chen (*Abstract Co-Author*) Nothing to Disclose
Yuantong Gao, MMedSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the impact of deep learning image reconstruction (DLIR) algorithms on myocardial extracellular volume (ECV) fractions calculation at 80-kV tube voltage.

**METHODS AND MATERIALS**

Consecutive patients who underwent coronary CT angiography (CCTA) at our hospital from February 2024 to March 2024 were enrolled. All patients underwent 256-row CT (GE Revolution APEX) scans including a 120-kV calcium scoring (CS), an 80-kV CS, a CCTA, a 120-kV late enhanced (LE) scan and an 80-kV LE. The CS images and LE images were all reconstructed using filtered back projection (FBP) and H-strength DLIR (DH). CT numbers and standard deviations (SD) of the left ventricular blood pool (LVB), the right ventricular blood pool (RVB) and interventricular septum (IS) were measured in CS and LE images. ECV fractions were calculated using the formula: ECV = (1- hematocrit) * (myocardial CT number in LE - myocardial CT number in CS) / (blood pool CT number in LE - blood pool CT number in CS). Additionally, signal-to-noise ratios (SNR) of LVB, RVB and IS, and contrast-to-noise ratios (CNR) of LVB-to-IS and RVB-to-IS were calculated and compared.

**RESULTS**

A total 80 patients were included. There was a statistically significant difference in the comparison of ECV among the four groups (120-kV DHgt;120-kV FBPgt;80-kV DHgt;80-kV FBP, Plt;0.001), the comparisons of DH versus FBP were not statistically different (for 120 kV and 80 kV, both Pgt;0.05) and the comparisons of 80-kV versus 120-kV were statistically different (for FBP and DH, both Plt;0.05). SNRs and CNRs were all statistically different among the four groups (Plt;0.001), with all of them being maximized by 120-kV DH, followed by 80-kV DH, 120-kV FBP, and 80-kV FBP, respectively (except, CNR of RVB-to-IS between 120-kV FBP and 80-kV FBP).

**CONCLUSION**

Reducing the tube voltage makes the calculated ECV fractions lower, while compared to FBP, DLIR does not interfere with the calculation of ECV fractions. And DH improves the image quality, especially the CNR of LVB and RVB contrast IS, making it easier to recognize the anatomy of the heart.

**CLINICAL RELEVANCE/APPLICATION**

Reducing the tube voltage makes the calculated ECV fractions lower, while compared to FBP, DLIR does not interfere with the calculation of ECV fractions. And DH improves the image quality, especially the CNR of LVB and RVB contrast IS, making it easier to recognize the anatomy of the heart.

## R5A-SPCH-1 OPENRADEVAL: AN OPEN-SOURCE LLM FOR LINE-BY-LINE, CLINICALLY RELEVANT RADIOLOGIST-LEVEL EVALUATIONS IN CHEST X-RAY REPORT GENERATION

Xiaoli Yang (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluating generated radiology reports is fundamental for benchmarking, validating models, and analyzing failure patterns in the development of generative radiology AI systems. An efficient evaluator also opens up opportunities to incorporate reinforcement learning into the development of report generation models. Existing non-LLM metrics are limited because they fail to provide details on the number, location, and significance of individual errors with a single aggregate score for report texts. In this work, we introduce OpenRadEval, an open-source LLM-based evaluator for radiology report generation. OpenRadEval provides line-level evaluations by locating individual errors, identifying their error types, and assessing the severity based on clinical significance levels.

### METHODS AND MATERIALS

There are two parts to our methodology.Clinically relevant evaluation framework for line-level error analysis. We develop a detailed evaluation framework to categorize differences between generated reports and ground-truth reports. This framework classifies differences in each generated report line into four error types based on their causes, such as contradicting findings. It then assigns errors to one of ten severity levels according to the resulting harm to patients clinically. The levels range from minor issues, like “rephrasing with no clinical effects”, to major issues, like “missed or wrong findings with the potential to cause loss of life/organs within a day”.Model training and evaluation. To finetune open-source LLMs to generate evaluations according to our proposed framework, we construct a dataset using 5000 MIMIC-CXR report pairs. We created ground truths for the dataset by prompting GPT-4 to generate pseudo evaluations for these report pairs. We then finetune Mistral-7B on this dataset. The resulting model, named OpenRadEval, is evaluated on ReFiSco-v1, a dataset consisting of line-level radiologist error annotations for 100 report pairs.

### RESULTS

We demonstrate that OpenRadEval achieves evaluation consistency close to that of radiologists. It also exhibits higher consistency in its evaluations compared to evaluation variability among individual radiologists.

### CONCLUSION

This work introduces an efficient line-level evaluation method and tool for radiology report generation and demonstrates radiologist-level performance This proposed method and tool has the potential to greatly reduce costs pertaining to the development of clinically sound report generation models.

### CLINICAL RELEVANCE/APPLICATION

To the best of our knowledge, ours is the first work to provide an open-source LLM evaluator to provide line-by-line error analysis with categories fine-grained enough that align with real clinical setting.

## R5A-SPCH-2 INTRAPULMONARY IMAGING FEATURES OF COMPLEX LYMPHATIC MALFORMATIONS IN THE CHEST

Qi Hao (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze the imaging features of conventional CT of thoracic complex lymphatic malformation (CLA) and explore the differences of the three groups of patients with different types, so as to clarify the diagnostic value of CT in this disease.

### METHODS AND MATERIALS

The clinical and imaging data of 119 patients with CLA were retrospectively analyzed, including 67 patients with GLA, 21 patients with Gorham-Stout disease (GSD), 31 patients with central conduction lymphatic abnormality (CCLA). All patients underwent routine CT and CTL examination, and the pulmonary imaging findings of the three groups were observed, including: ?GGO and morphology; ? peripheral interstitial changes; ? axial interstitial change; ? lung consolidation; (5) Pulmonary nodules; ? Special signs in the lung: a. frog egg sign, b. paving stone sign. Chi-square test or Fisher exact test was used, and Bonferroni test was used for pairwise comparison.

### RESULTS

Among 119 patients with complex thoracic lymphatic malformations, 67 patients had generalized lymphatic malformations (group A), 21 patients had Gorham-Stout disease (group B), and 31 patients had central conductive lymphatic malformations (group C). There were statistically significant

differences in pulmonary GGO (P=0.011) (FIG. 3), peripheral interstitial changes (P=0.013), compression lung consolidation (P=0.012) (FIG. 4) and cystic lung nodules (P=0.017) (FIG. 5) among the three groups, while there were no statistically significant differences in the remaining pulmonary signs. For three groups of patients after comparing the two findings: A group of patients in GGO lungs (P = 0.003), peripheral interstitial changes (P = 0.016) than group B, cyst type lung nodules (P = 0.014), compression type lung consolidation (P = 0.012) than in group C, the difference was statistically significant. There was no significant difference in pulmonary abnormalities between group B and group C.

**CONCLUSION**

The clinical and imaging manifestations of CLA are varied, and there are differences in pulmonary imaging manifestations among different types of patients. CT examination provides valuable imaging information for the diagnosis and differentiation of CLA, which is conducive to further accurate diagnosis and treatment.

**CLINICAL RELEVANCE/APPLICATION**

The clinical and imaging manifestations of CLA are varied, and there are differences in pulmonary imaging manifestations among different types of patients. CT examination provides valuable imaging information for the diagnosis and differentiation of CLA, which is conducive to further accurate diagnosis and treatment.

## R5A-SPCH-3 CT IMAGING OF BRONCHOSPASM IN ANAPHYLAXIS INDUCED BY NON-IONIC IODINATED CONTRAST MEDIA: A COMPARATIVE STUDY

Hidekazu Hattori, MD, PhD (*Presenter*) Research Grant, FUJIFILM Holdings Corporation

**PURPOSE**

Anaphylaxis, as outlined in the 2020 World Allergy Organization Anaphylaxis Guidance, is associated with bronchospasm, yet imaging findings have not been extensively documented. This study aims to compare bronchial lumen changes in patients with and without anaphylaxis caused by non-ionic contrast media using non-contrast-enhanced (non-CE-CT) and CE-CT scans.

**METHODS AND MATERIALS**

During April 2011 and October 2022, 69 cases who underwent non-CE- and CE-CT scans using non-ionic iodine contrast media were included in this study. The 69 cases were divided as follows: 46 patients without anaphylactic symptoms (non-Anaphylactic group), and 23 cases who required initial treatment for anaphylactic reactions (Anaphylactic group). The non-Allergic group was also divided as follows: 23 cases who had no contrast-induced symptoms at the time of CT examination (Normal group), and 23 cases who had mild to moderate allergic symptoms and no need for treatment (Allergic group). The normal group and allergic group were matched to the number of cases in the anaphylaxis group. All non-CE- and CE- CTs were reconstructed into 1mm section thickness and reviewed at lung window setting. The bronchial lumens of the right lung S9 to S10 were labeled by a board-certified radiologist. Then, the total lumen pixel was counted by self-made software for each case. In each patient, luminal change rate between non-CE- and CE-CTs was calculated. To determine the lumen pixel difference between non-CE- and CE-CTs in each group, paired t-test was performed. To compare luminal change rate between non-CE- and CE-CT among all subgroups, Tukey's HSD test was performed.

**RESULTS**

On comparison between non-CE- and CE-CTs, the lumen pixel of CE-CT was significantly smaller than non-CE-CT in the Anaphylactic group ($p<0.05$; p-value =0.0031). On comparison between non-CE- and CE-CTs, the lumen pixel of CE-CT was significantly larger than non-CE-CT in the Normal group ($p<0.05$; p-value =0.016). When comparing the luminal change rate among all subgroups, there was a significant difference between the Anaphylactic group and the Normal or Allergic group ($p<0.05$; p-value =0.00015 or 0.0067).

**CONCLUSION**

This study is the first to report visualization of bronchospasm in CT images of patients with anaphylaxis, adding to existing evidence that this symptom exists in such cases.

**CLINICAL RELEVANCE/APPLICATION**

Peripheral bronchospasm due to anaphylaxis can be demonstrated on CE-CT as compared with non-CE-CT and considered as may be one of the predictors for the onset of anaphylaxis.

## R5A-SPCH-4 DEEP LEARNING CHEST X-RAY AGE: ASSOCIATIONS WITH EPIGENETIC AND CARDIOPULMONARY AGING

Michael T. Lu, MD, MPH (*Abstract Co-Author*) Stockholder, NVIDIA Corporation;Institutional Research Grant, Kowa Company, Ltd;Institutional Research Grant, AstraZeneca PLC;Stockholder, Advanced Micro Devices, Inc;Stockholder, Intel Corporation
Vineet K. Raghu, PhD (*Abstract Co-Author*) Nothing to Disclose
Jay Chandra (*Presenter*) Nothing to Disclose

**PURPOSE**

Chronological age, the years since birth, is a cornerstone of medical decision-making. However, chronological age has limitations as individuals age at different rates. We recently released an open-source deep learning tool to assess biological age from chest radiograph images (CXR-Age), which predicts incident age-related disease better than chronological age. This abstract compares CXR-Age to established epigenetic aging clocks, to see which are more strongly associated with measures of cardiopulmonary disease.

**METHODS AND MATERIALS**

Our cohort consisted of 2,097 participants from the Project Baseline Health Study (PBHS), a prospective cohort study of individuals from four US sites enriched for cardiovascular and cardiometabolic disease risk factors. Each participant had posterior-anterior chest radiograph images and DNA Methylation data which were used to calculate CXR-Age and the Levine and Horvath epigenetic aging clocks, respectively. Linear regressions were used to assess the association of CXR-Age and epigenetic aging clocks with the coronary artery calcium (CAC) score, the 10-year atherosclerotic cardiovascular

disease (ASCVD) risk score, and measures of pulmonary function. Analyses were adjusted for chronological age, body mass index (BMI), sex, smoking status, and recruiting site.

**RESULTS**

There was moderate correlation between CXR-Age and chronological age (r=0.49, 95% CI: [0.47-0.53]), and a high correlation between epigenetic and chronological age (Levine: r = 0.93 [0.92-0.94], Horvath r = 0.95 [0.94-0.96]). There was no significant association between CXR-Age and both Levine age (ß = 0.11 [-0.01 - 0.22]) and Horvath age (ß = 0.02 [-0.07 - 0.11]) after adjusting for covariates including chronological age. Each year of CXR-Age was associated with a 1.13-fold [1.09-1.16] increase in CAC score, while there was no significant positive relationship between epigenetic ages and CAC. Similar trends were seen for the ASCVD risk score. Increasing CXR-Age was associated with worsening pulmonary function measures including FEV1/FVC ratio, DLCO, and FVC, while there was no relationship between epigenetic aging clocks and pulmonary function.

**CONCLUSION**

A deep learning-based CXR-Age was more strongly associated with subclinical coronary atherosclerosis and abnormal pulmonary function testing than two established epigenetic aging clocks.

**CLINICAL RELEVANCE/APPLICATION**

Opportunistic screening using CXR-Age may help identify high risk patients who could benefit from directed screening and prevention.

## R5A-SPCH-6 REVOLUTIONIZING HEALTH ASSESSMENT: THE EMERGENCE OF LDCT IN COMPREHENSIVE DISEASE SCREENING AND BODY ANALYSIS

Chun-Chieh Wang, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Low-dose CT (LDCT) screening is not only a lung cancer detection tool, we can extend the scope of LDCT to establish a comprehensive health assessment tool, incorporating evaluations of emphysema, coronary artery calcification (CAC) score, and body composition analysis (fat, bone density, muscle), as well as diagnosis like osteoporosis, sarcopenia, non-alcoholic fatty liver disease (NAFLD), and metabolic syndrome. This multifaceted approach enhances the value of LDCT in health assessment, clinical applications, and preventive healthcare.

**METHODS AND MATERIALS**

First, a cohort of 916 elderly participants underwent LDCT screening in five hospitals, and were prospectively analyzed. Besides, they received additional tests including laboratory tests, pulmonary function tests, Dual X-ray Absorptiometry (DXA) analysis, handgrip tests, and gaitspeed tests, for validation and training for body AI model. Advanced AI software for lung, was utilized for lung nodule detection, emphysema analysis, and CAC scoring (Big-3). Another AI tool assessed body composition metrics, including bone density, fat, and muscle (Body-3). Recently, another 448 mid-aged healthy participants were enrolled, and received big-3 and body-3 analysis. All these participants may have different data distribution and these data points contributed to the development of a potential health predictive tool.

**RESULTS**

The study observed strong correlation between the CAC score from LDCT and the Agatston score from EKG-gated CAC scans (R2 =.92). Moderate correlation was also noted between emphysema (Low attenuation area, LAA) volume and Forced Vital Capacity (FVC) (R2 =.33). For bone density in body composition, L1 bone HU from LDCT showed strong correlation with bone mineral density (BMD) and T-scores from DXA (R2 =.49). Additionally, the LDCT-based fat HU effectively classified varying degrees of NAFLD. About fat analysis, subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT) had different distribution in different sex. Besides, modified skeletal muscle index (SMI) by body AI was also strong correlated with DXA data (R2 =.53). All these data can give the participants a GOLD-CT Radar Index and an overall personal health profile by LDCT.

**CONCLUSION**

LDCT is not only a lung cancer screening tool, but also has more values to set up a health predictive model for healthy participants, and can be further refined with additional data.

**CLINICAL RELEVANCE/APPLICATION**

1. GOLD-CT Radar Index targets healthy participants, including lung cancer screening and health exam patients. 2. Give the correlation between clinical data (clinical disease) and health index. 3. Develop a predictive model based on GOLD-CT Radar Index, and this AI training model can be improved by enrolling more data.

## R5A-SPCH-7 ASSESSING THE IMPACT OF AI-ASSISTED TRIAGE ON ENDOTRACHEAL TUBE MANAGEMENT: A COMPARATIVE ANALYSIS OF WAIT TIMES

Eric P. Weinberg, MD (*Abstract Co-Author*) Nothing to Disclose
Jerome H. Avondo, PhD (*Abstract Co-Author*) Employee, Aidoc Ltd
Larry Stockmaster, BEng (*Abstract Co-Author*) Nothing to Disclose
Ali Vosoughi (*Abstract Co-Author*) Nothing to Disclose
Akhil Kasturi (*Abstract Co-Author*) Nothing to Disclose
Nathan Hadjiyski (*Abstract Co-Author*) Nothing to Disclose
Axel Wismueller, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the impact of a computer-assisted triage and prioritization artificial intelligence (AI) system in managing patients with misplaced endotracheal tubes (ETT).

**METHODS AND MATERIALS**

A total of 10,709 frontal chest radiographs were analyzed from the inpatient service of a large academic healthcare system between July 1, 2023 and December 31, 2023, using a commercial AI-based image analysis software (Aidoc Medical). A wait time metric was calculated for AI-notified cases with suspected malpositioned ETT findings and compared to negative non-AI-notified cases. Wait time was defined as the difference between the time of study acquisition completion to the time a radiologist opening the case for dictation. The median wait times were calculated for the AI-notified and non-AI-notified cases. A Mood’s median test was used to test for statistical significance.

## RESULTS

The AI solution provided prioritization notifications for 2.77% (297/10,412) suspected positive cases for ETT malpositioning. The median wait time was 32.1 minutes (IQR: 104.2 minutes) for the suspected positive cases compared to 63.2 minutes (IQR: 170.9 minutes) for the suspected negative cases. The observed median wait time reduction was statistically significant (p-value <0.05) at a 49.2% wait time reduction (31.1 minutes).

## CONCLUSION

This study provides compelling evidence that AI-assisted triage systems can play a critical role in enhancing the management of patients with potentially misplaced endotracheal tubes. The significant reduction in wait times for radiological assessment, as demonstrated by the 31.1-minute decrease in median response time, underscores the effectiveness of AI in prioritizing urgent cases in a clinical setting. These results suggest that AI can be a valuable tool in streamlining emergency care processes, ensuring that critical cases receive timely attention, which is paramount in preventing complications associated with delayed ETT repositioning.

## CLINICAL RELEVANCE/APPLICATION

The use of AI for triaging endotracheal tube placements can significantly enhance patient safety by promptly identifying suspected misplacements, thereby minimizing the risk of severe complications.

## R5A-SPER-1 DETECTION OF ACUTE ABDOMINAL AORTIC DISSECTION IN CT IMAGING AS A STRATEGY TO STREAMLINE WORKFLOWS

Frank G. Zoellner (*Abstract Co-Author*) Nothing to Disclose
Anish Raj (*Abstract Co-Author*) Nothing to Disclose
Johann S. Rink, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Life-threatening acute aortic dissection (AD) demands timely diagnosis for effective intervention. Many patients present with unspecific symptoms and due to a lack of prioritization are at risk for suboptimal clinical outcomes. To streamline intrahospital workflows, automated detection of AD in computed tomography (CT) scans seems useful to assist humans. As there are no solutions available for the abdominal region, we aimed at creating a robust convolutional neural network (CNN) based pipeline, capable of real-time screening for signs of AD.

### METHODS AND MATERIALS

In this retrospective study, abdominal CT data from AD patients presenting with AD and from non-AD patients were collected (n=195, AD cases=94, mean age: 65.9 years, female ratio: 35.8%). A CNN-based algorithm was developed with the goal of enabling a robust, automated, and highly sensitive detection of abdominal AD. Two sets from internal (n=32, AD cases=16) and external sources (n=1189, AD cases=100) were procured for validation. The abdominal region was extracted, followed by the automatic isolation of the aorta region of interest (ROI) and highlighting of the membrane via edge extraction, followed by classification of the aortic ROI as dissected/healthy. A 5-fold cross-validation was employed on the internal set, and an ensemble of the 5 trained models was used to predict the internal and external validation set. Evaluation metrics included receiver operating characteristic curve (AUC) and balanced accuracy. The computation time was about 45 seconds on average.

### RESULTS

The AUC, balanced accuracy, and sensitivity scores of the internal dataset were 0.932 (CI: 0.891-0.963), 0.860, and 0.885, respectively. For the internal validation dataset, AUC, balanced accuracy, and sensitivity scores were 0.887 (CI: 0.732-0.988), 0.781, and 0.875, respectively. Furthermore, for the external validation dataset, AUC, balanced accuracy, and sensitivity scores were 0.993 (CI: 0.918-0.994), 0.933, and 1.000, respectively.

### CONCLUSION

The proposed AI pipeline which was trained and validated on heterogenous internal and external data yielded promising results for detection of acute AD in abdominal CT scans, offering potential high generalizability.

### CLINICAL RELEVANCE/APPLICATION

The proposed automated pipeline could assist humans in improving patient triage and to expedite intrahospital AD management workflows. Broad clinical implementation could benefit especially the subgroup of patients which are clinically not suspected with AD before imaging.

Hiroko Ueda (*Abstract Co-Author*) Nothing to Disclose
Yasunori Nagayama, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the impact of body-optimized super-resolution deep-learning reconstruction (SR-DLR) on the image quality of thin-slice multi-phase abdominal CT for the assessment of pancreatic ductal adenocarcinoma (PDAC).

### METHODS AND MATERIALS

This retrospective study included 31 patients (15 men, mean age 71 ± 9 years) with pathologically confirmed PDAC (head, n=17; body, n=12; tail, n=2) who underwent multi-phase pancreatic CT during pancreatic parenchymal phase (PPP) and portal venous phases (PVP) using a 320-row scanner. The images were reconstructed using hybrid iterative reconstruction (HIR), normal-resolution deep-learning reconstruction (NR-DLR), and SR-DLR algorithms with body parameter at a 0.5 mm slice thickness. The matrix size was 512×512 for HIR and NR-DLR and 1024×1024 for SR-DLR. Background image noise and the contrast-to-noise ratio (CNR) of the pancreatic parenchyma, PDAC, arteries, and veins were quantified. The edge rise slope (ERS) was employed to quantify the edge sharpness of superior mesenteric artery during PPP, main portal vein during PVP, and pancreatic parenchyma during both enhancement phases. Image sharpness, noise magnitude, texture fineness, delineation of PDAC, peripancreatic vessels, main pancreatic duct, and diagnostic confidence were visually ranked (1=worst, 3=best) among the three image series.

### RESULTS

Quantitative image noise during PPP and PVP was lowest with SR-DLR (9.2±0.9 and 9.5±0.9 HU, respectively), followed by NR-DLR (10.9±1.1 and 11.4±1.1 HU, respectively) and HIR (14.9±1.7 and 15.8±1.4 HU, respectively), with significant differences among the three series (all $p<0.01$). SR-DLR achieved the highest CNR and ERS for all structures, followed by NR-DLR and HIR, with significant differences between the series (all, $p<0.01$). SR-DLR also attained higher scores for all visual evaluation criteria (median score: 3) than NR-DLR (median score: 2) and HIR (median score: 1) ($p<0.01$).

### CONCLUSION

Compared with HIR and NR-DLR, the novel SR-DLR algorithm enhanced spatial resolution, reduced image noise, and improved the delineation of pancreatic tumors and adjacent structures in thin-slice multi-phase pancreatic CT, thus increasing diagnostic confidence for the assessment of PDAC.

### CLINICAL RELEVANCE/APPLICATION

The recently introduced SR-DLR algorithm optimized for body CT may facilitate a more confident and detailed assessment of PDAC owing to its superior spatial resolution, noise performance, and visibility of tumor and adjacent structures compared to HIR and NR-DLR algorithms.

## R5A-SPGI-10 PREDICTION OF PANCREATIC DUCTAL ADENOCARCINOMA AGGRESSIVENESS USING CT-BASE RADIOMICS

Bachir Taouli, MD (*Abstract Co-Author*) Research Grant, Bayer AG;Research Grant, Takeda Pharmaceutical Company Limited;Consultant, Bayer AG;Consultant, Guerbet SA;Research Grant, Regeneron Pharmaceuticals, Inc
Valentin Fauveau, MSc (*Abstract Co-Author*) Nothing to Disclose
Octavia Bane, PhD, MS (*Abstract Co-Author*) Nothing to Disclose
Kevin R. Adams, MD (*Abstract Co-Author*) Nothing to Disclose
Kazuya Yasokawa, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the role of CT-based radiomics for prediction of outcomes in patients with pancreatic ductal adenocarcinoma (PDAC) who underwent neoadjuvant therapy (NAT) and resection.

**METHODS AND MATERIALS**

This is a single center retrospective study in which a cohort of 94 patients (M/F 42/52, mean age 67.9y) with PDAC who had pre-treatment CT were assessed. The cohort was divided into training and validation (70%/30%). 3D segmentation of the tumors was performed on post-contrast CT (portal venous phase) (Fig. 1) and radiomics features (shape, histogram, and texture features) were extracted from a volume of interest encompassing the tumor. The aggressiveness of PDAC was classified using histopathologic tumor grade (G1-2: well-moderately vs G3: poorly differentiated), and recurrence (absent vs present). The diagnostic performance of radiomics features to identify poorly differentiated tumors and to predict recurrence were assessed with ROC analysis. In addition, hazard ratios (HR) of clinical, CT and radiomics features for prediction of time to recurrence (TTR) and mortality were assessed using Cox uni/multivariate models.

**RESULTS**

Radiomic features predicted G3 tumors with AUC of 0.67 (CI [0.44; 0.89]) in the validation cohort (Fig. 2). CA19-9 combined with radiomics (AUC=0.61, CI [0.37; 0.85]) outperformed radiomics alone for predicting (AUC=0.56, CI [0.33; 0.78]) (Fig.3). Tumor size was predictive of TTR and mortality (HR=1.35, p=0.04 and HR=1.38, p=0.04, respectively), and 1 radiomics feature (Original Shape Compactness 1) was predictive risk of TTR (HR<0.0001, p=0.04). No radiomics features were predictive of mortality.

**CONCLUSION**

Larger tumor size and radiomics may predict TTR, to be confirmed.

**CLINICAL RELEVANCE/APPLICATION**

Tumor size and radiomics based on pre-treatment CT provide information for recurrence in patients with PDAC, which may help with personalized therapy and prognostication.

## R5A-SPGI-12 SPECTRAL CT PARAMETER COMBINATION WITH EXTRACELLULAR VOLUME IN PREOPERATIVE PREDICTION THE STATUS OF COLORECTAL CANCER PERINEURAL AND LYMPHOVASCULAR INVASION

Ting LU (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of spectral CT parameter and extracellular volume fraction (ECV) in the preoperative prediction of perineural invasion (PNI) and lymphovascular invasion (LVI) in colorectal cancer (CRC).

**METHODS AND MATERIALS**

A retrospective analysis was performed for 142 patients with CRC confirmed by postoperative pathology, all of whom underwent full abdominal contrast-enhanced spectral CT scan before surgery. Measure the iodine concentration (IC), standardized IC(NIC), effective-Z (Eff-Z) and extracellular volume fraction (ECV) in arterial phase(AP), venous phase(VP) and delay phase(DP), and compare the differences of various parameters between PNI and LVI group and non-PNI and LVI group. Logistic regression analysis was performed to determine the independent impact factors of CRC-PNI and LVI to construct combined parameters, and the performance of each parameter to distinguish between PNI and LVI group and non-PNI and LVI group individually and jointly was compared using the receiver operating characteristic (ROC) curves.

**RESULTS**

In thes tudy, a total of 142 patients were enrolled, including 80 cases of PNI and LVI, and 62 cases of non-PNI and LVI. The lesions in the PNI and LVI group were greater than those in the non-PNI and LVI group, including ICAP,Eff-ZAP,ICVP,NICVP,ECVVP,ICDP,NICDP,Eff-ZDP and ECVDP, and the differences between the two groups were statistically significant ($P < 0.05$), while the differences between NICAP, ECVAP and Eff-ZVP were not significant ($P > 0.05$). Among the single parameters, ECVDP was the best for predicting PNI and LVI and non-PNI and LVI, and the area under the curve (AUC) was 0.880 ($P <0.001$), which was significantly higher than that of other parameters. Multivariate logistic regression found that ECVDP (OR=1.132, 95%CI: 1.021-1.256, P=0.018) and Eff-ZDP (OR=1.046, 95%CI: 1.015-1.078, P=0.003) were independent risk factors for CRC-PNI, and the combined parameters of ECVDP and Eff-ZDP (AUC=0.902) were constructed. The sensitivity, specificity and accuracy were 95.20%, 73.80% and 83.10%, respectively.

**CONCLUSION**

The combination of spectral CT parameters and ECV can predict PNI and LVI in CRC before surgery. It is expected to promote further research and long-term clinical application of spectral CT in preoperative prediction of PNI and LVI in CRC.

**CLINICAL RELEVANCE/APPLICATION**

CRC-PNI and LVI is an independent risk factor for poor prognosis in CRC patients, but now can only through pathological evaluation of postoperative PNI and LVI. ECVDP and Eff-ZDP based on preoperative spectral CT can distinguish PNI and LVI, is expected to provide convenient and feasible imaging markers for preoperative prediction of CRC-PNI and LVI.

## R5A-SPGI-2 VALUE OF HISTOGRAM QUANTITATIVE SUSCEPTIBILITY MAPPING IN EVALUATING THE PATHOLOGICAL CHARACTERISTIC OF PANCREATIC DUCTAL ADENOCARCINOMA

Fuyao Liu (*Abstract Co-Author*) Nothing to Disclose
Junxin Lv (*Abstract Co-Author*) Nothing to Disclose
Jie Chen (*Abstract Co-Author*) Nothing to Disclose
Jinggang Zhang, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of histogram analysis quantitative susceptibility mapping (QSM) in preoperative prediction of pathological characteristic of pancreatic ductal adenocarcinoma (PDAC).

### METHODS AND MATERIALS

A total of 44 patients with pathologically confirmed PDAC were retrospectively analyzed. All patients underwent QSM and conventional MRI scans. According to the pathological results, they were divided into high-grade group and low-grade group. According to the fibrosis content of tumor tissue, more than 30% was defined as high fibrosis group, and less than 30% was defined as low fibrosis group. The histogram related texture parameters of quantitative susceptibility imaging were measured, including mean, minimum, maximum, standard deviation, skewness, kurtosis, entropy, 10% pixel value, 25% pixel value, 50% pixel value, 75% pixel value, and 90% pixel value. Independent sample t test (normal distribution) or Mann-Whitney rank sum test (skewed distribution) was used to compare the differences of QSM histogram parameters between high and low grade PDAC and high and low fibrosis PDAC. ROC was used to evaluate the efficacy of QSM histogram parameters in differentiating between high and low grade PDAC.

### RESULTS

The QSM mean value, maximum value, skewness, 50% pixel value, 75% pixel value and 90% pixel value of tumor tissues of patients with low-grade PDAC and high-grade PDAC were statistically different between the two groups (all $P < 0.05$). The minimum value, standard deviation, kurtosis, entropy, 10% pixel value and 25% pixel value had no statistical significance ($P > 0.05$). Among these parameters, mean had the largest area under the ROC curve (0.775) for differentiating between high and low grade PDAC. The mean value had the highest sensitivity (88.0%). The specificity of 50% and 75% pixel values was the highest (84.2%). However, there was no significant difference in QSM histogram parameters of PDAC between the high and low fibrosis groups ($P > 0.05$).

### CONCLUSION

In this study, QSM was applied to pancreatic ductal adencracinoma for the first time. QSM has certain value in predicting the pathologic grade of PDAC before surgery. Of course, further studies with a larger patient group are still needed to obtain data with a larger ample size to verify the value of QSM in evaluating the histological grading of PDAC.

### CLINICAL RELEVANCE/APPLICATION

QSM has certain value in predicting the pathologic grade of PDAC before surgery.

## R5A-SPGI-3 STUDY ON RESECTABLE EVALUATION OF PANCREATIC CANCERWITH VIRTUAL MONOCHROMATIC IMAGES OF SPECTRAL CT

Zixing Huang (*Abstract Co-Author*) Nothing to Disclose
Tao Shuai (*Abstract Co-Author*) Nothing to Disclose
Qianyuan Xue (*Abstract Co-Author*) Nothing to Disclose
Liqiong Liu (*Abstract Co-Author*) Nothing to Disclose
Haopeng Yu (*Abstract Co-Author*) Nothing to Disclose
Yuqi Wang (*Presenter*) Nothing to Disclose

### PURPOSE

Compared with conventional CT images, to discuss the application value of virtual monochromatic images of spectral CT in the evaluation of resectability of pancreatic cancer.

### METHODS AND MATERIALS

We retrospectively enrolled 47 consecutive patients who underwent pancreatic spectral CT enhanced examination in *** hospital from November 2019 to May 2021. All the patients were pathologically confirmed to be pancreatic cancer. Two observers measured tumor size and evaluated the resectability of pancreatic cancer according to the 2023 NCCN guidelines on conventional CT images and the optima monochromatic images. Interobserver agreements were determined by using kappa coefficient for the resectable assessment and ICC coefficient for tumor size. Taking the surgical pathological results as the gold standard, receiver operating characteristic curve was used to analyze the diagnostic efficacy of both images in evaluating the resectability of pancreatic cancer.

### RESULTS

Surgical pathological results confirmed that 16 cases were resectable, 13 cases were borderline resectable, and 18 cases were unresectable. Both tumor size and resectability on conventional CT images and optima monochromatic images demonstrated high agreement ($k=0.968$ vs 0.834, 0.989 vs 0.961, $p<0.05$). The sensitivity, specificity, negative predictive value, positive predictive value and accuracy of the optima monochromatic images in evaluating the resectable pancreatic cancer were 93.75%(95%CI: 69.77%~99.84%), 93.55%(95%CI : 78.58%~99.21%), 96.67%(95%CI :81.26%~99.49%), 88.24%(95%CI: 66.12%~96.65%), 93.62%(95%CI :82.46%~98.66%). Respectively the values for conventional images were 81.25%(95%CI: 54.35%~95.95), 80.65%(95%CI: 62.53%~92.55%), 89.29%(95%CI : 74.76%~95.91%), 68.42%(95%CI: 50.43%~82.19%), 80.85%(95%CI: 66.74%~90.85%). The area under the curve of both group was 0.920(95%CI :0.818~1.023) vs 0.811(95%CI :0.692~0.931), $z=2.269$,$p<0.05$.

### CONCLUSION

The consistency of both conventional CT images and the optimal monochromatic images was high. Compared with conventional CT images, the optimal monochromatic images had higher diagnostic value for resectability evaluation of pancreatic cancer.

### CLINICAL RELEVANCE/APPLICATION

Compared with conventional CT images, to discuss the application value of virtual monochromatic images of spectral CT in the evaluation of resectability of pancreatic cancer. It can provide a more accurate reference basis for the selection of pancreatic cancer treatment, thus effectively avoiding the emergence of "ineffective surgery" and "ineffective chemotherapy" and improving the survival rate and prognosis of patients.

## R5A-SPGI-6 QUANTITATIVE EVALUATION OF PANCREATIC CANCER DETECTION IN CT: COMPARISON OF PHOTON COUNTING DETECTOR CT AND DUAL ENERGY INTEGRATED DETECTOR CT

Kyo Noguchi, MD (*Abstract Co-Author*) Nothing to Disclose
Kazuma Nishikawa (*Abstract Co-Author*) Nothing to Disclose
Yasuhiro Kawahara (*Abstract Co-Author*) Nothing to Disclose
Aki Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Norihito Naruto (*Abstract Co-Author*) Nothing to Disclose
Ken Yamamoto (*Abstract Co-Author*) Nothing to Disclose
Mariko Doai (*Abstract Co-Author*) Nothing to Disclose
Takahito Niiyama (*Presenter*) Nothing to Disclose

**PURPOSE**

CT imaging is essential to determine the stage and resectability of pancreatic cancer. Advances in CT imaging technology have significantly enhanced the management of pancreatic cancer and impact clinical outcomes. The advent of dual-energy integrated detector CT (DE-CT) has improved the detection rate of pancreatic cancer compared to conventional single energy integrated detector CT (EID-CT). The recently developed photon counting detector CT (PCD-CT) is expected to have excellent tumor detection ability due to its ultra-high resolution and reduced radiation dose. Although there are reports showing that PCD-CT is superior to conventional EID-CT, no comparison with DE-CT was found. The purpose of this study is to quantitatively compare the ability of PCD-CT and DE-CT to detect pancreatic cancer.

**METHODS AND MATERIALS**

A total of 20 patients who underwent PCD-CT and 20 patients who underwent DE-CT for diagnostic workup of pancreatic cancer were included. Quantitative analysis was performed on the contrast ratio of the tumor and pancreas (TPR), and the contrast-to-noise ratio (CNR) of non-contrast CT images, early enhancement phase (42 sec), and late enhancement phase (180 sec). In addition, iodine concentrations were also measured in the aorta, pancreatic tumor, and normal pancreatic tissue on both early and late enhancement stages in 16 patients.

**RESULTS**

There was no significant difference in TPR (non-contrast: 0.71 vs. 0.98, P value 0.08, early enhancement stage: 0.60 vs. 0.58, P value 0.39, late enhancement stage: 1.16 vs. 1.08, P value 0.12, PCD-CT vs. DE - CT) and CNR (non-contrast: 2.55 vs. -0.23, P value 0.14; early enhancement stage: 17.01 vs. 19.55, P value 0.26; late enhancement stage: -4.01 vs. -2.18, P value 0.19). There was also no significant difference between PCD-CT and DE-CT regarding iodine concentration (initial 11.2 vs. 10.0, 1.42 vs. 1.78, 3.9 vs. 3.7, 3.7 vs. 3.8, 2.0 vs. 2.3, 2.0 vs. 2.3, respectively) in the aorta; pancreatic tumors, normal pancreatic tissue).

**CONCLUSION**

The image quality of pancreatic cancer in PCD-CT was comparable to DE-CT, and the tissue contrast in non-contrast and contrast-enhanced images was also not superior to DE-CT.

**CLINICAL RELEVANCE/APPLICATION**

PCD-CT and DE-CT were equivalent in detecting pancreatic cancer.

## R5A-SPGI-7 CT IMAGING FINDINGS FOLLOWING TREATMENT WITH COMBINATION SBRT AND CHEMOTHERAPY FOR LOCALLY ADVANCED PANCREATIC ADENOCARCINOMA

Olga R. Brook, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Bettina Siewert, MD (*Abstract Co-Author*) Editor, Wolters Kluwer nv;Reviewer, Wolters Kluwer nv
Alexander Brook, PhD (*Abstract Co-Author*) Nothing to Disclose
Robert G. Sheiman, MD (*Abstract Co-Author*) Nothing to Disclose
Abraham Fourie Bezuidenhout, MD (*Abstract Co-Author*) Nothing to Disclose
Vishaal Gudla, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Recognizing the CT imaging patterns of locally advanced pancreatic adenocarcinoma (LAPA) before, during and after stereotactic body radiotherapy (SBRT) is crucial when determining disease recurrence. Our study aims to evaluate the imaging features of patients with LAPA following treatment with combination SBRT and chemotherapy.

**METHODS AND MATERIALS**

This retrospective study examines the CT imaging features of LAPA patients who received combination SBRT and chemotherapy compared to those that received chemotherapy alone between 2005-2018. Comparisons were made both pre-treatment and at four standardized post-treatment intervals (1 month, 3-6 months, 7-12 months, greater than 12 months) to assess for change in imaging features over time in patients without disease progression. Evaluated variables included degree of vascular involvement graded on a standardized scale (0:no involvement, 1:encasement, 2:stenosis, 3:thrombosis), tumor location, tumor size, and peripancreatic mesenteric fat stranding. Patients in whom disease progression was noted, as determined by multidisciplinary tumor board based on clinical data and CA 19-9 trends, were excluded wherein data beyond the time of disease progression was excluded from analysis. Statistical analysis was performed including mixed effects logistic regression and ANOVA tests. A p value $<0.05$ was considered significant.

**RESULTS**

A total of 96 patients were included in this study, 64 treated with combination SBRT/chemotherapy (68 years +/- 11, 37 men) and 32 treated with chemotherapy only (69 years +/- 10, 17 men). The median length of follow up in the SBRT/chemotherapy group was 237 days, IQR 114-395, and in the chemotherapy group was 102 days, IQR 44-293. Vascular involvement as graded on CT was higher among the SBRT/chemotherapy group at all time intervals. Vascular involvement over time was significantly higher in the SBRT/chemotherapy group as compared to the chemotherapy group. ($p= 0.02$). The hepatic and celiac arteries were the most common vessels to demonstrate increased vascular involvement in the SBRT/chemotherapy group (23.4 and 20.3% of cases respectively) in the absence of disease progression.

**CONCLUSION**

Increased vascular involvement over time in LAPA patients treated with combination SBRT/chemotherapy should be an anticipated treatment effect of SBRT, not necessarily indicating disease progression.

**CLINICAL RELEVANCE/APPLICATION**

Vascular involvement progressing over time in LAPA patients treated with combination SBRT/chemotherapy could be due to the fibrotic response invoked by SBRT. In the absence of clinical disease progression, this should not be misconstrued as disease progression.

## R5A-SPGU-5 THREE-DIMENSIONAL CONTRAST-ENHANCED TRANSRECTAL ULTRASOUND FOR THE DETECTION OF CLINICALLY SIGNIFICANT PROSTATE CANCER

Yaqing Chen (*Abstract Co-Author*) Nothing to Disclose
Wenbin Guan (*Abstract Co-Author*) Nothing to Disclose
Yunkai Zhu (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the performance of 3D contrast-enhanced transrectal ultrasound (CE-TRUS) for the detection of clinically significant prostate cancer (csPCa).

### METHODS AND MATERIALS

This prospective study included 84 consecutive patients scheduled for prostate biopsy, with a median age of 69 years (interquartile range: 65-78 years) and PSA of 9.99 ng/ml (interquartile range: 6.32-15.69 ng/ml). Before the biopsy, all patients underwent both 2D and 3D CE-TRUS evaluation. 2D CE-TRUS was performed at the plane of hypoechoic lesion, or using a sweeping method in patients without hypoechoic lesion on conventional TRUS. Whole gland 3D CE-TRUS images were acquired continuously for 90 seconds. For image analysis, the transverse, sagittal and coronal images were reconstructed using iPAGE software, with a slice thickness of 1 mm. Both 2D and 3D CE-TRUS images were rated using a five-point Likert score based on contrast enhancement on CEUS. Regions with Likert=3 were selected for targeted biopsy (TB) in addition to 12-core systematic biopsy (SB). The primary outcome was the detection of csPCa, defined as PCa with GG=2 at biopsy histopathology. Differences in proportions were compared using McNemar's test for matched pairs.

### RESULTS

The diagnosis of csPCa was histologically confirmed in 50 patients. The detection rate for csPCa was 48.8% (41/84) with SB, 44.0% (37/84) with 2D CE-TRUS, and 53.6% (45/84) with 3D CE-TRUS. The csPCa detection rate of 3D CE-TRUS was comparable to that of SB (P=0.267), and significantly higher than that of 2D CE-TRUS (P=0.008). With the combination of 3D CE-TRUS and SB, the csPCa detection rate could be further improved when compared with SB alone (59.5% [50/84] vs 48.8% [41/84], P=0.004). 3D CE-TRUS was scored Likert 1-2, 3, 4 and 5 in 29 (34.5%), 19 (22.6%), 14 (16.7%) and 22 (26.2%). For patients with Likert=3, the csPCa detection rate of TB increased with higher Likert score, with 68.4% (13/19), 71.4% (10/14) and 95.5% (21/22) for patients with scores of 3, 4, and 5, respectively (P = 0.029). For patients with Likert 1-2, SB resulted in the detection of two patients (6.9%, 2/29) with csPCa.

### CONCLUSION

3D CE-TRUS is an operator-independent imaging method that enables standardized dynamic contrast-enhanced imaging for the entire prostate gland. The multiplanar step-sectional reconstruction of 3D CE-TRUS images provide better depiction of csPCa lesions than 2D CE-TRUS. 3D CE-TRUS might be an ideal method for performing TB to improve csPCa detection.

### CLINICAL RELEVANCE/APPLICATION

Characterized by the standardized and multiplanar whole gland imaging, 3D CE-TRUS is an ideal method for the detection and localization of csPCa.

## R5A-SPHN-1 IMPACT OF ADDITIONAL COMPUTED TOMOGRAPHY IN PATIENTS WITH LOW-RISK PAPILLARY THYROID MICROCARCINOMA ELIGIBLE FOR ACTIVE SURVEILLANCE

Ji Ye Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Taehyuk Ham, MD (*Abstract Co-Author*) Nothing to Disclose
Ji-Hoon Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Young Hun Jeon (*Presenter*) Nothing to Disclose

### PURPOSE

Active surveillance (AS) of low-risk papillary thyroid microcarcinomas (PTMC) is emerging as an alternative management option to immediate surgery. When considering the initiation of AS, it is crucial to confirm the appropriateness of the tumor to AS. Among several factors, the identification of clinically evident lymph node metastasis (LNM) is considered as inappropriate for AS and warrants immediate surgery. While the supplementary role of neck computed tomography (CT) is increasingly emphasized for detecting LNM in thyroid cancer, its role in the population appropriate for AS remains unclear. This study aims to investigate the impact of additional CT alongside ultrasound (US) for detecting cervical LNM and assessing the appropriateness of AS in patients with low-risk PTMC.

### METHODS AND MATERIALS

From February 2016 to December 2021, consecutive PTMC patients who underwent US and CT for staging were retrospectively analyzed. The number of patients with clinical N1 and pathologic N1 disease was assessed. The diagnostic performance of US, CT, and combined US/CT in assessing their nodal staging was calculated. The impact of CT on nodal staging revisions based on US was evaluated.

### RESULTS

Among 1,230 PTMC patients (mean age, 47.8 year ± 11.8 [SD], 967 female), 202 (16.4%) patients showed nodal positivity on preoperative imaging: 55 (4.5%) detected on both US and CT, 18 (1.5%) only on US, and 129 (10.5%) only on CT. Among them, 1,002 (81.5%) underwent surgery, 204 (16.6%) underwent AS, and 24 (2.0%) underwent radiofrequency ablation for their management. Among 977 patients who underwent thyroidectomy with neck dissection, 337 (34.5%) were diagnosed with pathologic N1 disease. Integrating CT with US significantly improved sensitivity for detecting microscopic (3.1% vs. 16.8%, $p < .001$), macroscopic (25.1% vs. 65.3%, $p < .001$), and all nodal metastases (15.0% vs. 42.8%, $p < .001$) without compromising specificity. In 156 cases (16.0%) with discordant nodal staging between US and CT, CT accurately identified 96 (9.8%) cases of nodal staging whereas US did not.

### CONCLUSION

The integration of CT with US altered nodal staging by increasing their sensitivity for detecting LNM in patients with low-risk PTMC eligible for AS. CT could be a useful risk stratification tool for eligibility assessments at the time of management plan decisions in patients with low-risk PTMC.

### CLINICAL RELEVANCE/APPLICATION

The combined approach of US and CT can identify more cases of LNM, which may not be detected using US alone in patients with low-risk PTMC. By providing a more accurate assessment of nodal staging, the combined approach could help in determining the most appropriate management strategy and potentially lead to outcomes in low-risk PTMC patients.

## R5A-SPHN-2 IMPROVING THE DIAGNOSTIC RISK STRATIFICATION OF BETHESDA INDETERMINATE THYROID NODULES VIA DEEP-LEARNING BASED INFERENCE

Chandra Sehgal, PhD (*Abstract Co-Author*) Nothing to Disclose
Hersh Sagreiya, MD (*Abstract Co-Author*) Nothing to Disclose
Jill E. Langer, MD (*Abstract Co-Author*) Nothing to Disclose
Lev Barinov, MD, PhD (*Presenter*) Research Consultant, Koios Medical, Inc;Stockholder, Koios Medical, Inc

### PURPOSE

Ultrasound is the primary imaging modality for risk stratifying thyroid nodules. For nodules deemed sufficiently suspicious on diagnostic imaging to warrant fine needle aspiration, up to 60% yield indeterminate cytopathology and necessitate subsequent molecular testing such as ThyroSeq®. Unfortunately, ThyroSeq®'s false positive rate can be as high as 50% in practice. We hypothesize that a deep learning-based analysis of indeterminate thyroid nodules on ultrasound can be used for effective risk stratification.

**METHODS AND MATERIALS**

A retrospective review of consecutive thyroid ultrasounds from 2021-2023 yielded 36,460 diagnostic studies containing 24,975 nodules. 5,214 were biopsied, and 2984 (57%) had either Bethesda III (atypia of undetermined significance) or IV (follicular neoplasm) cytopathological classification, which led to 1285 ThyroSeq® evaluations. We identified the subset that went on to receive hemi- or full thyroidectomy, which yielded 151 nodules across 145 patients; 48 (32%) were benign and 103 (68%) were malignant (or NIFTP) based on final surgical histopathology. Performance was evaluated via proportion metrics on the binary ThyroSeq® classifications and ROCAUC analysis on the continuous risk percentages. A ResNet-18-based convolutional neural network (CNN) was trained to delineate malignant and benign lesions. CNN performance was evaluated via 10-fold cross validation independently and as a fused-adjunct to the ThyroSeq® continuous risk percentages. We utilized TI-RADS assessments as a baseline to the performance of both ThyroSeq® and the CNN.

**RESULTS**

ThroSeq® sensitivity, specificity, PPV, and NPV were 85.44% [78.62 92.25], 41.67% [27.72 55.61], 75.86% [68.07 83.65], and 57.14% [40.75 73.54], respectively with 95% confidence intervals. TI-RADS, ThyroSeq®, CNN, and CNN+ThyroSeq® ROCAUCS were 0.55, 0.76, 0.64, and 0.77, respectively.

**CONCLUSION**

The false positive rate of ThyroSeq® is 58%, higher than what was originally published. This suggests that while there is some reduction in unnecessary surgery, most positive results are benign. CNN risk stratification is superior to TI-RADS with meaningful predictive power, but it is not yet as effective as ThyroSeq®. Fusing the CNN result with ThyroSeq® risk percentage improves AUC but does not impact the final operating point. Further development of the classifier may alleviate the need for additional expensive testing by analyzing already acquired diagnostic imaging.

**CLINICAL RELEVANCE/APPLICATION**

This study presents a method that can risk stratify indeterminate thyroid nodules more accurately than TI-RADS and beginning to approach the performance of diagnostic molecular assays.

## R5A-SPHN-3 PREDICTING LYMPH NODE METASTASIS OF PAPILLARY THYROID CARCINOMA USING DUAL-ENERGY CT NOMOGRAMS

Quanxin Yang (*Abstract Co-Author*) Nothing to Disclose
Kexin Zhang (*Abstract Co-Author*) Nothing to Disclose
Huizhi Mi (*Abstract Co-Author*) Nothing to Disclose
Xiaohui Li (*Abstract Co-Author*) Nothing to Disclose
Jiaxing Wu (*Abstract Co-Author*) Nothing to Disclose
Jingbin ZHANG (*Abstract Co-Author*) Nothing to Disclose
Haiqiao Sun (*Abstract Co-Author*) Nothing to Disclose
Bo Gao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the discriminative capacity of nomograms, integrating dual-energy CT (DECT) quantitative parameters and clinical data in distinguishing between metastatic and non-metastatic lymph nodes in papillary thyroid carcinoma (PTC)

**METHODS AND MATERIALS**

60 patients diagnosed with papillary thyroid carcinoma between 2021 and 2023 were retrospectively inculded. Preoperatively, all patients underwent cervical dual-energy contrast-enhanced CT. Following surgical resection, lymph nodes were categorized into metastatic lymph nodes (105 nodes) and non-metastatic lymph nodes (136 nodes). Groups based on pathological examination. various quantitative parameters, including iodine concentration (IC) of arterial phase, shape, short diameter, margin, enhancement degree, cystic change, calcification, arterial phase enhancement pattern, and capsule integrity, were analyzed in both groups. Independent risk factors for lymph node metastasis was identified through univariate and multivariate logistic regression analysis. A nomogram-based model was constructed and its calibration curve was generated.

**RESULTS**

Multivariate binary logistic regression analysis revealed that arterial phase iodine concentration =2.6 mg/ml, enhancement degree, enhancement pattern, short diameter =10mm, unclear margin, irregular shape, incomplete capsule of thyroid nodules were independent risk factors for predicting lymph node metastasis. The AUC of the nomogram model constructed based on this was 0.993 (95% CI 0.98~0.99), with a cutoff value of 0.5, sensitivity of 97.04%, and specificity of 95.28%.

**CONCLUSION**

The nomogram model derived from on dual-energy CT parameters and clinical data , demonstrates considerable clinical utility in preoperatively assessing lymph node metastasis in patients with papillary thyroid carcinoma , This model holds promise for informing, individualized treatment strategies.

**CLINICAL RELEVANCE/APPLICATION**

nomograms can help clinicians develop surgical approaches

## R5A-SPHN-4 DIAGNOSTIC PERFORMANCE OF AI MODEL FOR THYROID NODULES WITH INITIALLY NONDIAGNOSTIC CYTOLOGIC RESULTS

Jeong Hoon Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Eun Ju Ha, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Artificial intelligence (AI) model for thyroid ultrasonography (US) seems to be a promising diagnostic tool for patients with thyroid nodules. Prior studies have shown high diagnostic performance of AI models for predicting malignant thyroid nodules. However, studies on the role of AI model for thyroid nodules with initially nondiagnostic cytologic results are presently lacking. This study aimed to evaluate the diagnostic performance of AI model in thyroid nodules with nondiagnostic results at previous fine-needle aspiration (FNA).

**METHODS AND MATERIALS**

Between January 2019 and September 2023, 13,164 nodules underwent US-guided FNA at our institution. Among them, 413 nodules from 409 patients (121 men, 288 women) with a mean age of 51.3 years (age range, 18-81 years) with nondiagnostic results at previous FNA were reviewed retrospectively. AI-Thyroid, a deep learning model for identifying malignant thyroid nodules, was tested online (http://us.cdss.co.kr/). Model performance

was compared against blinded expert radiologist performance using Thyroid Imaging Reporting and Data System (TIRADS) interpretation. Sonographic characteristics associated with false positive diagnosis were analyzed.

**RESULTS**

A total of 413 thyroid nodules were analyzed, 102 (24.7%) comprising malignant nodules. Using AI-Thyroid, 318 nodules (77.0%, 318 of 413) had accurate diagnoses with high negative predictive value (92.9%, 234 of 252). The area under the receiver operative curve (AUROC), sensitivity, and specificity were 0.845, 82.4% (84 of 102), and 75.2% (234 of 311), respectively. The AUROC value was significantly higher for the AI-Thyroid, compared to the TIRADS-based classification (0.845 vs. 0.623, $p < 0.001$). The most important features associated with false positive diagnoses were presence of macrocalcifications and non-parallel orientation, respectively.

**CONCLUSION**

AI-Thyroid demonstrates high rates of accurate diagnoses with high negative predictive value in patients for whom previous FNA results were nondiagnostic, thereby reducing the need for unnecessary diagnostic surgery or repetitive FNAs.

**CLINICAL RELEVANCE/APPLICATION**

1. AI-Thyroid can be a promising diagnostic tool for patients with previous nondiagnostic FNA results to reduce the need for diagnostic surgery or repetitive FNAs. 2. AI-Thyroid showed high rates of accurate diagnoses (77.0%, 318 of 413) with high negative predictive value (92.9%, 234 of 252) in patients with previous nondiagnostic FNA results. 3. AI-Thyroid had a 23.0% incidence of incorrect diagnosis with macrocalcifications and non-parallel orientation being the main causes of false-positive diagnosis in patients with previous nondiagnostic FNA results.

## R5A-SPHN-5 DIAGNOSTIC VALUE OF CONTRAST-ENHANCED THYROID CT IMAGING WITH MODIFIED POSITIONING IN THYROID CANCER: PATHOLOGY AS REFERENCE

Huijun Xiao (*Abstract Co-Author*) Nothing to Disclose
Huijuan Huang (*Abstract Co-Author*) Nothing to Disclose
Wencong Yang (*Abstract Co-Author*) Nothing to Disclose
Weihua Lin (*Abstract Co-Author*) Nothing to Disclose
Dongyi Chen (*Abstract Co-Author*) Nothing to Disclose
Furong Luo (*Abstract Co-Author*) Nothing to Disclose
Ruigang Huang (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the performance of contrast-enhanced thyroid CT imaging with modified positioning in thyroid cancer-related diagnosis, with pathology as a reference.

**METHODS AND MATERIALS**

This prospective study enrolled 153 patients who underwent preoperative contrast-enhanced thyroid CT imaging and had pathology confirmed thyroid lesions. Patients were scanned with modified position (MP, n=70) and conventional position (CP, n=83). During scanning, an auxiliary postural support device was used in the MP group to ensure the patient's head was tilted back, shoulders sunk, and neck protruded, and no auxiliary postural device was used in the conventional position group. Two radiologists with different experience independently performed diagnosis from three perspectives: thyroid malignancy, thyroid tumor with capsular invasion, and cervical lymph node metastasis. With pathology as a reference, area under the curve (AUC), sensitivity, specificity, accuracy, negative predictive value (NPV), and positive predictive value (PPV) were calculated for evaluating the diagnostic performance.

**RESULTS**

Both junior and senior radiologists demonstrated improvements in diagnostic performance on MP images; the AUCs for diagnosing malignancy reached 0.9 (senior) and 0.83 (junior), for capsular invasion, 0.97 and 0.76, and for cervical lymph node metastasis, 0.84 and 0.79, while on CP images, those were 0.75 (senior) and 0.6 (junior) for malignancy identification, 0.82 and 0.77 for capsular invasion evaluation, and 0.74 and 0.61 for lymph node metastasis assessment, respectively. The sensitivity, specificity, accuracy, NPV, and PPV for the three conditions were also higher for radiologists with MP images. Particularly, the sensitivity, specificity, and accuracy were increased by 10% ~ 47% for junior, and by 5%~24% for senior. The kappa coefficients between junior and senior diagnosis were also improved to 0.76~0.79 for MP, compared to CP with 0.62~0.73.

**CONCLUSION**

Both junior and senior radiologists demonstrated improvements in diagnostic performance regarding thyroid malignancy, thyroid tumor with capsular invasion, and cervical lymph node metastasis on MP images.

**CLINICAL RELEVANCE/APPLICATION**

Modified positioning enhances the diagnostic efficacy of contrast-enhanced thyroid CT imaging, showing high clinical value in patients suspected of thyroid cancer.

## R5A-SPIN-1 BENCHMARKING OPTIMAL TRAINING DATA SIZE FOR ACCURATE CLASSIFICATION IN RENAL SURGICAL PATHOLOGY REPORTS

Tessa S. Cook, MD, PhD (*Abstract Co-Author*) Grant, Independence Blue Cross;Speaker, Sectra AB;
Darco Lalevic (*Abstract Co-Author*) Nothing to Disclose
Rithvik Sukumaran (*Abstract Co-Author*) Nothing to Disclose
Charles Chambers (*Abstract Co-Author*) Nothing to Disclose
Hanna M. Zafar, MD (*Abstract Co-Author*) Nothing to Disclose
Satvik Tripathi (*Presenter*) Nothing to Disclose

### PURPOSE

Natural language processing (NLP) shows promise for improving diagnostic processes. This study investigates the optimal training data size for a renal pathology report classification task while also exploring differences in data requirements between different types of models and comparing binary and multiclass versions of the same model.

### METHODS AND MATERIALS

We employed a multi-channel convolutional neural network (CNN), a recurrent neural network (RNN), and a long short-term memory network (LSTM) for the classification of summary text from 1239 renal surgical pathology reports from three health systems in the same state to train and benchmark models. The reports were labeled by two experienced radiologists as "malignant," "indeterminate," "benign," or "ignore" (n = 301, 113, 426, and 399, respectively). "Ignore" indicated any pathology not specifically from a mass lesion in the kidney. The multiple model variants were trained with increasing amounts of training data (10%, 25%, 50%, 75%, 85%, and 95% of total available data) and evaluated with a 5-fold cross-validation against a held-out validation set (n = 200). The same experiment was performed with a binary classification version of the CNN that considered only "malignant" (n=301) and "benign" (n=302) reports.

### RESULTS

Precision, recall, and F1 were measured across each iteration of the models. As training data size increased, model accuracy increased in smaller and smaller increments, indicating diminishing returns. The CNN and LSTM reached 90% accuracy or more when given enough training data, but the RNN only achieved middling performance even with larger amounts of data. While the LSTM achieved the highest performance of all models when trained on 95% of the available data, the CNN consistently outperformed all other models at lower levels of data, reaching acceptable performance with as low as 50% of the available training data. This led to a study of the CNN in a binary classification task, which performed better on all accounts and achieved higher accuracy at lower levels of data.

### CONCLUSION

Identifying the ideal model type and optimal training data size offers guidance to maximize model performance in renal pathology report classification while minimizing factors such as training time and costs. The study also highlights the impact of reducing problem scope from multiclass to binary classification—when possible—to enhance performance with less data.

### CLINICAL RELEVANCE/APPLICATION

Automatic labeling of renal pathology reports can be achieved without exorbitant amounts of data or effort, facilitating enhanced treatment experiences.

## R5A-SPIN-2 SELF-SUPERVISED PRETRAINING IMPROVES TRANSFORMER MODEL PERFORMANCE ON MRI METADATA STANDARDIZATION TASKS

Ajit Shankaranarayanan (*Abstract Co-Author*) Employee, Subtle Medical, Inc
Ben Duffy, PhD (*Abstract Co-Author*) Employee, Subtle Medical, Inc
Thomas C. Arnold, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Metadata inaccuracies and inconsistencies can disrupt radiology workflows and pose significant challenges to applications that rely on DICOM header information. Deep learning algorithms have demonstrated promise for correcting metadata inconsistencies and improving standardization, however obtaining a sufficiently large labeled training dataset remains a challenging aspect of building such systems. Here, we examine the impact of self-supervised pretraining using unlabelled data on a transformer model's performance for predicting MRI sequence and body part from DICOM metadata.

**METHODS AND MATERIALS**

We developed transformed-based models for two tasks, MRI sequence and body-part prediction using DICOM metadata. For self-supervised pretraining, we used the masked language modeling task and a large dataset consisting of 464,285 DICOM series. Fine-tuning was carried out using smaller manually labeled datasets. Data were divided into training (N=21,639), validation (N=2,401), and test (N=2,160) sets for the sequence classification task. The body part prediction dataset was partitioned into training (N=15,489), validation (N=1,721), and test (N=3,480) sets. The benefit of pretraining in a limited data regime was examined by restricting the maximum number of training examples per class to 40, 80, and 160 instances.

**RESULTS**

For both tasks, model performance improved as the maximum number of training examples per class increased from 40 to 160. The gap between the pretrained and random initialization models narrowed with increasing dataset size, demonstrating the benefits of pretraining are most significant in the few-shot regime. Despite training on 21,639 examples for the sequence prediction task and 15,489 instances for the body part prediction task, there remained a performance gap between random initialization and the pretrained models. The best performing model achieved an accuracy of 0.996 on the sequence classification task and 0.96 on the body part classification task. The majority of misclassified examples for the body part classification task were attributed to more general labels that contain more specific anatomical regions. The most common example was "prostate" as the ground-truth label with the prediction being "pelvis".

**CONCLUSION**

We demonstrated that for metadata standardization tasks, self-supervised pretraining was effective for reducing data labeling burden. Pretraining strategies are critical for integrating large amounts of data and developing systems that perform well across a wide range of inputs.

**CLINICAL RELEVANCE/APPLICATION**

Pretraining deep learning algorithms can improve metadata harmonization performance, thus facilitating data sharing and standardization across large health systems.

## R5A-SPIN-3 AUTOMATING BODY MRI PROTOCOL SELECTION WITH RADBERT

Ali H. Dhanaliwala, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tessa S. Cook, MD, PhD (*Abstract Co-Author*) Grant, Independence Blue Cross;Speaker, Sectra AB;
Satyam Ghodasara, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

As the volume of radiology examinations rises, the burden of ancillary tasks such as protocol selection are also rising. Fortunately, recent developments in natural language processing can help automate these tasks. We fine-tuned RadBERT, a transformer model pretrained on radiology reports, to select the best body MRI exam protocol given basic patient demographic information and free-text indications from the ordering provider.

**METHODS AND MATERIALS**

Protocol data for 15,956 body MRI examinations performed from 3/1/23-2/29/24 was obtained from our single academic medical center. The following data points were combined into a free-text field for each exam: patient age, patient gender, ordering provider specialty, patient's relevant diagnosis, ordering provider's exam indication, and anatomic region (abdomen, pelvis, or both). The model was fine-tuned to predict the single best of 57 unique protocols. Each protocol consisted of a study type (enterography, prostate, renal, etc.), post-contrast acquisition type (dynamic, non-dynamic, or unenhanced), and plane of post-contrast imaging (axial, coronal, or sagittal). RadBERT was fine-tuned over 3 epochs on this protocol data (80% training, 20% validation). The overall accuracy was measured as the micro average of the individual accuracies with respect to each of the 57 protocols both before and after fine-tuning.

**RESULTS**

The overall accuracy of the base RadBERT model prior to fine-tuning was 1.9%. After fine-tuning on our protocol data, this increased to 78.8%. While the most common study (routine abdomen with dynamic axial plane post-contrast imaging) was correctly classified in 684 instances, it was partially misclassified in 69 instances as a pancreatic-biliary study and in 37 instances as a renal study, although the model correctly predicted performing dynamic axial plane post-contrast imaging. Another common study (female pelvis with dynamic axial plane post-contrast imaging) was correctly classified in 212 instances but partially misclassified in 28 as sagittal plane post-contrast imaging.

**CONCLUSION**

Fine-tuning the RadBERT model on our own protocol data dramatically boosted performance, enabling it to accurately predict the majority of body MRI protocols given patient demographic information and the ordering provider's exam indication. The model's errors typically only involved one component of the protocol, such as the plane of post-contrast imaging, and reflects ambiguities in protocol selection that also frequently occur in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

The fine-tuned RadBERT model shows promise for use in clinical practice to assist radiologists in accurately selecting protocols for body MRI examinations.

## R5A-SPIN-4 COMPUTER VISION IN MEDICAL IMAGING SERVICE DELIVERY: EVALUATING PROCESS CAPACITY OF CT SCANS

Andrew D. Brown, MD (*Abstract Co-Author*) Nothing to Disclose
Aly Fawzy, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Effective coordination of CT scan resources enhances care access and quality while reducing costs. Despite the reliance on average wait times as a performance metric, current methods (manual tracking or tracking devices) lack comprehensive data to inform effective management decisions. Computer vision (CV) methods offer a more cost-effective, adaptable, and less intrusive alternative for data collection. The purpose of this study is to address this gap by developing and evaluating a CV system to automate the capture of essential process metrics—cycle time, throughput, maximum capacity, and utilization rate—during CT scans. This technology aims to enhance the efficiency of CT service delivery by providing accurate and precise real-time data to service providers.

**METHODS AND MATERIALS**

An edge computing device equipped with a Jetson Xavier NX and a camera was deployed in a CT suite at an academic hospital for one hour to capture real-time data. The system utilized a YOLOv7 neural network for anonymizing individuals into 2D representations and background subtraction to monitor equipment movement. This setup enabled a direct comparison of the CV-generated data with manual event timings recorded by research personnel. Three types of CT events were considered: preparing for scan, scanning, and discharging.

**RESULTS**

The CV system reported an average cycle time of 7.33 minutes per patient, broken down into preparation (2.01 mins), scanning (3.65 mins), and discharge (1.67 mins). The throughput was 4.2 patients per hour, with room utilization at 53%, and scanner utilization rate at 0.23 minutes per patient. The theoretical maximum capacity calculated was 7.3 patients per hour. The data from the CV system closely matched the manual records, demonstrating less than 1% variance.

**CONCLUSION**

The implemented CV system, employing YOLOv7 and background subtraction, has proven to be highly accurate and reliable in monitoring and improving the efficiency of CT scan processes. It provides a cost-effective, adaptable, and less intrusive alternative to traditional manual methods, significantly enhancing service quality and decision-making in medical imaging.

**CLINICAL RELEVANCE/APPLICATION**

This study highlights a significant advancement in the application of CV and deep learning within medical imaging, presenting a novel, efficient approach for operational enhancement of CT services. By automating data collection and analysis, the CV system not only surpasses outdated manual methods in terms of cost-effectiveness, adaptability, and intrusiveness but also supports improved resource allocation and decision-making. This has the potential to set a new standard for process monitoring, enhancing efficiency and service quality in radiology departments.

## R5A-SPIN-5 ARE WE ON THE RIGHT WAY FOR EVALUATING AI ALGORITHMS FOR MEDICAL SEGMENTATION?

Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Yucheng Tang, PhD (*Abstract Co-Author*) Nothing to Disclose
Sergio Decherchi (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Andrea Cavalli (*Abstract Co-Author*) Nothing to Disclose
Wenxuan Li, BS (*Abstract Co-Author*) Nothing to Disclose
Pedro Ricardo Ariel Salvador Bassi (*Presenter*) Nothing to Disclose

**PURPOSE**

To provide a large-scale, open benchmark across 44 advanced AI algorithms in anatomical structure segmentation across three critical dimensions, including accuracy, efficiency, and robustness.

**METHODS AND MATERIALS**

We have established a large-scale AI benchmark attracting 44 international research teams from 12 countries. These teams develop their AI algorithms, which they either authored first or last, using our expansive annotated CT database. In total, the database consists of 22,682 annotated CT volumes (i.e., 7.9M images) collected from 94 hospitals and 19 countries, where 5,195 out of 22,682 CT volumes are available for training AI algorithms, the remaining are reserved for external validation. Our benchmark evaluates a wide range of AI algorithms, categorized as CNN, Transformer, Mamba, Vision-Language. In addition, we also evaluate publicly available AI frameworks—which are more flexible and can support different backbones—in terms of their segmentation capacity. These frameworks include Auto3DSeg from NVIDIA, nnU-Net from DKFZ, and numerous other open-source repositories developed by researchers. These models and frameworks, which collectively have garnered over 102,000 citations, are evaluated independently by our team using an unseen dataset of 13,420 CT volumes from 12 hospitals to determine their performance measured by segmentation accuracy (DSC and NSD) and inference efficiency (running time per case). Our benchmarking effort is featured in challenges hosted by ISBI-2024 and MICCAI-2024, invited as a Lighthouse Challenge in MICCAI-2025, and is planned to expand over the next five years.

**RESULTS**

We have received 15 AI algorithms and expect at least 35 more. DSC scores vary from 82% (SegVol) to 92% (UniSeg) across AI algorithms, 70% (aorta) to 96% (liver spleen) across anatomical structures, and inference times range from 0.12 (SegVol) to 0.61 (Diff-UNet V2) seconds per CT slice.

**CONCLUSION**

Our AI benchmark addresses critical limitations in existing medical AI evaluations by ensuring that: (I) creators of 44 renowned AI algorithms use consistent training and testing splits to mitigate biased reproductions by other teams, (II) our team conducts all evaluations independently, prohibiting test-time adjustments that could lead to overfitting, and (III) the test set comprises a comprehensive, diverse, and entirely unseen collection of 13,420 CT volumes from 12 hospitals, making it the largest test set used to date.

**CLINICAL RELEVANCE/APPLICATION**

The outcome will be translated into clinical prototypes. These AI prototypes have been deployed and beta-tested in JHU and UCSF to assist radiologists in automated organ volume measurement and support surgeons in precise surgical navigation.

## R5A-SPIN-7 FROM SPOKEN WORDS TO COMPHRENSIVE REPORTS: TRANSFORMING RADIOLOGISTS' VERBAL DESCRIPTIONS INTO COMPREHENSIVE RADIOLOGY REPORTS VIA SPEECH RECOGNITION AND LARGE LANGUAGE MODELS

Jia Li (*Presenter*) Nothing to Disclose

**PURPOSE**

This study combines speech recognition with large language models to transform radiologists' intermittent verbal descriptions into coherent, fully-formed radiology reports, reducing manual editing and data entry burdens.

**METHODS AND MATERIALS**

We developed an advanced radiology reporting system (RRS) integrating state-of-the-art speech recognition algorithms and a domain-specific large language model. The system was evaluated in a retrospective study involving 10 radiologists who reviewed chest imaging studies from 607 patients. The study compared the performance of the RRS against a benchmark system utilizing GPT-4 for report generation.

**RESULTS**

The RRS reduced report generation time by 45%, decreased mouse and keyboard clicks by 93%, and lessened radiologist fatigue. The system improved report coherence (from 3.5±0.5 to 4.9±0.1) and logicality (from 3.8±0.6 to 4.94±0.06). RRS enhanced accuracy to a perfect score of 5.0±0.0,

eliminating hallucinations. The system reduced manual editing from 10±2 to 3.2±0.8 edits per report.In a comparison based on 50 reports, RRS outperformed GPT-4 in coherence (4.90 vs. 4.30), logicality (4.94 vs. 4.38), and hallucination prevention (5.00 vs. 4.96). GPT-4 showed a slight advantage in accuracy (4.88 vs. 4.80).

**CONCLUSION**

The integration of large language models, such as the RRS, into the radiology reporting workflow represents a innovation approach. By automating report transcription and organization, this technology reduces report generation time, minimizes manual input, and improves overall report quality. Freeing radiologists to concentrate on image analysis, enhancing diagnostic accuracy and efficiency.

**CLINICAL RELEVANCE/APPLICATION**

The integration of large language models for radiology report generation markedly enhances the radiological workflow, focusing on improved patient care and diagnostic precision. By enabling radiologists to devote their full attention to image analysis, this technology minimizes distractions associated with manual transcription, thereby reducing errors and increasing diagnostic accuracy.

## R5A-SPIR-2 ENERGY CONSUMPTION IN INTERVENTIONAL RADIOLOGY: STATUS QUO AND EFFECTIVE REDUCTION

Meinrad J. Beer, MD (*Abstract Co-Author*) Nothing to Disclose
Billurvan Taskin (*Presenter*) Nothing to Disclose

### PURPOSE

Strategies to reduce energy consumption through imaging modalities in healthcare are an essential topic in the era of climate and energy crises. Angiography imaging systems have the second highest energetic impact, shortly behind MRI as the leading consumer. Currently, real-world measurements of angio systems in interventional radiology (IR) are largely lacking, as are extrapolations regarding reduction of idle times and/or smart utilization of biplane systems.

### METHODS AND MATERIALS

During a 6-weeks power consumption period, RIS log files and PACS reports were collected of a biplane angiography system (Azurion 7 B20, Philips) in a multifunctional tertiary hospital for neurologic, oncological and vascular diseases. Times for procedure, standby and turn-off were tracked, as well as the number and type of procedures, energy used (in kWh) and power (in W). Standby periods were subdivided into longer than 30, 60 and 120 min. The system was used in real biplane and sole monoplane mode. Extrapolated values were calculated for energy consumption in order to quantify the expectable yearly effects of three different energy reductions approaches.

### RESULTS

The evaluated system was in stand by for 17%, in procedure for 10% and turned off for 72% of the measurement period. Average power usage was slightly lower in standby mode than during an ongoing procedure (4.44 kW vs 4.98kW, $p<0.001$). In the off state, power usage was with 0.24 kW remarkably low. 82% of the standby periods were longer than 60 minutes. Thus, shutting down the system after 15 minutes of idle time has the potential to save 43% or 5464 kWh of annual energy. The already implemented shutdown periods on weekends and at night, will save 68% or 26629 kWh of annual energy compared to a full standby system. An option for selected procedures to use the genuine biplane system as a monoplane system (switch-off of the second tube + detection) would result in a further reduction in energy consumption of 5.3% or 681 kWh in a full year.

### CONCLUSION

The largest portion of the consumed energy of a biplane system is used for long standby periods since power usage is only slightly lower in standby than during an ongoing procedure. Turning off the device after 15 min of idle time would save nearly half of energy consumption. Moreover, an option to switch off the second tube plus detector during procedures, which do not require this dual use (e.g. in peripheral vascular interventions) would save an additional 5%.

### CLINICAL RELEVANCE/APPLICATION

Imaging modalities in IR consume significant amounts of energy. Optimization is mandatory in times of climate and energy crises. Reduction of idle times and smart use of biplane systems can have a major impact.

## R5A-SPIR-3 SAFETY AND EFFICACY OF DUAL ANTIPLATELET TREATMENT WITH TICAGRELOR AND ASPRIN IN STENT INVOLVING ENDOVASCULAR TREATMENT OF UNRUPTURED BRAIN ANEURYSMS: SINGLE CENTER EXPERIENCE

Abdurrahman Avcioglu (*Abstract Co-Author*) Nothing to Disclose

Tugrul Cem Unal, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Endovascular treatment (EVT) of brain aneurysms involving stents is a commonly used method that necessitates the use of antiplatelets. Antiplatelet treatment proves to be a major concern which may have a negative impact on the safety of the procedure, efficacy, and stability of treatment in the long-

term. The purpose of this study is to report a single center's experience with ticagrelor and acetylsalicylic acid(ASA) in terms of thromboembolic and hemorrhagic complications in stent-assisted EVT.

**METHODS AND MATERIALS**

128 patients treated at a single center between 2019 and 2023 for brain aneurysms via endovascular technique were included in this study. All aneurysms were treated with stents (59 with single stent assisted coiling; SSAC, 39 with flow diverters; FD, 26 with Y stent-assisted coiling and six with stent monotherapy). All patients received ticagrelor 90 mg twice daily and ASA 100 mg daily starting the day before treatment and continued with dual treatment for three months after the procedure and ASA for at least one year. This study was conducted with approval from the ethics committee, encompassing data from the hospital management system and the imaging archive (PACS) through retrospective scanning.

**RESULTS**

Out of 128 patients treated endovascularly, 99 (77%) were female, and 29 (23%) were male. The average follow-up duration of the patients was 20.5 (1-60) months and average age was 55.3 years (21-79). In both the FD and Y-stent groups, no intra or extra-cranial hemorrhagic events (HE) were observed during follow-up. In the FD group, there was one early clinical thromboembolic event (cTE) (0.7%). No significant difference in the frequency of cTEs or gender distribution was observed between the two groups (p=0.420 and p=0.633, respectively). No cTE event was detected in the SSAC group. There were three early HE (2.3 %). No significant relationship was found between the SSAC and Y-stent groups regarding the frequency of HE (p=0.238). No significant difference was observed between the SSAC and the FD groups regarding cTE and HE (p= 0.228 and p=0.142, respectively). Overall HE rate was 0.7% and cTE rate was 2.3% in this group of patients treated with stents (Table 1).

**CONCLUSION**

Overall cTE complication rate was lower when compared with results from literature involving other P2Y12 receptor inhibitors, and HE rate was not increased. The rate of complication development is the highest in treatment with SSAC, but no statistically significant difference was found between SSAC, FD, and Y-stent techniques in terms of complication development.

**CLINICAL RELEVANCE/APPLICATION**

This report may contribute to the literature in terms of predicting complications of antiplatelet treatment in EVT of unruptured brain aneurysms involving stents.

## R5A-SPIR-4 REAL-TIME DOSIMETRY IN INTERVENTIONAL RADIOLOGY - COMPARING SCATTER RADIATION DOSE IN LOWER EXTREMITY AND ABDOMINAL PROCEDURES

Thorsten A. Bley, MD (*Abstract Co-Author*) Speakers Bureau, F. Hoffmann-La Roche Ltd;Research Consultant, F. Hoffmann-La Roche Ltd;Speakers Bureau, Novartis AG;Research Consultant, Novartis AG;Research Consultant, Baltimore RH Typing Laboratory
Wolfram Voelker, MD (*Abstract Co-Author*) Nothing to Disclose
Annette Thurner (*Abstract Co-Author*) Nothing to Disclose
Ralph Kickuth, MD (*Abstract Co-Author*) Nothing to Disclose
Jan P. Grunz, MD (*Abstract Co-Author*) Research Consultant, Siemens AG
Kristina Krompass (*Presenter*) Nothing to Disclose

**PURPOSE**

In the last decade, the number of interventional radiology procedures has increased considerably, highlighting a growing need for personnel dosimetry of medical staff. Due to its unpredictable nature, scattered radiation represents a risk factor for carcinogenesis in interventional radiologists. Optimization of radiation safety procedures has spurred the development of real-time dosimetry systems in recent years. This study investigated the occupational dose exposure of interventional radiologists' cranium/eye lens, hand, and body trunk during lower extremity and abdominal procedures.

**METHODS AND MATERIALS**

Over a 14-month period, real-time dosimetry was performed during 102 consecutive interventions (51 lower extremity, 51 abdominal). Radiation protection measures included protective glasses (lead equivalent 0.5 mm), thyroid shielding (0.5 mm), vests (0.35 mm), skirts (0.25 mm), as well as movable acrylic and table shields (both 0.5 mm) during all procedures. Dosimeters were attached to the protective glasses of the interventional radiologist on the side of the x-ray tube, to the dominant hand, and under the vest. Dose-area products and equivalent doses in all three positions were recorded for each intervention. For the latter, standardized values over time were used to account for time differences between the interventions.

**RESULTS**

Pelvic-leg interventions were associated with a substantially lower dose-area product (7.53±6.05 vs. 88.50±83.85 Gy×cm2) and exposure time (8.6±5.7 vs. 16.2±13.2 min) than abdominal procedures (both P<.001). For lower extremity interventions, the radiation exposure recorded by the hand, cranium/eye lens, and body trunk dosimeters was 4.13±4.86 µSv/min, 0.05±0.10 µSv/min, and 0.70±2.44 nSv/min, respectively. Abdominal procedures were associated with substantially higher equivalent doses to the hand (12.15±12.68 µSv/min), cranium/eye lens (0.88±1.32 µSv/min), and body trunk (0.12±0.15 µSv/min; all P<.001).

**CONCLUSION**

Real-time dosimetry confirmed sufficient protection against scatter radiation with the application of standardized safety measures even in high-dose abdominal procedures. The dominant hand of interventional radiologists is by far subjected to the highest radiation exposure, followed by the cranium/eye lens and the body trunk.

**CLINICAL RELEVANCE/APPLICATION**

Dedicated protective measures are essential to achieve compliance with the International Commission on Radiological Protection (ICRP) guidelines for occupational exposure in interventional radiology.

## R5A-SPIR-5 TRANSITIONING FROM INTERVENTIONAL RADIOLOGY

Richard B. Towbin, MD (*Abstract Co-Author*) Nothing to Disclose

Chase Irwin (*Abstract Co-Author*) Nothing to Disclose
Stacy Ruther, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

Interventional radiologists at some point will transition from Interventional Radiology (IR) to pursue other interests or retire. In this survey, we assessed factors that affect interventional radiologists' decision to transition from IR, and determined what activities they pursue following the transition.

**METHODS AND MATERIALS**

An online questionnaire gauging potential influences on interventional radiologists' decision to transition from IR was posted to the Society of Interventional Radiology Connect Forum. 167 questionnaires were completed voluntarily by respondents. 27/167 (16%) were interventionalists who had already transitioned from IR, 28/167 (17%) were in the process of transitioning, and 112/167 (67%) had not yet transitioned.

**RESULTS**

Nighttime call responsibilities (36/55, 65%), burnout (23/55, 42%), and age (20/55, 36%) were the major factors in those who were, or were currently, transitioning from IR. 21/53 (40%) respondents report they took on a greater Diagnostic Radiology (DR) workload during their transition. Other than DR, the most commonly pursued activities following transition were athletics (17/55, 31%) and mentorship to students/trainees (15/55, 27%). The greatest benefits of transitioning from IR among those who have transitioned include: more time with family/friends (33/55, 60%), reduced stress (27/55, 49%), and more time for non-medical hobbies/travel (27/55, 49%). Among respondents who have not yet transitioned, nighttime call responsibilities (81/112, 72%), burnout (64/112, 57%), and age (59/112, 53%) are the most influential factors in their decision of when to transition from IR. Among all respondents, job satisfaction during their career in IR has: increased (42/167, 25%), stayed the same (43/167, 26%), or decreased (82/167, 49%). 81% (136/167) of all respondents reported they would pursue the field of IR again.

**CONCLUSION**

Nighttime call responsibilities, burnout, and age are major influences in the decision to transition from IR. Job satisfaction decreases for nearly half of interventionalists during their career in IR.

**CLINICAL RELEVANCE/APPLICATION**

By determining the factors that influence interventionalists to transition from the field, action can be taken to minimize their impact, ultimately improving job satisfaction and longevity.

## R5A-SPIR-6 VIRTUAL REALITY EXPERIENCE IN INTERVENTIONAL RADIOLOGY: IRVARI STUDY. A RANDOMIZED CONTROLLED TRIAL

Henri GARREAU (*Abstract Co-Author*) Nothing to Disclose
Jean-Pierre J. Pelage, MD, PhD (*Abstract Co-Author*) Research Grant, Merit Medical Systems, Inc;Consultant, Merit Medical Systems, Inc;Research Grant, Cook Group Incorporated;Consultant, Cook Group Incorporated;Research Grant, Keocyt;Medical Board, Keocyt;Research Grant, Terumo Corporation;Consultant, Terumo Corporation;Research Grant, ALN;Consultant, ALN;Consultant, Boston Scientific Corporation;Research Grant, BTG International Ltd
Remi Morello (*Abstract Co-Author*) Nothing to Disclose
Audrey Fohlen, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the feasibility, safety and efficacy of a Virtual Reality (VR) experience during interventional radiology (IR) procedures to reduce patient anxiety and pain.

**METHODS AND MATERIALS**

This prospective randomized controlled trial enrolled 192 patients with indication for liver biopsy, transarterial chemoembolization, varicocele embolization, pelvic vein embolization or uterine fibroid embolization. Two groups were defined: VR conditions vs control. Intervention-induced anxiety was evaluated immediately after the procedure by the State-Trait Anxiety Inventory using its state anxiety part (STAI-YA). We also evaluated with a numeric rating scale (NRS) anxiety and pain before, during and after intervention. Evolution of hemodynamics parameters was recorded as well as medications consumption and procedure time. Side effects and patient satisfaction of VR experience were reported. The difference in anxiety between the two groups, as measured with the STAI-YA scale was compared using the Student's t test. The same statistical method was applied for the comparison of the pain experienced by patients as assessed by the NRS scale. The Pearsons' coefficient was applied to investigate the relationships between preoperative anxiety and the pain levels experienced during the procedure, quantified using the NRS.

**RESULTS**

The study included 72 patients in VR conditions and 71 for control group. The VR group had significantly lower mean score for anxiety according STAI-YA of 21.2% (25.4 vs 32.3; $p<0.01$) with an important effect size (Cohen's $d=0.717$). Evolution of anxiety and pain evaluated with NRS was significantly better ($p<0.001$) in the VR group. Systolic arterial blood pressure was significantly lower in the VR group ($p<0.001$). No difference was identified between both groups in terms of antalgic used or procedure time. Side effects were reported in 1.5% of patients while 88.9% of patients were satisfied with the VR experience.

**CONCLUSION**

Virtual Reality is safe, effective, and well tolerated and demonstrated reduced pain and anxiety during IR procedures.

**CLINICAL RELEVANCE/APPLICATION**

Virtual reality experience is associated with reduced anxiety and pain in patients undergoing interventional radiology procedures. Routine use of virtual reality may be advocated in patients undergoing interventional radiology procedures.

## R5A-SPIR-7 PRO-TRANSLATE IR: TRANSLATION OF INTERVENTIONAL RADIOLOGY PROCEDURAL INSTRUCTIONS USING LARGE LANGUAGE MODELS TO IMPROVE INFORMATION ACCESS TO NON-ENGLISH-SPEAKING PATIENTS

Sara E. Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Michael Dezube (*Abstract Co-Author*) Nothing to Disclose

Shakthi K. Ramasamy, MD (*Abstract Co-Author*) Nothing to Disclose
Satvik Tripathi (*Abstract Co-Author*) Nothing to Disclose
Tarig Elhakim, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the utility of GPT-4, for generating and translating Interventional Radiology (IR) procedural instructions. The study aims to assess its effectiveness in generating layman-friendly explanations for the technical terminology and medical jargon prevalent in IR. This can potentially provide insights to improve healthcare communication and patient understanding in multilingual settings.

## METHODS AND MATERIALS

Three commonly performed IR procedures were selected for assessment, including Radiofrequency Ablation (RFA), TransArterial ChemoEmbolization (TACE) and Uterine Fibroid Embolization (UFE). Prompts were prepared with a goal to explain the procedure in layman-friendly terms, followed by answering the 15 most common questions patients could potentially ask about a procedure. Once GPT-4 provided an answer, a prompt was then performed to translate from English to Spanish and to Arabic as a proof of concept. The evaluation involved a panel of 3 clinical assessors using a three-tier ordinal scale (fully, somewhat, and not appropriate) and up to 6 non-clinical assessors using a four-tier ordinal scale (poor, fair, good, and excellent understanding). Data was collected using an online survey tool.

## RESULTS

Responses generated by GPT-4 received a fully appropriate rating from clinical assessors for all three procedural instructions translated to Arabic. For the Spanish version, 2 instructions were fully appropriate while RFA instruction was deemed 66.7% fully appropriate and 33.3% somewhat appropriate. The 5 Arabic-speaking non-clinical assessors rated the RFA and TACE instructions as 80% excellent and 20% good understandability and clarity of the Arabic translated version while the UFE achieved 60% excellent and 25% good understandability and clarity. For the Spanish-version, the UFE and TACE instructions were rated as 83.3% excellent and 16.7% good understandability and clarity while the RFA achieved 66.7% excellent and 33.3% good understandability and clarity.

## CONCLUSION

GPT-4 has a great potential to provide translated educational instructions and answer the most common questions about various IR procedures with excellent to good clarity for non-English Speakers. Future studies can expand upon this foundation to develop validated patient educational materials accessible through a multi-language platform. This can significantly enhance patient-centered care in IR by ensuring easily accessible information for non-native English speakers.

## CLINICAL RELEVANCE/APPLICATION

Large Language Models can effectively translate instructions for Interventional Radiology procedural, thereby improving Information access to Non-English-Speaking Patients and enhancing patient centered care in IR

## R5A-SPMK-1 VALIDATION OF THE BONE REPORTING AND DATA SYSTEM (BONE-RADS™) FOR CLASSIFYING FOCAL BONE LESIONS

Yusuhn Kang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Choong Guen Chee, MD (*Abstract Co-Author*) Nothing to Disclose
Youngjune Kim, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To validate the performance of Bone-RADSTM in discriminating benign and malignant bone lesions and to evaluate the inter-observer agreement of Bone-RADSTM assessment

### METHODS AND MATERIALS

This single-center retrospective study included patients visited our orthopedic oncology department between January 2019 and December 2020 for a focal bone tumor. Three musculoskeletal radiologists assessed the initial radiograph series performed for evaluating tumor-of-interest. First, they assessed whether the tumor is eligible for Bone-RADSTM assessment considering the axial location and radiodensity of the tumors. For the tumors judged to be eligible for Bone-RADSTM assessment, the radiologists rated descriptors of Bone-RADSTM (margin, periosteal reaction, endosteal reaction, pathologic fracture, and soft-tissue mass) and Bone-RADSTM categories were calculated accordingly. The performance in discriminating malignant bone lesion was assessed in terms of sensitivity and area under receiver-operating-characteristic curve (AUC). Gwet's AC1 was calculated for evaluating interobserver agreement of Bone-RADSTM category. The malignancy rate according to Bone-RADSTM category was calculated.

### RESULTS

A total of 379 patients (mean age ± standard deviation, 36.7 ± 22.5 years; 160 women; and 103 malignancy) were finally included. The reader 1 judged 283 tumors eligible for the assessment; reader 2, 283; and reader 3, 269. The sensitivities and AUCs in discriminating malignancy with Bone-RADSTM were 91.4-97.9% and 0.907-0.921. There was substantial interobserver agreement of Bone-RADSTM category with Gwet's AC1 of 0.619 (95% confidence interval, 0.558-0.679). The malignancy rates ranged 0.0-1.2% in Bone-RADSTM category 1; 3.8-9.1% in category 2; 18.5-25.6% in category 3; and 78.9-80.9% in category 4, respectively.

### CONCLUSION

Bone-RADSTM showed high sensitivity and AUC in discriminating malignant bone lesion despite substantial inter-observer agreement across the radiologists.

### CLINICAL RELEVANCE/APPLICATION

Bone-RADSTM could be utilized as a useful screening tool in discriminating malignant bone lesion using radiographs.

## R5A-SPMK-2 BONE STRESS INJURY DETECTION IN TIBIAL AND FIBULAR CORTICAL BONE USING QUANTITATIVE ULTRASHORT ECHO TIME MAGNETIC RESONANCE IMAGING: AN IN VIVO FEASIBILITY STUDY

Eric Y. Chang, MD (*Abstract Co-Author*) Nothing to Disclose

Alecio F. Lombardi, MD (*Abstract Co-Author*) Nothing to Disclose
Niloofar Shojaeiadib (*Abstract Co-Author*) Nothing to Disclose
Dina Moazamian, MD (*Abstract Co-Author*) Nothing to Disclose
James Lo, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This study investigates the capability of ultrashort echo time (UTE)-MRI to quantify changes induced by stress injuries in vivo in fibular and tibial cortical bone.

### METHODS AND MATERIALS

Institutional review board approval and written informed consent were obtained for all recruited subjects. The injured and asymptomatic legs of four patients with a tibial or fibular stress injury (BSI) (21.5±3.3 years old, three male, one female) were scanned in the axial plane on a 3T clinical scanner (MR750, GE) employing an 8-channel transmit/receive knee coil. Scanning coverage was centered around the painful site reported by the patients. A dual-echo 3D Cones UTE sequence was performed [repetition time (TR) = 80 ms, echo times (TEs) = 0.032 and 2 ms, flip angle (FA) = 45°) for porosity index (PI) measurement (Eq.1)]. Off-resonance magnetization transfer (MT) weighted 3D Cones UTE sequence was performed without and with an MT pulse (pulse power = 1000° and a frequency offset of 2kHz, FA=8°, number of spokes=11) for MT ratio (MTR) measurement. The matrix dimension, the field of view (FOV), nominal in-plane pixel size, and slice thickness were 160×160×24, 140×140×120 mm3, 0.87 mm, and 5 mm, respectively. The total scan time was ~7 minutes.

### RESULTS

UTE-MTR and UTE-PI pixel maps of the tibial cortical bone of a representative patient are presented in Fig.1A and Fig.1B for the asymptomatic and injured leg, respectively. The box plots of the UTE-MTR and UTE-PI values of the injured vs. asymptomatic legs are presented in Fig.1C and Fig.1D. Significant differences in UTE-MTR and UTE-PI values were observed between the injured and asymptomatic legs.

### CONCLUSION

The capability of evaluating the in vivo BSI in lower leg cortical bone was investigated using quantitative UTE-MRI. The ex vivo capability of UTE-MRI detecting BSI was shown in a previous study (1). Lower MTR but higher PI values of the injured cortical bone were likely due to increased water content in potential microcracks and a reduced or disrupted organic matrix structure (2). More investigations should be performed with larger sample sizes to validate such conclusions while employing more sophisticated methods specific to organic matrix assessments, such as UTE-MT modeling.

### CLINICAL RELEVANCE/APPLICATION

Validating the capability of UTE-MRI techniques in the quantitative assessment of BSI may provide a more accurate diagnostic and monitoring tool and an improved return-to-activity plan for patients.

## R5A-SPMK-3 ASSESSMENT OF TIBIAL PLATEAU FRACTURES COMPARING A CT-LIKE 3D T1-WEIGHTED SPOILED MULTI-ECHO GRADIENT-ECHO MRI SEQUENCE (FRACTURE) WITH CONVENTIONAL CT

Frank Oliver G. Henes, MD (*Abstract Co-Author*) Nothing to Disclose
Inka Ristow, MD (*Abstract Co-Author*) Nothing to Disclose
Gerhard B. Adam, MD (*Abstract Co-Author*) Nothing to Disclose
Lennart Well, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic performance of a CT-like 3D T1-weighted spoiled multi-echo gradient-echo MRI sequence (FRACTURE-MRI) for the detection of tibial plateau fractures compared with conventional CT.

### METHODS AND MATERIALS

In this prospective, two-center study, all patients who received MRI of the knee due to presentation to the emergency departments following acute trauma of the knee from 05/2022 to 03/2024 were included. All patients underwent magnetic resonance imaging (MRI) at 3T including FRACTURE-MRI. FRACTURE-MRI consisted of a 3D T1-weighted spoiled multi-echo gradient-echo sequence (FOV 130 x 160 $mm^2$; Matrix ACQ 144 x 174; Voxel ACQ 0.9 x 0.92 x 0.9 $mm^3$; TR 23 ms; TE 4.6 ms; delta TE 5 ms). Following acquisition, a magnitude summation of all echoes was created and images from the last echo were subtracted from the summated images. Patients with acute fractures received a CT. CT served as the standard of reference for all fractures. Two radiologists independently evaluated FRACTURE-MRI for presence of fractures and image quality. Intraarticular tibial fractures were rated according to the AO/OTA classification and a 10-segment classification score. Diagnostic accuracy and agreement between MRI and CT and between radiologists were assessed. Image quality of FRACTURE-MRI was graded on a five-point scale. Image quality was assessed by estimated marginal means. Interreader assessment was evaluated by weighted Cohen's ?.

### RESULTS

The study collective comprised 126 patients (68 female, mean age= 39.6 years ± 14.5 years). CT revealed intraarticular fractures in 42/126 patients (33.3 %). According to the AO/OTA classification, fractures were rated by CT as: 2xA1; 2xA2; 1xA3, 7xB1, 11xB2, 8xB3, 11xC3. Fractures were correctly identified by both readers in 36/42 cases (85.7%). In the 10-segment classification score, CT identified 151/420 segments as fractured. The sum of correctly identified segments by both readers was 261/302 (86.4%). 45 segments were falsely classified as intact and 52 segments were falsely identified as fractured. Sensitivity and specificity of FRACTURE-MRI for detection of intraarticular fractures was 89.3% (95%-CI: 80.6 - 95%) and 94.6% (95%-CI: 90.1 - 97.5%), respectively. Estimated marginal means for image quality of FRACTURE-MRI were 4.3 (CI: 4.2 - 4.4). Cohen's ? was 0.937 ($p<0.001$) for the AO/ATO classification and 0.886 ($p<0.001$) for the 10-segment classification.

### CONCLUSION

Assessment of proximal tibial fractures using CT-like 3D T1-weighted spoiled multi-echo gradient-echo sequence (FRACTURE) at 3T is feasible and comparable to CT.

### CLINICAL RELEVANCE/APPLICATION

FRACTURE-MRI might pose a helpful alternative to conventional CT in an acute trauma setting by reducing both costs and radiation exposure.

## R5A-SPMK-5 DUAL-ENERGY COMPUTED TOMOGRAPHY (DECT) FOR THE ASSESSMENT OF SOFT TISSUE TUMOR RECURRENCE AND SCAR: COMPARISON WITH APPARENT DIFFUSION COEFFICIENT (ADC) VALUE

Yingyi Zhu (*Abstract Co-Author*) Nothing to Disclose
Lin Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Jiachun Zhuang (*Abstract Co-Author*) Nothing to Disclose
Haijun Wu, MD,PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the recurrence of lesions in patients with soft tissue tumors, patients with soft tissue tumors require regular examination after surgery. It is necessary to evaluate the dual-energy computed tomography (DECT) quantitative parameters and apparent diffusion coefficient (ADC) values for predicting recurrence and scar in patients with soft tissue tumors, This study seeks to contribute to the optimization of imaging protocols and diagnostic algorithms that can be utilized in the management of patients with soft tissue tumors.

### METHODS AND MATERIALS

38 patients with soft tissue tumor underwent postoperative DECT from December 2021 to November 2023, and 30 patients among them were performed in postoperative MRI. DECT quantitative parameters and ADC values were compared between recurrent lesions and scars using the Mann-Whitney U test and Independent Samples T test. Receiver-operating characteristic (ROC) analysis was used to assess the ability of DECT quantitative parameters and ADC values to diagnose recurrent lesions and scars.

### RESULTS

This study demonstrated significant differences in DECT parameters between recurrence and scar groups. Specifically, weighted averages in arterial, early venous, and late venous phases, along with iodine concentration and CT number differences, were higher in the recurrence group, with statistical significance ($P < 0.05$). Similarly, Diffusion-Weighted Imaging (DWI) results showed the Apparent Diffusion Coefficient (ADC) was significantly lower in the recurrence group, indicating its utility in distinguishing between recurrence and scar tissue. The ROC curve analysis revealed that DECT and DWI parameters could accurately identify recurrent lesions and scars, with areas under the curve ranging from 0.700 to 0.808.

### CONCLUSION

The combined use of DECT and DWI is shown to be effective in accurately detecting soft tissue tumors, highlighting their potential as valuable diagnostic tools in postoperative evaluations.

### CLINICAL RELEVANCE/APPLICATION

In this study, the postoperative DECT and MRI examination parameters of patients with soft tissue tumors were studied to determine their significance in predicting tumor recurrence, with the goal of advancing predictive capabilities and standardizing the management of patients in advance.

## R5A-SPMK-6 UNVEILING HETEROGENEITY IN RESPONSE EVALUATION OF SOFT TISSUE SARCOMA TO NEOADJUVANT RADIOTHERAPY: ASSOCIATIONS BETWEEN RADIOLOGY AND PATHOLOGY FINDINGS

Regina G. Beets-Tan, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Annemarie Bruining, MD (*Abstract Co-Author*) Nothing to Disclose
Yuri Velichko, PhD (*Abstract Co-Author*) Nothing to Disclose
Stefano Trebeschi (*Abstract Co-Author*) Nothing to Disclose
Zuhir Bodalal (*Abstract Co-Author*) Nothing to Disclose
Nicolo Gennaro, MD (*Presenter*) Nothing to Disclose

### PURPOSE

For high-grade and locally advanced soft tissue sarcoma (STS), neoadjuvant radiotherapy (nRT) has emerged as a well-established treatment option. Despite being the best non-invasive modality for assessing response to nRT, MRI shows limited correlations with pathology findings. This study aimed to analyze changes in imaging and pathology findings after nRT and explore correlations between them.

### METHODS AND MATERIALS

In a study of 107 patients with histopathologically confirmed intermediate/high-grade soft tissue sarcoma (STS), tumor diameter, volume, and tumor-to-muscle signal intensity (SI) ratio were measured before and after neoadjuvant radiotherapy (nRT). These measurements were correlated with post-treatment pathology findings (viable cells, percentage of necrosis, and fibrosis) using the Spearman Rank test. Pathological complete response (pCR) was defined as the absence of any viable tumor cells, while near-complete pathological response (near-pCR) was defined as the presence of less than 10% viable cells.

### RESULTS

The median amount of necrosis, viable cells, and fibrosis after nRT were 10%, 30%, and 25%, respectively. Seven percent of patients achieved pCR and 22% achieved near-pCR. No significant changes in tumor volume were found overall. However, for specific subtypes changes were significant: myxoid liposarcoma (mLPS) showed a decrease of -54.47%, undifferentiated pleomorphic sarcoma (UPS) and dedifferentiated liposarcoma (dLPS) showed an increase of +24.22% and +35.91%, respectively. Median change in tumor-to-muscle SI ratio was -19.74% for the entire population, whereas it was more pronounced for UPS (-19.55%) and mLPS (-36.26%). Statistically significant correlations (positive and negative) were found between change in volume and the presence of necrosis ($rs=0.44$) or fibrosis ($rs=-0.438$), as well as between tumor-to-muscle SI ratio and viable cells ($rs= 0.331$) or fibrosis ($rs=-0.278$).

### CONCLUSION

STS displays extensive heterogeneity in response to nRT. For some subgroups, changes in tumor size and tumor-to-muscle SI ratio show significant correlations with the percentage of viable cells, fibrosis, and necrosis.

### CLINICAL RELEVANCE/APPLICATION

Strong correlation between radiology and pathology findings improves the interpretation of tumor response to nRT. It also highlights the limitations of RECIST criteria for specific STS histotypes, laying the ground for further research on the complimentary role of imaging in assessing neoadjuvant therapy for STS.

## R5A-SPMS-1 THEINFLUENCE OFDEEPLEARNINGIMAGERECONSTRUCTIONALGORITHM (DLIR) ONMULTIPARAMETERS OFLUMBARSPINEENERGYSPECTRUM CT

Yanhong Zhao, MMed,MMed (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the effect of deep learning image reconstruction (DLIR) on the image quality of lumbar spine spectral CT monochromatic image, effective atomic number image, hydroxyapitite (HAP)-water image and HAP-fat image by comparing with FBP and hybrid iterative reconstruction-veo (ASIR-V) algorithms.

### METHODS AND MATERIALS

20 patients with suspected lumbar diseases were selected. The spine spectral CT imaging was performed with revolution apex CT. Five groups of images were reconstructed by filtered back projection reconstruction (FBP), 40% ASIR-V reconstruction ,low level of DLIR (DLIR-L), middle level of DLIR (DLIR-M) and high level of DLIR (DLIR-H). 40-140keV monochromatic image, energy spectrum curve, base substance image (HAP-water, HAP-fat image) and effective atomic number image were reconstructed using the energy spectrum analysis software. CT values of monochromatic images (40 keV, 70 keV and 100 keV), HAP concentration of HAP-water image and HAP-fat image, effective atomic number and image noise of lumbar vertebrae were measured in five groups ,the signal-to-noise ratio (SNR) of each image was calculated, and the differences in the quality of the five groups of images were compared.

### RESULTS

There was no significant difference in CT values of 40 keV, 70 keV, 100 keV among five groups of images (all $P > 0.05$), the effective atomic number, the HAP concentration of HAP-water and the HAP concentration of HAP-fat image were also not significantly different among five groups (all $P>0.05$). There was significant difference in image noise and SNR of single energy images (40 keV, 70 keV and 100 keV), effective atomic number image, HAP-water image and HAP-fat image among five groups of images (all $P > 0.05$). The lumbar vertebrae image noise of FBP, 40%ASIR-V, DLIR-L , DLIR-M and DLIR-H images were 101.72±13.06,77.75±12.34,77.19±12.59,71.28±12.97and 64.85±13.37 HU,the noise of DLIR-H reconstruction algorithm is 36.25% lower than that of FBP, and 16.65% lower than that of 40% ASIR-V.Compared with FBP and 40% ASIR-V, the image noise of DLIR is lower than that of FBP and 40% ASIR-V, and the image signal-to-noise ratio is improved (all P values <0.05). DLIR -H has the lowest noise and the highest signal-to-noise ratio.

### CONCLUSION

In lumbar spine spectral CT imaging, DLIR has lower noise and higher signal-to-noise ratio than FBP and 40% ASIR-V in single-energy image, effective atomic number image, HAP-water image and HAP-fat image.

### CLINICAL RELEVANCE/APPLICATION

Compared with FBP and 40% ASIR-V reconstruction algorithm, deep learning image reconstruction algorithms have great potential and application value in improving the image quality of lumbar spine spectral CT .

## PURPOSE

Erdheim-Chester disease (ECD) is a rare, non-Langerhans cell histiocytosis frequently affecting the central nervous system (CNS), leading to a dire prognosis. The long-term effects of ECD disease activity in the CNS are not well understood. This study aims to characterize the brain MR imaging findings in a cohort of 58 patients with ECD and to evaluate the relationship between these findings and the BRAFV600E pathogenic variant.

## METHODS AND MATERIALS

ECD patients of any gender and ethnicity, aged 2-80 years, with biopsy-confirmed ECD based on pathology of affected organs were eligible to enrol in this study. Two radiologists experienced in evaluating ECD CNS disease activity reviewed the MRI studies. Any disagreements were resolved by a third reader. Frequencies of the observed involvements were reported. The association between the distribution of CNS involvements and the BRAFV600E pathogenic variant was evaluated using Fisher's exact test and odd ratio.

## RESULTS

The brain MRI of all 58 patients with ECD revealed some form of CNS involvement, most likely due to ECD. Cortical lesions was noted in 27/58 (46.6%) patients, cerebellar lesions in 15/58 (25.9%) patients, brain stem lesions in 17/58 cases (29.3%), and pituitary involvement in 10/58 (17.2%) patients. The frontal lobe was the most affected area the cerebrum. Premature cortical atrophy was observed in 8/58 (13.8%) patients. BRAFV600E pathogenic variant was significantly associated with cerebellar lesions (p-value = 0.016) and bilateral brain stem involvement (p-value = 0.043). A trend toward significance was noted for cerebral atrophy (p-value = 0.053).

## CONCLUSION

The study provides valuable insights into the brain MRI findings in ECD and their association with BRAFV600E pathogenic variant particularly its association in cases with bilateral lesions. We are expanding our understanding of how ECD affects cerebral structures.

## CLINICAL RELEVANCE/APPLICATION

The correlation between BRAFV600E mutation and brain MRI findings in ECD particularly bilaterality provides critical insights for prognosis and treatment planning, leading to more personalized and effective clinical management strategies, ultimately improving patient outcomes.

Julia Brosch-Lenz (*Abstract Co-Author*) Nothing to Disclose
Saeed Ghandili, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Kidneys represent one major organ at risk for radiopharmaceutical therapy (RPT). In this work, we aimed to evaluate the kidney absorbed dose in patients undergoing 177Lu-PSMA and 177Lu-DOTATATE RPTs for prostate and neuroendocrine cancers, respectively.

### METHODS AND MATERIALS

Multi-time point quantitative 177Lu SPECT/CT scans performed after each RPT cycle assessed the absorbed renal dose of 93 patients. Organs at risk were manually segmented in MIM at three 177Lu SPECT/CT time points for each treatment. Organ-absorbed doses were then calculated using MIM. Renal absorbed dose was analyzed in our patient population, and the average and cumulative absorbed dose for each patient was reported.

### RESULTS

All 93 patients receiving RPT demonstrated acceptable renal absorbed dose. 26 patients were treated with 177Lu-DOTATATE, and 67 received 177Lu-PSMA treatment. Certain patients were unable to complete the full course of treatment or attend the scheduled dosimetry scans for various reasons. On average, neuroendocrine cancer patients received dosimetry at 2.7 cycles and prostate cancer patients at 4.1 cycles. For 177Lu-DOTATATE, the median cumulative absorbed kidney dose was 8.0Gy across all cycles, the minimum dose across cycles (cumulative) was 2.5Gy, and the maximum dose across cycles was 15.9; also the maximum dose for one patient for one cycle was 7.1Gy. For 177Lu-PSMA, the median cumulative absorbed kidney dose was 8.1Gy across all cycles, the minimum dose across cycles (cumulative) was 1.1Gy, and the maximum dose across cycles was 18.2Gy; also, the maximum dose for one patient for one cycle was 9.4Gy. In general, we observed an increase of kidney absorbed dose towards later therapy cycles.

### CONCLUSION

Our assessment of kidney-absorbed dose for 177Lu-PSMA and 177Lu-DOTATATE demonstrated that patients in our population tolerate routine patient specific dosimetry following RPT. In our population, many patients had favorable personalized renal doses in consideration of future RPT. Also, some patients had a higher than expected personalized renal dose for a particular treatment, highlighting the importance of routine measurement for accurate cumulative dose calculation. Increased kidney absorbed dose with increasing therapy cycles may be attributed to the tumor sink effect. Additional efforts are needed to correlate patient specific renal dose and other patient specific factors with kidney function over time to better define the appropriate tolerated renal dose for specific RPTs to prevent radiation induced toxicity if patients were to have additional RPTs in the future.

### CLINICAL RELEVANCE/APPLICATION

To emphasize the relevance of personalized dosimetry after radiopharmaceutical therapy to monitor organ at risk absorbed dose.

## R5A-SPNPM-2 IMPACT OF BRIEF MINDFULNESS ATTENTION TRAINING ON RADIOLOGIST ATTENTION AND NODULE DETECTION: A PILOT RANDOMIZED CONTROL TRIAL

Lilyane Saleh, MD (*Abstract Co-Author*) Nothing to Disclose
Tia Bhayana (*Abstract Co-Author*) Nothing to Disclose
Satheesh Krishna, MD (*Abstract Co-Author*) Nothing to Disclose
Yangqing Deng (*Abstract Co-Author*) Nothing to Disclose
Rajesh Bhayana, MD, FRCPC (*Presenter*) Nothing to Disclose

### PURPOSE

Attention lapses contribute to perceptual errors in radiology, which can impact patient outcomes. Mindfulness attention training (MAT) improves attention and visual perception in many domains. The purpose of this study was to assess whether brief MAT can improve radiologist attention and lung nodule detection.

### METHODS AND MATERIALS

In this IRB-approved pilot randomized control trial, 24 radiologists were included. At baseline (T1), participants performed the Sustained Attention to Response Task (SART), with attentional lapses (errors of commission) recorded and subjective attention, general wellbeing and burnout reported. An exploratory visual attention nodule detection (VAND) task was performed, in which participants detected and counted lung nodules on 50 CT images, with the number of correct answers recorded. At repeat assessment one-month later (T2), participants were randomly assigned to either receive brief MAT (10-minute video) or control (10-minute radiology video) prior to reassessment. Results for each group were compared between T1 and T2 using Wilcoxon signed rank tests. Changes from T1 to T2 were compared between both groups using Wilcoxon rank sum tests.

### RESULTS

Compared to baseline, radiologists had significantly fewer attentional lapses post-MAT (-14%, p=0.025). However, MAT did not significantly reduce attentional lapses compared to the control group (-14 vs -8%, p=0.45). MAT improved radiologist reported attention compared to control (likert +0.8 vs -0.2, p=0.04). Compared to control, MAT did not significantly improve wellbeing (+0.5 vs 0.1, p=0.29) or cognitive burnout (+0.1 vs -0.1, p=0.56). Radiologists who had MAT demonstrated greater raw improvement in nodule detection task scores than control (+6 vs 0.3%), but the difference was not significant in this pilot (p=0.54). Based on our pilot results, larger sample sizes are required to detect a difference between intervention and control groups for attentional lapses (n=176) and nodule detection task performance (n=348) with 80% power.

### CONCLUSION

Brief mindfulness attention training reduced attentional lapses in radiologists compared to baseline, but not more than control; it improved radiologist reported attention over control; it did not significantly improve nodule detection performance over control. Future studies with larger cohorts and more intensive training should be explored.

### CLINICAL RELEVANCE/APPLICATION

Brief interventions that improve radiologist attention could help reduce perceptual errors in radiology practice.

## R5A-SPNR-1 DIAGNOSTIC PERFORMANCE ANALYSIS ACROSS PEDIATRIC AGE GROUPS OF AI-BASED INTRACRANIAL HEMORRHAGE DETECTION SOFTWARE

Su Jeong Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Tae Jin Yun, MD (*Abstract Co-Author*) Nothing to Disclose
DURI HWANG (*Abstract Co-Author*) Nothing to Disclose
Miran Han, MD (*Abstract Co-Author*) Nothing to Disclose
Woosang Jung (*Abstract Co-Author*) Nothing to Disclose
Jin Wook Choi, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Multiple commercial AI-based intracranial hemorrhage (ICH) detection software products are available for adults; however, options for pediatric ICH are limited. Recent studies lack evidence on the performance of AI-based ICH detection software for adults when applied to pediatric cases. This study aims to evaluate the diagnostic accuracy of an AI-based ICH detection software across different pediatric age groups.

### METHODS AND MATERIALS

We retrospectively collected data on pediatric patients diagnosed with or without ICH by searching the PACS between January 2020 and December 2023. A neuroradiologist with 15 years of experience reviewed the pediatric brain CT images to confirm the presence of ICH. We analyzed the performance of InsightPlus (Medical Insight+ Brain Hemorrhage, SK CC, Republic of Korea) by evaluating the sensitivity, specificity, and AUC for each pediatric age group: newborns and infants (0 to 23 months), children (2 to 11 years), and adolescents divided into two groups (12 to 14 years, and 15 to 18 years).

### RESULTS

This study included data from 282 pediatric patients diagnosed with ICH and 1722 without a diagnosis of hemorrhage. For newborns and infants, the AUC was 0.81 ([95% CI: 0.753, 0.87]; $p < .001$) with a sensitivity of 54.1% and specificity of 92.1%. For children, the AUC was 0.879 ([95% CI: 0.816, 0.914]; $p < .001$) with a sensitivity of 56.1% and specificity of 99.4%. For early adolescents, the AUC was 0.94 ([95% CI: 0.882, 0.992]; $p < .001$) with a sensitivity of 65.5% and specificity of 100%. For older adolescents, the AUC was 0.95 ([95% CI: 0.916, 0.994]; $p < .001$) with a sensitivity of 82.9% and specificity of 100%.

### CONCLUSION

Across all pediatric age groups, the software effectively ruled out non-hemorrhagic cases with high specificity. Particularly in adolescents, the AI-based software demonstrated a higher diagnostic performance, suggesting that this AI-based software significantly enhances the accuracy of detecting ICH.

### CLINICAL RELEVANCE/APPLICATION

The study validates the high accuracy of AI-based InsightPlus software in detecting intracranial hemorrhage across pediatric age groups, highlighting its potential to enhance diagnostic precision and improve clinical outcomes by enabling timely and age-appropriate interventions. The results shows that AI-based software is helpful for optimizing clinical workflows and resource allocation in pediatric emergency care settings.

## R5A-SPNR-11 MRI IN DETECTION OF ACUTE OPTIC NEURITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Stephan Altmayer, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Denise Sisterolli Diniz (*Abstract Co-Author*) Nothing to Disclose
Giovanni B. Torri, MD (*Abstract Co-Author*) Nothing to Disclose
Fillipe T. Xavier de Campos, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza G. Schmitt, MD (*Abstract Co-Author*) Nothing to Disclose
Guilherme De Oliveira (*Abstract Co-Author*) Nothing to Disclose
Naga Siva Naveen Chodisetti (*Presenter*) Nothing to Disclose

### PURPOSE

MRI if frequently performed as part of the diagnostic workup of patient with suspected acute optic neuritis (AON). Conflicting results exists regarding the overall diagnostic performance of MRI and the different MRI protocols in the diagnosis of AON. Our purpose was to perform a systematic review and meta-analysis evaluating the diagnostic performance of MRI for the detection of AON.

### METHODS AND MATERIALS

Relevant databases were searched through April 2024. Studies identified were assessed independently by two authors. Published original articles that met the following criteria were considered eligible for meta-analysis: (a) evaluated diagnostic performance of MRI compared to a valid reference standard and (b) provided data for the meta-analytic calculations. The bivariate random-effects model was used to find the pooled sensitivity and specificity of MRI for AON and 95% CIs. The hierarchical summary receiver operating characteristic model was used to draw the summary receiver operating characteristic curve and calculate area under the curve (AUC). Data analysis was conducted using RStudio version 2023.06.0+421.

### RESULTS

A total of 10 studies involving 5 sequences, 492 patients and 820 optic nerves, met the inclusion criteria and were included in the meta-analysis. MRI had a pooled sensitivity and specificity of 85.9% (95% CI: 76.5; 91.9) and 87.4% (95% CI: 79.5; 92.6), respectively. In the subgroup analysis per sequence, contrast-enhanced T1W (CE-T1W) sequence demonstrated the highest significant sensitivity 81.1% (95% CI: 67.9; 89.7), while FLAIR sequence demonstrated the highest significant specificity 83.1% (95% CI: 66.6; 92.4), among all sequences. The AUC of MRI was 90.6% (95% CI: 82.7, 91.5).

### CONCLUSION

MRI has a high sensitivity and specificity for the diagnosis of AON.

### CLINICAL RELEVANCE/APPLICATION

Incorporating contrast into MRI may increase the detection of AON. Brain or orbital dedicated FLAIR sequences can help to confirm clinical suspected AON.

## R5A-SPNR-12 COMPARATIVE STUDY OF SLASER AND PRESS TECHNIQUES IN MAGNETIC RESONANCE SPECTROSCOPY OF NORMAL BRAIN

Jae Hyoung Kim (*Abstract Co-Author*) Nothing to Disclose
Sung Hyun Baik (*Abstract Co-Author*) Nothing to Disclose
Byungse Choi, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Leonard Sunwoo, MD (*Abstract Co-Author*) Nothing to Disclose
Se Jin Cho, MD (*Abstract Co-Author*) Nothing to Disclose
Yun Jung Bae, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Cheolkyu Jung, MD (*Abstract Co-Author*) Nothing to Disclose
SHINKU KIM (*Presenter*) Nothing to Disclose

### PURPOSE

The commonly used PRESS technique in magnetic resonance spectroscopy (MRS) has a limitation of incomplete water suppression. The recently developed sLASER technique is known for its improved effectiveness in suppressing water signal. However, no prior study has compared both sequences in a normal human brain. In this study, we firstly aimed to compare the performances of both techniques in brain MRS

### METHODS AND MATERIALS

From January 2023 to July 2023, thirty healthy participants (mean age 38 years, 17 male, 13 female) without underlying neurological diseases were enrolled in this study. All participants underwent single-voxel MRS using both PRESS and sLASER techniques on 3T MRI. Two regions-of-interest were allocated in the left medial thalamus and left parietal white matter (WM) by a single reader. The SpectroView Analysis (SW5, Philips, Netherlands) provided automatic measurements, including signal-to-noise ratio (SNR) and peak_height of water, N-acetylaspartate (NAA)-water/Choline (Cho)-water/Creatine (Cr)-water ratios, and NAA-Cr/Cho-Cr ratios. The measurements from PRESS and sLASER techniques were compared using paired T-tests and Bland-Altman methods, and the variability was assessed using coefficients of variation (CV).

### RESULTS

SNR and peak_heights of the water were significantly lower with sLASER compared to PRESS (left medial thalamus, sLASER SNR/peak_height 2092±475/328±85 vs. PRESS 2811±549/440±105); left parietal WM, 5422±1016/872±196 vs. 7152±1305/1150±278; all, $P<0.001$, respectively). Accordingly, NAA-water/Cho-water/Cr-water ratios and NAA-Cr/Cho-Cr ratios were significantly higher with sLASER than with PRESS (all, $P< 0.001$, respectively). The variabilities of NAA-water/Cho-water/Cr-water ratios and Cho-Cr ratio in the left medial thalamus were lower with sLASER than with PRESS (CV, sLASER vs. PRESS, 19.9 vs. 58.1/19.8 vs. 54.7/20.5 vs. 43.9 and 11.5 vs. 16.2)

### CONCLUSION

The sLASER technique demonstrated enhanced background water suppression, resulting in increased signals and reduced variability in brain metabolite measurements of MRS. Therefore, sLASER could offer a more precise and stable method for identifying brain metabolites

### CLINICAL RELEVANCE/APPLICATION

sLASER in MRS can enhance brain metabolite measurement precision, crucial for diagnosing and managing neurological disorders such as neurodegenerative, demyelinating, and metabolic diseases. It may improve early detection and treatment monitoring by accurately distinguishing between healthy and diseased tissues, especially in brain tumors, aiding in personalized treatment. This advancement promises significant clinical improvements both in neurology and radiology.

## R5A-SPNR-13 MOTOR TASK MULTIBAND FUNCTIONAL MRI COMPARED TO ROUTINE NON-MULTIBAND ACCELERATED FUNCTIONAL MRI IN PATIENTS WITH BRAIN LESIONS

Michele Aizenberg, MD (*Abstract Co-Author*) Research support, Arbor Pharmaceuticals Inc
Sean Kelly, MD (*Abstract Co-Author*) Nothing to Disclose
Yan Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Fang Yu (*Abstract Co-Author*) Nothing to Disclose
Matthew L. White, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Functional MRI (fMRI) is a technique for brain mapping. Its utilization can enhance tumor resection with functional preservation. Multiband (MB) fMRI is a novel approach to acquire fMRI data and MB fMRI has been found to demonstrate increased signal. There has been limited MB fMRI analysis in patients with brain tumors which is a potential application of this technique. The increased signal detected with MB fMRI might be related to the faster acquisition of signal (2-6x) than conventional MRI. This greater speed allows for the activation signals to be sampled closer to where the activation occurs before the

BOLD signal changes in the blood are washed out by venous blood flow from non-activated areas.Hypothesis: MB fMRI motor tasks will demonstrate greater statistical activation patterns and activation closer to the areas of interest than seen with routine fMRI sequences.

**METHODS AND MATERIALS**

10 patients with gliomas and 5 with metastatic lesions (average age 45 yo (range 26-68)). 18 fMRI acquisitions were acquired. MRI: Philips 3T Ingenia MRI with multiband capabilities and a 32-channel head coil. Routine fMRI: voxel= 3mm x 3mm x 3mm , TR= 3000 , TE=35 , Sense= 1.8 , 5 minute acquisition, 100 time points. 4x MB fMRI: voxel= 3mm x 3mm x 3mm, TR= 750 , TE=30 , 5 minute acquisition, 400 time points. All tasks were block design with 9 finger tap, 8 ankle movement and 1 lip movement task. The fMRI maps were produced utilizing a test p-value that resulted in the best expected activation map. Bonferroni correction was applied. The fMRI data was processed with Olea software. Two analyses were performed. 1) The distance from the edge of the activation map to the edge of the area of interest was measured. 2) The p-value data were compared between the 4x MB and routine fMRI maps using a paired t test to account for the repeated measures design. One fMRI activation task was completely excluded from analyses since the routine fMRI failed. Another task excluded from the p-value analysis due to poor signal.

**RESULTS**

The average distance from the edge of the 4x MB fMRI activation map to the area of interest was 6.9 mm and for the routine fMRI was 11.12 mm (p-value< 0.00066). The average p-value for the 4x MB fMRI maps was 3.6x10-7 and for the routine fMRI 1.3x10-1. The 4x MB fMRI map p-values were significantly smaller (p-value=0.0000088).

**CONCLUSION**

4x MB fMRI with a motor task in patients with brain lesions demonstrate activation maps that extend closer to areas of interest than the routine fMRI sequence. The p-values utilized for the 4x MB fMRI analysis of the data were significantly smaller than that utilized for the routine fMRI data maps.

**CLINICAL RELEVANCE/APPLICATION**

4x MB fMRI data has a potential greater sensitivity to localize motor functions leading to more precise pre-operative brain mapping.

## R5A-SPNR-16 EXPLORING THE EFFICACY OF LARGE-SCALE GRANGER CAUSALITY (LSGC) IN DIAGNOSIS OF PARKINSON'S DISEASE USING FMRI NEUROIMAGING

Nathan Hadjiyski (*Abstract Co-Author*) Nothing to Disclose
Akhil Kasturi (*Abstract Co-Author*) Nothing to Disclose
Axel Wismueller, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ali Vosoughi (*Presenter*) Nothing to Disclose

**PURPOSE**

To create and test a machine learning approach for identifying individuals with Parkinson's Disease (PD) using large-scale Granger Causality (lsGC) to analyze changes in resting-state functional MRI (fMRI) brain connectivity.

**METHODS AND MATERIALS**

We analyzed 30 rsfMRI data sets from Parkinson’s Disease (PD) patients and healthy controls (15 PD, 15 controls) in-house acquired and preprocessed from [blinded for review]. To calculate directed functional connectivity between brain regions, we used the large-scale Granger Causality (lsGC) algorithm, which leverages dimensionality reduction for causal modeling in high-dimensional fMRI time series. We applied 10-iteration cross-validation with 85%/15% train/test ratio, Kendall's tau rank correlation feature selection, and support vector machine classification. To evaluate the diagnostic accuracy of lsGC in classifying PD patients and healthy controls, we compared its performance with multiple other methods, including local model (LM) connectivity, anti-symmetric correlation (ASC), and the current clinical standard for fMRI analysis, cross-correlation (CC). We report accuracy, area under the ROC curve (AUC), and f1-score to quantitatively evaluate lsGC performance.

**RESULTS**

The lsGC method outperformed all competing methods in classifying PD patients from healthy controls with AUC 0.844 (±0.161), accuracy 80.0% (±0.0%), and f1-score 81.1% (±2.3%).; local models also reached 80.0% accuracy but with slightly lower AUC and f1-scores of 0.850 (±0.179) and 75.2% (±7.2%), respectively, while ASC had AUC of 0.778 (±0.108), accuracy 78.7% (±5.0%), and f1-score 78.4% (±7.6%). Clinical standard CC technique fell behind, with AUC 0.828 (±0.133), accuracy 75.3% (±8.5%), and f1-score 72.0% (±10.5%). F1-score differences between lsGC versus CC and local models were statistically significant ($p<0.01$, Wilcoxon signed rank test).

**CONCLUSION**

Our results suggest that lsGC significantly enhances the diagnostic accuracy of identifying Parkinson's Disease (PD) patients from rsfMRI neuroimaging. We conclude that lsGC better captures disease-related changes of brain network connectivity in PD patients compared to conventional CC analysis, local models, and anti-symmetric correlation.

**CLINICAL RELEVANCE/APPLICATION**

The lsGC method effectively differentiates between PD patients and healthy individuals by identifying brain connectivity changes in fMRI scans. This indicates its value as a potential diagnostic tool for neurological disorders.

## R5A-SPNR-17 DIAGNOSIS OF AUTISM SPECTRUM DISORDER FROM FUNCTIONAL MR IMAGING USING LARGE-SCALE NONLINEAR GRANGER CAUSALITY (LSNGC)

Akhil Kasturi (*Abstract Co-Author*) Nothing to Disclose
Nathan Hadjiyski (*Abstract Co-Author*) Nothing to Disclose
Ali Vosoughi (*Abstract Co-Author*) Nothing to Disclose
Axel Wismueller, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To create and test a novel machine learning approach for identifying individuals with Autism Spectrum Disorder (ASD) using large-scale Nonlinear Granger Causality (lsNGC) to analyze brain connectivity in resting-state functional MRI (fMRI).

**METHODS AND MATERIALS**

We analyzed a subset of 59 resting-state fMRI data sets from ASD patients and healthy controls from the Olin Institute of Living at Hartford Hospital longitudinal sample, which is part of the publicly available Autism Brain Imaging Data Exchange II (ABIDE II) data repository. We calculated directed functional connectivity between brain regions using the recently developed large-scale Nonlinear Granger Causality (lsNGC) algorithm, which leverages

dimensionality reduction and non-linear prediction for causal modeling in high-dimensional fMRI time series. We applied 10-iteration cross-validation with 85%/15% train/test ratio. For feature selection, Kendall's tau was used, followed by support vector machine classification. To evaluate diagnostic accuracy of lsNGC, we compared its performance with multiple other methods, including local model (LM) connectivity, anti-symmetric correlation (ASC), and the current clinical standard for fMRI analysis, cross-correlation (CC). We report accuracy, area under the ROC curve (AUC), and f1-score to quantitatively evaluate lsNGC performance.

**RESULTS**

The lsNGC method outperformed all competing methods in classifying ASD patients from healthy controls with AUC 0.963 (±0.059), accuracy 89.6% (±7.5%), and f1-score 88.4% (±8.2%); local models achieved 83.7% accuracy but lower AUC and f1-scores of 0.913 (±0.075) and 81.5% (±8.5%), respectively, while ASC had AUC 0.918 (±0.075), accuracy 81.9% (±6.1%), and f1-score 78.9% (±7.4%). Clinical standard CC technique fell behind, with AUC 0.877 (±0.105), accuracy 81.9% (±11.3%), and f1-score 76.9% (±18.8%). Differences between lsNGC and competing methods were statistically significant ($p<0.01$, Wilcoxon signed rank test).

**CONCLUSION**

Our results suggest that lsNGC outperforms conventional CC, local models, and anti-symmetric correlation at detecting Autism Spectrum Disorder (ASD) from fMRI data. We conclude that lsNGC has the capability to identify disease-related changes in brain network connectivity in ASD patients and could serve as a promising diagnostic imaging biomarker for neurologic disease.

**CLINICAL RELEVANCE/APPLICATION**

The potential value of lsNGC as a diagnostic imaging biomarker for neurologic disease is demonstrated by its ability to accurately identify changes in fMRI connectivity that can classify patients with Autism Spectrum Disorder (ASD) and healthy controls. This suggests that lsNGC could be a useful tool for diagnosing and studying neurologic diseases.

## R5A-SPNR-18 VISUALIZATION OF LENTICULOSTRIATE ARTERIES ON CTA USING PHOTON-COUNTING DETECTOR CT: A POTENTIALLY CONSIDERABLE RECONSTRUCTION PARAMETER

Ji Liang Chen (*Abstract Co-Author*) Nothing to Disclose
Yan E Zhao (*Abstract Co-Author*) Nothing to Disclose
Dong Sheng Jin (*Abstract Co-Author*) Nothing to Disclose
Song Luo (*Abstract Co-Author*) Nothing to Disclose
Wen-Tian Tang (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess capability of head and neck photon-counting detector computed tomography (PCD-CT) angiography for visualizing lenticulostriate arteries and to identify an optimal reconstruction parameter.

**METHODS AND MATERIALS**

Patients who underwent head and neck CTA using PCD-CT and were found to have no significant intracranial vascular stenosis were retrospectively included in this study from January 2024 to April 2024. Each examination involved reconstruction of 0.2 mm thickness threshold three dimension(T3D) images, 0.4 mm thickness T3D images, 0.4 mm thickness vascular spectrum post-processing(VSPP) images, and 0.8 mm thickness T3D images(simulating energy-integrating detector CT images). Image quality and vascular visualization were assessed by radiologists using a four-point Likert scale and quantitative measures, respectively. The Friedman test with Holm-Bonferroni correction was used to compare characteristics from the four reconstruction images.

**RESULTS**

A total of 27 patients (61 years±15; 15 males) were included. The 0.4 mm VSPP images displayed the highest counts of lenticulostriate arteries(right side 4.15±1.06; left side 3.96±0.98). Regarding the measurements of the longest lenticulostriate arteries, the 0.4 mm VSPP images also indicated the maximum length(right side 24.77mm±4.54; left side 26.08mm±4.71), with no significant difference from the 0.2 mm T3D images and 0.4 mm T3D images, but significantly greater than the 0.8 mm T3D images(all $P < 0.01$). In Likert scale evaluations, the 0.2 mm T3D images presented the highest noise yet the sharpest edges. The 0.4 mm VSPP images scored highest in vascular smoothness, vascular contrast, and diagnostic confidence, notably outperforming the 0.8 mm T3D images (all $P < 0.05$).

**CONCLUSION**

Head and neck CTA using PCD-CT exhibits considerable potential in the visualization of lenticulostriate arteries, with the 0.4 mm VSPP images potentially offering greater imaging advantages.

**CLINICAL RELEVANCE/APPLICATION**

CTA using PCD-CT may provide valuable insights for the prevention and treatment of potential cerebral small vessel disease(CSVD) and intracranial atherosclerotic stenosis(ICAS) patients through the visualization of lenticulostriate arteries.

## R5A-SPNR-2 MYELIN LOSS DETECTION WITH 2D ADIABATIC T1ρ-PREPARED FAST SPIN ECHO (2D ADIAB-T1ρ-FSE) IMAGING AND ASSOCIATED BEHAVIORAL CHANGES IN AN OPEN-FIELD LOW-INTENSITY BLAST MOUSE MODEL OF MILD TRAUMATIC BRAIN INJURY (MTBI)

Jiang Du, PhD (*Abstract Co-Author*) Nothing to Disclose
Qingbo Tang (*Abstract Co-Author*) Nothing to Disclose
Dina Moazamian, MD (*Abstract Co-Author*) Nothing to Disclose
Yajun Ma (*Abstract Co-Author*) Nothing to Disclose
Jiyo Athertya (*Abstract Co-Author*) Nothing to Disclose
Eric Y. Chang, MD (*Abstract Co-Author*) Nothing to Disclose
James Lo, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

This study investigates the utility of Adiab-T1?-FSE MRI to detect myelin loss in mice with mild traumatic brain injury (mTBI) caused by an open-field low-intensity blast (LIB) injury model and associated behavioral disorders compared with the normal group (Sham).

### METHODS AND MATERIALS

All animal experiments followed approved protocols for the Care and Use of Laboratory Animals. 30 male 8-week-old C57BL/6 mice (Jackson Labs, ME) were randomly divided into mTBI (n=15) and sham (n=15) groups. The anesthetized mTBI mice experienced a reproducible open-field LIB injury with 350g explosion C4. After 5 days, behavioral testing (light Spot, open-field(FO)tests) assessed motor activity and anxiety. Later, They MRI-scanned using a 3T Bruker system with a 1-inch coil. The 2D Adiab-T1?-FSE technique was used with the following parameters: repetition time=1500ms, Echo time= 5.5ms, spin-locking time (TSL)= 0, 24, 48, and 96ms (number of adiabatic full passage (AFP) pulses=0,4,8, and 16), FA=180°, number of spokes=25; bandwidth=5000HZ, Slice thickness=0.3mm, FOV=11×11cm2, matrix size =120×120. The total scan time was 7 minutes. Medial of the corpus callosum (MCC) was selected to compare Adiab-T1? for the two groups. Velocity, movements, and time in the center by the FO test, and time in shelter (TIS) and time outside shelter (TOS) by the light Spot test were compared between groups with independent T-test and two-way ANOVA, respectively. (P values <0.05 significant).

### RESULTS

T1? fitting curves and pixel maps of a representative sham and a mTBI mouse are presented in Fig.1 A, B, and Fig.1 C, D, respectively. The average±SD, and percentage of differences are presented in Fig.1E. Significant, small T1? differences between the two groups were found. Fig1. F-H shows a significantly increased velocity and a reduced trend of movements and time in the center, respectively. Fig1. I-J shows significantly increased TIS and reduced TOS in mice, respectively.

### CONCLUSION

For the first time, the 2D Adiab-T1?-FSE technique can be used as a quantitative method for detecting open-field LIB-induced myelin loss in the brain's white matter. Significantly higher T1? values in the CC of mTBI mice could be due to changes in neuronal cellular density content. The mechanisms underlying these relaxation differences should be investigated in future studies. Our study shows acute decreased motor activity and increased anxiety, indicated by light Spot test and FO results.

### CLINICAL RELEVANCE/APPLICATION

The 2D Adiab-T1?-FSE sequence is a new approach for evaluating myelin loss in mTBI. It can ultimately be used for diagnosis and treatment monitoring which often remains under-diagnosed due to the lack of symptoms immediately after exposure as well as negative findings on conventional imaging.

## R5A-SPNR-5 DIFFUSION-RELAXATION CORRELATION SPECTROSCOPIC IMAGING FOR EVALUATING CHANGE OF WHITE MATTER OF X-LINKED ADRENOLEUKODYSTROPHY

Ru Wen (*Abstract Co-Author*) Nothing to Disclose
Liang Tan (*Abstract Co-Author*) Nothing to Disclose
Xingang Wang (*Abstract Co-Author*) Nothing to Disclose
Chen Liu (*Presenter*) Nothing to Disclose

### PURPOSE

To measure the changes in white matter composition and microenvironment in ALD patients using diffusion-relaxation correlation spectroscopic imaging (DR-CSI)

### METHODS AND MATERIALS

A total of 8 participants with 4 groups including health control(HC), Cerebral ALD(CALD), AMN, and Carrier (each group has 2 participants) were enrolled in this study. Examinations of all participants were performed on a 3.0 Tesla MRI scanner using a 32-channel Head coil. The DR-CSI was acquired using an axial singleshot spin-echo echo-planar-imaging (SE-EPI)-based DWI sequence, with 36 acquisitions of six different TEs. Imaging by DR-CSI is basically a two-dimensional correlation MRI method, simultaneously considering the signal attenuation caused by both the diffusion and the relaxation time of multiple components. For quantitative analysis, the spectra were segmented into three compartments, labeled by A (higher diffusivity, shorter T2), B (higher diffusivity, longer T2), and C (lower diffusivity). Boundaries of different compartments were decided case-by-case according to the principle that each compartment separately contain the three main peaks observed from spectral observations. The DR-CSI compartment volume fractions Vi (i = A, B, C) were calculated for each voxel by spectral integration, and then averaged for each patient. The ROIs were manually delineated on axial DWI with a short TE (50 msec), and were chosen to include the anterior, medial, posterior of white matter (Figure 1).

### RESULTS

This study evaluated white matter change in ALD patients by DR-CSI in terms of microenvironment analysis (Figure 2). Specifically, characteristic peaks have been observed (Figure 2), and difference have been found between DR-CSI-derived volume fractions of compartments A and B in the different area (Figure 2). Statistical analysis results show in anterior white matter (Figure 3), the HC group has highest fA compare to other group. In medial white matter (Figure 4), the HC group also has highest fA compare to other group, carrier group achevie highest fC and AMN group achevie highest fB. In posterior white matter (Figure 5), the HC group also has highest fA compare to other group, and AMN group achevie highest fB.

### CONCLUSION

Our findings may illustrate the potential of applying an invivo DR-CSI method for the evaluation changes of white matter of ALD. Specifically, DR-CSI could differentiate signal contributions from diverse compartments with different diffusion and relaxation properties.

### CLINICAL RELEVANCE/APPLICATION

The phenotypes of ALD are heterogeneous, exhibiting a variety of cerebral imaging changes. Changes in brain areas of different types of participants can be demonstrated by changes in f for each tissue compartment in voxels.

John Eddins (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the ability of Computed Tomography (CT) images of the brain to predict biological brain age and evaluate the utility of these predictions to identify subjects with Alzheimer's Disease.

**METHODS AND MATERIALS**

A brain age prediction model was trained using subjects from the Open Access Series of Imaging Studies (OASIS) and a single academic medical system with a level 1 trauma center. Cognitively normal (CN) patients defined as a normal neuropsychiatric evaluation in the OASIS dataset or local patients presenting for trauma without intracranial pathology and no history neurodegenerative disease between the ages of 18-80 were included (N=1656). Subjects with AD (Alzheimer's dementia) were added to the testing dataset (N=226). The CN set of subjects were split by a training, validation, and testing ratio of 70, 20, and 10 respectively. Further, the split was done in a stratified sampling manner, to preserve the ratio of age groups - wherein subjects are binned by decade - in each subset. The CN subject sets had an age distribution by decade ratio as follows: 20's: 17% ; 30's: 12% , 40s: 10% , 50s: 14%, 60s: 15% , 70s: 23% , 80s: 8%. Brain age prediction was achieved by training a Simple Fully Convolutional Neural Network (SFCN) model using CT data as inputs and subjects' chronical age as the target value to be predicted. Data augmentations of ±5° rotations and ±10 voxel translations were done to reduce the risk of model overfitting. Brain ages were then corrected using a linear method. Brain ages were then predicted for the testing set that included both CN and AD subjects. Brain Age Gap (BAG) was then calculated by subtracting subject's chronological age from their predicted brain age. The Mann-Whitney-U test was used to compare the BAG of CN vs. AD subjects.

**RESULTS**

The brain age prediction model achieved a Mean Absolute Error (MAE) of 5.97 on the CN validation set, 6.05 on the CN testing set, and 8.86 on the AD testing set. The AD group (mean BAG = 4.505) was significantly higher than the CN group (mean BAG = 0.865) (p=0.002).

**CONCLUSION**

A supervised machine learning AI model trained on CT brain images can reasonably estimate the biological brain age in cognitively normal subjects. Furthermore, the brain age to chronological gap measured shows that subjects with Alzheimer's Disease have a significantly wider gap than cognitively normal subjects. Adding pre-processing steps to segment brain regions of interest may improve model performance.

**CLINICAL RELEVANCE/APPLICATION**

Brain CT is a widely available and commonly used diagnostic test. The estimation of brain age and calculation of BAG may facilitate opportunistic screening to identify patients at risk of Alzheimer's or other neurodegenerative disease.

**PURPOSE**

Obesity and higher adiposity in midlife are recognized as contributors to Alzheimer disease, where vascular compromise and brain hypoperfusion play a role. In this study, we aimed to investigate the associations of body mass index (BMI), abdominal visceral and subcutaneous adipose tissue (VAT, SAT) with brain cerebral blood flow (CBF) in cognitively normal midlife individuals.

**METHODS AND MATERIALS**

A total of 66 middle-aged cognitively normal adults (age: 49.86 years, females: 66.7%, obesity: 51.5 %, BMI: 31.72 kg/m2) underwent abdominal and brain MRI, and brain PET scan. Using an in-house MATLAB-based program, abdominal VAT and SAT were automatically segmented followed by manual editing. A 3D Pseudo-Continuous Arterial Spin Labeling (pCASL) sequence, with a single post-labeling delay of 2.025 s, was used for assessing CBF. SPM 12 was used to generate ASL difference and absolute CBF (aCBF) maps with a single compartment model, co-registered to the gray matter segmentations, normalized to MNI space, and spatial smoothing with a 6mm FWMH Gaussian kernel. Using AAL3 atlas and Matlab, region of interest masks were created for amygdala, hippocampus, posterior cingulate, precuneus, parahippocampal, medial orbitofrontal, middle temporal, and Calcarine cortices, and applied to absolute CBF (aCBF) maps. The whole-brain and regional aCBF differences between the obese vs. non-obese, the low- vs. high-VAT, and low- vs. high-SAT group, and the association between whole-brain amyloid PET Centiloids were assessed. Also, BMI, VAT, and SAT as separate predictor variables, were used for voxel-wise analysis, with age and sex as covariates.

**RESULTS**

The high-VAT group showed lower whole-brain aCBF (p=0.004), particularly in the bilateral Calcarine gyri (p=0.001, 0.002). A lower whole-brain aCBF was found in the obese group (p=0.005), more prominent in the left middle temporal lobe (p=0.002). No significant difference was observed in global and regional aCBF in the high-SAT vs. low-SAT groups. Voxel-wise analyses showed significantly lower aCBF in association with BMI in small temporal, occipital, and frontal lobe clusters after false discovery rate correction. No association was found between whole-brain Centiloids and aCBF.

### CONCLUSION

Obesity and increased visceral abdominal fat are associated with a lower cerebral blood flow, with a more prominent decrease in the middle temporal cortex, as an AD-signature area, in cognitively normal midlife individuals. These findings highlight the role of obesity, especially visceral obesity, in brain hypoperfusion and potentially Alzheimer disease risk, as early as midlife.

### CLINICAL RELEVANCE/APPLICATION

Modifying visceral obesity can potentially improve brain perfusion and reduce the risk of Alzheimer disease.

## R5A-SPNR-8 MULTICOMPARTMENT IMAGING OF THE BRAIN IN MULTIPLE SCLEROSIS USING A COMPREHENSIVE MR IMAGING PROTOCOL

Graeme M. Bydder, MBChB (*Abstract Co-Author*) Nothing to Disclose
Kevin Du (*Abstract Co-Author*) Nothing to Disclose
Jiyo Athertya (*Abstract Co-Author*) Nothing to Disclose
Yajun Ma (*Abstract Co-Author*) Nothing to Disclose
Melissa Lou Silva, MD (*Abstract Co-Author*) Nothing to Disclose
James Lo, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This study uses a new 3D magnetic resonance imaging (MRI) protocol to quantify and compare all the major tissue components in the brain, including macromolecules, myelin water, intra/extracellular water, and free water, between healthy volunteers and patients with multiple sclerosis (MS).

### METHODS AND MATERIALS

Five MS patients (55±11 years old, four females) and ten healthy volunteers (27±2 years old, six females) were scanned with the novel protocol that comprises four different sequences: 1) magnetization transfer prepared Cones (MT-Cones) for two-pool MT modeling to quantify macromolecular content; 2) short-TR adiabatic inversion-recovery prepared Cones (STAIR-Cones) for myelin water (MW) imaging; 3) proton-density weighted Cones (PDw-Cones) for total water imaging; and 4) highly T2 weighted Cones (T2w-Cones) for free water (FW) imaging, on a 3T clinical scanner (MR750, GE) employing an 8 channel head coil. By integrating these techniques, we quantified the brain macromolecular proton fraction (MMPF), MW proton fraction (MWPF), intra/extracellular water proton fraction (IEWPF), and free water proton fraction (FWPF). Regions of interest (ROIs) were drawn and measured in eight white matter (WM) regions, two grey matter (GM) regions, and apparent lesions. Measured brain tissues in healthy volunteers were considered as normal WM (NWM) or normal GM (NGM) while MS patients were considered as normal-appearing WM (NAWM), normal-appearing GM (NAGM), or lesions. Independent t-tests were calculated comparing all the PF measurements between NWM and NAWM, NWM and lesions, NAWM and lesions, and NGM and NAGM. P values $< 0.05$ were considered significant.

### RESULTS

MMPF and MWPF values of lesions (4.8%, 2.6%) and NAWM (9.6%, 7.2%) were lower than those in NWM (11.6%, 8.5%), respectively, consistent with diffuse demyelination. IEWPF values of NAWM (80.1%) were higher than both NWM (78.7%) and lesions (74.7%), while NGM (89.7%) were higher than those of NAGM (88.3%), consistent with elevated levels of extracellular water. In the FWPF, NAWM (3.1%) and NAGM (2.3%) measurements were higher than those of NWM (1.1%) and NGM (0.7%), respectively. Moreover, we observed dramatically higher FWPF values in lesions (18.4%) compared to those in both NWM and NAWM regions, a change consistent with the transition from lesion to cerebrospinal fluid due to atrophy. All comparisons, excluding those between MMPF and MWPF NGM and NAGM, were significant.

### CONCLUSION

The multicompartment brain imaging protocol can detect distinct and significant differences in the MMPF, MWPF, IEWPF, and FWPF measurements between normal volunteers and patients with MS.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrates the capability of our protocol to detect brain compositional changes in MS.

## R5A-SPNR-9 TASK-SPECIFIC ARTIFICIAL INTELLIGENCE FOR SEGMENTATION OF IDH-MUTANT GLIOMAS

Albert D. Jiao, MD (*Abstract Co-Author*) Nothing to Disclose
Raymond Y. Huang, MD, PhD (*Abstract Co-Author*) Advisory Board, Vysioneer Inc;Consultant, Nuvation Bio, Inc ;Institutional research support, Bristol-Myers Squibb Company
Ian Pan, MD (*Presenter*) Consultant, MD.ai, Inc;Consultant, Centaur Labs Inc;Consultant, Diagnosticos da America SA;Consultant, CoRead AI

### PURPOSE

To develop a task-specific deep learning-based artificial intelligence (AI) model for segmentation of preoperative and postoperative isocitrate dehydrogenase (IDH)-mutant gliomas.

### METHODS AND MATERIALS

1,251 multiparametric MRI examinations (T1-weighted, T2-weighted, FLAIR, and post-contrast T1-weighted sequences) from 1,133 patients with glioblastoma in the Brain Tumor Segmentation (BraTS) Challenge dataset were used to train an initial segmentation model with 3 classes: 1) nonenhancing T2 signal abnormality, 2) enhancing tumor, and 3) necrosis. The segmentation model was based on the X3D convolutional neural network (CNN) architecture. 257 preoperative and 471 postoperative examinations from 262 patients, manually segmented by a board-certified neuroradiologist, with pathologically-proven IDH-mutant gliomas were then used to fine-tune the model. Performance was measured by the Dice similarity coefficient (DSC), and statistical comparison between the initial and fine-tuned models was performed using the bootstrap.

### RESULTS

No IDH-mutant gliomas in our dataset demonstrated necrosis; thus we report only on nonenhancing T2 signal abnormality and enhancing tumor. The initial BraTS-trained model achieved DSCs of 0.208 and 0.039 for these 2 entities, respectively, compared to a five-fold cross-validated DSCs of 0.806 and 0.263 for the fine-tuned model ($p<0.001$). For preoperative studies, the initial and fine-tuned models achieved DSCs of 0.306 and 0.057 vs. 0.870 and 0.316 ($p<0.001$). For preoperative studies, the initial and fine-tuned models achieved DSCs of 0.154 and 0.029 vs. 0.771 and 0.238 ($p<0.001$).

### CONCLUSION

Our IDH-mutant-specific glioma segmentation model achieved high performance for segmentation of nonenhancing T2 signal abnormality in both preoperative and postoperative examinations. Performance for enhancing tumor was lower, as many tumors demonstrated no or mild enhancement. The

fine-tuned model achieved significantly higher performance than the initial model, especially for postoperative studies.

**CLINICAL RELEVANCE/APPLICATION**

Task-specific segmentation models for IDH-mutant gliomas can improve performance for this tumor subgroup. Future studies will evaluate generalizability of these models to external datasets and correlate volumetric data obtained from these algorithms with tumor progression and patient outcomes.

## R5A-SPPD-2 SCREENING FOR INTRACRANIAL ANEURYSMS IN PEDIATRIC PATIENTS WITH POLYCYSTIC KIDNEY DISEASE

Zekordavar Rimba, MD (*Abstract Co-Author*) Nothing to Disclose
Arastoo Vossough, PhD, MD (*Abstract Co-Author*) Research Consultant, Syneos Health;Stockholder, DeepSight Technology, Inc
Amirreza Manteghinejad, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Autosomal dominant polycystic kidney disease (ADPKD) and autosomal recessive polycystic kidney disease (ARPKD) are disorders marked by the growth of numerous cysts in the kidneys. ADPKD and ARPKD also have extrarenal manifestations. The most serious extrarenal complication of polycystic kidney disease is intracranial aneurysm, which is commonly seen in ADPKD patients. The prevalence of intracranial aneurysms in ADPKD patients is 4 times higher than in the general population (7-13% vs. 2-3%). Moreover, patients with ADPKD have an intracranial aneurysm rupture at an approximate 10-year younger median age than those without ADPKD. As a result, intracranial aneurysm screening is recommended in adults with ADPKD.In contrast to the adult population, the data regarding intracranial aneurysms in pediatric PKD patients is very scarce. However, pediatric patients with PKD are sometimes screened for intracranial aneurysms. This study aimed to determine the yield of positive screening studies for intracranial aneurysms in pediatric patients with polycystic kidney disease.

### METHODS AND MATERIALS

This retrospective study included patients under 21 years of age referred to be screened by magnetic resonance angiography (MRA) for intracranial aneurysms based on their history of polycystic kidney disease between 1995 and 2022. In addition to imaging reports by pediatric neuroradiologists, a second board-certified pediatric neuroradiologist re-evaluated all the MRAs and the follow-up imaging in cases of suspicious screening to assess the presence or absence of aneurysms. The study sample size had >80% power for showing increased aneurysm prevalence.

### RESULTS

Thirty-six cases with a median age of 15.12 years (interquartile range, 8.89 - 17.16 years) were included in this study. The inheritance pattern of 25 (69.45%) cases was autosomal dominant, 5 (13.89%) was autosomal recessive, and 6 (16.66%) was unknown. Two patients (5.56%) had initially suspicious MRA for intracranial aneurysms. A confirmatory MRA for the first patient proved that the lesion was an infundibulum with the finding of a small branch vessel arising from the dome of the suspected outpouching. A volume rendering of the second patient's MRA study also showed the initial lesion to be an artifact, resulting in a final yield of 0% for screening intracranial aneurysms.

### CONCLUSION

Screening for intracranial aneurysms in pediatric patients with polycystic kidney disease has a low-to-zero prevalence and yield.

### CLINICAL RELEVANCE/APPLICATION

Although adult patients with polycystic kidney disease have an increased risk of developing intracranial aneurysms, screening pediatric polycystic kidney disease patients has very little to no yield for early detection of aneurysms.

## R5A-SPPD-3 NEUROIMAGING DELINEATION AND PROGRESSION OF SLSMD SYNDROMES

Amirreza Manteghinejad, MD (*Presenter*) Nothing to Disclose

### PURPOSE

We sought to determine the hallmarks of SLSMD syndromes and define their expected imaging progression to delineate their natural history further.

## METHODS AND MATERIALS

A retrospective, longitudinal study of 40 individuals diagnosed with SLSMDs at three major mitochondrial disease clinical centers was performed. MRI studies were reviewed to assess the prevalence and progression of brain lesions in different regions with statistical significance testing and Kaplan-Meier analysis. Hierarchical cluster analysis was performed for all the involved brain regions to stratify MRI findings into imaging phenotype groups.

## RESULTS

Among 40 SLSMD patients (median age of 9.26 years; IQR: 5.16-13.1), 67.5% had KSS, 15% exhibited KSS with a history of other clinical syndromes, mostly Pearson syndrome progressing to KSS (PSKSS), and 10% had Pearson syndrome only. A well-delineated phenotype could not be specified (NOS) for 1 (2.5%) individual, and 2 (5%) individuals had CPEO-plus (CPEO + additional extra-ocular symptoms). Initial MRI of KSS patients regardless of initial presentation revealed predominant lesions within selective areas of the upper brainstem tegmentum. Follow-up MRIs available for 26 patients showed lesion progression along other brainstem areas and white matter, the latter with typical centripetal progression. Log-rank tests demonstrated varying onset times by lesion type. Cluster analysis revealed two distinct neuroimaging groups: (1) pure KSS, CPEO-plus, and PSKSS versus (2) pure PS and NOS individuals. KSS and PSKSS showed indistinguishable neuroimaging features regardless of initial clinical presentation.

## CONCLUSION

We describe the first comprehensive cross-sectional and longitudinal neuroimaging pattern analysis in a multi-center clinical SLSMD disease cohort, delineating a predictable progression of brain lesions regardless of their presenting clinical feature. Understanding this complex pattern and disease progression will facilitate earlier diagnosis, natural history understanding, and future design of targeted interventions and therapies in SLSMD disorders.

## CLINICAL RELEVANCE/APPLICATION

This study provides a detailed imaging analysis of SLSMDs, highlighting distinctive imaging features and predictable imaging progression of KSS patients which are overall indistinguishable from CPEO-plus and PSKSS individuals, but highly different from isolated PS. KSS disorders manifest a distinct pattern of lesion distribution in the brain, with selective involvement of the brainstem nuclei, tegmental tracts, and basal ganglia structures representing the early imaging manifestations of these disorders.

## R5A-SPPH-10 REDUCTION OF RADIATION BURDEN DUE TO MR-ONLY TREATMENT PLANNING FOR PROSTATE RADIOTHERAPY

Stefano Presilla (*Abstract Co-Author*) Nothing to Disclose
Margherita Casiraghi (*Abstract Co-Author*) Nothing to Disclose
Jeanne Berg (*Abstract Co-Author*) Nothing to Disclose
Luca Bellesi, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The use of MR-based synthetic CT (sCT) for radiotherapy (RT) planning improves target and OARs delineation, and enhances patient comfort and safety by reducing exams and imaging dose. We aim to evaluate the decreased radiation burden on the Ticino population from sCT for prostate RT.

### METHODS AND MATERIALS

The study included 188 prostate cancer patients treated with RT at our center. The percentage undergoing MR-only RT was determined. The validity of sCT planning was previously assessed by comparing dose distributions for 50 patients calculated on both sCT and standard planning CT (pCT), with a 1% dose difference acceptance threshold. The Radimetrics application was used to assess the mean cumulative effective dose (CED) per patient from pCTs. Using Ticino cancer register and our center data, the annual number of prostate patients benefiting from MR-only RT in our region was obtained. The total spared effective dose was calculated and the decrease in the collective dose was obtained considering the population subgroup of males over 40 years. The reduction of radiation-induced tumors was estimated based on BEIR VII data for the same subgroup.

### RESULTS

65% of patients could be treated with MR-only RT, while the remaining had a pCT. 5% of patients had contraindication to MR, and 30% required pCT as a backup due to sCT reconstruction failures from issues like metal implants, non-standard anatomy, or rectum-bladder preparation. The mean CED per patient was 14.2 mSv with 16% of patients having more than one pCT due to preparation issues. MR-only RT in Ticino resulted in an annual dose sparing of 1.1 Sv, leading to a collective dose spare of 11.4 μSv/year per capita and a reduction of 0.1 radio-induced tumors/year. Extrapolating to the Swiss population indicated a reduction of 2.6 tumors/year.

### CONCLUSION

While pCT dose is a small part of the dose delivered to RT patients, it impacts the lifetime CED and the population radiation burden. The wider use of MR-only RT, beyond clinical benefits, holds the potential to mitigate the detriment from medical exposure.

### CLINICAL RELEVANCE/APPLICATION

reducing imaging dose in radiation Therapy using MRI will be the future approach to optimize the dose to targe and Organs at risk.

## R5A-SPPH-2 LOW-DOSE HIGH-RESOLUTION PHOTON-COUNTING CT OF THE PARANASAL SINUS IN ADULTS WITH CYSTIC FIBROSIS: AN INTRAINDIVIDUAL RADIATION DOSE AND QUALITY STUDY

Marko Frings, MSc (*Abstract Co-Author*) Nothing to Disclose
Cornelius Deuschl (*Abstract Co-Author*) Nothing to Disclose
Yan Li (*Abstract Co-Author*) Nothing to Disclose
Denise Bos, MD (*Abstract Co-Author*) Nothing to Disclose
Sebastian Zensen, MD (*Abstract Co-Author*) Nothing to Disclose
Marcel Opitz, MD (*Abstract Co-Author*) Nothing to Disclose
Michael Forsting, MD (*Abstract Co-Author*) Nothing to Disclose
Abdullatif Kocak, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Patients diagnosed with Cystic fibrosis (CF) routinely undergo low-dose, high-resolution (LD-HR) CT scans of the paranasal sinuses as a crucial component of their clinical care plan and for disease management. The aim of this study was to assess and compare the intra-individual radiation dose and image quality between photon-counting CT (PCCT) and energy-integrating detector system (EID-CT) CT scanners using LD-HR protocols.

### METHODS AND MATERIALS

This retrospective analysis included 23 people with CF who underwent LD-HR CT scan of the paranasal sinuses with EID-CT and PCCT in clinical routine. In all patients, image quality was assessed using the signal-to-noise ratio (SNR). Three radiologists rated the overall image quality, sharpness, and noise of the paranasal sinuses on a 5-point Likert scale. To evaluate the radiation dose, an intra-individual comparison was performed in patients who had

previously undergone a similar examination with an EID-CT using the following parameters: effective dose, dose-length product (DLP) and volumetric CT dose index (CTDIvol).

**RESULTS**

PCCT demonstrated a reduction in radiation dose of approximately 37% compared to EID-CT (0.09 vs. 0.15 mSv, p<0.0001). The effective organ dose reduction was 43% for the eye lens (3.65 vs. 6.38 mSv, p<0.0001) and 39% for the brain (2.29 vs. 3.75 mSv, p<0.0001). PCCT consistently achieved superior scores for both overall image quality and image sharpness in comparison to EID-CT (p<0.0001). The mean SNR of PCCT was higher compared to the EID-CT (p<0.0001).

**CONCLUSION**

PCCT scans of the paranasal sinuses offer superior image quality and substantially reduce radiation exposure compared to EID-CT scans in people with cystic fibrosis.

**CLINICAL RELEVANCE/APPLICATION**

Since CF is a hereditary disease and patients accumulate a significant radiation exposure throughout their lives, the importance of radiation-associated diseases and the need for comprehensive strategies to minimize radiation exposure are paramount to avoid the risk of malignancy and damage to adjacent radiosensitive organs.

## R5A-SPPH-4 LATINSAFE INITIATIVE: MULTICENTER INTERNATIONAL STUDY TO ESTABLISH CLINICAL INDICATION BASED DIAGNOSTIC REFERENCE LEVELS FOR HEAD CT IN LATIN AMERICA

Valdair F. Muglia, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Javier Contreras Yametti, MD (*Abstract Co-Author*) Nothing to Disclose
Roshan Fahimi, MD (*Abstract Co-Author*) Nothing to Disclose
Lina Karout, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The LatinSafe initiated efforts to establish clinical indication-based diagnostic reference level (DRLCI) for pediatric CT across multiple Latin American countries. In the ongoing initiative, we describe the initial results for DRLCI of head CT in children across multiple sites in Latin America.

**METHODS AND MATERIALS**

With local ethical committee approvals, we received data from 13 sites from 5 Latin American countries on 831 children (age < 18 years; F:M 427:831). All patients underwent head CT examinations. Collected data included demographic data (age, sex), CT scanner information (brand, model, number of detectors), scan acquisition factors (kV, mA, number of phases), clinical indication for CT, and radiation doses (dose length product - DLP and median volume CT dose index -CTDIvol). We calculate the total DLP (in mGy.cm) and median CTDIvol (mGy). We estimated overall and site-specific 50th (achievable doses - AD) and 75th percentile (diagnostic reference level - DRL) CTDIvol and DLP for each patient age group (0-<1, 1-<2, 2-<6 and 6-18 years) and clinical indication groups.

**RESULTS**

The ADs for the CTDIvol for Latin America were lower than the US standards for all age groups [0-<1 year: 17 vs. 19 mGy for US, 1-<2 years: 20 vs. 22 mGy for US, 2-<6 years: 21 vs. 25 mGy for US, 6-18 years: 31 vs. 46 mGy for US) (p<0.001). However, the ADs for DLP values were significantly higher than the US standards for all age groups (0-<1 year: 583 vs. 267 mGy for USA, 1-<2 years: 577 vs. 350 mGy for USA, 2-<6 years: 732 vs. 409 mGy for USA, 6-18 years: 937 vs. 748 mGy for USA) (p<0.001). Almost 95% (782/831) of all head CT were performed with a single acquisition phase. Compared with the typical 12-14 cm scan length for head CT exams, higher DLP was attributed to longer scan lengths with 15% of the head CTs with >23 cm scan lengths. Interestingly, there was a significant difference in radiation doses in all age groups between CT manufacturers with the highest dose CT vendor (0<1 year: CTDIvol 36 [26-44] mGy, 1-<2 years: CTDIvol=29 [22-40] mGy, 2-<6 years: CTDIvol=32[26-42] mGy and 6-18 years: CTDIvol=45[41-50]mGy) being significantly different from the lowest dose CT vendor (0<1 year: CTDIvol=11[8-17] mGy, 1-<2 years: CTDIvol=14[14-24] mGy, 2-<6 years: CTDIvol=14[14-17] mGy and 6-18 years: CTDIvol=16[14-26]mGy) (p<0.001).

**CONCLUSION**

Longer than necessary scan lengths for head CT are responsible for higher DLP in most Latin American sites despite having substantially lower CTDIvol values.

**CLINICAL RELEVANCE/APPLICATION**

There is a need for education and optimization regarding scan length reduction for head CT examinations.

## R5A-SPPH-5 ALL-IN-ONE DEEP LEARNING FRAMEWORK FOR MR IMAGE RECONSTRUCTION

Hyeonsoo Kim (*Abstract Co-Author*) Nothing to Disclose
Kyungeun Jang (*Abstract Co-Author*) Nothing to Disclose
Joonyoung Yang (*Abstract Co-Author*) Nothing to Disclose
Jeewook Kim (*Abstract Co-Author*) Nothing to Disclose
Geunu Jeong (*Presenter*) Nothing to Disclose

**PURPOSE**

This research introduces a novel, all-in-one deep learning framework for MR image reconstruction, enabling a single model to enhance image quality across multiple aspects of k-space sampling and to be effective across a wide range of clinical and technical scenarios.

**METHODS AND MATERIALS**

1.5 million MR raw data of various pulse sequences and anatomical regions from three vendors were collected. Multi-dimensional degradation was applied to raw k-space data to generate training input. This process involved a combined application of noise addition and multiple patterns of undersampling (uniform, random, kmax, partial Fourier, elliptical), with each method being applied across a range of factors to cover extensive sampling scenarios. Contextual data, including scan parameter information, were prepared to serve as auxiliary input to address the challenges posed by the unique learning task for each training pair, which arise from the varied degradation scenarios. The U-Net was modified to include an additional pathway for integrating contextual data.

**RESULTS**

Six performance evaluations were conducted through visual comparisons. 1) A series of deep learning reconstructions (DLRs) was applied to the same image, each adding a new dimension of improvement - starting with noise reduction, then adding frequency kmax, phase partial Fourier, phase kmax, to slice kmax. Incremental enhancement along each added dimension was demonstrated, confirming simultaneous multi-dimensional improvements. 2) A relative edge sharpness of approximately 3.0 between original and DLR images, indicating effective super-resolution, was achieved in each of the three encoding directions. 3) DLR images showed reduced truncation and intravoxel dephasing artifacts, which are prominent at lower resolutions, attributed to slice-directional super-resolution. 4) Images obtained from eight different sets of scan parameters that adjusted sampling and reconstruction pipeline, along with 5) images from three unseen vendors, demonstrated significant quality improvement after DLR, highlighting broad compatibility. 6) Image pairs from standard and fast protocols across four anatomical regions were acquired, with the fast images undergoing DLR. The DLR fast images exhibited superior quality compared to the standard images, demonstrating the feasibility of reducing scan times.

**CONCLUSION**

The proposed model enhances image quality in a multi-dimensional manner and offers versatility.

**CLINICAL RELEVANCE/APPLICATION**

The proposed model is compatible with a broad spectrum of scenarios, including various vendors, pulse sequences, scan parameters, and anatomical regions. Its DICOM-based operation particularly enhances its applicability for real-world applications.

## R5A-SPPH-6 BEAM CHARACTERIZATION AND IMAGE QUALITY ANALYSIS OF A SILVER FILTER FOR LOW DOSE LUNG CANCER SCREENING CT: A PHANTOM STUDY

Izabella Barreto, PhD (*Abstract Co-Author*) Nothing to Disclose
Graham Stoddard, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

A commercial silver filter was introduced to reduce radiation dose in low dose lung cancer screening CT (LDCT) exams. This study compares x-ray beam quality and phantom image quality using clinical LDCT protocols with and without the silver filter.

**METHODS AND MATERIALS**

We looked at two filters commercially installed in the same CT scanner: a large bowtie filter and a new flat silver filter. Half-value layer (HVL) was measured with all available kVp settings using a parked x-ray tube and with a helical scan and lead aperture. The ACR CT accreditation phantom was scanned with 5 dose levels (0.5, 0.9, 1.6, 2.1, 2.8 mGy) using 120 kVp, 0.275 s rotation time, pitch of 0.81, and 40 x 0.5 mm beam width. Images were reconstructed using a deep learning algorithm with 0.5 and 1.0 mm slices using a body sharp kernel and 0.5 mm slices using a lung kernel. Task Transfer Function (TTF), Contrast to Noise Ratio (CNR), and Noise Power Spectrum (NPS) were measured using an image analysis tool, imQuest.

**RESULTS**

For all kVp settings, HVL was significantly higher for the silver filter (Range: 10.71 - 15.91 mm Al) than the large bowtie filter (Range: 7.68 - 11.56 mm Al) ($p<0.05$). With its increased filtration, the silver filter had to use higher tube currents to achieve the dose levels. For all dose levels the 10% TTF value was 9.5% lower on average and for the 2 highest dose levels, this caused the scanner to use the larger focal spot, degrading spatial resolution compared to the large bowtie filter. For example, the bone insert reconstructed with the body sharp kernel had a 10% TTF of 1.04 mm-1 for the silver filter and 1.25 mm-1 for the large filter ($p<0.05$). At equivalent dose levels, the silver filter produced better noise (average: 9% lower) and CNR (average: 16.1% higher) than the large filter. For example the 0.5 mm thick lung images had a noise magnitude of 45.43 HU for the silver filter and 62.5 HU for the large filter ($p<0.05$). The silver filter did not significantly affect the noise texture at any dose level or reconstruction ($p>0.05$), indicating a similar visual match.

**CONCLUSION**

We measured that the silver filter can maintain noise and CNR with lower doses, or alternatively, produce better noise and CNR at matched dose levels. However, we also found worsened spatial resolution, which may be detrimental in annual LDCT exams. CT imaging is a balance and the reduced spatial resolution underscores why image quality must be considered for clinical adoption of new technology.

**CLINICAL RELEVANCE/APPLICATION**

A CT filter made of silver can reduce radiation dose in annual LDCT exams, however its effect on image quality demonstrates why protocol optimization for specific clinical tasks is vital. The technology presents multiple options for radiation dose and image quality optimization to meet clinical needs.

## R5A-SPPH-8 EVALUATION OF DOSE AND IMAGE QUALITY IN INNER EAR IMAGING: COMPARISON BETWEEN COMPUTED TOMOGRAPHY AND 3D ROTATIONAL ANGIOGRAPHIC ACQUISITIONS

alessandro cianfoni, MD (*Abstract Co-Author*) Nothing to Disclose
Elisa Ventura (*Abstract Co-Author*) Nothing to Disclose
Francesco Magoga, BSc (*Abstract Co-Author*) Nothing to Disclose
Gaetano Cancellato (*Abstract Co-Author*) Nothing to Disclose
Stefano Presilla (*Abstract Co-Author*) Nothing to Disclose
Luca Bellesi, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

An intercomparison was made to evaluate the relationship between radiation dose and image quality of two different diagnostic modalities carried out on inner ear diagnostic studies. Evaluations were made by comparing the diagnostic examinations, both simulated on two different phantoms, made by a multi-detector computed tomography (MDCT) scanner with respect to the same examinations carried out with an interventional angiography system, which can perform 3D rotational acquisitions (3DRA) reconstructed with CT-like advanced techniques.

## METHODS AND MATERIALS

All radiological images were acquired both using a 256-slice MDCT scanner and a biplane interventional angiography system integrated with 3DRA. Image quality for radiological systems was evaluated both using a CT Catphan phantom and a head anthropomorphic phantom. The scans of the two phantoms were performed both with standard and optimized protocols of study. Dosimetric measurements were also performed using a head-CTDI phantom and a pencil-type CT chamber connected with a calibrated electrometer. Dosimetry evaluation were done taking into account CTDI, DLP, DAP and effective dose calculated, for both MDCT and 3DRA acquisitions, using two different Monte Carlo systems to convert dose parameters to effective dose. Image quality was assessed, on phantom images, with an interventional radiologist evaluating high contrast spatial resolution, image noise and details detectability.

## RESULTS

Effective doses calculated with Monte Carlo systems, for both MDCT and 3DRA image acquisitions, are comparable in terms of numerical absolute values. The measures, carried out with the support of a pencil-type CT chamber, provide a slightly higher value for the images acquired using the interventional angiography system compared to the MDCT acquisitions; it is worth noting that each measurement obtained with the 3DRA has been multiplied by two because it is necessary to acquire one temporal bone at a time while, for MDCT, it is sufficient one single acquisition. 3DRA images showed a higher general image quality level compared to the MDCT images. Image quality was better for the 3DRA images which showed better high contrast spatial resolution, lower image noise and improved details detectability.

## CONCLUSION

Evaluations of image quality, for both the CT Catphan phantom and head anthropomorphic phantom, are in favour of the 3DRA in terms of better high contrast spatial resolution, image noise and details detectability. The dosimetric comparisons show a substantial equivalence between the two types of imaging modalities.

## CLINICAL RELEVANCE/APPLICATION

Knowing and using new imaging methodologies is essential to improve procedures in neurological interventional radiology

## R5A-SPRO-1 INVESTIGATION OF THE ANTI-ANGIOGENIC EFFECT OF CARBON ION IRRADIATION ON C6 GLIOMAS IN RATS

Yu feng Li, MMedSc (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the effects of carbon ion irradiation (CIR) in inhibiting angiogenesis in rat C6 gliomas by combining imaging and molecular pathology.

### METHODS AND MATERIALS

Establishing 78 rat C6 glioma models. Before CIR, all rats were subjected to energy-spectral CT-enhanced scans and 6 rats were randomly selected as molecular pathology controls, the rest were randomly divided into three groups using different doses of carbon ions irradiation (0 Gy, 1 Gy and 2 Gy). Energy-spectral CT-enhanced scans on day 7, 14 and 21 after CIR to obtain the best single-energy CT value (CT 70 keV), iodine concentration (IC) and slope of the energy-spectral curve (K (40-70 keV)) in the solid tumour area and to measure the tumour volume. Then, three rats were randomly selected for HE and immunohistochemical staining for HIF-1 a, VEGF, CD34, a-SMA at each time point in each group; three rats were randomly selected on day 7 and 14 after CIR to collect tumour tissues for the detection of vascular-associated protein expression by WB method.

### RESULTS

The tumour volume in the three groups still increased at 7 days after CIR, gradually decreased at 14 days in the 1 Gy and 2 Gy groups, and decreased significantly at 21 days in the 2 Gy group, while some tumour volumes increased at 1 Gy.Compared with the 0 Gy group, the tumour blood perfusion was reduced in the 2 Gy group at 7 days after CIR, and CT 70 KeV, IC and K (40-70 KeV) decreased; at 14 days after CIR, CT 70 KeV, IC and K (40-70 KeV) decreased significantly in the 1 Gy and 2 Gy groups; at 21 days after CIR, K (40-70 KeV) increased in the 1 Gy and 2 Gy groups. There was a good correlation between the percentage of HIF-1a, VEGF , CD34 and a-SMA positive cells and each quantitative parameter of the energy spectrum CT in each groups. The expression of vascular-related proteins in the 2 Gy group was gradually downregulated after CIR. Survival analysis showed that the survival time of the 1 Gy and 2 Gy groups were significantly higher than the 0 Gy group.

### CONCLUSION

Carbon ion radiotherapy inhibits the angiogenic effects of gliomas.Energy-spectral CT can be used as a non-invasive dynamic monitoring tool to respond to the inhibitory effect of carbon ions on angiogenesis in rat C6 gliomas.

### CLINICAL RELEVANCE/APPLICATION

CIR has the advantages of inverted deep dose distribution and high relative biological effects, and may provide an effective treatment for malignant and recurrent brain tumors. The quantitative energy spectrum parameters allow non-invasive and dynamic monitoring of the inhibitory effect of CIR on the angiogenesis of C6 gliomas in rats and provide a basis for the development of clinical treatment strategies. Our study provides an experimental basis for the clinical application of carbon ion radiation therapy for glioma.

## R5A-SPVA-2 ENHANCING VESSEL VISUALIZATION IN MOYAMOYA DISEASE: A COMPARATIVE ANALYSIS OF RAPID SPIRAL MRA TECHNIQUE

Bing Zhang (*Abstract Co-Author*) Nothing to Disclose
Maoxue Wang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Moyamoya vessels, leptomeningeal and transdural anastomoses play a crucial role in maintaining cerebral perfusion in patients moyamoya disease (MMD). Traditional MRA have a long scan time for visualizing small collaterals. Therefore, finding a fast and effective imaging technique capable of visualizing these collaterals is essential. This study aims to compare the vessel visualization in spiral MRA (MRAspiral) and compressed SENSE MRA (MRACS) in moyamoya disease (MMD) patients, with digital subtraction angiography (DSA) as the reference standard.

### METHODS AND MATERIALS

We prospectively collected MRAspiral with different acquisition windows (t = 4, 6, 10ms), MRACS and DSA images in MMD patients. Contrast-to-noise ratio (CNR) was measured in the M1, M2, M3, and M4 segments of the middle cerebral artery (MCA) for each MRA sequence. Vessel visualization of the distal MCA, leptomeningeal artery (LMA) collaterals, distal external carotid artery (ECA), and distal internal carotid artery (ICA) stenosis was qualitatively analyzed using scoring systems compared to DSA. A linear fixed-effects model was used to evaluate differences among the four sequences.

### RESULTS

A total of 98 hemispheres from 55 MMD patients (28 males, 46 years old ± 12.7) were included. Sixty-seven hemispheres had DSA within 3 months. CNR in the M2, M3 and M4 segment of the MCA was not significantly different between MRACS and MRAt4 or MRAt6, but it was significantly higher than MRAt10 (all $P<0.05$). MRAspiral sequences provided better visualization of the distal MCA, LMA collaterals and distal ECA compared to MRACS (all $P<0.001$). Visualization of distal ICA stenosis was superior in MRAt4 (2.90±0.35) and MRAt6 (2.87±0.39) compared to MRACS ($P<0.001$), while no significant differences was observed between MRCS and MRAt10.

### CONCLUSION

MRAspiral demonstrated superior vessel visualization in MMD patients compared to MRACS, with DSA as the reference standard. MRAt6 significantly reduced acquisition time by 32.31% while maintaining reliable image quality compared to MRACS.

### CLINICAL RELEVANCE/APPLICATION

MRAt6 can be considered as a contrast-free imaging method for evaluating vessels in MMD patients, which could aid in surgical decision-making and follow-up assessment.

## R5B-SPBR-1 BACKGROUND ECHOTEXTURE CLASSIFICATION OF PREOPERATIVE AUTOMATED BREAST US: ASSOCIATION WITH OUTCOMES IN EARLY-STAGE BREAST CANCER PATIENTS

Ji Soo Choi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Myoung Kyoung Kim (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate whether the background echotexture classification of preoperative ABUS is associated with the accurate preoperative evaluation of tumor extent or post-treatment recurrence in early-stage breast cancer patients.

### METHODS AND MATERIALS

A retrospective review of the collected databases of the multicenter prospective study (NCT04607473) identified women with early-stage breast cancers (clinical Tis, T1-2/N0) treated by surgery who had undergone ABUS adjunct to FFDM for preoperative local tumor staging between Oct 2019 and Apr 2021 at our institution. BE of preoperative ABUS was assessed in contralateral normal breast with BI-RADS classification (homogeneous-fat, homogeneous-fibroglandular, or heterogeneous) in all patients. In patients with mammographically dense breasts, glandular tissue component (GTC) was additionally assessed and grouped (high [moderate or marked] or low [minimal or mild]). Logistic regression was used to determine factors associated with accurate preoperative tumor extent evaluation of ABUS. Cox regression modeling was used to determine factors associated with post-treatment recurrence.

### RESULTS

Among 409 women (mean age, 50.2 years ± 8.7 [standard deviation]), 11 recurrences with a median follow-up of 26 months were detected. For preoperative local tumor stating, moderate or marked BPE on MRI (HR, 2.3 [95% CI: 1.1, 5.0], P=.033) was associated with inaccurate ABUS evaluation in patients with dense breasts. However, BE or GTC of ABUS showed no association with ABUS accuracy. For post-treatment recurrence, receiving adjuvant chemotherapy (HR, 4.6 [95% CI: 1.1, 19.2]; P =.039), pathologic invasive cancer size (HR, 2.2 [95% CI: 1.1, 4.2]; P =.022) and heterogeneous BE on ABUS (HR, 6.5 [95% CI: 0.3, 162.2]; P =.002) were independently associated with an increased risk of recurrence in all patients. In patients with dense breasts, pathologic invasive cancer size (HR, 2.1 [95% CI: 1.1, 4.1]; P =.028), moderate to marked GTC on ABUS (hazard ratio [HR], 10.4 [95% CI: 2.6, 42.4]; P = .001) and heterogeneous BE on ABUS (HR, 17.7 [95% CI: 3.2, 97.5]; P =.001) were independently associated with an increased risk of recurrence.

### CONCLUSION

In early-stage breast cancer patients, heterogeneous BE on ABUS was associated with recurrence but not with the accuracy of its preoperative local tumor staging. In patients with mammographic dense breasts, moderate to marked GTC of ABUS was also associated with recurrence but not with the accuracy of its preoperative local tumor staging.

### CLINICAL RELEVANCE/APPLICATION

Based on our research findings, BE and GTC of ABUS may serve as imaging markers to predict prognosis in early-stage breast cancer patients when ABUS is used as their preoperative staging tool.

## R5B-SPBR-10 RATES AND CHARACTERISTICS OF FALSE-NEGATIVE CANCERS WITH DIGITAL BREAST TOMOSYNTHESIS AMONG CAUCASIAN, AFRICAN AMERICAN, AND ASIAN WOMEN

Manisha Bahl, MD, MPH (*Abstract Co-Author*) Consultant, Lunit Inc;Expert Advisory Committee, 2nd.MD
Ariel Kniss, MD, PhD (*Presenter*) Intern, General Electric Company

### PURPOSE

Recent United States Preventive Services Task Force guidelines emphasize disparities in breast cancer outcomes among racial groups and comment about insufficient evidence about the effectiveness of mammographic screening for certain subgroups of women. The symptomatic false-negative rate (FNR), or interval cancer rate, of screening digital breast tomosynthesis (DBT) is considered to be a surrogate marker for long-term patient outcomes. The purpose of this study is to determine rates and characteristics of false-negative (FN) cancers with DBT among Caucasian, African American, and Asian women.

### METHODS AND MATERIALS

In this IRB-approved and HIPAA-compliant study, consecutive screening mammograms from January 2013 to June 2019 at an academic medical center were retrospectively reviewed. During this time period, all women presenting for screening mammography underwent combined DBT and digital 2D mammography. Breast cancers were considered FN cancers if diagnosed within 365 days of a negative screening examination. Medical records were

reviewed for patient age, race, mammographic breast density, mode of detection of the FN cancer, biopsy pathology results, and surgical pathology results. Rates and characteristics of FN cancers were compared among Caucasian, African American, and Asian women using standard statistical tests.

**RESULTS**

The overall FNR was 0.8 per 1000 screening examinations (231/279,165). The FNR was 0.9 per 1000 screening examinations in Caucasian women, 0.5 per 1000 in African American women, and 0.6 per 1000 in Asian women (p=0.25). The proportions of FN cancers detected on high-risk screening MRI in Caucasian, African American, and Asian women were 30.8%, 0%, and 50.0%, respectively. Asian women had the lowest proportion of invasive relative to in situ FN cancers, with 60.0% invasive cancers and 40.0% in situ cancers (p=0.02). In African American women, invasive FN cancers were more likely to be grade 3 (p<0.01) and triple-negative (p=0.01). No significant differences were observed in invasive FN cancer size at surgery or lymph node positivity among Caucasian, African American, and Asian women.

**CONCLUSION**

In our study cohort undergoing breast cancer screening with DBT, the FNR was 0.8 per 1000 screening examinations. The results suggest that FN cancers in African American women are more aggressive than FN cancers in Caucasian and Asian women.

**CLINICAL RELEVANCE/APPLICATION**

Further research is needed to understand factors associated with more aggressive FN breast cancers in African American women, which may include lower utilization of high-risk screening MRI; the role of supplemental screening with MRI in women at risk for interval cancers with DBT alone; and the impact of screening with DBT on long-term patient outcomes.

## R5B-SPBR-2 COMPARISON OF LONG-TERM PERFORMANCE METRICS FOR SCREENING MAMMOGRAPHY USING DIGITAL BREAST TOMOSYNTHESIS COMPARED WITH 2D MAMMOGRAPHY

Liane E. Philpotts, MD (*Abstract Co-Author*) Nothing to Disclose
Jihyun Kang, MD (*Abstract Co-Author*) Nothing to Disclose
Rasha Ismail, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Digital breast tomosynthesis (DBT) has been shown in many studies to have improved metrics compared with 2D mammography. Whether initial improvements in metrics are sustained over time is less well established. The purpose of our study was to evaluate long-term screening performance metrics and outcomes of 2D mammography versus digital breast tomosynthesis.

**METHODS AND MATERIALS**

This is a retrospective historical cohort study utilizing the electronic breast imaging database (PenRad, Buffalo, MN) at a multisite tertiary care academic institution. Our study includes women aged 40-79 years who underwent screening 2D mammography (either film-screen or digital mammography) over a 12-year period (August 1999 to July 2011) and women who underwent screening DBT over the subsequent 12-year period (August 2011 to July 2023). All studies were read by dedicated, subspecialized breast imagers that varied over the 24 years. We compared the outcomes of recall rate (RR) over all 24 years. Information on Cancer Detection Rate (CDR) and positive predictive value of recall (PPV1) was available from 2006 through 2023. In addition, the recall rates for the two cohort groups were assessed by breast density categories. (A: almost entirely fatty; B: scattered areas of fibroglandular density; C: heterogeneously dense; D: extremely dense).

**RESULTS**

109,801 2D mammograms and 300,451 DBT mammograms were interpreted during the respective periods for a total of 410,252 screening mammograms. The RR for 2D mammography averaged 12.5% (range 10-15). DBT had a lower average RR of 7.8% (range 7-9). This difference is statistically significant. (p<0.00001). DBT had a sustained significantly higher CDR (average 5.5 per 1000, range 5-6) compared with 2D (3.4 per 1000, range 3-4) and higher positive predictive value of recall (PPV1) (7.4 for DBT vs. 3 for 2D) (p<0.00001). 2D mammography had a significantly higher RR than DBT for all dense breast categories (A:8% vs 4%; B:11% vs 7%; C:17% vs 8%; D:14% vs 8%,respectively) (p<0.00001).

**CONCLUSION**

DBT has significantly better performance metrics than 2D mammography with sustained lower RR and higher CDR and PPV1 rates.

**CLINICAL RELEVANCE/APPLICATION**

Our study further supports the use of DBT over 2D mammography by reducing unnecessary callbacks from screening while improving cancer detection. Clinically, this should improve breast cancer outcomes.

## R5B-SPBR-3 PROGNOSTIC ANALYSIS AND RISK FACTORS FOR REGIONAL RECURRENCE IN BREAST CANCER: CLINICAL SIGNIFICANCE OF INTERVAL REGIONAL RECURRENCE

Eun Sook Ko, MD (*Abstract Co-Author*) Nothing to Disclose
Myoung Kyoung Kim (*Presenter*) Nothing to Disclose

**PURPOSE**

Adjuvant treatment advancements have reduced isolated regional breast cancer recurrence to <2%. However, research on interval regional recurrence in women with personal breast cancer history (PHBC) is limited. This study examines survival outcomes and risk factors for screening-detected and interval regional recurrences.

**METHODS AND MATERIALS**

This retrospective cohort study examined medical records of patients who underwent invasive breast cancer surgery at a single institution from January 2011 to December 2019. Surveillance breast ultrasound, including axilla, internal mammary, and supraclavicular areas, was conducted semiannually for five years, then annually for those with PHBC. Interval regional recurrences were recurrences diagnosed after negative screening but before the next scheduled screening. Overall survival (OS) rates were estimated and compared across cohorts using time-dependent Cox regression. Factors associated with regional and interval regional recurrences were evaluated using the multivariable Fine-Gray subdistribution hazard model.

**RESULTS**

Among 13,406 women (mean: 49.8 years ± 10 [SD]), 126 (0.9%) developed regional breast cancer recurrence during a median follow-up of 6.5 years. This included 61 ipsilateral axillary, 39 ipsilateral internal mammary, 22 ipsilateral supraclavicular, one both axillary and internal mammary, and three both axillary and supraclavicular lymph node recurrences. Among these, 37 cases (0.3%) were interval regional recurrences. Patients with screening-detected and interval regional recurrences showed significantly poorer OS than those without recurrence. While interval regional recurrences tended to

have worse OS, it was not statistically significant (HR: 1.7 [0.6, 4.3]; P = .27). High nuclear grade (HR: 4.4 [0.2, 1.7]; P = .003) and high nodal stage at initial diagnosis (HR: 2.1 [1.2, 3.6]; P = .008) were associated with increased risk for regional recurrence. For interval regional recurrence, high nuclear grade, high nodal stage, and lymphovascular invasion were associated with increased risk, with hazard ratios of 7.7 (0.9, 63.2; P = .05), 1.3 (0.6, 2.1; P = .03), and 3.1 (1.5, 6.5; P = .002), respectively.

**CONCLUSION**

Our study indicates that patients with interval regional recurrence exhibit significantly poorer overall survival, associated with higher nuclear grade, higher nodal stage, and the presence of lymphovascular invasion.

**CLINICAL RELEVANCE/APPLICATION**

Enhanced postoperative screening protocols are recommended for patients at risk of interval regional recurrence, including those with higher nuclear grade, higher nodal stage, and lymphovascular invasion. Chest CT or PET-CT could offer early detection, potentially improving survival outcomes.

## R5B-SPBR-4 PATIENT SELF-PAY FOR AI-DRIVEN ENHANCED REVIEW PROGRAM IN SCREENING MAMMOGRAPHY: INITIAL EXPERIENCE

Leeann Louis, BS, PhD (*Abstract Co-Author*) Researcher, RadNet, Inc
A. Gregory Sorensen, MD (*Abstract Co-Author*) Employee, RadNet, Inc;Board member, IMRIS Inc;Board member, Siemens AG;Board member, DFB Healthcare Acquisitions Corp;Board member, inviCRO, LLC;;;;
Jacqueline S. Holt, MD (*Abstract Co-Author*) Nothing to Disclose
Janet M. Storella, MD, MD (*Abstract Co-Author*) Nothing to Disclose
Bryan Haslam, PhD (*Presenter*) Employee, RadNet, Inc

**PURPOSE**

Though AI for screening mammography has garnered significant attention, adoption has been modest, perhaps in part because AI is not reimbursed. Some practices have elected to offer AI at additional cost, much like what was done when digital breast tomosynthesis was originally deployed. While quantification of benefit will require prospective controlled trials, and it is difficult to separate enrollment bias from the effectiveness of AI, we seek to share data from experience with initial implementations from several different practices that implemented a self-pay AI program.

**METHODS AND MATERIALS**

A self-pay AI-driven screening mammography program was deployed across 10 clinical practices ranging from a few sites up to 64 sites at the largest practice. Women who enrolled had FDA-cleared AI software applied to their mammogram and in relevant cases a safeguard review by a second interpreting radiologist. Cancer detection rate, recall rate and positive predictive value were calculated per practice using routine MQSA methodology.

**RESULTS**

Results were collected on 747,604 women who underwent screening mammography over a 12 month period and who were offered the option to pay for the AI-driven enhanced review. 23% of women chose to enroll, with the enrollment rate increasing over time (final month, 33% enrollment). The overall cancer detection rate was on average 43% higher for enrolled women vs unenrolled women (5.95 vs 4.15 per 1000). Overall, the recall rate was 21% higher for enrolled vs unenrolled women (10.9% vs 8.8%) and the positive predictive value (PPV1) was 15% higher (5.4% vs 4.6%). The higher PPV1 indicates each recall resulted in more cancer diagnoses in the enrolled population. All 10 practices saw a substantially higher CDR in enrolled women compared to unenrolled women.

**CONCLUSION**

Initial data shows significantly higher rates of cancers detected in a population enrolling in an AI-enhanced breast screening program. One limitation of these initial results is that the differences observed are a combination of the impact of the AI program and patient self-selection, this merits further research.

**CLINICAL RELEVANCE/APPLICATION**

Self-pay programs may be a way for patients to get access to AI-enhanced screening care that could result in more cancers detected early.

## R5B-SPBR-5 EXAMINING THE EFFICACY: DOES TELEPHONE COMMUNICATION OF BREAST DENSITY ENHANCE SCREENING BREAST ULTRASOUND UPTAKE

Stamatia V. Destounis, MD (*Presenter*) Medical Advisory Board, iCad, Inc

**PURPOSE**

To determine if communicating breast density via telephone would increase the likelihood that a woman would pursue screening breast ultrasound.

**METHODS AND MATERIALS**

Beginning in June 2023, we incorporated a telephone call to communicate with patients with heterogeneously dense or extremely dense breast tissue. The purpose of the call was to inform patients of their breast density and the option for supplemental screening with breast ultrasound. In this timeframe, we have had approximately 7,755 patients identified as having dense tissue but not having a screening breast ultrasound scheduled. 542 patients were excluded from being contacted due to: being recalled from their screening mammogram, having been spoken to at the time of their appointment about their breast density, had previously expressed they were not interested in having a screening ultrasound, resulting in 7,213 patients remaining. These patients were personally contacted by one of 4 trained staff members to review with the patient that she has dense breast tissue and to discuss the recommendation for supplemental screening ultrasound.

**RESULTS**

At the time of the telephone conversation, approximately 23.5% (1693/7213) scheduled an ultrasound for either the same year or at the time of their next annual screening mammogram. 21% (n=1487) declined scheduling an ultrasound; 65/1487 (4.4%) did call back and schedule. Lack of insurance coverage was the predominant reason for the decline. 8% of patients (n=606) stated they would like to speak with their primary care physician and would call back if they would like to pursue scheduling; of which 15% (n=88) did call back and schedule. 45% (3270/7213) had a message left or there was no answer, or no voicemail set up. Of these, 18% called back and scheduled (602/3270). 9 (0.1%) patients expressed that they were unhappy with receiving a phone call.

**CONCLUSION**

The overall response from patients was positive when receiving a phone call to discuss their breast density and the recommendation for screening ultrasound. We found that 33% of patients contacted scheduled a screening ultrasound. The biggest barrier to pursuing ultrasound from the patient's

perspective was the lack of insurance coverage.

**CLINICAL RELEVANCE/APPLICATION**

In NYS we have had breast density notification legislation since 2013. Since that time our private practice has been notifying patients in writing of their tissue type and offering screening breast ultrasound. Despite years of notification, some patients have not pursued additional screening.

## R5B-SPBR-7 EARLY PREDICTION OF NEOADJUVANT CHEMOTHERAPY RESPONSE IN BREAST CANCER PATIENTS BASED ON 3D PRESSURE ESTIMATION

**PURPOSE**

Elevated interstitial fluid pressure in breast cancers may promote disease progression by preventing the effective uptake of therapeutic agents. The aim of this ongoing multi-site study is to develop a new functional marker for early prediction of breast cancer response to NAC based on 3D pressure estimates using contrast-enhanced US (CEUS).

**METHODS AND MATERIALS**

This ongoing, prospective study enrolls patients scheduled to undergo NAC for breast cancer at two clinical sites. 3D CEUS with subharmonic-aided pressure estimation (SHAPE) was used to estimate the pressure gradient between breast tumor and adjacent tissue noninvasively. SHAPE utilizes the strong inverse linear relationship between subharmonic signal intensity from US contrast agents and ambient pressure. At 0, 10, and 30% completion of NAC, 3D SHAPE data were collected using a built-in subharmonic mode on a Logiq E9 scanner with an RSP 6-16D probe (GE HealthCare, transmit frequency of 9 MHz). The data were collected with and without intravenous infusion of Definity (Lantheus Medical Imaging). The gradient in the mean subharmonic signal intensity between the tumor and adjacent tissue as well as tumor volume at each time point were compared with the pathological and radiologic NAC response outcomes, independently and in combination. Subjects with tumor volume reduction =90% at 100% completion of NAC were considered radiologic responders.

**RESULTS**

The analysis included 31 subjects with 1 subject pending pathological outcome and 1 subject missing radiologic outcome. There were 11 subjects with pCR and 16 radiologic responders. The subharmonic signal difference between the tumor and adjacent tissue was significantly higher in pCR than in non-pCR subjects as well as in radiologic responders than in non-responders at 10% and 30% completion of NAC ($p<0.05$). The tumor size was not significantly different between pCR and non-pCR or between the radiologic responders and non-responders at any time point ($p>0.1$ and $p>0.06$, respectively). The areas under the receiver operating characteristic curves (AUCs) for detecting pCR/radiologic responders by the pressure gradient at 10% and 30% completion of NAC were 0.69/0.76 and 0.86/0.82, respectively. The AUCs for detecting pCR/radiologic responders at 10% completion of NAC were further improved to 0.82/0.87 by combining the pressure gradient and tumor volume.

**CONCLUSION**

Our preliminary results suggest that the SHAPE pressure gradients at two early time points, i.e.,10 and 30% completion of NAC, may predict pCR and radiologic responders independently or combined with the standard tumor volume measurements.

**CLINICAL RELEVANCE/APPLICATION**

The SHAPE gradient at 10% and 30% completion of NAC can be a new marker to predict NAC response in breast cancer patients.

## R5B-SPBR-8 DIAGNOSTIC MAMMOGRAM WITH TOMOSYNTHESIS IS SUFFICIENT IN THE EVALUATION OF FOCAL PAIN IN "ALMOST ENTIRELY FATTY" BREASTS

Xiaoqin J. Wang, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Aurela I. Clark, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To identify whether ultrasound (US) can be safely omitted in patients 30 years and older, with "almost entirely fatty" breasts, presenting only with focal pain.

**METHODS AND MATERIALS**

In this retrospective cohort, all initial negative/normal Digital Breast Tomosynthesis (DBT) mammograms for focal breast pain without associated symptoms were reviewed for women 30 years and older with "almost entirely fatty" breast composition who presented at our institution over a 5-year period (5/2016 - 5/2021). Subsequently performed targeted US were also reviewed. Women with prior reduction mammoplasty, excisional or benign core biopsy were included. Women were excluded with focal pain in the axilla, additional symptoms, prior history of breast cancer, or implants.

**RESULTS**

45 women ages 30-84 years old (age: mean +/- std, 55 +/- 15) met the inclusion criteria. 9 reported bilateral pain. A total of 54 diagnostic exams were performed, each exam consisted of a unilateral DBT mammogram followed by a focused breast US at the region of the focal pain. 50 out of 54 exams were concordant, both DBT and US were negative. 4 our of 54 exams were discordant, negative DBT, but positive US; 2 US findings were benign at initial assessment, BR2 (6mm cyst and 8mm mass consistent with fat necrosis, with prior sonographic stability), 1 US finding was probably benign, BR3 (a probable intramammary lymph node) confirmed stable at follow up imaging and downgraded to a BR2, and 1 US finding was of low suspicion for malignancy, BR4 with subsequent ultrasound guided biopsy revealing fat necrosis. 33 women with a total of 38 exams had follow up imaging, ranging

from 6 months to7 years, without cancer present at original site of pain. 12 women with a total of 16 exams, had no imaging follow up, and review of clinical notes did not mention pain as a persistent complaint, presumed resolved.

**CONCLUSION**

In our cohort of women with "almost entirely fatty" breasts presenting with focal pain without lump or discharge, we found that the addition of US to a negative or normal DBT did not increase the sensitivity for cancer detection. Our findings suggests that US may be safely omitted in the evaluation of focal breast pain in women who are 30 years and older when initial assessment with DBT mammography is negative for pain.

**CLINICAL RELEVANCE/APPLICATION**

Omitting US in the “almost entirely fatty” breast when initial DBT mammogram is negative/benign, will expedite patient care, reduce patient and health care costs, and increase imaging access for more patients.

## R5B-SPBR-9 PREDICTORS OF MALIGNANCY FOR MAMMOGRAPHIC ARCHITECTURAL DISTORTION

Onalisa D. Winblad, MD (*Abstract Co-Author*) Nothing to Disclose
John Eddy, DO (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study was to determine the effects of associated imaging findings on the likelihood of malignancy for architectural distortion (AD) identified on mammography.

**METHODS AND MATERIALS**

This IRB approved, retrospective cohort study included females, aged 18 and older, without concurrent ipsilateral breast malignancy who underwent needle biopsy at a single academic institution between 01/01/15- 12/31/20 for AD on diagnostic mammogram. Imaging and charts were reviewed to document any associated imaging findings, including mass, calcification, asymmetry, and ultrasound (US) correlate. Pathology outcomes were compared for AD with and without additional imaging findings to determine the positive predictive value (PPV) of AD for malignancy, benign with upgrade potential (BWUP) lesions, or other benign lesions. For BWUP lesions that underwent surgical excision, final surgical pathology was used for analysis.

**RESULTS**

There were 446 patients (mean age 57.6 + 13.3 years) meeting inclusion criteria with pathology yielding breast malignancy in 45.7% (204/446), BWUP lesion in 16.8% (75/446), benign lesion in 37.2% (166/446), and non-breast malignancy in 0.2% (1/446). Of the 446 patients, 59.6% (266/446) had AD with at least one associated mammographic finding and 40.4% (180/446) had no additional findings. For AD with associated mammographic findings, the PPV for malignancy was 57.5% (153/266), for BWUP lesion was 10.5% (28/266), and for benign lesion was 32.0% (85/266). For AD without associated mammographic findings, the PPV for malignancy was 28.3% (51/180), for BWUP lesion was 26.1% (47/180), and for benign lesion was 45.0% (81/180). US was not performed in 3.8% of patients (17/446). US correlate was identified in 95.1% (194/204) cases of malignancy, 73.3 % (55/75) BWUP lesions, and 69.2% (115/166) benign lesions. AD with US correlate had the highest relative risk for malignancy, 4.6 (95% CI: 2.6-9.0).

**CONCLUSION**

AD with at least one associated imaging finding has a high likelihood of malignancy. Isolated AD is most often a benign or BWUP lesion, though still necessitates biopsy due to gt;2% likelihood of malignancy. Close imaging-pathology correlation is needed for cases of AD with US correlate or mammographic mass as these are the strongest imaging predictors of malignancy.

**CLINICAL RELEVANCE/APPLICATION**

AD is increasingly identified on mammography due to widespread adoption of digital tomosynthesis. AD has gt;2% chance of malignancy and requires biopsy. Pathology of AD frequently yields cancer or BWUP lesions which historically undergo surgical excision. Implications of associated imaging findings may help guide management of AD, as newer literature supports surgical de-escalation in select BWUP cases.

## R5B-SPCA-1 EVALUATING EXPERIMENTAL TANTALUM OXIDE CONTRAST MATERIAL VERSUS IODINE FOR CALCIUM SIGNAL SEPARATION IN CORONARY ARTERY CALCIFICATIONS ON 4 DECT PLATFORMS: A PHANTOM STUDY

Peter Bonitatibus Jr. (*Abstract Co-Author*) Nothing to Disclose
Benjamin M. Yeh, MD (*Abstract Co-Author*) Grant, Koninklijke Philips NV;Grant, General Electric Company;Consultant, Canon Medical Systems Corporation;Speaker, Canon Medical Systems Corporation;Royalties, Oxford University Press;Shareholder, Nextrast, Inc;Board Member, Nextrast, Inc
Zhye Yin (*Abstract Co-Author*) Employee, General Electric Company
Brian Bales (*Abstract Co-Author*) Nothing to Disclose
Yuxin Sun, BS, MSc (*Abstract Co-Author*) Stockholder, Nextrast, Inc
Te Yu Lin, MS (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the calcium/contrast signal separation in a calcified coronary phantom between an experimental tantalum oxide nanoparticle (TaCZ) contrast agent and commercial iodine contrast in four DECT platforms.

### METHODS AND MATERIALS

We used a coronary phantom containing 6 groups of vessels with concentric and eccentric calcified plaques at 60, 40, and 20% HAP (hydroxyapatite) concentrations, and lumen diameters of 9, 6, and 3 mm. A seventh group without calcifications served as reference. The phantom was serially filled with water, iodine (Iopromide, Bayer), and tantalum (TaCZ, Nextrast Inc) solutions at 8 mg/mL and scanned on 4 commercial DECT scanners: Discovery CT750 HD and Revolution (GE HealthCare), IQon (Philips), and SOMATOM Force (Siemens). Vendor proprietary software was used to generate contrast- and calcium-specific image pairs. Calcium plaque and vessel lumen areas were calculated using an image threshold-based analysis to compare the signal separation accuracy between iodine and tantalum agents across all scanners.

### RESULTS

Across all scanners (n=4) for concentric plaques at all vessel diameters (n=3) and HAP concentrations (n=3), iodine (Iod) and tantalum (Ta) underestimated calcium area in 27/36 and 28/36 instances, respectively. However, in terms of accuracy of calcium plaque area quantifications, Ta exhibited superior performance compared to Iod in 30/36 comparisons (26/30 with $p<0.05$). For eccentric plaques, Iod and Ta agents underestimated calcium area in 27/36 and 34/36 instances, respectively. Based on percent error, Ta showed more accurate calcium area quantification in 32/36 comparisons (26/32 with $p<0.05$). For concentric plaques, vessel lumen area accuracy was underestimated with Iod at two scanners (18/36) and overestimated at the other two (18/36). While with Ta, 31/36 instances across all 4 scanners underestimated lumen area. Yet, Ta showed more accurate lumen area quantification than Iod in 31/36 comparisons (31/31 with $p<0.05$). For eccentric plaques, lumen area was also underestimated with Iod (18/36) and Ta (24/36), but based on percent errors, Ta outperformed Iod in 34/36 comparisons (29/34 with $p<0.05$).

### CONCLUSION

Tantalum-based contrast material enables more effective material separation from calcium plaque than iodine-based contrast across four different commercial DECT scanners. These results will inform clinical trials currently being planned.

### CLINICAL RELEVANCE/APPLICATION

Tantalum-based contrast agents hold promise over conventional iodine agents to better delineate vascular anatomy at DECT across different scanner platforms in the setting of calcified plaque.

## R5B-SPCA-2 DEEP-SILICON PHOTON-COUNTING CT VERSUS DUAL-ENERGY CT: COMPARISON OF CALCIUM FROM IODINE, GADOLINIUM, AND TANTALUM CONTRAST SIGNAL SEPARATION IN A CORONARY CALCIFICATION PHANTOM

Benjamin M. Yeh, MD (*Abstract Co-Author*) Grant, Koninklijke Philips NV;Grant, General Electric Company;Consultant, Canon Medical Systems Corporation;Speaker, Canon Medical Systems Corporation;Royalties, Oxford University Press;Shareholder, Nextrast, Inc;Board Member, Nextrast, Inc
Yuxin Sun, BS, MSc (*Abstract Co-Author*) Stockholder, Nextrast, Inc
Zhye Yin (*Abstract Co-Author*) Employee, General Electric Company
Peter Bonitatibus Jr. (*Abstract Co-Author*) Nothing to Disclose
Brian Bales (*Abstract Co-Author*) Nothing to Disclose
Te Yu Lin, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the performance of deep-silicon photon-counting CT (PCCT) and dual-energy CT (DECT) for material separation of iodine, gadolinium, or tantalum contrast signal from calcified plaques in a coronary calcification phantom.

**METHODS AND MATERIALS**

A thorax phantom with 6 groups of coronary vessels with concentric and eccentric calcified plaques at 60, 40, and 20% w/w HAP (hydroxyapatite), and lumen diameters of 9, 6, and 3 mm, and a seventh group without calcifications, was used. Contrast solutions of iodine (Iod), gadolinium (Gd), or tantalum (Ta) at concentrations of 8 mg/mL was serially filled into the vessels. The phantom was scanned on a prototype deep-silicon PCCT (GE HealthCare) and commercial DECT scanner (GE Revolution). Material decomposition contrast(no calcium) or calcium(no contrast) image maps were generated using GE PCCT prototype and proprietary AW Server 3.2 software. Accuracy of signal separation between contrast and plaques was assessed by image analysis to 1) compare the difference between the vessel lumen area on the contrast map and the true value on 120 kVp image; and by 2) calculating the percent error between the attenuation values within the vessel lumen and background on the calcium map.

**RESULTS**

In comparison of lumen area percent error across vessel sizes (n=3), degrees of calcification (n=3), calcification shapes (n=2), and contrast agents (n=3), 45/54 instances showed superior PCCT accuracy in material separation over DECT (42/45 with $p<0.05$). At DECT, between the 3 agents, Ta showed more accurate lumen area delineation compared to Iod or Gd (15/18 and 18/18 instances, respectively with $p<0.05$). Between agents at PCCT, Iod showed the most accurate lumen area measurements in 10/18 instances while Ta performed best in the remaining 8/18 instances (14/20 and 7/16, respectively with $p<0.05$). For lumen value error, PCCT consistently exhibited smaller errors compared to DECT for all agents across all 54/54 instances (49/54 with $p<0.05$). At DECT, Iod gave smaller lumen value percent errors in 13/18 instances, with Ta performing best in 5/18 instances (24/26 and 10/10, respectively with $p<0.05$). At PCCT, the lumen value error was lowest with Iod in 11/18 comparisons, and 7/18 with Ta (17/22 and 7/14, respectively with $p<0.05$).

**CONCLUSION**

Deep-silicon PCCT can outperform DECT in accuracy of delineating vessel lumen contrast signal (iodine, gadolinium, or tantalum-based) from calcified plaques, with particular improvement in iodine material separation. Further PCCT reconstruction algorithm optimizations are ongoing.

**CLINICAL RELEVANCE/APPLICATION**

Deep-silicon PCCT promises to improve accuracy over DECT for differentiating calcified plaque from both iodine and future non-iodine contrast agents now in development.

## R5B-SPCA-4 FEASIBILITY OF QUANTITATIVE MATERIAL DECOMPOSITION OF CORONARY PLAQUES INTO CONSTITUENT WATER, LIPID, PROTEIN, AND CALCIUM FRACTIONS WITH PHOTON COUNTING CT - A SIMULATION STUDY

**PURPOSE**

To assess the mathematical feasibility of photon counting CT(PCCT)-based material decomposition of coronary plaques into their constituent water, lipid, protein, and calcium fractions. Accurate compositional analysis of coronary plaques may potentially improve identification and risk stratification of vulnerable plaques, such as those with thin fibrous capsules, low density lipid cores, and spotty calcifications.

**METHODS AND MATERIALS**

The energy-dependent X-ray mass attenuation coefficient spectra of water, lipid, protein, and calcium were obtained from the ICRU Report 44. Corresponding linear attenuation coefficient spectra were generated using the physical densities of each material. The linear attenuation coefficient spectra were then converted into Hounsfield unit (HU) spectra ranging from 30 to 130 KeV, matching the reconstruction range of clinical PCCT. The HU of each material at reconstruction energies of 40, 50, and 75 KeV were then extracted, corresponding to low, mid, and high-energy HU calibration coefficients. Next, four different virtual coronary plaques were generated with water, lipid, protein, and calcium mass fractions of: #1 - 80%, 5%, 15%, 0%; #2 - 60%, 35%, 5%, 0%; #3 - 70%, 15%, 10%, 5%; and #4 - 50%, 25%, 10%, 15%, where each plaque had a corresponding low, mid, and high-energy HU to which Gaussian image noise was added. PCCT-based material decomposition was then simulated using noise standard deviations from 5 - 50 HU, and plaque volumes from 1 - 1000 mm3. In each case, the average root-mean-square-error (RMSE) of decomposition was assessed. All simulation and analyses were performed in MatLab (Version 2020a, MathWorks, Inc., USA).

**RESULTS**

The average RMSE (%) of plaque decomposition into water, lipid, protein, and calcium fractions, for plaque volumes of 150 mm3 and image noise of 10 HU was 16.9 ± 0.5%, 5.7 ± 0.2%, 11.2 ± 0.3%, and 0.2 ± 0.0%, respectively. For volumes of 150 mm3 and noise of 25 HU, the RMSE was 45.2 ± 1.3%, 15.1 ± 0.4%, 29.7 ± 0.8%, and 0.4 ± 0.0%. For volumes of 250 mm3 and noise of 10 HU, the RMSE was 14.4 ± 0.3%, 4.8 ± 0.1%, 9.5% ± 0.2%, and 0.1 ± 0.0%. For volumes of 250 mm3 and noise of 25 HU, the RMSE was 33.6 ± 2.7%, 11.2 ± 0.9%, 22.1 ± 1.8%, and 0.3 ± 0.0%. Overall, the RMSE of decomposition increased in proportion to image noise and decreased in proportion to plaque volume.

**CONCLUSION**

Accurate quantitative PCCT-based material decomposition of coronary plaques into their constituent components - water, lipid, protein, and calcium - is mathematically feasible, assuming low enough reconstruction image noise and high enough plaque volume.

**CLINICAL RELEVANCE/APPLICATION**

Quantitative PCCT-based material decomposition of coronary plaques may improve identification and risk stratification of vulnerable plaques.

## R5B-SPCA-5 EXTRACELLULAR VOLUME QUANTIFICATION IN CARDIAC MAGNETIC RESONANCE IMAGING: A BRIGHT PROSPECT OR A DEAD END IN CLINICAL APPLICATION? EVALUATION OF INFLUENCING FACTORS

Tilman S. Emrich, MD (*Abstract Co-Author*) Speaker, Siemens AG;Travel support, Siemens AG;Advisory Board, Siemens AG
Moritz Halfmann, MD (*Abstract Co-Author*) Nothing to Disclose

Anton Kilburg (*Abstract Co-Author*) Nothing to Disclose
Philipp Locherer (*Presenter*) Nothing to Disclose

**PURPOSE**

Myocardial extracellular volume fraction (ECV) is quantified from cardiac MRI either by manual or semi-automated post-processing methods and requires the blood hematocrit (Hct). It has previously been shown that both the timing of the blood sample in relation to the cardiac MRI and type of post-processing used to calculate the ECV can significantly influence results. Therefore, this study aimed to investigate the influence of using a synthetic hematocrit and a semi-automated software solution compared to the reference standard of blood-sampling based hematocrit and manual calculation.

**METHODS AND MATERIALS**

A total of 78 consecutive patients with cardiomyopathies who had undergone cardiac MRI at 3 Tesla were retrospectively included in this study. Additionally, 50 prospectively recruited healthy volunteers were included as a control group to establish a formula for the estimation of the synthetic Hct based on in-scanner blood sampling. T1 maps were acquired using commercially available MOLLI sequences prior and 15 minutes after the injection of Gadolinium (0,2 mmol/ml/kg body weight). Pre- and post-contrast T1 maps were used to calculate ECV values either manually or by using a semi-automated software solution (CVI42, Calgary, Canada) and either by inputting the blood-sampling-based or synthetic hematocrit, respectively. Agreement of measurements was assessed by Wilcoxon signed-rank test, Pearson's correlation, ICC and Bland-Altman analyses. Diagnostic Accuracy to differentiate cardiomyopathies from healthy volunteers was assessed by ROC-curves and DeLong-Analysis.

**RESULTS**

ECV values based on the four different calculation methods showed high level of agreement (r = 0,83 - 0,93, all ICC > 0,9) with no systematic bias. However, the manual calculation led to significantly lower absolute ECV values, i.e. ECV Manual / Lab-based Hct: 26,73 % ± 4,61 % vs. ECV Automated / Synthetic Hct: 27,78 % ± 4,95 %, P<.001. Despite these, there was no evidence of a difference in regard to diagnostic accuracy in the differentiation between cardiomyopathy patients and healthy volunteers (AUC 0,66 to 0,76; P>.14).

**CONCLUSION**

Cardiac MRI based myocardial ECV can be quantified using synthetic hematocrit values and semi-automated assessment with clinically acceptable variation and similar diagnostic accuracy compared to the manual and blood-sampling based reference method.

**CLINICAL RELEVANCE/APPLICATION**

The results show potential to further automate ECV quantification from cardiac MRI, thus facilitating more widespread clinical implementation due to ease of use.

## R5B-SPCA-6 DEEP LEARNING RECONSTRUCTION IMPROVED THE IMAGE QUALITY OF LGE AND ENHANCED MYOCARDIAL SCAR DETECTION IN PATIENTS WITH VENTRICULAR ARRHYTHMIAS

An Sun (*Presenter*) Nothing to Disclose

**PURPOSE**

Cardiac magnetic resonance (CMR) late gadolinium enhancement (LGE) has been used for detecting myocardial scar tissue in patients with myocardial diseases. However, accurate detection still remains challenging in sustained ventricular tachycardia (VT)/aborted SCD patients. Assess the effectiveness of deep learning reconstruction (DLRecon) in detecting myocardial scars using CMR LGE, and its clinical application value in VT/SCD patients.

**METHODS AND MATERIALS**

Seventy-two patients with suspected or known cardiomyopathy were prospectively scanned with 3.0T CMR. Short-axis LGE images were reconstructed using conventional reconstruction (ConRecon) and deep learning-based reconstruction (DLRecon). Image quality of ConRecon and DLRecon images was scored on a 4-point scale (poor to excellent). Subgroups were analysed according to the presence of combined ventricular arrhythmia, left ventricular (LV) systolic dysfunction (LV ejection fraction <50%), and high heart rate (=75beats/min), and were compared using the nonparametric Wilcoxon test in terms of contrast ratio (CR), signal-to-noise ratio (CNR), and subjective image quality scores. The scar size was also quantified using standard deviation (SD) thresholding technique and full width at half maximum (FWHM) technique. Intra- and inter-observer agreement was analysed using the intraclass correlation coefficient (ICC).

**RESULTS**

Sixty-four patients (37 NVST patients, 27 VT/SCD patients) with a mean age (45±8 years, 38% female) and LV ejection fraction of 52% (IQR: 33%-64%) were finally included. In the VT/SCD group, DLRecon image quality was significantly higher than ConRecon LGE images (subjective quality score 3.7±0.6 vs. 2.9±0.6, P<0.001), and DLRecon images had improved CNR and CR for scar/blood pool and scar/cardiac (P<0.05). Using the 5SD quantification method, DLRecon LGE results were significantly higher than ConRecon images, and better LGE quantification results LGE were obtained especially in patients with high heart rate with combined VT/SCD. There was a good agreement of the measured results between physicians (all ICC >0.85).

**CONCLUSION**

Deep learning-based reconstruction of LGE images can indeed improve the quality of CMR LGE images in patients with VT/SCD, better display myocardial scars, and perform well in patients with VT/SCD with combined high heart rate.

**CLINICAL RELEVANCE/APPLICATION**

The application of DLRecon to CMR LGE can improve the image contrast between myocardial scar and adjacent structures, allowing for accurately diagnosing subtle subendocardial lesions in cardiomyopathy patients with VT/SCD.

## R5B-SPCA-7 PHOTON-COUNTING CT BASED HEMODYNAMIC EVALUATION OF EXTRINSIC OUTFLOW GRAFT STENOSES DURING LVAD THERAPY: AN INNOVATIVE COMPUTATIONAL APPROACH

Ann Bolger, MD (*Abstract Co-Author*) Nothing to Disclose
Tino Ebbers, PhD (*Abstract Co-Author*) Nothing to Disclose
Marten Sandstedt, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Linus Ohlsson, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Implantable left ventricular assist devices (LVAD) connect the left ventricle apex to the aorta via an outflow graft in patients with advanced heart failure. Extrinsic obstruction of the outflow graft (eOGO) is associated with serious morbidity and mortality and recently led to an FDA Class 1 device recall of HM3. The assessment of eOGO relies on anatomic imaging of the stenosis cross sectional area but not its functional severity. This study aimed to provide

a better understanding of the hemodynamic impact of eOGO by basing an innovative computational numerical approach on in vivo images acquired using state-of-the-art photon-counting computed tomography (PCCT).

**METHODS AND MATERIALS**

Cardiac scans of 2 asymptomatic patients with radiologically-identified HM3 eOGO were acquired using PCCT (NAETOM Alpha, Siemens Healthineer, Erlangen, Germany). Images were evaluated by the consensus of two experienced cardiovascular radiologists. Numerical evaluations of hemodynamics were conducted using a high-fidelity three-dimensional Computational Fluid Dynamics (CFD) approach using the patient-specific graft geometries, 2 virtually augmented stenotic severities, and 3 device flows.

**RESULTS**

Radiologic evaluation showed a baseline cross-sectional area (CSA) reduction of 29% and 36% respectively. The virtually augmented stenoses had CSA reductions up to 52% and 61% respectively. Visual analysis identified increased velocity, pressure, and turbulent flow in the outer anterior curvature of the outflow graft, however changes in graft pressure gradients were slight (1 to 9 mmHg) across the range of stenosis severities and flow rates tested. The correlation profiles between pressure and minimal CSA, peak velocity and turbulent flow demonstrated considerable variation between the baseline cases and their corresponding augmented stenosis severities.

**CONCLUSION**

Evidence of eOGO during HM3 support and the recent device recall may promote clinical apprehension and intervention. This numerical study of 2 asymptomatic patients revealed low hemodynamic impact of in vivo and numerically augmented eOGO severities. The hemodynamic impact of eOGO may be difficult to predict and easily overestimated when assessed only by visual evaluation and quantification of cross-sectional area reduction.

**CLINICAL RELEVANCE/APPLICATION**

These results suggests that, for clinically encountered flow rates and stenosis severities below 61% in cross-sectional area decrease, eOGO may have low hemodynamic impact in a clinically stable patient. This suggests that patients with demonstrable eOGO but without symptoms or signs suggesting hemodynamically significant obstruction might be managed expectantly.

## R5B-SPCA-8 EXPLORING THE RELATIONSHIP BETWEEN NT-PROBNP LEVELS AND CMR PARAMETERS IN HEART FAILURE WITH PRESERVED EJECTION FRACTION: IMPLICATIONS FOR DIAGNOSIS AND PROGNOSIS

Yi Zhu (*Abstract Co-Author*) Nothing to Disclose
Rui Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

Heart Failure with Preserved Ejection Fraction(HFpEF) is a complex syndrome with a high incidence. N-terminal pro-B-type natriuretic peptide (NT-proBNP) is a commonly used biomarker in cardiovascular diseases, but the test for NT-proBNP requires blood sampling and may exhibit variations due to the patient's health condition and other influencing factors.This study aims to investigate the correlation between NT-proBNP levels and CMR parameters in patients with HFpEF to identify markers that indirectly reflect NT-proBNP, enhancing cardiovascular disease assessment.

**METHODS AND MATERIALS**

In this retrospective study, patients with HFpEF underwent CMR imaging using a 3.0 T scanner. NT-proBNP levels were measured, and CMR parameters including left ventricular volumes, extracellular volume, and myocardial strain were assessed by the commercially available software (cvi42). Statistical analyses were conducted to evaluate correlations between NT-proBNP and CMR findings.

**RESULTS**

The study included 43 patients with HFpEF, with a median NT-proBNP value of 277 pg/mL. The results of this study showed that compared with patients with lower NT-proBNP, patients with higher levels of NT-proBNP had higher LVESVi, but there was no difference in LVEDVi, and SV, CO and LVEF were significantly reduced. NativeT1, Enhanced T1 and ECV showed no significant difference between the two groups. On the surface of myocardial stress-related parameters, GCS, GRS and GLS were significantly reduced in patients with higher NT-proBNP level compared with patients with lower NT-proBNP level.

**CONCLUSION**

NT-proBNP levels were associated with various CMR parameters in patients with HFpEF, indicating its potential as a biomarker for assessing cardiac function and remodeling in this population.NT-proBNP serves as an essential biomarker in assessing and predicting changes in left ventricular function in HEpEF patients, indicating its potential as a biomarker for assessing cardiac function and remodeling in this population. The revelation that myocardial stress parameters and Native T1 can serve as Non-invasive indirect indicators of NT-proBNP levels, facilitating the evaluation of heart failure severity and subsequent survival rates in patients.

**CLINICAL RELEVANCE/APPLICATION**

The findings suggest that NT-proBNP may serve as a valuable tool in evaluating cardiac structure and function in HFpEF patients undergoing CMR imaging, aiding in the management and monitoring of heart failure.

## R5B-SPCA-9 EVALUATION OF DIAGNOSTIC PERFORMANCE IN DEEP-LEARNING BASED CONTRAST MODEL OF CARDIAC CT ON MYOCARDIAL DISEASE: A COMPARATIVE STUDY WITH DELAYED-PHASE CMR

Sung Min Ko, PhD (*Abstract Co-Author*) Nothing to Disclose
Sung-Jin Cha, BS (*Abstract Co-Author*) Nothing to Disclose
Donghee Koh (*Abstract Co-Author*) Nothing to Disclose
Pil-Hyun Jeon, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Cardiac computed tomography (CCT) obtains not only arterial phase images but also 5-7minute delayed phase images and is used as an aid for left ventricular(LV) myocardial diagnosis. However, since the delayed examination is performed with minimal radiation exposure, image noise increases and the degree of contrast enhancement is unclear. Therefore, we attempted to demonstrate clinical effectiveness by emphasizing the degree of contrast enhancement and improving image quality using deep learning-based contrast boosting(DL-CB) method, a recently developed artificial intelligence(AI)-based CCT contrast enhancement.

## METHODS AND MATERIALS

In this retrospective study, 150 patients with cardiomyopathies who visited from July 2020 to December 2023, had CCT with delayed contrast enhancement (MDE) and cardiac magnetic resonance imaging (CMR) intervals of less than one month, were selected. The collected subjects were classified according to clinical information at the time of examinations. Each lesion was classified into myocardial infarction (MI), hypertrophic cardiomyopathy (HCMP), dilated cardiomyopathy (DCMP) and aortic stenosis (AS). MDE-CT with modeled iterative reconstruction(MBIR) was obtained 5 minutes after iodinated contrast agent administration and was performed after arterial phase-CCT acquisition. The obtained MDE-CCT image was applied to DL-CB to generate an iodine contrast enhancement and CMR-LGE (late gadolinium enhancement).

## RESULTS

In the quantitative evaluation, the noise of ADMIRE MDE-CT and AI-CEM MDE-CT obtained by PACS decreased by 12.94 ± 4.50, higher SNR 7.13 ± 4.47 and higher CNR 10.32 ± 6.07. All P-Values except epicardial fat showed statistical significance of less than 0.05. In AI-CEM MDE-CCT, the measured HU values of LV septum, LV lateral wall, descending aorta, and LV blood pool excluding epicardial fat increased by 21.1% on average. In the qualitative evaluation, the average score of AI-CEM MDE-CCT rose from 2.63 ± 0.78 on ADMIRE MDE-CCT to 3.75 ± 0.84, showing a score improvement of 42.7% ($p<0.05$).

## CONCLUSION

By applying AI-CEM to the standard technique and retrospectively reconstructing MDE-CCT images, the quality of MDE-CCT images and detection of lesions are better than those using MBIR, which can be widely applied to the diagnosis of LV myocardial diseases. MDE-CCT images could help detect LV myocardial lesions in clinical practice.

## CLINICAL RELEVANCE/APPLICATION

The proposed AI-CEM for MDE-CCT enables accurate detection compared to the reference standard, LGE-CMR, and effectively improves the diagnosis of various LV myocardial diseases. Our results expand the role of cardiac CT in detecting LV myocardial disease as well as coronary evaluation for a variety of cardiac diseases.

## R5B-SPCH-1 THE IMPACT OF QUANTITATIVE ASSESSMENT USING CT PERFUSION FOR IDENTIFYING EXERCISE PULMONARY HYPERTENSION PATIENTS ACCORDING TO THE 2022 ESC/ERS GUIDELINE: A PROSPECTIVE STUDY

Midori Ueno, MD (*Abstract Co-Author*) Nothing to Disclose
Takatoshi Aoki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoshiko Hayashida, MD (*Abstract Co-Author*) Nothing to Disclose
Haruka Oku (*Presenter*) Nothing to Disclose

### PURPOSE

The hemodynamic definition of pulmonary hypertension (PH) was recently updated in the 2022 European Society of Cardiology (ESC)/European Respiratory Society (ERS) guidelines and a new definition of exercise PH was introduced. Although the performance of imaging methods (eg. CT, MRI, and nuclear medicine) in identifying patients with a high risk of PH has been assessed, noninvasive imaging capable of identifying the exercise PH is not revealed at all. The purpose of this study is to assess the utility of quantitative assessment using CT perfusion for distinguishing the exercise PH patients from the non-PH patients.

### METHODS AND MATERIALS

We prospectively evaluated the patients clinically suspected of having PH who underwent CT perfusion at our institution. They all examined with exercise-stressed right heart catheterization. Among them, we selected non-PH patients and exercise PH patients defined by mean pulmonary artery pressure (mPAP) <20mmHg and mPAP/cardiac output slope >3mmHg/L/min during the transition from rest to end-exercise in this study. Maximum enhancement (ME) at pulmonary trunk (PT) and at bilateral main pulmonary arteries (mPA), and lung parenchymal enhancement of over 18 set areas on axial perfusion map images avoiding major vessels (Ameli-Tenani, et al. J Thorac Imaging 2014;29:98-106) were analyzed. Statistical analysis was performed with Mann-Whiteny U test, and diagnostic capability was assessed using ROC analysis.

### RESULTS

Thirty exercise PH patients and 12 non-PH patients were included in this prospective study (mean age 64.7, range 23-82). Right mPA-ME (589.5 HU) and left mPA-ME (609.5 HU) of exercise PH patients were significantly higher than those of non-PH groups (494.9 HU and 514.3 HU, $P<0.05$). The corresponding AUCs in ROC analysis for exercise PH were 0.7 for right mPA-ME and 0.703 for left mPA-ME, respectively. There was no significant difference between 2 patient groups for ME at PT and for lung parenchymal enhancement.

### CONCLUSION

Main pulmonary artery enhancement derived from CT perfusion can be a noninvasive predictor to identify exercise PH.

### CLINICAL RELEVANCE/APPLICATION

Quantitative assessment using CT perfusion would be useful for screening of early PH, and may minimize the need for invasive exercise-stressed right heart catheterization.

## R5B-SPCH-2 MECHANICAL OBSTRUCTION CONTRIBUTES DIFFERENTIALLY TO CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION (CTEPH) PATHOPHYSIOLOGY DEPENDENT ON PATIENT FACTORS

John T. Granton, MD (*Abstract Co-Author*) Nothing to Disclose
Micheal McInnis, MD (*Abstract Co-Author*) Speakers Bureau, Boehringer Ingelheim GmbH;Speakers Bureau, Bayer AG
Laura Donahoe (*Abstract Co-Author*) Nothing to Disclose
Aly Muhammad Ladak (*Abstract Co-Author*) Nothing to Disclose
Marc Deperrot, MD (*Abstract Co-Author*) Nothing to Disclose
Gauri R. Karur, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Dayana Davoudi (*Presenter*) Nothing to Disclose

### PURPOSE

The correlation of chronic pulmonary embolism (PE) burden and pulmonary hypertension (PH) severity in CTEPH is poor as mechanical obstruction is just one factor in the pathophysiology of CTEPH. The purpose of this study was to correlate chronic PE burden CT scores with hemodynamic parameters and to identify subgroups where mechanical obstruction contributes greatest to PH severity.

### METHODS AND MATERIALS

This single centre retrospective study included adult patients who underwent pre-operative CT pulmonary angiography and pulmonary endarterectomy for CTEPH between 01/2017 and 09/2021. CT scans were scored by a blinded thoracic radiologist according to a previously reported 32-vessel model of the lung wherein each vessel was scored as patent, partly occluded, or occluded. Subsegmental disease was noted. Composite scores, the Qanadli index, and CT level of disease (CTLD) were calculated. Correlations were explored between these metrics and the pre-operative pulmonary vascular resistance (PVR) and reported as Spearman correlation coefficients. A p-value of <0.01 was considered significant given multiple comparisons.

### RESULTS

A total of 157 subjects (mean age 57±15 years, 54% female) were included. Qanadli index was weakly correlated with PVR (r=0.27, p=0.002) as was the total number of involved vessels (r=0.29, p<0.001), but a better correlation was seen with the number of lesions at the segmental level (r=0.35, p<0.001). Number of occlusions (p=0.09) and CTLD (p=0.54) did not correlate significantly with PVR. Number of involved segmental vessels was more strongly correlated with PVR in those who are younger than the median age of 60 years (r=0.45, p<0.001 vs. r=0.32, p=0.002), in patients with proximal disease (e.g., main or lobar vessel involvement, r=0.41, p<0.001) but not distal disease (p=0.02), in those who are obese (r=0.33, p=0.007) but not in non-obese (p=0.015), in patients with a history of PE (r=0.33, p<0.001) but not those without PE (p=0.2), and with no difference between sexes. Further subgroup analysis revealed stronger relationships between clot burden and PH in men under 50 years of age (Qanadli index: r=0.73, p=0.005) with no significant correlation in women under 50 years old (p=0.08).

### CONCLUSION

Correlation of clot burden with PVR was modest, likely because mechanical obstruction plays a varying role in the pathophysiology of CTEPH. Clot burden correlated best with PVR in young men, in proximal disease, and in those with history of PE.

### CLINICAL RELEVANCE/APPLICATION

Radiologists must be aware that mechanical obstruction is but one contributor to CTEPH and to tailor assessment of the vasculature to patient risk factors.

## R5B-SPCH-3 DETECTION OF THORACIC ASCENDING AORTIC DILATION FROM CHEST X-RAY

Ki Seok Choo, MD (*Abstract Co-Author*) Nothing to Disclose
Jong-Min Kim, PhD (*Abstract Co-Author*) Employee, Medical IP Co, Ltd
Sangjoon Park (*Abstract Co-Author*) Nothing to Disclose
Samuel Cho (*Abstract Co-Author*) Nothing to Disclose
Hyeyun Lee, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Dilation of the thoracic ascending aorta (TAA) is typically not read from a chest radiograph (CXR), as the overlap of tissues and skeleton makes it difficult to reliably discern the aorta with the human eye. However, unmonitored aorta aneurysm can lead to a 95% mortality, urging the need for an inexpensive method of screening, as rural or medically underserved communities do not have sufficient access to more advanced medical imaging equipments. Here, an external validation was performed of an AI algorithm, which visualizes the TAA and diagnoses for aneurysm from a single chest X-ray.

### METHODS AND MATERIALS

Patients who underwent both CT scan and CXR were recruited (n=236). The AI algorithm extracted the aorta image from the CXR using deep learning and then measured the maximum diameter perpendicular to the direction of the blood flow using image processing. This maximum diameter was compared to the maximum diameter from the CT, measured using a commercial software. Clinical guideline suggests thresholds of 4 cm and 4.5 cm for diagnosing dilation and aneurysm in the ascending aorta, respectively. Using these thresholds, the diagnosis from the AI algorithm was compared with the diagnosis from the CT. In addition, a team of two radiologists attempted to diagnose aortic aneurysm from the CXR, and the performance was compared with the performance of the AI algorithm.

### RESULTS

The maximum diameter from the AI algorithm showed good consistency with the GT maximum diameter. The mean absolute error (MAE) was 0.64 cm [0.58-0.71] and the mean absolute percent error (MAPE) was 14.3% [13.09-15.47]. In diagnosing dilation, AUROC was 0.85 [0.80-0.90] with sensitivity of 0.94 [0.91-0.98] and specificity of 0.39 [0.26-0.52]. In diagnosing aneurysm, AUROC was 0.74 [0.67-0.80] with sensitivity of 0.79 [0.72-0.86] and specificity of 0.54 [0.44-0.63]. For comparison, the team of two radiologists also attempted to diagnose dilation in the TAA. In result, the AUROC was 0.61 [0.55-0.66] with sensitivity of 0.31 [0.24-0.38] and specificity of 0.90 [0.81-0.98]. Compared to the radiologists, AI algorithm outperformed in accurately quantifying the dimensions of the TAA with high sensitivity.

### CONCLUSION

Generating the maximum diameter of the ascending aorta from a single CXR is a difficult task, but the AI algorithm can reliably screen for dilation and aneurysm in the TAA and outperforms human expert diagnosis.

### CLINICAL RELEVANCE/APPLICATION

An inexpensive and accessible screening method for TAA is needed, as a missed case of aneurysm can lead to a medical emergency. The AI algorithm can potentially screen for patients during routine chest X-ray examination, after which further testing can be done to confirm the diagnosis.

## R5B-SPCH-4 ROLE OF AI FOR CHEST X-RAY INTERPRETATION: IS IT A VALID SUPPORT?

Luca Giuliani (*Abstract Co-Author*) Nothing to Disclose
Nicholas Landini, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Carlo Catalano, MD (*Abstract Co-Author*) Nothing to Disclose
Valeria Panebianco, MD (*Abstract Co-Author*) Nothing to Disclose
Giorgio Maria Masci, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate whether AI represents an added value for chest X-ray (CXR) interpretation.

### METHODS AND MATERIALS

A dataset of CXR performed between March 2023 and January 2024 were retrospectively selected from the institutional PACS by a senior thoracic radiologist. The dataset included both normal and abnormal CXR with variable level of complexity. All CXR were evaluated by two young radiologists with

1 year of experience in chest imaging, who assessed the presence of several findings (consolidation, nodule, atelectasis, fibrosis, calcification, pneumothorax, cardiomegaly, pleural effusion, mediastinal enlargement, pneumoperitoneum). All examinations were then analyzed with an AI tool (Lunit INSIGHT CXR, Version 3.110) which assessed the same features. Finally, an additional AI-assisted evaluation was performed by the two radiologists. The ground truth was established by the radiologist in charge of image selection who classified the abnormalities as either visible or not visible on the radiograph. Sensitivity and specificity were measured using paired t tests.

**RESULTS**

A total of 548 CXR examinations were selected, of which 48 were excluded for low-image quality or presence of artifacts. From the 500 CXR analyzed, a total of 876 findings were reported either from the radiologists or from the AI tool. The two radiologists showed a sensitivity/specificity of 80.6%/93.2% and 87.2%/95.3%, respectively. AI showed a sensitivity/specificity of 96.9%/64.3%. With AI assistance, the sensitivity of the two radiologists increased to 82.9% (+2.3%) and 89.3% (+2.1%), while specificity decreased to 87.2% (-6%) and 89.5% (-5.8%), respectively. The abnormalities for which the radiologists showed higher disagreement with AI were fibrosis and calcification ($p<0.0001$), whilst the abnormalities for which the radiologists more often changed interpretation after AI evaluation were nodules, calcification, and pneumothorax ($p<0.0001$).

**CONCLUSION**

AI does not show significant increase of the diagnostic performance compared to standard radiological evaluation of CXR. Particularly, AI slightly increases sensitivity but at cost of a significant decrease in specificity. Therefore, standard radiological interpretation still remains the gold standard for CXR.

**CLINICAL RELEVANCE/APPLICATION**

Our study demonstrates that AI-assistance does not represent an added value for CXR interpretation compared to standard radiological evaluation.

## R5B-SPCH-6 QUANTITATIVE ASSESSMENT OF PULMONARY BLOOD FLOW REDISTRIBUTION IN THE CLASSIFICATION OF GROUP 1 AND GROUP 4 PULMONARY HYPERTENSION

Cong Shen JR, PhD,MD (*Presenter*) Nothing to Disclose

**PURPOSE**

All the patients with pulmonary hypertension (PH), without confirmed left-sided heart or lung diseases, need the the further distinguish between pulmonary arterial hypertension (PAH) and chronic thromboembolic pulmonary hypertension (CTEPH). This study aimed to investigate the value of the quantitative assessment of pulmonary blood flow redistribution in the further classification.

**METHODS AND MATERIALS**

Forty-six patients who underwent echocardiography and computed tomography pulmonary angiography at our hospital were included and categorized into a non-PH group (18 cases), a PAH group (12 cases), and a CTEPH group (16 cases). The diameter of the left ventricle, left atrium, right ventricle, and right atrium were measured. Additionally, the volumes of the main, right, and left pulmonary arteries were calculated. The total blood volume (TBV), the blood volume of vessels at the cross-section with an area <5 mm2 (BV5),-5-10 mm2 (BV5-10) and >10 mm2 (BV10), and the blood volume of the pulmonary arteries and veins, were quantitatively assessed.

**RESULTS**

The right ventricular diameter and volumes of the main and right pulmonary arteries were significantly higher in the PAH and CTEPH group than in the non-PH group ($P < 0.05$). The TBVs for the right lung and left upper lobe, arterial TBV, and BV10 were significantly higher in the PAH group than in the non-PH group ($P < 0.05$). The TBV of the right lung and right upper lobe and BV10 of the right lung and right lower lobe were significantly lower in the CTEPH group than in the non-PH group ($P < 0.05$). The TBV and BV10 were significantly lower in the CTEPH group than in the PAH group ($P < 0.05$). Age and BV10 of the right upper lobe were the most discriminative parameters, with an area under the curve of 0.950 in distinguishing PAH and CTEPH ($P < 0.05$).

**CONCLUSION**

Pulmonary vessel volume increased in PAH, particularly in larger-caliber vessels and the pulmonary artery, while it decreased in CTEPH, especially in larger-caliber vessels and the right lower lobe.

**CLINICAL RELEVANCE/APPLICATION**

By the quantitative assessment of pulmonary blood flow, can we tell the difference between PAH and CTEPH non-invasively.

## R5B-SPCH-8 ARTIFICIAL INTELLIGENCE APPLIED TO PRE-OPERATIVE CHEST X-RAYS: CAN WE ENTRUST AUTOMATED READINGS?

Angelo Vanzulli, MD (*Abstract Co-Author*) Nothing to Disclose
Luca A. Carbonaro, MD (*Abstract Co-Author*) Nothing to Disclose
Andrea Cuzzolin (*Abstract Co-Author*) Nothing to Disclose
Gianluca Folco, MD (*Abstract Co-Author*) Nothing to Disclose
Caterina B. Monti, MD, PhD (*Abstract Co-Author*) Travel support, Bracco Group
Francesco Rizzetto, MD (*Presenter*) Travel support, Bracco Group

**PURPOSE**

Pre-operative chest X-rays (CXRs) typically show a low likelihood of disease, making them ideal candidates for automated analysis by artificial intelligence (AI). This could expedite radiologists' workflow by automatically excluding exams identified as negative from the review process. Therefore, we aimed to assess the performance of a commercial AI software in reading pre-operative CXRs unsupervised.

**METHODS AND MATERIALS**

All pre-operative CXRs in two projections (posteroanterior and lateral) from standing adult patients (=18 years old), performed in January 2022 at a high-volume surgery center, were retrospectively analyzed using a commercial AI software. The software identifies lung consolidations, pulmonary nodules, pleural effusion, pneumothorax, and mediastinal alterations on CXRs. AI results were compared with radiology reports to appraise agreement for such findings. Sensitivity (SE), specificity (SP), positive likelihood ratio (PLR), negative likelihood ratio (NLR), and accuracy (ACC) were calculated, along with their 95% confidence intervals (CI95%). We also evaluated the number of CXRs with reports indicating findings other than those for which the AI was trained, assessing their clinical relevance.

## RESULTS

CXRs from 730 patients (416, 57% males) with a median age of 67 years (range: 18-93 years) were analyzed. Among them, 346 (47%) had a negative report, while 87 (12%) showed findings from the categories identified by the AI. For the analysis of these CXRs, AI demonstrated SE=57% (CI95%: 46-68%), SP=86% (CI95%: 83-88%), PLR=3.97 (CI95%: 3.06-5.16), NLR=0.50 (CI95%: 0.39-0.64), and ACC=82% (CI95%: 79-85%). Findings outside the categories identified by AI were present in the remaining 297 (41%) CXRs, most of which (77%) were identified as negative by AI. In 79 (27%) cases, these were findings with potential clinical relevance, such as emphysema, reticulations, cardiomegaly, aortic alterations, vertebral collapses, or hiatal hernia.

## CONCLUSION

The diagnostic performance of AI for pre-operative CXRs is still suboptimal, limiting its ability to provide reliable, standalone automated readings.

## CLINICAL RELEVANCE/APPLICATION

Despite the low likelihood of disease in pre-operative CXRs, further enhancing AI sensitivity and expanding its range of identified pathologies are necessary to enable accurate unsupervised readings.

## R5B-SPER-1 DIAGNOSTIC PERFORMANCE OF ULTRASOUND FOR DETECTION OF PEDIATRIC ELBOW FRACTURE. A META ANALYSIS

Sun Hwa Lee (*Abstract Co-Author*) Nothing to Disclose
Seong Jong Yun, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this meta-analysis was to evaluate the diagnostic performance of ultrasound for detection of elbow fracture in pediatric patients with trauma.

**METHODS AND MATERIALS**

PubMed and EMBASE databases were searched for diagnostic accuracy studies that used ultrasound for detection of elbow fracture in pediatric patients. Bivariate modelling and hierarchical summary receiver operating characteristic (HSROC) modelling were performed to evaluate diagnostic performance. The pooled proportions of the false-negative rate were assessed using a DerSimonian-Laird random-effects model. We performed meta-regression analyses for heterogeneity exploration.

**RESULTS**

Ten articles involving a total of 519 patients were included. The summary sensitivity, summary specificity, and area under the HSROC were 96% (95% confidence interval [CI], 88%-99%), 89% (95% CI, 82%-94%), and 0.97 (95% CI, 0.95-0.98), respectively. The pooled proportion of the false-negative rate of ultrasound was 3.7%. Among the various potential covariates, presence of extra musculoskeletal ultrasound training (trained [musculoskeletal radiologists, trained pediatric emergency physicians, or trained emergency physicians] vs. not trained [pediatricians or orthopedic surgeons]) were associated with heterogeneity of the specificity.

**CONCLUSION**

Elbow ultrasound demonstrated high performance in the diagnosis of pediatric elbow fracture, particularly in studies of musculoskeletal radiologists or physicians with extra-training in musculoskeletal ultrasound.

**CLINICAL RELEVANCE/APPLICATION**

Ultrasound may be performed by musculoskeletal radiologists or trained physicians as a first-line diagnostic tool to diagnose pediatric elbow fracture.

## R5B-SPGI-1 RADIOGRAPHIC IMAGING OF ACUTE SPLENIC DISEASE IN PATIENTS WITH BABESIOSIS

John J. Hines JR, MD (*Abstract Co-Author*) Nothing to Disclose
Sarah Byun (*Abstract Co-Author*) Nothing to Disclose
Douglas S. Katz, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To better understand the occurrence of splenic disease as a manifestation of babesiosis by retrospectively estimating the frequency of acute splenic injury on abdominal CT in a cohort of patients with babesia infection.

### METHODS AND MATERIALS

In a search of our single institution, suburban teaching community hospital database, 57 patients were found to have positive babesia infection between the years 2021-2023. 29 of these patients underwent abdominal CT (22 with and 7 without intravenous contrast), and 3 underwent abdominal ultrasound without any CT.

### RESULTS

20/32 patients who underwent any type of abdominal imaging had splenomegaly. 11/22 patients that underwent intravenous contrast-enhanced abdominal CT were male and 11/22 patients were female. 4/22 of these patients were found to have splenic infarction. One patient had multiple rounded hypoenhancing non-peripheral foci on both CT and MRI which did not meet criteria for infarction, in association with splenomegaly, and which resolved after treatment.

### CONCLUSION

Our study shows that splenic infarction is an uncommon manifestation of babesiosis in our retrospective CT series. Although our results are limited by the small sample size and the single center retrospective nature of our study, we found no association between parasitemia levels and presence of splenic infarction.

### CLINICAL RELEVANCE/APPLICATION

Babesiosis is a disease caused by babesia, a species of intraerythrocytic protozoa that are endemic to the northeastern and midwestern regions of the United States. It most often occurs in the summer months and is known to cause a wide range of clinical presentations from asymptomatic to severe disease. Symptoms can include fever, abdominal pain, pancytopenia, acute respiratory failure, renal and hepatic failure, and splenic disease. There is relatively sparse literature detailing splenic manifestations of acute babesia infection, including splenic enlargement, infarction and rupture. Results of our study show that acute splenic injury is an uncommon manifestation of babesiosis. This manuscript is pertinent as the prevalence of babesiosis infection has been steadily increasing in endemic regions, making it important for abdominal radiologists to be aware of this entity in the differential diagnosis for splenic infarction or non-traumatic rupture on abdominal CT scan.

## R5B-SPGI-10 EARLY DETECTION OF LIVER FIBROSIS IN PATIENTS UNDERGOING PRE- AND POST-HEMATOPOIETIC STEM CELL TRANSPLANTATION: A PRELIMINARY COMPARISON BETWEEN ULTRASOUND ELASTOGRAPHY AND TRANSIENT ELASTOGRAPHY

Maria Camarena (*Abstract Co-Author*) Nothing to Disclose
Paola Lopez-Gomez, MD (*Abstract Co-Author*) Nothing to Disclose
Joaquim Amorim Sortino, MD (*Abstract Co-Author*) Nothing to Disclose
Enrique de Miguel Campos (*Abstract Co-Author*) Nothing to Disclose
Mihail Poida, MD (*Abstract Co-Author*) Nothing to Disclose
Angela Garcia (*Abstract Co-Author*) Nothing to Disclose
Maria Luisa Prieto (*Abstract Co-Author*) Nothing to Disclose
Claudia Gerlotti, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Veno-occlusive disease (VOD) is a serious complication following post-hematopoietic stem cell transplantation (HSCT), with a mortality rate exceeding 80%, underscoring the critical need for early detection. Ultrasound and/or elastography suggestive of VOD onset are one of the criteria set by the EBMT. A preliminary comparison was done between ultrasound elastography (UE) and transient elastography (TE) to enhance liver fibrosis (LF) detection.

### METHODS AND MATERIALS

43 patients who had undergone HSCT were retrospectively studied from January 2023 to February 2024. Pre- and +14-day post-HSCT evaluation was done with TE (FibroScan) and 2D Shear Wave Elastography (2D-SWE) complemented with B-mode ultrasound and Doppler imaging. Inclusion criteria comprised patients aged more than18 years old, undergoing HSCT for an hematologic condition. LF staging utilized Metavir score and Canon Score categorizing TE and 2D-SWE respectively into F0-F1, F2, F3, and F4.

### RESULTS

The pre-HSCT group showed very poor UE-TE correlation with Lin's coefficient result equal to 0.19 and Kappa's coefficient result equal to -0.62. The post-HSCT group exhibited moderate correlation with Lin's coefficient result equal to 0.59 and Kappa's coefficient equal to 0.55. Significant dispersion was noted, specially, for grades F2, F3, and F4. Also, there was no statistically significant difference between UE and TE before and +14-day after HSCT.

### CONCLUSION

Post-HSCT UE and TE demonstrated moderate correlation, highlighting the potential advantages of UE in detecting VOD onset. The observed very poor pre-HSCT correlation may stem from varied evaluation times, patient basal conditions, and technique performance, being necessary for more standardized evaluation guidelines. Additionally, no significant difference was noted pre- and post-HSCT UE and TE, suggesting no onset of classical VOD during this period; however, posterior follow-up of these patients was not included in this analysis.

### CLINICAL RELEVANCE/APPLICATION

Early VOD diagnosis in patients undergoing HSCT is crucial. Ultrasound offers additional information, aiding VOD detection through gray-scale B-mode and Doppler imaging, demonstrating features such as hepatomegaly, splenomegaly, portal vein hypertension sings, hepatic venous abnormalities, gallbladder wall thickening and abdominal free fluid, compared to TE's singular fibrosis grade result.

## R5B-SPGI-11 QUANTITATIVE ASSESSMENT OF LIVER FIBROSIS: B1 INHOMOGENEITY-CORRECTED VFA T1 MAPPING ON GADOBENATE DIMEGLUMINE-ENHANCED MRI

Gongzheng Wang (*Abstract Co-Author*) Nothing to Disclose
Lianbang Wang (*Abstract Co-Author*) Nothing to Disclose
Ximing Wang (*Abstract Co-Author*) Nothing to Disclose
Hui Ma (*Abstract Co-Author*) Nothing to Disclose
Jin Cui (*Abstract Co-Author*) Nothing to Disclose
Xinya Zhao (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of gadobenate dimeglumin (Gd-BOPTA)-enhanced T1 mapping using B1 inhomogeneity-corrected variable flip angle (VFA) method for staging liver fibrosis in rats.

### METHODS AND MATERIALS

Sprague-Dawley rats were divided into a control group (n = 6) and carbon tetrachloride-induced liver fibrosis groups (n = 22). T1 mapping using B1 inhomogeneity-corrected VFA was performed before and 90 min after Gd-BOPTA administration. Pre-contrast T1 values (T1pre), post-contrast T1 values (T1post), and the reduction rate of T1 values (?T1%) were quantified on T1 mapping images. Their correlations with liver fibrosis stages and hepatocyte transporters expression levels were analyzed. The diagnostic performance was evaluated by area under the receiver operating characteristic curve (AUC).

### RESULTS

T1post and ?T1% showed significant correlations with liver fibrosis stages ($r = 0.832$, $p < 0.001$; $r = -0.798$, $p < 0.001$, respectively), whereas T1pre were not significantly correlated with fibrosis stages ($r = 0.357$, $p = 0.062$). The AUCs of T1post and ?T1% were higher than SIpost for diagnosing stage F2-F4 (0.936, 0.941 vs. 0.791; $p = 0.043$, 0.038, respectively), F3-F4 (0.928, 0.861, vs. 0.660; $p = 0.003$, 0.028, respectively) and F4 (0.965, 0.896 vs. 0.761; $p = 0.021$, 0.049, respectively). Oatp1a1 and Mrp2 expression levels correlated significantly with T1post ($r = -0.859$, $p = 0.001$; $r = -0.697$, $p = 0.017$) and ?T1% ($r = 0.891$, $p < 0.001$; $r = 0.685$, $p = 0.020$), respectively.

### CONCLUSION

Gd-BOPTA-enhanced T1 mapping using B1 inhomogeneity-corrected VFA is an accurate and reliable tool for quantifying liver fibrosis stages.

### CLINICAL RELEVANCE/APPLICATION

Liver fibrosis can be noninvasively assessed by Gd-BOPTA-enhanced B1-corrected T1 mapping. Accurate early diagnosis and assessment of liver fibrosis are important for treatment and prognosis.

## R5B-SPGI-12 PREDICTIVE VALUE OF MULTI-PARAMETER ULTRASOUND COMBINED WITH PHYSIOLOGICALINDICATORSFOR HIGH-RISK HEPATITIS IN PATIENTS WITH CHRONIC LIVER DISEASE

Liyun Xue, PhD (*Abstract Co-Author*) Nothing to Disclose
Hong Ding, MD (*Abstract Co-Author*) Nothing to Disclose
Guangwen Cheng (*Abstract Co-Author*) Nothing to Disclose
Xueqi Li (*Abstract Co-Author*) Nothing to Disclose
Xiaohui Qiao (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the predictive value of shear wave elastography (SWE), shear wave dispersion (SWD), attenuation imaging (ATI) and blood indexes for high-risk hepatitis in patients with chronic liver disease.

### METHODS AND MATERIALS

The patients with metabolic dysfunction-associated steatotic liver disease (MASLD) and other chronic liver diseases such as viral, autoimmune and drug-induced liver diseases were enrolled in this prospectively study. All patients underwent liver biopsy and were divided into training set and validation set by the proportion of 8:2 according to the enrollment time. Before liver biopsy, SWE, SWD and ATI were carried out and the obtained measurement was respectively liver stiffness (LS), dispersion slope (DS) and attenuation coefficient (AC). Meanwhile, the baseline data and serological indicators were recorded. High-risk hepatitis was defined as significant inflammation and fibrosis based on pathological results. The logistic regression analysis was used to screen the risk factors and construct predictive model. The receiver operating characteristic (ROC) curve and calibration curve were applied to evaluate the diagnostic efficacy and stability of the model.

**RESULTS**

A total of 247 patients with chronic liver disease were included, 197 in the training set and 50 in the validation set, with no significant difference of the baseline characteristics between the two groups. The Logistic regression analysis revealed that LS, DS, ALT and fasting blood glucose (FBG) were the risk factors of high-risk hepatitis ($P < 0.05$), and a prediction model was developed based on these indicators. In training set, the area under curve (AUC) of LS, DS and the predictive model for identifying high-risk hepatitis was respectively 0.888, 0.887 and 0.926, and in validation set it was 0.743, 0.732 and 0.835, respectively. Calibration curve analysis exhibited good consistency of the predicted and actual high-risk hepatitis in both training and validation sets.

**CONCLUSION**

The prediction model based on SWD, SWD, ALT and FBG can effectively identify high-risk hepatitis in patients with chronic liver disease, providing important reference basis for timely clinical intervention.

**CLINICAL RELEVANCE/APPLICATION**

Early identification of high-risk hepatitis in patients with chronic liver disease can reduce the incidence of liver-related events. The invasiveness of liver biopsy makes it unsuitable for universal screening of high-risk hepatitis population. The prediction model can assist doctors in risk stratification of patients with chronic liver disease to reduce unnecessary invasive biopsy.

## R5B-SPGI-2 AI-BASED HEPATIC STEATOSIS DETECTION IN NON-CONTRAST ABDOMEN CT: A NOVEL APPROACH TO ALTERNATING MR PROTON DENSITY FAT FRACTION

Jong H. Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Sihwan Kim, MSc (*Abstract Co-Author*) Nothing to Disclose
Changmin Park (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate a deep learning model automatically classifying hepatic steatosis from non-contrast abdomen CT by using CT-derived fat fraction (CDFF) substituting MR proton density fat fraction (PDFF).

**METHODS AND MATERIALS**

Retrospective analysis of paired 814 abdominal CT and MRI exams (397 dual-energy and 417 single energy) from 2016 to 2023 was performed. SECT images scanned with 120kV tube voltage were used for estimation model training; DECT images with blended 120kVp (4:6 ratio for 80kV/150kV) were used for testing. Four key features of hepatic steatosis were extracted: liver HU mean, skewness of liver HU, liver-spleen HU ratio (L/S ratio), and liver-spleen HU difference (L-S difference). For automatic liver and spleen segmentation, commercial AI-software (ClariHepato, Seoul, Republic of Korea) was used. To find the best estimation model for classifying hepatic steatosis, four models were compared: linear regression, multi-variable regression, support vector machine (SVM), and multi-layer perceptron (MLP). We defined the output of each model as the CDFF (%) predicting fat fraction from non-contrast CT images. Besides, to minimize the time difference variation of patient's physiological status, a subgroup with a study date difference of less than 60 days was additionally analyzed.

**RESULTS**

In the diagnostic performance, AUROC showed an overall performance of 0.83 or higher. While sensitivity and specificity are similar for each model(Sensitivity: 0.75 vs 0.81 vs 0.77 vs 0.82 and Specificity: 0.82 vs 0.82 vs 0.81 vs 0.82 respectively), the MLP model achieved the highest diagnostic accuracy. The multi-variable HU-based inference method appears to outperform the method that only reflects liver HU values. Diagnostic performance improved for all estimation models when a study date difference between CT and MRI was within 60 days. Depending on the severity of the fatty liver to be detected, it is deemed appropriate to select the optimal cutoff and apply it to the clinical environment.

**CONCLUSION**

In this study, we developed and evaluated four different estimation models to classify hepatic steatosis based on key features extracted from non-contrast abdomen CT. MLP-based hepatic steatosis classification accuracy indicated 0.82, demonstrating the feasibility of automatic hepatic steatosis classification from CT. This method has enough potential to replace traditional MR-PDFF for clinically practical fat quantification.

**CLINICAL RELEVANCE/APPLICATION**

Automatic quantification of liver fat in non-contrast abdomen CT can improve clinical workflow efficiency and reduce the cost compared to the MRI exam. The suggested AI-based algorithm allows radiologists to conveniently assess liver fat content without additional MRI examinations.

## R5B-SPGI-3 THE UTILITY OF ULTRASOUND VERSUS CT FOR THE DIAGNOSIS OF ACUTE CHOLECYSTITIS IN THE EMERGENCY SETTING

Brittany L. Miles, MD (*Abstract Co-Author*) Nothing to Disclose
Peter Young, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Acute cholecystitis is one of the most common diagnoses in the emergency department that requires surgical intervention. The diagnosis of acute cholecystitis is traditionally made with ultrasound, though CT (computed tomography) has been increasingly more common as routine imaging for any patient presenting to the emergency department. Patients often receive both ultrasound and CT simultaneously for the evaluation of abdominal pain. We evaluated patients who received either abdominal ultrasound or abdominal CT to assess for the incidence of laparoscopic cholecystectomy within 48 hours of imaging.

**METHODS AND MATERIALS**

The TriNetX Diamond network was used for this study. TriNetX provides access to anonymized medical record information on more than 213 million patients in 92 large healthcare organizations. Two cohorts were created using the Current Procedural Terminology (CPT) codes. One cohort received abdominal ultrasound (CPT 76700 or 76705) and patients were excluded if they had received any CT of the abdomen or pelvis the same day. The other cohort received abdominal or pelvic CT (CPT 74150, 74160, 74170, 74176, 74177, 74178) and patients were excluded if they had received an abdominal ultrasound. The cohorts were balanced for age, race, gender, and ethnicity, resulting in 3,167,651 patients in each arm. They were then evaluated for undergoing laparoscopic cholecystectomy within 48 hours of imaging.

**RESULTS**

Patients who underwent abdominal CT were 20-fold less likely to undergo surgery (RR 0.052, 95% CI (0.051,0.054), p-value <0.0001.

### CONCLUSION

This study shows that patients who underwent ultrasound imaging were 20-fold more likely to undergo surgery for acute cholecystitis. As ultrasound is cheaper, widely available, and does not require the use of intravenous contrast, it remains the standard of care for initial abdominal imaging in this setting. Patients who present to the emergency department with the clinical suspicion of acute cholecystitis have a statistically significant increased percentage of receiving surgical intervention if ultrasound was performed over CT.

### CLINICAL RELEVANCE/APPLICATION

Abdominal CT is a mainstay in the emergency setting for the evaluation of abdominal pain, and many patients seemingly automatically receive a CT during their visit. However, the diagnosis of acute cholecystitis resulting in surgical intervention is higher in patients who undergo abdominal ultrasounds. An abdominal CT can often be performed faster than ultrasound and has the benefit of evaluating the entire abdomen. We hope this shows that abdominal CT does not need to be reflexively ordered on patients with the clinical suspicion of acute cholecystitis if an abdominal ultrasound is already being performed.

## R5B-SPGI-4 DOPPLER ULTRASOUND AND 2D SHEAR WAVE ULTRASOUND ELASTOGRAPHY FOR LIVER FIBROSIS EVALUATION IN FONTAN-ASSOCIATED LIVER DISEASE IN ADULTS

Nattaporn Sriwicha (*Abstract Co-Author*) Nothing to Disclose
Nakarin Inmutto, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To explore Doppler ultrasound findings in Fontan patients. We hypothesize that both Doppler ultrasound and 2D shear wave ultrasound are valuable tools in assessing the degree of hepatic fibrosis.

### METHODS AND MATERIALS

A retrospective study included 27 Fontan patients between January 2020 to December 2022. Participants underwent liver Doppler ultrasound, 2D-SWE, and biopsy. Data collected encompassed specifics of the Fontan operation, cardiac diagnosis, and relevant laboratory tests. Fibrosis severity, assessed via METAVIR scoring system.

### RESULTS

In 27 post-Fontan patients (mean age: 19 years). Most prevalent cardiac diagnosis was tricuspid atresia (37%). The APRI score in non-significant fibrosis was 0.26 ± 0.06. The APRI score in significant/cirrhosis groups was 0.38 ± 0.115. The FIB-4 score in non-significant fibrosis was 0.45 ± 0.13. The FIB-4 score in significant/cirrhosis groups was 0.67 ± 0.2. The Peask systolic velocity, resistive index and acceleration time of the hepatic artery between non-significant fibrosis group and significant/cirrhosis groups were not statically significant difference. The diameter of the main portal vein was not significantly different between the two groups, 0.86 cm and 0.85 cm. The mean velocity of main portal vein in significant/cirrhosis groups was slightly lower than non-significant fibrosis group, 11.38 cm/s and 13.24 cm/s respectively. Ultrasound liver elastography showed no significant difference in median stiffness among groups.

### CONCLUSION

Serum marker scoring system could be valuable in determining significant fibrosis / cirrhosis in FALD patients. Ultrasound elastography proved less helpful in definite non-significant fibrosis and significant fibrosis in FALD patients due to confounding factor from liver congestion.

### CLINICAL RELEVANCE/APPLICATION

Doppler ultrasound findings may offer a new tool in fibrosis monitoring, warranting further research.

## R5B-SPGI-5 ASSESSING THE PREDICTIVE VALUE OF ABDOMINAL VOLUMETRY FOR POST-SURGICAL COMPLICATIONS IN INCISIONAL HERNIAS WITH LOSS OF DOMAIN AT A TERTIARY HEALTH CENTER

Monica Chapa-Ibarguengoitia, MD (*Abstract Co-Author*) Nothing to Disclose
Denny Lara Nunez, MD (*Abstract Co-Author*) Nothing to Disclose
Jose A. Cienfuegos Alvear, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana De Los Ssantos Carmona, MD (*Abstract Co-Author*) Nothing to Disclose
Axel A. Torres Monarrez, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluating the Role of Abdominal Volumetry in Predicting Postoperative Complications in Patients with incisional hernias with loss of domain at a Tertiary Care Hospital.

### METHODS AND MATERIALS

This cross-sectional study encompassed all patients diagnosed with incisional hernias with loss of domain who were referred to our institution between 2007 and April 2023. Patients lacking postoperative outcome data or with inadequate tomographic scans would be excluded from the trial. We conducted a retrospective analysis of 199 CT scans using the post-processing software "IntelliSpacePortal" version 9.0 from IQon Spectral CT. These scans were taken from 152 patients who had been diagnosed with incisional hernias with loss of domain.

### RESULTS

We retrospectively analyzed CT scans (n = 199) using post-processing software from 152 patients diagnosed with incisional hernias with loss domain. The two most common operations previously performed by these patients were Hartmann's procedure (15.13%, n=22) and intestinal resection (14.81%, n=21).CT scans were categorized as lacking or having the Valsalva maneuver; 121 CT scans were analyzed from the first group, and the subsequent measurements were documented: The average hernia index was 7.87 $cm^3$ (IQR 25-75: 4.56-11.82), total abdominal volume was 8358.5 $cm^3$ (IQR 25-75: 6754-9808.5), and hernia volume was 680 $cm^3$ (IQR 25-75: 407-1217). The total volume was 9262.6 $cm^3$ (IQR 25-75: 7519-10559).For the 47 CT scans performed with the Valsalva maneuver, the following measurements were observed: total abdominal volume was 7643 $cm^3$ (IQR 25-75: 6365-6625), hernia volume was 923 $cm^3$ (IQR 25-75: 468-2191), total volume was 9510 $cm^3$ (IQR 25-75: 7477-10911), and the average hernia index was 12.38 (IQR 25-75: 5.5-20.97).From the total patients, 61 (40.13%) experienced complications: 31 patients (20.39%) had postoperative wall complications, 15 patients (9.86%) had intra-abdominal complications, 39 patients (25.65%) had systemic complications.Finally, a significant correlation was found between the volumetric hernia ratio (CT scans without the Valsalva maneuver, n = 121) and postoperative complications in 48 patients (p: 0.0123).

### CONCLUSION

The volumetric hernia ratio can predict post-operative problems, helping surgeons plan pre-surgery IHLD. Therefore, a systematic and reproducible volumetric approach for hernias with loss of domain is needed.

### CLINICAL RELEVANCE/APPLICATION

The risk of complications caused by incisional hernias with loss of domain can be estimated by assessing the volumetric hernia ratio before surgical intervention. This information is important for surgeons, enabling them to reliably forecast postoperative difficulties prior to doing surgery for IHLD.

## R5B-SPGI-7 PERFORMANCE OF VENDOR SPECIFIC ULTRASOUND DERIVED FAT QUANTIFICATION METRICS USING LIVER BIOPSY AS THE REFERENCE STANDARD

Cheng Fang, MBBS (*Abstract Co-Author*) Nothing to Disclose
Paul S. Sidhu, BSc, FRCR (*Abstract Co-Author*) Consultant, Samsung Electronics Co, Ltd;Speaker, Samsung Electronics Co, Ltd;Speaker, Bracco Group;Consultant, Itreas Ltd;Speaker, Siemens AG
Nuran Seneviratne, MA, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

The accuracy of four vendor-specific ultrasound hepatic fat quantification metrics was assessed using steatosis histology grades as a reference standard. Tissue attenuation imaging™ (TAI) and tissue scatter distribution imaging™ (TSI) metrics were based on beam attenuation and backscatter, respectively. Fat fraction (FF), calculated from these metrics, along with an automated hepatorenal index (Ez-HRI™ Samsung Medison, Seoul, Korea) were also determined.

### METHODS AND MATERIALS

Patients with chronic liver disease, including suspected metabolic dysfunction associated fatty liver disease (MAFLD), scheduled for liver biopsy were prospectively enrolled. Five measurements for each metric were recorded on a Samsung RS85 Prestige™ ultrasound machine. FF was calculated using the manufacturer provided formula for median TAI and TSI scores.

### RESULTS

Preliminary results for the first 55 patients (30 male, median age 47 years, median body mass index [BMI] 28.4 mg/kg2, 36.4% MAFLD) are presented. Non-targeted liver biopsy was performed [Oberon1] in all participants. Liver steatosis on histopathology was graded as normal (S0, <5% steatosis, n=27), mild (S1, 5-33% fat, n=14), moderate (S2, 33-66% fat, n=10) and severe (S3, >66% fat, n=4). Correlation was good to excellent between each metric and steatosis grade (TAI 0.712, TSI 0.733, FF 0.773, Ez-HRI 0.838; all $P<0.05$ using Kruskall Wallis test). Multivariate analysis showed all metrics were not affected by age, BMI, or fibrosis stage. Performance was excellent for all metrics in differentiating mild (S1) or greater steatosis (TAI 0.85, TSI 0.88, FF 0.89, Ez-HRI 0.95; all $P<0.05$) and moderate (S2) or greater steatosis (TAI 0.9, TSI 0.88, FF 0.91, Ez-HRI 0.96; all $P<0.05$). Pairwise comparisons using Dunn-Bonferini post-hoc test showed significant differences between mild, moderate, and severe steatosis versus normal for TAI, FF, and Ez-HRI. Significant differences were seen between mild and moderate versus normal for TSI.

### CONCLUSION

The evaluated ultrasound-derived fat quantification metrics showed good correlation with steatosis grade, with an excellent ability to differentiate between normal, mild, and moderate liver steatosis.

### CLINICAL RELEVANCE/APPLICATION

Non-invasive hepatic fat assessment software is becoming more readily available in modern ultrasound machines. They provide an accurate estimate of hepatic steatosis, which can be used for screening and monitoring MAFLD, an increasing public health problem.

### PURPOSE

It is unclear if the Vesical Imaging, Reporting and Data System (VI-RADS) can replace repeated transurethral resection of bladder tumour (Re-TURBT) as in the new VI-RADS-based algorithm. To evaluate if VI-RADS can distinguish between non-muscle-invasive bladder cancers (NMIBC), muscle-invasive bladder cancer (MIBC), and high-risk non-muscle-invasive bladder cancers (HR-NMIBCs).

### METHODS AND MATERIALS

Sensitivity, specificity, and positive (PPV) and negative (NPV) predictive values of the VI-RADS score were calculated for mpMRI performance in patients undergoing TURBT and HR-NMIBC patients for only Re-TURBT.

### RESULTS

Of In 283 cases, when VI-RADS=3 lesions were considered muscle-invasive, its sensitivity was 95.7% and specificity was 92.5%. PPV and NPV were 86.6% and 97.7%, respectively. The area under the curve (AUC) was 0.942 (p <.001). Of Of the 89 patients undergoing post-Re-TURBT, 41 (46%) were tumour-free, and 47 (50.5%) showed permanent HR-NMIBC, and 3 (2.2%) were upgraded to MIBC. Per the new VI-RADS-based approach, 73 (41%) of the 178 HR-NMIBCs with VI-RADS= 2 would not undergo Re-TURBT. Of the 75 patients with VI-RADS = 4, 6 (6) had HR-NMIBCs (8%) would not undergo Re-TURBT. When incomplete resections were excluded, 35 60.3%) of the patients had complete resection, and 23 (39.7%) had residual disease, and complete resection would not have been performed in these patients, and 2 (100%) still had residual disease.

### CONCLUSION

The new VI-RADS-based algorithm helped VI-RADS = 4 patients by switching to radical treatment. Since the residual disease is high in cases with VI-RADS = 2, even if incomplete resections are excluded, TURBT should be continued.

### CLINICAL RELEVANCE/APPLICATION

VI-RADS-based decision-making will enable a paradigm shift from current TURBT-dependent practice, and our newly proposed algorithm may form the basis for further discussion.

## R5B-SPGU-4 USE OF 3D PRINTING IN SURGICAL PLANNING OF THE CLOACAL MALFORMATIONS: UC DAVIS EXPERIENCE

Zoe Saenz (*Abstract Co-Author*) Nothing to Disclose
Lotfi Hacein-Bey, MD (*Abstract Co-Author*) Nothing to Disclose
Osama A. Raslan, MD, MBBCh (*Abstract Co-Author*) Research Grant, Bracco Group;Contract, Shanghai United Imaging Healthcare Co, Ltd
Neha Antil, MD (*Presenter*) Nothing to Disclose

### PURPOSE

We aim to evaluate the use of 3-D cloacogram derived printed model for pre-operative planning of complex cloacal malformations, using intraoperative findings as the reference standard and comparing 3-D cloacogram data with endoscopic findings.

### METHODS AND MATERIALS

A retrospective case-based review was performed in patients with cloacal anomalies who underwent endoscopy, 2D and 3D cloacograms, and reconstruction surgery between 2020 and 2024. 3-D printing models were generated after 3-D cloacogram and cone beam CT were performed. The CT images were then imported into Mimics in Print 2.0 software (Materialise NV, Leuven, Belgium) and the following structures were segmented by the radiologist: common channel, bladder, rectum, vagina, uterus, and pelvic bone. Segmented data were then exported as standard tessellation language (STL) files and the models were printed and used for surgical planning. Demographics, imaging measurements (length of common cloacal channel), surgical approach planning, level of surgeon's readiness and confidence and level of parental understanding were recorded. Pre-operative imaging measurements were compared to the reference standard intraoperative measurement.

**RESULTS**

Five female patients with a median age of 30.52 +/- 12.61 months underwent endoscopy, 3D cloacogram and surgical repair. The abdomino perineal approach was used in 3, a perineal approach in one and transabdominal repair was used in one patient for cloacal repair. The length of the common channel on 3D cloacogram, endoscopy, and 3D printing model was accurately correlated to operative findings in 4/5 patients, 3/5 patients and 5/5, respectively. There were 3 anatomical discrepancies between endoscopy and 3D cloacagram/ 3D printed model, which led to abdominoperineal approach instead of perineal or transabdominal alone in 3/5 (60%) of cases. The model was pivotal for surgeon's better understanding of anatomy and parent's education and counseling.

**CONCLUSION**

In our experience, 3D cloacogram and 3D printed model accurately measured the common channel length and outperforms endoscopy and resulted in improved surgical planning and parent's understanding.

**CLINICAL RELEVANCE/APPLICATION**

3-D printing can be a useful tool for surgeons to better visualize the ideal anatomical simulation for surgical planning, especially in complex anatomy such as cloacal malformation. It can also be a valuable tool to educate families about the challenges of reconstruction and counsel on prognosis for future continence.

## R5B-SPGU-5 VALUE OF QUANTITATIVE SYNTHETIC DWI FOR DETECTING PI-RADS 3 CLINICALLY SIGNIFICANT PROSTATE CANCER

Akira Yamamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Takeshi Fukunaga (*Abstract Co-Author*) Nothing to Disclose
Yu Ueda, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Higaki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuichi Kojima (*Abstract Co-Author*) Nothing to Disclose
Yoshihiko Fukukura, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tsutomu Tamada, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To validate if multiparametric quantitative maps including ADC, T1, and T2 simultaneously obtained from synthetic diffusion-weighted imaging (syDWI) can bring added value to differentiate cancer from noncancer in suspicious lesions with PI-RADS category 3, which is about 30% cancer detection rate.

**METHODS AND MATERIALS**

Eighty-six patients with 103 PI-RADS v2.1 category 3 lesions were evaluated among those who underwent MRI-ultrasound fusion-guided prostate biopsy for lesions suggestive of prostate cancer on pre-biopsy multiparametric MRI between October 2021 and January 2024. All MR images were obtained with a 3T MRI (Ingenia Elition 3.0T; Philips). SyDWI acquisition includes b0 images acquired with two different TR and TE, and b1000 and b2000 acquired with single TR and TE (Figure 1). The detailed imaging parameters are described in Figure 2. The T1 can then be estimated by using the signal from 2 b0 images, varying TR and keeping TE constant, while T2 can be estimated from 2 b0 images with constant TR but varying TE. T1, T2, and ADC calculated from images at b-value of 0 and 1000 s/mm2 values were compared between PI-RADS category 3 target biopsy-proven cancers (Gleason score (GS) =7) and noncancers (GS=6 or benign tissue) by using Mann-Whitney U test. Logistic regression was used to assess T1, T2, and ADC in the differentiation of cancers versus noncancers. ROC curves and AUC were obtained from ordinary logistic regression of the binary outcome. $P < 0.05$ was considered to indicate a statistically significant difference.

**RESULTS**

Biopsy-proven prostate cancers and noncancers among 103 PI-RADS category 3 lesions were identified in 31 lesions and 72 lesions, respectively. Thus, the cancer detection rate was 30.1%. T1 (ms), T2 (ms), and ADC (×10-3 mm2/s) in PI-RADS category 3 target biopsy-proven cancers were significantly lower than those of noncancers (1947±267 and 2100±288, 59±10 and 70±17, and 1.00±0.18 and 1.14±0.22, respectively) ($P = 0.025$ to $P< 0.001$) in Figure 3. For separation between PI-RADS category 3 cancers and noncancers, the AUC for T2 (0.73) was higher than the AUC for T1 (0.64) and ADC (0.69) in Figure 4. Cut-off value was 58 for T2, 1983 for T1, and 1.07 for ADC, respectively. The combination of T1, T2, and ADC yielded an AUC of 0.75. Figure 5 shows representative clinical cases with cancer and noncancer.

**CONCLUSION**

Our results indicate that T1, T2, and ADC calculated from syDWI might enable more accurate diagnosis of suspicious lesions with PI-RADS category 3.

**CLINICAL RELEVANCE/APPLICATION**

T1, T2, and ADC calculated from syDWI acquisition used for synthetization of DW images may differentiate more accurately insignificant from significant lesion in suspicious cancers with PI-RADS Category 3, reducing unnecessary biopsies.

## R5B-SPGU-6 USEFULNESS OF URINARY BIOMARKER-BASED RISK SCORE AND MULTIPARAMETRIC MRI FOR CLINICALLY SIGNIFICANT PROSTATE CANCER DETECTION IN BIOPSY-NAïVE PATIENTS

Carlos Nicolau, MD (*Abstract Co-Author*) Nothing to Disclose
Mindaugas Jievaltas (*Abstract Co-Author*) Nothing to Disclose
Kristina Zviniene (*Abstract Co-Author*) Nothing to Disclose
Ingrida Pikuniene (*Abstract Co-Author*) Nothing to Disclose
Gytis Cholstauskas (*Abstract Co-Author*) Nothing to Disclose
Mantvydas Lopeta (*Abstract Co-Author*) Nothing to Disclose
Jurate Kemesiene, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to investigate the accuracy of magnetic resonance imaging (MRI), genetic urinary test (GUT) and prostate cancer prevention trial risk calculator version 2.0 (PCPTRC2) for the clinically significant prostate cancer (csPCa) diagnostic in biopsy-naḭve patients.

**METHODS AND MATERIALS**

In a single center study between 2021 and 2024 participants underwent prostate mpMRI, GUT and ultrasound (US) guided biopsy. The csPCa risk was calculated using PCPTRC2. Post digital rectal examination (DRE) GUT was performed measuring RNA levels of PCA3 and T:E fusion genes. The McNemar test compared detection rates between modalities.

### RESULTS

208 (mean age 62.9 years +/- 8.2) men were included prospectively. A positive GUT score was found in 67.8% and PIRADS =3 in 81.7% of all cases. The combination of GUT with mpMRI showed significantly higher sensitivity (99.1%) than GUT and mpMRI alone, 84.4% and 93.8%, respectively (p = 0.05). Similarly, very high sensitivity (99.0%) was achieved by combining mpMRI with PCPTCR2. Nevertheless, mpMRI plus GUT combination exceeded mpMRI plus PCPTCR2 by allowing to save a higher fraction of unnecessary biopsies, 25% and 2,4%, respectively.

### CONCLUSION

GUT and mpMRI combination would allow saving a substantial fraction of unnecessary biopsies with minimal risk of missing csPCa cases.

### CLINICAL RELEVANCE/APPLICATION

The combination of genetic urinary testing (GUT) and MRI enhanced the detection sensitivity of csPCa while substantially reducing unnecessary biopsies, thereby improving diagnostic efficiency and patient outcomes.

## R5B-SPGU-8 UNENHANCED COMPUTED TOMOGRAPHY-BASED RADIOMICS SIGNATURE IN DISTINGUISHING RENAL CYST FROM RENAL CARCINOMA

Wei Wei (*Abstract Co-Author*) Nothing to Disclose
Jinjing Yang (*Presenter*) Nothing to Disclose

### PURPOSE

To establish and validate a predictive radiomics model for prediction of renal cyst and renal carcinoma respectively in patients with renal disease using unenhanced CT.

### METHODS AND MATERIALS

In this retrospective study, a total of 79 patients with 39 cases of renal cyst and 40 cases of renal carcinoma were enrolled from September 2023 to February 2024. Lesion segmentation was conducted by using ITK-snap 3.8. The dataset was randomly assigned in a 7:3 ratio to either the training cohort or testing cohort. Radiomics features were extracted from unenhanced CT images using Pyradiomics and the most useful features in the training set were selected using LASSO algorithm. The selected features were then combined into a Rad-score, which was further assessed by ROC curve analysis in the training and testing sets.

### RESULTS

A total of 103 radiomics features were extracted and 3 features which met the criteria were selected. By evaluating the diagnostic value, the predictive model showed a good performance (area under the curve [AUC], 0.89; 95% confidence interval [CI] 0.78-0.96; sensitivity, 0.78; specificity, 0.99 in training cohort; AUC, 0.91; 95% confidence interval [CI] 0.71-0.99; sensitivity, 0.99; specificity, 0.84 in testing cohort). Decision curve analysis confirmed the clinical usefulness of the model.

### CONCLUSION

Unenhanced CT-based radiomics model could be helpful for prediction of renal cysts and renal carcinoma in patients with renal disease.

### CLINICAL RELEVANCE/APPLICATION

Renal round-like lesions tend to appear on Abdominal or chest unenhanced CT scans. Distinguishing renal cyst from renal carcinoma based on unenhanced CT images is challenge. Therefore, it is critical to build a radiological model only using unenhanced CT scan to identify renal cyst and renal carcinoma, and to screen out high-risk lesions, which is valuable for the clinical management of patients.

## R5B-SPGU-9 VALUE OF DUAL ENERGY CT DELAYED PHASE IODINE OVERLAY MAPS RADIOMICS IN DIFFERENTIATING TYPE I AND TYPE II OVARIAN CANCER

Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Ye Li (*Abstract Co-Author*) Nothing to Disclose
Qingling Song (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of dual energy CT delayed phase iodine overlay maps radiomics in differentiating type I and type II ovarian cancer.

### METHODS AND MATERIALS

A total of 154 patients with ovarian cancer underwent dual energy CT were randomly divided into training dataset (N = 123) and test dataset (N = 31). The clinical features included age, menstrual status, FIGO stage, and serum tumor markers including CA125, CA19-9 and HE4 were collected. The radiomics features were extracted from CT images of each patient. Multivariate logistic regression was employed to construct clinical and radiological models. The correlation analysis and least absolute shrinkage and selection operator algorithm were used to select radiomics features and build radiomics model. The important clinical, radiological factors, and radiomics features were integrated into a combined model by multivariate logistic regression. Receiver operating characteristics curve with area under the curve (AUC) were used to evaluate and compare predictive performance.

### RESULTS

FIGO stage was the independent clinical predictor. Laterality, 21 radiological features were left after dimensionality reduction. In the training dataset, the AUCs for the clinical and radiomics models in differentiating type I and type II ovarian cancer were 0.869 and 0.883, respectively. In the test dataset, the AUCs for two models were 0.886 and 0.977, respectively. The combined model in both the training and the test datasets with AUCs 0.948 and 0.977.

### CONCLUSION

Dual-energy delayed iodine overlay imaging model and clinical-imaging combined model can distinguish type I and type II ovarian cancer, which is helpful to the clinical management of patients with pre-treatment ovarian cancer.

### CLINICAL RELEVANCE/APPLICATION

Dual-energy CT, combined with clinical features and radiomics analysis, offers a robust method to differentiate between type I and type II ovarian cancer subtypes. This approach enhances pre-treatment planning and patient management, aiding in personalized treatment strategies for ovarian cancer patients.

## R5B-SPHN-1 CONTRAST-ENHANCED US WITH PERFLUOROBUTANE TO DIAGNOSE THYROID BED NODULES AFTER PAPILARY THYROID CARCINOMA SURGERY

Longzhong Liu (*Abstract Co-Author*) Nothing to Disclose
Lingli Guo (*Presenter*) Nothing to Disclose

### PURPOSE

Approximately 34-55% thyroid bed (TB) nodules can be detected by ultrasound during follow-up of postoperative patients with papillary thyroid carcinoma (PTC). 2015 American Thyroid Association guidelines indicates that conventional ultrasound (US) is difficult to differentiate benign and malignant TB nodules. Our previous study (DOI:10.1145/radiol.221465) showed that contrast-enhanced US (CEUS) with perfluorobutane has a better diagnosis of metastatic small lateral cervical lymph nodes (LNs) in PTC. The purpose of this retrospective cohort study is to evaluate the diagnostic performance of CEUS with perfluorobutane for TB nodules.

### METHODS AND MATERIALS

This retrospective study included consecutive patients from October 2020 to January 2024 in our center. All patients had underwent total thyroidectomy or lobectomy and central lymph node dissection for PTC. All TB nodules underwent US and CEUS with intravenous perfluorobutane. The status of TB nodules were confirmed by fine-needle aspiration cytopathology or surgical histopathology. Features and diagnostic performance of US and CEUS were analyzed and compared by Pearson ?2 test and the area under the receiver operating characteristic curve (AUC).

### RESULTS

We retrospectively reviewed 63 lesions from 50 patients (median age, 39 years [IQR, 35-51 years]; 39 women), including 21 benign nodules and 42 malignant nodules. Increased vascularization was more often seen in malignant nodules in US (p=0.002). Both centripetal perfusion pattern in the vascular phase and non-isoenhancement (including hypoenhancement, partial enhancement, and no enhancement) in the postvascular phase of CEUS were significantly associated with malignant nodules (P=0.001 and P<0.001, respectively). 45.24% of malignant nodules (19/42) showed centripetal perfusion pattern + non-isoenhancement in the postvascular phase on CEUS. The AUC of CEUS (perfusion pattern + postvascular phase features) was significantly higher than that of US (0.90 vs 0.69; P<0.001).

### CONCLUSION

The perfusion pattern and postvascular phase features of CEUS with perfluorobutane demonstrated excellent performance for diagnosing TB nodules.

### CLINICAL RELEVANCE/APPLICATION

CEUS with perfluorobutane may be an effective and noninvasive method for the evaluation of TB nodules after PTC surgery, which provides more references for continued follow-up or invasive intervention for TB nodules.

## R5B-SPHN-2 THYROID NODULE CHARACTERIZATION: WHICH TIRADS IS MORE ACCURATE? A COMPARISON BETWEEN RADIOLOGIST WITH DIFFERENT EXPERIENCES AND AI SOFTWARE

Emanuele David (*Abstract Co-Author*) Nothing to Disclose
Carmen Solito (*Abstract Co-Author*) Nothing to Disclose
Vincenzo Dolcetti (*Abstract Co-Author*) Nothing to Disclose
Carlo Catalano, MD (*Abstract Co-Author*) Nothing to Disclose

Vito Cantisani, MD, PhD (*Abstract Co-Author*) Speaker, Canon Medical Systems Corporation;Speaker, Bracco Group;Speaker, Samsung Electronics Co, Ltd;
Chiara Di Bella, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare: the performance of K-TIRADS, EU-TIRADS and ACR TIRADS when used by operators with different levels of experience compared with the gold standard cytology; to evaluate the diagnostic performance of CAD compared with TI-RADS systems.

### METHODS AND MATERIALS

323 thyroid nodules were evaluated in Patiens who were candidates for needle aspiration. Three operators with different levels of experience evaluated the diagnostic accuracy of three risk stratification systems (ACR TI-RADS, EU-TIRADS, K-TIRADS) and CAD software (S-Detect) in characterizing the

nodules. The results were compared with citology examination. All nodules were characterized in terms of shape, margins, composition, calcifications, size, echogenicity, microcalcifications and stratifyg individual nodules by using the three TIRADS systems; then S-detect software was applied and the data were compared with each other and with the gold standard.

**RESULTS**

At cytology, 308 benign and 33 malignant nodules were identified. ACR-TIRADS showed a sensitivity of 100%, a specifity of 86%, a positive predictive value of 43% and a negative predictive value of 100%. EU-TIRADS showed a sensitivity of 100%, a specifity of 79%, a positive predictive value of 33% and a negative predictive value of 100%. K-TIRADS showed a sensitivity of 100%, a specifity of 89%, a positive predictive value of 50% and a negative predictive value of 100%. S-DETECT combined with EU-TIRADS showed a high agreement (>95%) with gold standard.

**CONCLUSION**

K-TIRADS positive predictive power was slightly better than other TIRADS, suggesting greater accuracy in correctly diagnosing positive cases. S-DETECT combined with EU-TIRADS has similar results as S-DETECT with ACR- and K- TIRADS in terms of sensitivity, specificity and negative predictive power. However, it has a slightly better positive predictive power, suggesting greater accuracy in correctly diagnosing positive cases than the ACR- and K- classification systems. In general, S-Detect cannot yet be considered a substitute for the human operator but only an important support for human evaluation and an excellent and fast help to provide a comprehensive and complete report.

**CLINICAL RELEVANCE/APPLICATION**

S-Detect is a valuable tool for characterizing thyroid nodules, when integrated with radiologist evaluation. It is also an important support tool for less experienced operators. Particularly interesting is the approach of use in integrated combination of the K-TIRADS by the human operator with S-Detect using EU-TIRADS, which could increase the overall diagnostic efficiency of the systems used individually. CAD-classification systems, infact, appear to have more specificity, potentially helping to avoid unnecessary cytological examinations.

## R5B-SPHN-3 ASSESSMENT OF THYROID NODULES USING LOGISTIC REGRESSION ANALYSIS OF CONVENTIONAL AND FUNCTIONAL MRI FEATURES

Fan Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Juan Tao (*Abstract Co-Author*) Nothing to Disclose
Peng Sun, MD,MD (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Shuyi Peng (*Abstract Co-Author*) Nothing to Disclose
Wenying Zhu (*Abstract Co-Author*) Nothing to Disclose
Jie Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

Given the common occurrence of thyroid nodules among patients, there is a pressing need for an accurate diagnostic approach to differentiate between benign and malignant nodules. Fine-needle aspiration biopsy (FNAB) and thyroid ultrasound are currently used for this purpose. However, FNAB is complicated, time-consuming and expensive, and the accuracy of ultrasound varies significantly despite its reputation for being rapid and highly sensitive. Leveraging the advantageous soft tissue imaging capabilities of magnetic resonance imaging (MRI), this study aims to devise a diagnostic tool using logistic regression analysis with both conventional and functional MRI to effectively distinguish between malignant and benign thyroid nodules.

**METHODS AND MATERIALS**

A total of fifty-eight nodules (33 benign,25 malignant) confirmed by pathology were included. Imaging data comprised conventional MRI sequences (T1WI, T2WI) and functional imaging sequences (DCE, DWI). Nodule characteristics including shape, coverage, enhancement, cystic changes, hemorrhage/calcification, and ADC values were assessed. Significant risk factors for malignancy were identified by multivariable logistic regression, and ROC analysis was used to evaluate diagnostic performance.

**RESULTS**

Logistic regression identified three key MRI features (coverage, cystic changes, ADC values) for malignancy prediction. The logistic regression model was Logit(p)=-25.001+2.541×cystic +3.417×covering +22.561× ADC. Using a threshold of P>0.5 for malignancy, diagnostic accuracy reached 94.8%, with an AUC of 0.955.

**CONCLUSION**

Cystic degeneration, covering, and ADC values are pivotal for differentiating benign and malignant thyroid nodules. The logistic regression model utilizing both conventional and functional MRI is a valuable tool for nodule characterization.

**CLINICAL RELEVANCE/APPLICATION**

The logistic regression model with both conventional and functional MRI features (Cystic degeneration, covering, and ADC) is a valuable tool for thyroid nodule assessment.

## R5B-SPHN-4 ASSESSING THE UTILITY OF ACR-TIRADS ULTRASOUND CLASSIFICATION IN GUIDING MANAGEMENT OF THYROID NODULES DIAGNOSED AS TIR3A AT FNAC

Giovanni G. Pompili, MD (*Abstract Co-Author*) Nothing to Disclose
Gianpaolo Carrafiello, PhD (*Abstract Co-Author*) Nothing to Disclose
Alessia Moro, MD (*Abstract Co-Author*) Nothing to Disclose
Silvia Tresoldi, MD (*Abstract Co-Author*) Nothing to Disclose
Giovanni Irmici, MD (*Abstract Co-Author*) Nothing to Disclose
Loredana De Pasquale, MD (*Abstract Co-Author*) Nothing to Disclose
Filippo Locatelli (*Abstract Co-Author*) Nothing to Disclose
Elena Grimaldi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the correlation between ultrasound (ACR-TIRADS 2018) and cytological (SIAPEC-SIE) classifications in thyroid nodules categorized as Tir3a on fine-needle aspiration cytology (FNAC).

**METHODS AND MATERIALS**

In this ethical-committee approved retrospective study, all nodules diagnosed as TIR3A on fine needle aspiration cytology (FNAC) in consecutive patients over a 4-year period were selected, upon acquisition of informed consent. US was used to calculate Thyroid Imaging Reporting and Data System

(TIRADS) scores, with repeat assessments and FNAC performed six months post-diagnosis. Those still classified as Tir3a on cytology were further evaluated for either surgery or continued US follow-up. This study extended the follow-up period to five years after the initial cytological examination, providing insights into the outcomes of Tir3a nodules. High-frequency linear array probes and 23G or 25G needles were used for US and FNAC, respectively. Descriptive statistics were applied for analysis.

**RESULTS**

Between January 2016 and December 2019, 54 Tir3a thyroid nodules were identified in 54 patients, with a mean age of 61 years (±14 years, range 21-87 years). A total of 20.4% (11/54) patients were excluded due to retrospective TIRADS evaluation challenges. Initial evaluation revealed 5.5% (3/54) of Tir3a nodules classified as TIRADS 2, 35.2% (19/54) as TIRADS 3, 35.2% (19/54) as TIRADS 4, and 3.7% (2/54) as TIRADS 5. After six months, 7% (3/43) were reclassified as Tir2, while 91% (39/43) remained Tir3a with one reclassified as Tir3b. Nine Tir3a patients had a final diagnosis after surgery (2 papillar microcarcinoma - TIRADS 3; 2 hyperplasia - TIRADS 3; 5 adenomas - 3 TIRADS 3 and 2 TIRADS 4). The remaining 30 nodules were monitored for 12 months, with no progression exceeding 10%. Among these, 20 patients continued annual follow-up, confirming nodule stability.

**CONCLUSION**

TIRADS aids in monitoring thyroid nodules, particularly low TIRADS nodules showing no malignancy. US follow-up is recommended for Tir3a nodules with TIRADS score =3. Larger longitudinal studies will enhance understanding of ACR TIRADS' role in screening indeterminate thyroid nodules.

**CLINICAL RELEVANCE/APPLICATION**

This study offers insights into improving diagnostic accuracy and guiding appropriate management decisions for patients with thyroid nodules. These findings have the potential to empower clinicians by providing a reliable method to combine ultrosound characteristics with cytological results, thus optimizing patient care and potentially reducing unnecessary procedures or surgeries.

## R5B-SPIN-1 GUIDANCE FOR CORRECTING SEGMENTATION ERRORS USING CONDITIONAL DIFFUSION MODELS TRAINED ON DIVERSE ANNOTATION MASKS IN CT IMAGES

Min Jin Lee, PhD (*Abstract Co-Author*) Nothing to Disclose
Helen Hong, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyu Won Shim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jinseo An, BS (*Presenter*) Nothing to Disclose

### PURPOSE

The study aims to offer guidance for manually correcting segmentation results, which are challenging to differentiate from surrounding tissues in CT images due to low contrast and ambiguous boundaries. We propose a method for generating multiple plausible segmentation outputs using a conditional diffusion model(CDM) by learning from the distribution of diverse annotation masks. Additionally, we provide meaningful guidance for manually correcting results in area where segmentation performance is low.

### METHODS AND MATERIALS

A dataset consisting of 71 facial CT images was divided into 57 train sets and 14 test sets. Each set was manually annotated by a neurosurgeon with over 15 years of experience(NS-A) and two senior medical students(MS-B, MS-C). To address discrepancies between three manual annotation masks caused by the ambiguous boundaries and thin structure, all annotation masks were utilized to learn diverse data distribution. We employed MedSegDiff-V2, which integrates a transformer mechanism with a U-Net backbone and uses feature maps extracted from the CT images through another U-Net to provide supplementary context. Segmentation performance was evaluated in regions vulnerable to discrepancies between manual annotations, specifically the orbital medial wall and orbital floor. Ground truth was established using masks generated by the STAPLE algorithm. In the experiment, we generated 20 segmentation masks for each image. Ambiguity-aware map was generated based on the frequency of occurrence from these masks and the final binary segmentation mask was determined by majority voting among these masks.

### RESULTS

The segmentation results obtained from the CDM indicated a DSC of 83.6% for the orbital medial wall and 89.95% in the orbital floor. The ambiguity-aware map, which incorporated 20 segmentation masks, effectively demonstrated the discrepancies among the diverse manual annotation masks. Furthermore, it was confirmed that these discrepancies correspond to the areas of the orbital bones characterized by ambiguous boundaries and thin structure.

### CONCLUSION

Our approach effectively leveraged the CDM to learn diverse expertise, presenting a range of segmentation results and ambiguity-aware maps to help clinicians in identifying uncertainty that may require correction. (This research was supported by a grant of the Korea Health Technology RD Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health Welfare, Republic of Korea (grant number: HI22C1496))

### CLINICAL RELEVANCE/APPLICATION

Our study is expected to provide guidance for manual correction of segmentation results, enabling more accurate surgical planning and creation of customized bone templates for 3D printing applications.

## R5B-SPIN-2 COLOR VISION DEFICIENCY AND RADIOLOGY: ADDRESSING AN UNDERAPPRECIATED INCLUSIVITY AND ACCESSIBILITY BLIND SPOT

Joshua D. Warner, MD,PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Most medical imaging data is viewed in grayscale, but color images represent a persistent and growing minority. From nuclear medicine to Doppler ultrasound to elastography, color images are used for diagnostic decisions and convey key information to referring providers and our patients. Color vision deficiency, a.k.a. red-green color blindness, is a common male-predominant congenital disorder with two major forms: deuteranopia (affecting approximately 6% of males) and protanopia (affecting approximately 2% of males). Recent improved models of the human visual system allow quantitative evaluation and perceptual comparison of color in those with and without color vision deficiency. The purpose of this work is to determine how well 4 color maps commonly used in medical imaging from DICOM Supplement 133 map to the color perception of those with and without color vision deficiency and propose accessible perceptually uniform alternatives.

### METHODS AND MATERIALS

We use the CAM02-UCS perceptually uniform color space; reference implementation provided by the `colospacious` Python library. The framework contains models for deuteranopia and protanopia. We calculate the derivative in perceptual space and find the root mean square error (RMSE) of the color transitions in the four DICOM color maps for full color perception, grayscale, and simulated deuteranopia/protanopia. We compare these results to a best-practice perceptually uniform public domain color map. Finally, we design and propose perceptually uniform alternatives.

### RESULTS

All color maps from DICOM Supplement 133 were poor in perceptual uniformity, even to people without color vision deficiency, and became quantitatively poorer representations of the underlying data in the models for color vision deficiency relative to the best-practice color map. Our alternatives are objectively superior color representations to those in the DICOM standard.

### CONCLUSION

Radiology and standards bodies have neglected advances in the science of human color perception, leaving behind those with color vision deficiency. We prove this is the case, but it need not be this way, as we demonstrate color map alternatives which are superior in accessibility and inclusivity. These or similar should be added to the DICOM standard.

### CLINICAL RELEVANCE/APPLICATION

Color vision deficiency or color blindness is a common congenital limitation of visual perception in the population. The color maps defined in the DICOM standard do not incorporate these advances and are poor perceptual representations. We confirm this quantitatively and provide a path forward to replacing these historic color maps with objectively superior modern analogues to best serve radiologists, referring providers, and our patients.

## R5B-SPIN-3 GENERATING LABELS FOR TRAINING CONVOLUTIONAL NEURAL NETWORKS FROM RADIOLOGY REPORTS USING OPEN SOURCE LARGE LANGUAGE MODELS

Keno K. Bressem, MD (*Abstract Co-Author*) Nothing to Disclose

Lisa C. Adams, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Fares Al Mohamad (*Presenter*) Nothing to Disclose

### PURPOSE

The use of deep learning algorithms in radiology has received a lot of attention in the recent past for its ability to assist radiologists in increasing their accuracy and save time on several tasks especially in the field of musculoskeletal radiology. However, training Convolutional Neural Networks (CNN) requires large data sets with labelled data, which can be very labour-intensive to prepare. Radiology reports contain a lot of potentially useful information for such tasks, but because they are often unstructured, they cannot be directly used for training. Many attempts have been made in the field of Natural Language Processing to harvest this information and interpret it in a structured manner to make it accessible for research and clinical purposes. The recent progress in transformer-based Large Language Models (LLMs) might introduce a new useful tool in interpreting radiology reports.

### METHODS AND MATERIALS

The LLM Mixtral-8x7B-Instruct-v0.1 was used for classifying radiology reports of ankle x-ray images. Various prompting strategies were tested on a small, manually labelled dataset of radiology reports. The best performing prompt was then tested on a different dataset of labelled reports to determine its accuracy. This prompt was then used to classify all available reports. The generated labels were then used to train a CNN with the DenseNet121 architecture to recognize fractures of the ankle. A separate small dataset of x-ray images of ankles labelled by a board-certified radiologist was used for validation and testing.

### RESULTS

The validation and test datasets of radiology reports consisted of 250 reports each. A total of 7780 radiology reports were available. Using common prompting strategies an accuracy of 92.4% was reached on the validation dataset of radiology reports. On the test data set this prompt reached an accuracy of 92%. Across all tested prompts (n = 31) zero-shot prompting resulted in higher accuracies (0.876 ± 0.025) compared to few-shot prompting (0.792 ± 0.108) $p < 0.001$. The CNN was trained for 200 epochs with the best performing model occurring on epoch 149. On the test dataset this model reached an accuracy of 87.4%, an area under the receiver operating characteristics curve of 0.921.

### CONCLUSION

In this work, we were able to demonstrate that radiology reports can be classified automatically with the help of an LLM. We were able to successfully utilise the resulting structured data as training data for a deep learning model without further manual classification or review by a radiologist.

### CLINICAL RELEVANCE/APPLICATION

LLMs can be used to obtain structured data from unstructured texts, such as radiology reports, avoiding the labour-intensive task of manually reviewing these texts.

## R5B-SPIN-4 STREAMLINING COMMON DATA ELEMENT CREATION: INTRODUCTION OF A NOVEL TOOLCHAIN THAT TRANSFORMS USER TEXT INPUT INTO FULLY ENCODED JSON

Tarik K. Alkasab, MD, PhD (*Abstract Co-Author*) Consultant, Nuance Communications, Inc;Medical Advisory Board, Nuance Communications, Inc
Roshan Fahimi, MD (*Abstract Co-Author*) Nothing to Disclose
Heather Chase, BS (*Abstract Co-Author*) Nothing to Disclose
Michael Hood, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To achieve the goal of encoding the rich, granular information contained within unstructured text of diagnostic radiology reports into standardized data, the expansion of a vast library of imaging Common Data Elements (CDEs) is essential. We introduce a novel toolchain developed to expedite the production of CDEs by enabling physician experts to efficiently contribute by authoring content in a simple, user-friendly text format.

### METHODS AND MATERIALS

The toolchain is written in Python and employs a three-stage process for CDE development: 1) initial authoring in a Markdown text file; 2) conversion of the text file to a preliminary "compact" CDE in JavaScript Object Notation (JSON) format; and 3) enrichment with standardized anatomic tags from ontologies including RadLex, SNOMED, and the American College of Radiology Common Anatomic Location Index to produce a fully annotated CDE in JSON. This final JSON file is capable of generating a message in the Fast Health Interoperability Resources (FHIR) specification, termed as a CDE-labeled FHIR Observation object. In practical use, the input Markdown format is uncomplicated and allows content experts to easily draft CDEs, which then are automatically converted into JSON while maintaining structural and metadata accuracy. This toolchain also facilitates rapid updates to CDEs, as iterative edits in the Markdown document are reflected in the JSON output.

### RESULTS

The pilot of this toolchain has successfully facilitated the creation of fully annotated JSON files that can generate CDE-labeled FHIR Observation objects, which are instrumental in encoding diagnostic radiology reports within the FHIR framework.

### CONCLUSION

The developed toolchain simplifies the process of developing imaging CDEs by enabling radiologists, particularly users who may not be familiar with a complex data structure like JSON, to directly contribute to their creation using a user-friendly Markdown format. This approach effectively lowers the technical barrier associated with CDE generation and permits content experts to engage in the process without the need for specialized knowledge in data coding. Ultimately, the democratization of this process is crucial, as a vast number of validated CDEs must be created and rigorously reviewed to build a comprehensive model capable of encoding complete diagnostic radiology reports.

### CLINICAL RELEVANCE/APPLICATION

The toolchain presented greatly reduces the technical barrier to CDE development by enabling content experts to contribute directly using a simple text input format.

## R5B-SPIN-5 NODE-RADS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF DIAGNOSTIC PERFORMANCE, CATEGORY-WISE MALIGNANCY RATES, AND INTER-OBSERVER RELIABILITY

Huan Zhang (*Abstract Co-Author*) Nothing to Disclose
Weiwu Yao (*Abstract Co-Author*) Nothing to Disclose
Jingyu Zhong, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To perform a systematic review and meta-analysis to estimate diagnostic performance, category-wise malignancy rates, and inter-observer reliability of Node Reporting and Data System 1.0 (Node-RADS).

### METHODS AND MATERIALS

Five electronic databases were searched for primary studies on the use of Node-RADS to report the possibility of cancer involvement of lymph nodes on CT and MRI from January 1, 2021, until April 15, 2024. The study quality was assessed by modified Quality Assessment of Diagnostic Accuracy Studies (QUADAS-2) and Quality Appraisal of Diagnostic Reliability (QAREL) tools. The diagnostic accuracy was estimated with the bivariate random-effects model, while category-wise malignancy rates were obtained with the random-effects model.

### RESULTS

Six Node-RADS-CT studies and three Node-RADS-MRI studies covering nine types of cancer were included. The study quality was mainly damaged by unclear index test and unknown flow and timing according to QUADAS-2, and inappropriate blindness during rating process according to QAREL. The aera under hierarchical summary receiver operating characteristic curve (95% conventional interval, CI) was 0.92 (0.89-0.94) for Node-RADS = 3 as positive, and 0.91 (0.88-0.93) for Node-RADS = 4 as positive, respectively. The pooled sensitivity (95% CI) and specificity (95% CI) of Node-RADS for identifying were 0.77 (0.59-0.90) and 0.90 (0.86-0.92) for Node-RADS = 3 as positive, and 0.54 (0.40-0.67) and 0.98 (0.95-0.99) for Node-RADS = 4 as positive, respectively. The diagnostic odds ratios (95% CI) were 30.85 (14.17-67.13) for Node-RADS = 3 as positive, and 57.78 (23.46-142.33) for Node-RADS = 4 as positive, respectively. The heterogeneity for the meta-analyses was low to high. The publication bias was not identified. The pooled malignancy rates (95% CI) for Node-RADS 1, 2, 3, 4, and 5 were 4.4 (1.1-7.7) %, 33.0 (3.4-62.6) %, 55.1 (34.5-75.7) %, 78.8 (61.4-96.2) %, and 89.9 (78.7-100.0) %, respectively. The pooled inter-observer reliability was not available due to insufficient data.

### CONCLUSION

Node-RADS presented high diagnostic performance with appropriate probability of malignant for each category. However, the evidence for inter-observer reliability of Node-RADS is lacking, and may hinder the implementation in routine clinical practice for lymph node assessment.

### CLINICAL RELEVANCE/APPLICATION

Node-RADS is a useful tool that standardized for reporting the possibility of cancer involvement of regional and distant lymph nodes on CT and MRI with high diagnostic performance. The malignancy rates were increasing with the Node-RADS rating. However, it is unclear whether the tool is with appropriate inter-observer reliability for clinical practice.

## R5B-SPIN-6 EVALUATING THE ACCURACY OF LUNG-RADS SCORE EXTRACTION FROM RADIOLOGY REPORTS: MANUAL ENTRY VERSUS NATURAL LANGUAGE PROCESSING

Stuart L. Cohen, MD (*Abstract Co-Author*) Consultant, Beijing Infervision Technology Co, Ltd;Research support, Siemens AG
Amir Gandomi (*Abstract Co-Author*) Nothing to Disclose
Brett Bade (*Abstract Co-Author*) Nothing to Disclose
Matthew L. Inra, MD (*Abstract Co-Author*) Nothing to Disclose
Gerard Silvestri, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Makhnevich, MD (*Abstract Co-Author*) Nothing to Disclose
Suhail Raoof (*Abstract Co-Author*) Nothing to Disclose
Jesse Chusid, MD (*Abstract Co-Author*) Nothing to Disclose
Subroto Paul (*Abstract Co-Author*) Nothing to Disclose
Eusha Hasan (*Presenter*) Nothing to Disclose

**PURPOSE**

Adherence to follow-up is essential for lung cancer screening (LCS). Lung CT Screening Reporting and Data System (Lung-RADS) is a structured radiology scoring system providing recommendations for LCS follow-up that are utilized (a) in clinical care and (b) by LCS programs monitoring rates of adherence to follow-up. Extraction of structured Lung-RADS scores from free-text radiology reports is critical in determining rates of adherence to follow-up. Unfortunately, due to variability in radiology reports, extraction of Lung-RADS scores is non-trivial, and best practices do not exist. The purpose of this project is to compare mechanisms to extract Lung-RADS scores from free-text radiology reports.

**METHODS AND MATERIALS**

We retrospectively analyzed reports of LCS low-dose computed tomography (LDCT) examinations performed at a multihospital integrated healthcare network in New York State between January 2016 and July 2023. We compared three methods of Lung-RADS score extraction: manual physician entry at time of report creation, manual LCS specialist entry after report creation, and an internally developed, rule-based natural language processing (NLP) algorithm. Accuracy, recall, precision, and completeness (i.e., the proportion of LCS exams to which a Lung-RADS score has been assigned) were compared between the three methods.

**RESULTS**

The dataset includes 24,060 LCS examinations on 14,243 unique patients. The mean patient age was 65 years, and most patients were male (54%) and white (75%). Completeness rate was 65%, 68%, and 99% for radiologists' manual entry, LCS specialists' entry, and NLP algorithm, respectively. Accuracy, recall, and precision were high across all extraction methods (>94%), though the NLP-based approach was consistently higher than manual entry in all metrics.

**CONCLUSION**

An NLP-based method of LCS score determination is an efficient and more accurate means of extracting Lung-RADS scores than manual review and data entry. NLP-based methods should be considered best practice for extracting structured Lung-RADS scores from free-text radiology reports.

**CLINICAL RELEVANCE/APPLICATION**

NLP represents a highly valuable tool for retrospectively tracking LCS program adherence. By using a tested NLP algorithm to identify Lung-RADS scores, LCS programs may concurrently increase data accuracy and the efficiency of their team. This would allow an LCS program to deliver more data-driven care based on the historical aggregate behavior of its respective patient population.

## R5B-SPIN-7 ENHANCING ORBITAL BONE SEGMENTATION ACCURACY IN CT IMAGES USING PROMPT-BASED SEGMENTATION WITH SELECTIVE MULTIPLE POINT PROMPTS

Min Jin Lee, PhD (*Abstract Co-Author*) Nothing to Disclose
Helen Hong, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyu Won Shim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jinseo An, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Ambiguous anatomical structures pose challenges in generating consistent label data, which may impact the segmentation results of conventional CNN-based methods relying on such labels. To improve the segmentation accuracy of orbital bones with thin structures and unclear boundaries in CT images, we propose a prompt-based segmentation method utilizing selective multiple point prompts.

**METHODS AND MATERIALS**

A dataset consisting of 355 facial CT images was divided into 228 for training, 56 for validation, and 71 for test sets. The orbital bone region was manually annotated by a neurosurgeon with over 15 years of experience. Our prompt-based segmentation network employs a 2D U-Net as the backbone, incorporating a transformer-based cross-attention module at the bottleneck layer to effectively integrates image feature maps from the encoder with specific prompts containing coordinate and label information. To evaluate the effect of point prompts, we assessed the performance of the orbital medial wall, characterized by low contrast and unclear boundaries. Within this region, we strategically selected multiple points and compared the results of CNN-based segmentation, including U-Net and MSDA-Net with a multi-scale dual-attention module.

**RESULTS**

Among the results obtained using one- to four-point prompts, the application of two-point prompts exhibited the highest segmentation performance, achieving a DSC of 85.65%, precision of 84%, and recall of 87.68%. In particular, the recall was significantly improved by 9.64% compared to U-Net and 6.75% compared to MSDA-Net, indicating the effectiveness of our prompt-based segmentation network in addressing segmentation failures caused by the misidentification of unclear boundary regions. Our prompt-based segmentation network demonstrated statistically significant differences in terms of DSC and recall compared to CNN-based segmentation results ($p<0.05$).

**CONCLUSION**

Our prompt-based segmentation network outperformed the CNN-based segmentation network, particularly in regions with unclear boundaries within the orbital bone. This approach enables more accurate segmentation of orbital bone by allowing clinicians to utilize selective multiple point prompts in regions with unclear boundaries. (This research was supported by a grant of the Korea Health Technology RD Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health Welfare, Republic of Korea (grant number: HI22C1496))

**CLINICAL RELEVANCE/APPLICATION**

Our study can help mitigate issues related to noisy annotations and provide more accurate segmentation result, which can be utilized in creating customized bone templates for 3D printing.

Tarig Elhakim, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Geographic Information Science (GIS) integrate geographical data with descriptive analytics, enhancing our understanding of spatial patterns to facilitate better decision-making. Despite its potential, the application of GIS in assessing the global landscape of Interventional Radiology (IR) remains underdeveloped. This gap is critical as more than half of the global population lacks access to IR services due to various unexplored factors.

### METHODS AND MATERIALS

An anonymous survey was designed to collect information regarding the state of IR practice and education worldwide and to identify factors that impact access to IR services. The survey was distributed to members of major global IR societies and shared on social media. It remained open from 6/2022 to 9/2023. The survey data was then connected to a shapefile for geographical analysis. ArcGIS was utilized to create an interactive map for country-level survey responses. A logistic regression analysis was used to compare continent level responses.

### RESULTS

1263 respondents completed the survey, including 902 IRs, 176 DRs, 260 attending/consultants and 197 trainees, among others. Geographically, 413 (33%) of respondents practiced in Asia, 399 (32%) Europe, 189 (15%) Africa, 187 (15%) North America, 43 (3.5%) South America, and 14 (1.1%) Oceania. For country-level responses, an ArcGIS interactive map was created and hosted at arcgis.com (https://tinyurl.com/5hber8wu). IR public awareness was the greatest practice need globally, followed by patient referrals and education/training. Other challenges included hospital support and competition with other specialties. Compared to North America, there were significant shortages of IR training programs in Africa (OR 0.06, $p < 0.001$), Asia (OR 0.50, $p = 0.004$), Europe (OR 0.12, $p < 0.001$), and Oceania (OR 0.12, $p < 0.001$). Significant shortage of any IR exposure during radiology training was observed in Africa (OR 0.31, $p < 0.001$), Asia (OR 0.16, $p < 0.001$), and South America (OR 0.14, $p < 0.001$). The top three interventions recommended to provide the highest impact included establishing IR training programs in Africa (OR 7.51, $p<0.001$), access to online education in Africa (OR 3.03, $p <0.001$) and holding multidisciplinary conferences in South America (O.R 2.63, $p=0.005$).

### CONCLUSION

The survey results can help guide societal efforts to improve global access to IR. Geospatial mapping can be utilized to regularly collect country-level data to assess local IR needs, track development and support the expansion of IR worldwide.

### CLINICAL RELEVANCE/APPLICATION

There is a universal recognition of the need to increase public awareness about IR. Improving access to IR education and training is additionally important. Geospatial mapping can assist in IR expansion

## R5B-SPIR-3 QUANTIFYING THE LEARNING CURVE FOR INTERVENTIONAL RADIOLOGY ATTENDINGS: WHICH PROCEDURES HAVE THE LONGEST LEARNING CURVE?

Ernesto G. Santos Martin, MD (*Abstract Co-Author*) Nothing to Disclose
Ken Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Hooman Yarmohammadi, MD (*Abstract Co-Author*) Grant, Guerbet SA
Vlasios S. Sotirchos, MD (*Abstract Co-Author*) Nothing to Disclose
Joseph P. Erinjeri, MD,PhD (*Abstract Co-Author*) Advisory Board, AstraZeneca PLC;Consultant, Canon Medical Systems Corporation;
Chenyang Zhan, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Matthew Lynn, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

To quantify the learning curve for interventional radiology procedures performed by new attendings at a cancer center.

### METHODS AND MATERIALS

Between August 2010 and December 2023, 69014 procedures across 24 attending physicians were examined. Procedural information including procedural length, inpatient vs. outpatient status, anesthesia status, and months of attending practice was collected. To account for both 1) inter-faculty variability and 2) inter-procedure variability, median career procedure times by faculty and procedure were computed and subtracted from individual procedure times to create a normalized procedure time. The learning curve for IR procedures was constructed by stratifying normalized procedure times by months of practice. We examined the difference in normalized procedure times between the first 6 months and 6-12 years of practice using student's t test.

### RESULTS

There was a significant decrease in procedure time over the years of practice (-0.99 mins/procedure/year, $p< 0.001$). There was a biphasic learning curve, with rapid decrease in normalized procedure times in first 9 months of practice (-8.0 mins/procedure/year, $p< 0.06$), followed by slower steady significant decrease in normalized procedure times between 9 months and 9 years of practice (-0.87 mins/procedure/year, $p<0.001$). The procedures with show the greatest improvement in normalized procedure time between the first 6 months and 6-12 years of practice were SIRspheres treatment (-42 min, 19 vs -22, $p<0.006$), vascular chemoinfusion (-24 min, 8.8 vs -15, $p<0.029$), Therasphere treatment (-23 min, 8.6 vs -15, $p<0.017$), lung ablation (-20 min, 5.4 vs -15, $p<0.019$) and mapping arteriogram (-19 min, 10 vs -8.7, $p<0.006$). Procedures which showed no significant change in normalized procedure time between the first 6 months and 6-12 years of practice were CT guided abscess drain (-1.8 mins, 1.2 vs -0.7, $p<0.64$), thoracostomy placement (-1.3 min, 2.8 vs 1.5, $p<0.84$), nephrostomy placement (1.2 mins, 2.9 vs 4.1, $p<0.81$), abscess catheter check (-1.8 mins, -0.7 vs -2.5, $p<0.64$, and conversion of surgical drain to IR drain (1.2 min, -4.2 vs -3, $p<0.86$).

### CONCLUSION

Locoregional cancer treatments, such as Y-90 mappings/treatments, lung ablations and vascular chemoinfusions have the longest learning curves for new IR attendings. Procedures with little or no learning curve for new IR attendings include abscess catheter placement/check/exchange, nephrostomy placement and chest tube placement.

### CLINICAL RELEVANCE/APPLICATION

Quantifying the learning curve for interventional radiology procedures will allow department and hospital leaders to allocate appropriate time for procedures for new IR attendings.

## R5B-SPIR-4 GENICULAR ARTERY EMBOLIZATION FOR THE TREATMENT OF SYMPTOMATIC KNEE-OA: A COMPREHENSIVE ANALYSIS OF 167 PATIENTS

Florian N. Fleckenstein, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Genicular artery embolization (GAE) is an innovative minimally invasive therapy for patients with symptomatic knee osteoarthritis (OA) refractory to conservative treatments, aiming to reduce synovial arterial hypervascularity. This study evaluates the safety and efficacy of GAE for the treatment of symptomatic knee OA.

### METHODS AND MATERIALS

A retrospective, single-center study was conducted at our institution. Patients enrolled in the study were aged 40 to 90 years, had moderate to severe knee OA (Kellgren-Lawrence grade 2 to 4), and had previously experienced failure of conservative therapy. Baseline pain (assessed using the visual analog scale [VAS]) and symptom scores (Knee Injury and Osteoarthritis Outcome Score [KOOS]) were evaluated. After achieving femoral arterial access via a 4 Fr sheath, embolization was performed using Imipenem/Cilastatin. Target vessels were determined using digital subtraction angiography in correlation with the patients' pain points. Adverse events and symptom scores were assessed at six weeks, three months, and six months after GAE.

### RESULTS

167 patients with a total of 246 treatments were enrolled, with a median age of 69 years (IQR, 61, 74). Knee OA severity was grade 2 in 12% of cases, grade 3 in 41%, and grade 4 in 47%. Technical success was achieved in 100% of procedures. Transient skin discoloration and transient mild knee pain after the procedure were noted in 18% of all cases, as expected. No severe complications were reported. The KOOS quality of life index and VAS improved by 87% and 71%, respectively, at six months from a median baseline of 57 (of 100) and 7 (of 10), respectively.

### CONCLUSION

This retrospective study in a large patient cohort demonstrates that GAE is an effective and safe treatment for reducing OA-associated symptoms that are refractory to conservative therapy.

### CLINICAL RELEVANCE/APPLICATION

The development of this novel, minimally invasive technique allows interventional radiology communities worldwide to treat chronic joint disorders more efficiently. However, comprehensive and standardized data from large-scale studies remain limited. This study aims to provide a thorough analysis to support the standardization of GAE as a routine treatment for knee-OA.

## R5B-SPIR-5 OPIOID AND NON-OPIOID ANALGESIC MEDICATION USE IN PATIENTS WITH OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES BEFORE AND AFTER KYPHOPLASTY OR VERTEBROPLASTY

Rylie Ju, MD (*Abstract Co-Author*) Nothing to Disclose
Bassel Ibrahim (*Presenter*) Nothing to Disclose

**PURPOSE**

Kyphoplasty (KP) and Vertebroplasty (VP) are two minimally invasive procedures that are commonly performed to treat painful osteoporotic vertebral fractures (OVF) refractory to medical management alone. However, recent studies show conflicting outcomes regarding their effect on reducing pain symptoms and analgesic medication use. The purpose of this study was to analyze the prevalence of opioid and non-opioid use in patients with OVF before and after undergoing KP or VP procedures.

**METHODS AND MATERIALS**

This retrospective study analyzed electronic health records from 65 healthcare organizations across the United States between April 2014 and April 2024. Inclusion criteria included adult patients with OVF refractory to medical management who underwent KP or VP within 1 year of PVF diagnosis. Patients were excluded if they had received an opioid prescription before OVF diagnosis, had a history of malignancy, or underwent surgical procedures within 1 year following the intervention. Patient demographics at baseline and new persistent opioid and non-opioid analgesic medication use at 1-mo pre-op and 1, 3, 6, and 12-mo post-op were reported.

**RESULTS**

Among 209,314 patients identified with OVF, 7633 underwent KP (mean age 75.2 ± 10.4, 68.53% female), and 2655 underwent VP (mean age 76.7 ± 10.7, 73.97% female). In the KP group, 94% of patients had new persistent opioid prescribing 1 month before the procedure. This number decreased to 17%,16%,17%, and 13% at 1, 3, 6 and 12 months, respectively. In the VP group, 96% of patients had OVF-associated persistent opioid prescribing 1-mo before the procedure. This number decreased to 19%,11%,19%, and 13% at 1,3,6 and 12 months, respectively. There was a statistical difference in opioid use between KP and VP at 1-mo pre-op ($p=.0001$), at 1-mo post-op ($p=.025$), and at 3-mo post-op ($p=.045$). Trends in the use of non-opioid analgesics were not statistically different between any period in both the KP and VP groups.

**CONCLUSION**

Patients undergoing VP had significantly higher opioid prescription rates than those undergoing KP 1-mo pre-op. KP led to a greater reduction in opioid refills compared to VP at 1, 3, and 6 mo post-op; however, this difference was not observed at 12 mo post-op. The use of non-opioid analgesics did not show statistically significant differences between the KP and VP groups during any of the periods measured. Following treatment, both KP and VP were associated with a reduction in opioid prescription fills, however, there was no change in the use of OVF-associate non-opioid analgesic use.

**CLINICAL RELEVANCE/APPLICATION**

Understanding the effect of KP and VP procedures on trends in opioid use is crucial for long-term pain management strategies in patients with osteoporotic vertebral compression fractures

## R5B-SPIR-6 IMPACT OF AN ENDOVASCULAR SIMULATOR AND VIDEO GAMES ON MEDICAL STUDENT INTERVENTIONAL RADIOLOGY INTEREST AND PROCEDURAL SKILL

Mina S. Makary, MD (*Abstract Co-Author*) Nothing to Disclose
Mina Dawod (*Abstract Co-Author*) Nothing to Disclose
Matthew Yoder (*Abstract Co-Author*) Nothing to Disclose
Mensur Koso, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine if student interactions with an endovascular stimulator will increase confidence performing procedures and interest in interventional radiology (IR) while assessing if past or present video game experience confers procedural skill.

**METHODS AND MATERIALS**

This IRB-approved prospective randomized control study evaluated medical student specialty interest and procedural performance from February to April of 2024. Participants were required to complete a pre-procedure survey and an initial simulated procedure utilizing an endovascular simulator before being randomized to either a Video Game (VG) or control arm. Students then proceeded to complete a second simulated procedure and a post-procedure survey. Before starting the procedure, a standardized explanation was read to each participant. Students randomized to the VG arm would play a video game within a ten-minute slot between the two procedures, while control arm students would rest. Survey data collected included demographic information, history of video gaming, confidence performing endovascular procedures, and interest in procedural specialties. Primary outcomes included self-reported procedural confidence and specialty interest on a five-point scale (five being the highest). Secondary outcomes included procedural skill as measured by time to completion for the simulated procedures.

**RESULTS**

A total of 48 medical students (mean age, 25.8 years; male 58%) participated in this study, with 24 students randomized to the VG arm and the remainder to the control arm. The cohort's average confidence performing procedures prior to participation was 2.4 (out of five), interest in procedural specialties was 4.1, and interest in IR was 2.9. After participation in the study, confidence performing procedures rose by 58% to 3.8 ($p<0.0001$), interest in procedural specialties rose by 7% to 4.4 ($p=0.04$), and interest in IR increased by 27% to 3.6 ($p<0.0001$). The time to completion for the first procedure for the VG group was 4 minutes while for the control it was 3.5 minutes. Time to completion for the second procedure was 3.1 minutes for the VG group compared to 2.5 minutes for control. The differences between the groups were not significant.

**CONCLUSION**

Student confidence performing procedures significantly increased after participating in the study, as did student interest in procedural specialties in general and in IR specifically. A history of video games and prospective VG group participation did not confer procedural skill as measured by time to completion.

**CLINICAL RELEVANCE/APPLICATION**

Increasing medical student confidence performing procedures and improving awareness of IR is critical to setting the foundations for procedural competency and attracting talent to the specialty.

## R5B-SPIR-7 BLEOMYCIN ELECTROSCLEROTHERAPY OF SLOW-FLOW MALFORMATIONS - OUTCOME IN ADULTS AND CHILDREN

Vanessa F. Schmidt, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the safety and clinical outcome of bleomycin electrosclerotherapy (BEST) for treating extracranial slow-flow malformations.

**METHODS AND MATERIALS**

In this retrospective investigation of a multicenter cohort presenting symptomatic slow-flow malformations, patient records were analyzed with respect to procedural details and complications. A treatment-specific, patient-reported questionnaire was additionally evaluated, obtained 3-12 months after the last treatment, to assess the subjective outcomes, including mobility, aesthetic aspects, and pain, as well as the occurrence of postprocedural skin hyperpigmentation. All outcome parameters were compared according to patients' age.

**RESULTS**

Overall, 325 BEST treatments were performed in 233 patients after intralesional and/or intravenous bleomycin injection. The total complication rate was 10.2% (33/325), including 29/352 (8.9%) major complications. Patient-reported mobility decreased in 10/133 (8.8%), was stable in 30/113 (26.5%), improved in 48/113 (42.5%), and was rated symptom-free in 25/113 (22.1%) patients. Aesthetic aspects were rated impaired compared to baseline in 19/113 (16.8%), stable in 21/133 (18.6%), improved in 62/113 (54.9%), and perfect in 11/133 (9.7%) patients. Postprocedural skin hyperpigmentation occurred in 78/113 (69%) patients, remaining unchanged in 24/78 (30.8%), reduced in 51/78 (65.5%), and completely resolved in 3/78 (3.8%) patients. The median VAS pain scale was 4.0 (0-10) preprocedural and 2.0 (0-9) postprocedural. Children/adolescents performed significantly better in all parameters compared to adults (= 16 years) (mobility, $p = 0.011$; aesthetic aspects, $p < 0.001$; pain, $p < 0.001$).

**CONCLUSION**

BEST is effective for treating slow-flow vascular malformations, with few but potentially significant major complications. Regarding patient-reported outcomes, children seem to benefit better compared to older patients, suggesting that BEST should not be restricted to adults.

**CLINICAL RELEVANCE/APPLICATION**

Bleomycin electrosclerotherapy is a safe and effective approach and therapy should not be restricted to adults due to good clinical outcomes in children.

## R5B-SPIR-8 *IN-VITRO*-MR-GUIDED STENTING WITH A NOVEL DEMONSTRATOR USING A PRINTED VENOUS PHANTOM

Klaus During (*Abstract Co-Author*) Nothing to Disclose
Lisa Regler (*Abstract Co-Author*) Nothing to Disclose
Fabian Bamberg, MD, MPH (*Abstract Co-Author*) Speakers Bureau, Bayer AG;Speakers Bureau, Bracco Imaging;Speakers Bureau, Siemens AG;Research Grant, Siemens AG
Wibke Uller, MD (*Abstract Co-Author*) Nothing to Disclose
Michael Bock, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, MaRVis Interventional GmbH
Simon Reiss (*Abstract Co-Author*) Nothing to Disclose
Niklas Verloh, MD (*Presenter*) Speaker, Bayer AG;Research Funded, Bayer AG

**PURPOSE**

MR-guided venous stenting offers 3D vein imaging without ionizing radiation, and improved soft-tissue contrast over X-ray angiography, but MR-safe interventional instruments are lacking. This study uses a realistic pelvic venous phantom to test a new braided venous stent with an MR-compatible delivery system.

**METHODS AND MATERIALS**

A new braided nitinol venous stent (Alaxo, Germany) was tested in combination with an MR-compatible delivery system with repositioning possibility (MaRVis, Germany). This system was compared to a clinically available braided nitinol stent (Blueflow, Plus Medica, Germany) using a realistic phantom of the iliac vein (UnitedBiologics, USA). Positional accuracy was measured by the deviation of the stent's final position from its target. Stent expansion and apposition were assessed by comparing the post-deployment diameter to the nominal diameter and calculating the contact percentage with the vessel wall. Stent migration was evaluated by measuring the stent displacement after deployment. Image quality was determined from the visibility of the stent edges (5-point Lickert scale), and the number of successful repositions was recorded.

**RESULTS**

The two stents were successfully deployed and securely placed within the venous phantom. The delivery system demonstrated easy stent repositionability with a complete success rate of up to three repositioning attempts without compromising stent integrity or placement accuracy. Real-time MR images of the stent deployment with the MR-compatible delivery system had an image clarity of 5/5, clearly visible stent edges, and minimal artifacts. The stents were placed within ±2 mm from the targeted position, and no stent migration was observed. Post-deployment diameter measurements showed a 95% apposition to the vessel walls.

**CONCLUSION**

The study confirmed the feasibility of MR-guided venous stenting using a novel MR-compatible delivery system and a range of nitinol stents. This technique offers a promising non-ionizing alternative to conventional fluoroscopy, providing detailed, real-time 3D visualization of stent deployment and positioning, which is critical for enhancing venous interventions' safety and efficacy.

**CLINICAL RELEVANCE/APPLICATION**

MRI offers a safe alternative with superior soft-tissue contrast, 3D imaging capabilities, and reduced contrast agent use for minimally invasive stenting pelvic venous stenosis, thereby lowering radiation exposure and allergy risks, especially beneficial for younger women.

### PURPOSE

Undifferentiated Pleomorphic Sarcoma (UPS) is a rare, aggressive and heterogenous tumor associated with high frequent recurrence, poor overall survival, and limited treatment options. Neoadjuvant radiotherapy (nRT) has been shown to improve surgery outcomes. However, evaluation of treatment response without surgical pathology remains a challenge. This study aims to correlate the tumor's pathological response with changes in its size measured on MRI scans before and after nRT.

### METHODS AND MATERIALS

In an IRB approved study of 38 patients with pathologically proven UPS, tumor size measurements were collected before and after nRT. Four independent readers, including three trained radiologists and a researcher, performed the measurements, including two perpendicular diameters in the axial plane and the longest vertical diameter. In addition to measurements, three cross-sectional areas and the volume were calculated. Inter-reader agreement was evaluated using Kendall's concordance coefficient. Patients with less or equal than 10% viable cells on pathology were classified as responders (R). Patients who did not meet this criterion were classified as non-responders (NR). Changes in tumor size were compared between responders and non-responders using one-way ANOVA and Tukey's honestly significant difference (HSD) test for multiple comparisons of means.

### RESULTS

The dataset included 14 responders and 24 non-responders. Inter-reader agreement for all size measurements was high (Kendall's $W > 0.85$, $p > 1E-6$). Responders exhibited a significantly greater increase in tumor size across multiple measures compared to non-responders. For example, the percentage change in the longest diameter (RECIST) was +31.9% for responders and +12.4% for non-responders, demonstrating a statistically significant difference of 19.5% (95% CI: 7.2 - 31.8, $p = 0.002$). Similarly, the change in cross-sectional area in the axial plane showed a statistically significant difference. Responders experienced a larger increase (+83.3%) compared to non-responders (+34.5%), with a difference of 48.8% (95% CI: 13.3 - 84.3, $p = 0.007$).

### CONCLUSION

UPS demonstrate an increase in tumor size after nRT, which is counterintuitive to the expected response of tumor shrinkage. Moreover, responders demonstrate a larger increase in size compared to non-responders. These findings were statistically significant across various measurements, including the longest diameter, cross-sectional area in the axial plane, and tumor volume.

### CLINICAL RELEVANCE/APPLICATION

While RECIST criteria may not be a reliable indicator of response to nRT in UPS, this study provides insights that can guide the development of more accurate methods for treatment response assessment in UPS population.

## R5B-SPMK-2 LEVERAGING DEEP LEARNING FOR PREDICTION OF INVOLVEMENT OF POST-SURGICAL TISSUE MARGINS IN SOFT TISSUE SARCOMA USING MULTI-PARAMETRIC MRI

Matthew J. Nyflot, PhD (*Abstract Co-Author*) Nothing to Disclose
Arash Azhideh, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Paul E. Kinahan, PhD (*Abstract Co-Author*) Co-founder, PET/X LLC
Majid Chalian, MD (*Abstract Co-Author*) Grant, The Boeing Company
Atefe Pooyan, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Ehsan Alipour, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

Complete resection of the tumor in treating patients with soft tissue sarcoma (STS) is necessary. Positive tissue margins after resection are one of the most important risk factors for the recurrence of STS. This necessitates the development of strategies that can identify the patients who are at a higher risk for positive tissue margins. We propose a deep learning approach that uses pre and post-neoadjuvant treatment MR images of the tumor to predict the margin status after surgical removal of the tumor.

### METHODS AND MATERIALS

A retrospective cohort of patients with soft tissue sarcoma were selected. We included every patient with soft tissue sarcoma that had at least one pre-neoadjuvant treatment MRI. We extracted the latest MRI before neoadjuvant treatment and the earliest MRI after the neoadjuvant treatment before the resection. We used 4 MR sequences: fat saturated T2, Fat saturated T1 before and after intravenous contrast and T1. Preprocessing steps included resampling, z-score normalization of the intensity values and cropping them using a bounding box around the tumor boundaries that included 1cm of surrounding tissue on each side. Input images were 3D images of size 16*128*128 that had 8 channels, each channel corresponding to an individual sequence for the pre or post treatment images. The data was split into training and testing sets. We fine-tuned a pretrained 3D ResNet10 model to predict if the patient had a positive tissue margin based on the post-surgical biopsy report. 4-fold cross-validation on the training set was used to identify the best model. The final model was tested on the hold-out test set.

### RESULTS

Our cohort included 202 patients (159 training and 44 testing). There were 71 female and 131 male patients. The average age of diagnosis of STS was 54 years old. 52 patients had positive post-surgical tissue margins. The model that used both pre and post neoadjuvant therapy images achieved an AUROC of 0.74 on the hold out test set (57% sensitivity and 69% specificity using the optimum threshold determined using the Youden index) and 0.73 on cross validation. The model using only preneoadjuvant therapy images archived an AUROC of 0.65 on the test set and 0.71 on crossvalidation.

### CONCLUSION

We demonstrated that our 3D ResNet model can predict the involvement of post-surgical tissue margin status in patients with soft tissue sarcoma. We also demonstrated that incorporating post neoadjuvant therapy MR images in addition to pretreatment images can significantly improve the performance of the model.

### CLINICAL RELEVANCE/APPLICATION

Our model could be used in clinical practice to identify patients at a higher risk for post-surgical tissue margin involvement. This can help adjust treatment plans and provide more personalized care to patients with STS.

## R5B-SPMK-3 PREDICTING TREATMENT RESPONSE TO NEOADJUVANT RADIOIMMUNOTHERAPY (NRIT) IN SOFT TISSUE SARCOMA (STS) WITH MRI-BASED RADIOMIC SIGNATURE

Paul E. Kinahan, PhD (*Abstract Co-Author*) Co-founder, PET/X LLC
Matthew J. Nyflot, PhD (*Abstract Co-Author*) Nothing to Disclose
Atefe Pooyan, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Stephanie K. Schaub, MD (*Abstract Co-Author*) Nothing to Disclose
Arash Azhideh, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Majid Chalian, MD (*Abstract Co-Author*) Grant, The Boeing Company
Ehsan Alipour, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

Early prediction of cancer treatment success is crucial for patients, particularly for high-grade soft tissue sarcoma (STS) cases. STS recurrence occurs in about 50% of cases, often leading to unresectable tumors or limb amputation. Given the limited effectiveness of existing STS treatments, there is growing interest in combining neoadjuvant radiotherapy and immunotherapy, termed neoadjuvant radioimmunotherapy (NRIT). In this study, we used radiomics features extracted from multiparametric STS magnetic resonance imaging (MRI) data in combination with radiologist evaluations, clinical data and pathology data to create a model to predict and monitor pathologic treatment response in patients undergoing NRIT.

### METHODS AND MATERIALS

We identified a list of patients with soft tissue sarcoma that had received neoadjuvant therapy and had pretreatment MRI imaging post-excision pathology reports. Regions of interest were manually segmented on each sequence by two radiologists. MRI sequences used included fat saturated T2-weighted images, Fat saturated T1-weighted before and after intravenous contrast administration and T1-weighted images. A list of important semantic radiologic features was extracted by the radiologists as the basis for comparison. Pathologic treatment response was considered good when above 50%. Univariate analysis and 5-fold cross-validation were used. XGBoost method was used to select the relevant features and develop the models. Shapley values were used for model explanation.

### RESULTS

The final cohort consisted of 229 patients (16 on the prospective wing). There were 173 cases in the training set and 40 in the testing set. The mean age of diagnosis was 53 (SD: 15.6) years old. There were 81 female patients compare to 132 male patients. The best performing model was the model that used all radiomics features in addition to the clinical and semantics features. By using 31 features, the mode achieved an AUROC of 0.73 (0.5-0.87) on the hold-out testing set and 0.7 on cross-validation. The Semantics only model achieved an AUROC of 0.65 on cross-validation. The best model achieved an AUROC of 0.63 on the prospective wing of the study that underwent NRIT.

### CONCLUSION

Our findings show that multi-modal radiomics based models can identify patients that are at a higher risk for not responding to neoadjuvant therapy. In addition, we demonstrated that radiomics based models perform at least as well as models based on radiologist evaluations in doing so. Our model can be used in clinical practice to identify patients that are at a higher risk of treatment failure.

**CLINICAL RELEVANCE/APPLICATION**

Our model can be used in clinical settings to identify patients who are at higher risk for bad treatment outcomes and direct treatment planning accordingly.

## R5B-SPMK-4 MRI DERIVED RADIOMICS MODEL FOR PREDICTING INTRATUMORAL TERTIARY LYMPHOID STRUCTURES IN SOFT TISSUE SARCOMA AND ITS PROGNOSTIC VALUE

Dapeng Hao, PhD (*Abstract Co-Author*) Nothing to Disclose
Tongyu Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

Intratumoral tertiary lymphoid structures (TLSs) of soft-tissue sarcoma (STS) is a biomarker associated with immunotherapy effect and prognosis, which is anticipated to be identified noninvasively through radiomics techniques.To develop an MRI-based radiomics model for predicting intratumoral TLSs status and to explore its prognostic value.

**METHODS AND MATERIALS**

This retrospective study included three cohorts from two medical centers between January 2017 and December 2021. The Laoshan and Shinan campus of the Affiliated Hospital of Qingdao University provided the development cohort (n=142) and internal validation cohort (n=58), respectively, while the Provincial Hospital Affiliated to Shandong First Medical University provided the external validation cohort (n=102). The preoperative MRI examinations of 302 patients were evaluated. Intratumoral and peritumoral radiomics features were extracted from axial fat-suppressed T2-weighted imaging and T1-weighted imaging sequences. The intratumoral, peritumoral, and combined radiomics models were built using a logistic regression algorithm. The univariate and multivariate analyses were performed to select independent risk factors from clinical, radiological, and pathological parameters. The performances were evaluated and compared by the area under the receiver operator characteristic curve (AUC) and the Delong test.

**RESULTS**

Among 302 STS patients, 114 (38%) were confirmed as TLSs-positive status. The combined radiomics model achieved the optimal performance than intratumoral model and peritumoral model, with an AUC of 0.878, 0.778, and 0.772 in the development cohort, internal validation cohort, and external validation cohort. Patients in the high Rad-score group (Rad-score = 0.5) showed a longer progression-free survival (PFS) time.

**CONCLUSION**

An MRI-based radiomics model enabled accurate prediction of intratumoral TLS status in STS patients, and this model was also correlated with PFS time.

**CLINICAL RELEVANCE/APPLICATION**

This combined radiomics model can help identify patients who may benefit from immunotherapy. It is beneficial to choose an individualized treatment plan for STS patients.

## R5B-SPMK-6 DIAGNOSTIC ACCURACY OF MRI FOR THE DETECTION OF LOCALLY RECURRENT MUSCULOSKELETAL SOFT TISSUE SARCOMA: SYSTEMATIC REVIEW AND META-ANALYSIS

Aashna Uppal (*Abstract Co-Author*) Nothing to Disclose
James Man Git Tsui (*Abstract Co-Author*) Nothing to Disclose
Soterios Gyftopoulos, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Samir Paruthikunnnan, MBBS (*Abstract Co-Author*) Nothing to Disclose
Natalia Gorelik, MD, FRCPC (*Abstract Co-Author*) Research Grant, General Electric Company
Lora Tzaneva (*Presenter*) Nothing to Disclose

**PURPOSE**

To systematically review the diagnostic accuracy of MRI in detecting local recurrence (LR) of musculoskeletal soft tissue sarcoma (STS).

**METHODS AND MATERIALS**

Medline, Embase, Scopus, and Cochrane CENTRAL were searched for original research studies published in peer-reviewed journals in the English or French language on the diagnostic accuracy of MRI in detecting LR of musculoskeletal STS in adults following curative resection. Study quality was assessed with an adapted QUADAS-2 tool. Per-scan sensitivity and specificity were pooled using a bivariate random-effects model. Diagnostic accuracy values between protocol subgroups were compared using a Chi-squared test.

**RESULTS**

A total of 4821 titles and abstracts were screened. Thirteen studies were included, comprising 10 cohort studies (7 retrospective, 3 prospective) and 3 case-control studies. A total of 2843 patients (mean age 50.2 years) were studied. Eight studies were at risk of bias, and 8 studies also had applicability concerns. The overall pooled sensitivity and specificity of all protocols combined were 85% [95% Confidence Interval 67%-92%] and 93% [85%-97%], respectively. Protocols based on T1 and fluid-sensitive fat-saturated (FS) sequences yielded a pooled sensitivity of 55% [45%-64%] and pooled specificity of 92% [68%-98%]. Protocols based on T1, fluid-sensitive FS, and T1 FS contrast-enhanced sequences achieved a pooled sensitivity and specificity of 88% [69%-96%] and 93% [82%-97%], respectively. Protocols based on T1, fluid-sensitive FS, T1 FS contrast-enhanced, and dynamic contrast-enhanced (DCE) sequences yielded a pooled sensitivity and specificity of 80% [17%-99%] and 90% [66%-98%], respectively. A statistically significant difference (p=0.01) in sensitivity was noted between protocols. There was no statistically significant difference (p=0.93) in specificity between protocols.

**CONCLUSION**

MRI achieves moderate to high sensitivity and high specificity in detecting LR of musculoskeletal STS, although the quantity and quality of evidence is limited. Protocols that include contrast-enhanced sequences improve the sensitivity of MRI examinations in detecting STS LR. Protocols that include DCE sequences do not appear to offer additional diagnostic accuracy benefits when compared to protocols with static contrast-enhanced images alone.

**CLINICAL RELEVANCE/APPLICATION**

MRI offers high accuracy for the detection of musculoskeletal STS LR. Protocols for routine surveillance should include contrast-enhanced sequences to improve early detection of LR and allow for early treatment, although protocols using DCE do not appear to offer higher performance than protocols with static contrast enhancement alone.

## R5B-SPMS-2 ULTRA-HIGH-FREQUENCY ULTRASOUND EVALUATION OF CUTANEOUS TUMORS: CORRELATION WITH DERMOSCOPY AND HISTOLOGY

Leticia Cavalcante (*Abstract Co-Author*) Nothing to Disclose
Laura S. Lima, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana Galupo (*Abstract Co-Author*) Nothing to Disclose
Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ivana Gibbons (*Abstract Co-Author*) Nothing to Disclose
Soraia Damiao, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To describe the sonographic characteristics of cutaneous tumors in ultra-high-frequency (UHF) ultrasound and compare them with dermoscopy and histology.

### METHODS AND MATERIALS

This IRB-approved, prospective, single-center study included patients with suspicious skin lesions before surgical resection. All lesions were documented with clinical and dermatoscopic photos using a specific dermatoscope. Subsequently, UHF ultrasound was performed with a dedicated 24 MHz device (Aplio i800, Canon Medical Systems), and B-mode and Doppler parameters were described. After the ultrasonographic examination, the lesions were excised and sent for histopathological examination. All examinations were performed by a single observer.

### RESULTS

289 lesions were included, comprising 108 benign lesions and 181 malignant lesions, of which 105 were basal cell carcinomas (BCCs), 35 squamous cell carcinomas, 24 melanomas, 2 Merkel cell carcinomas, 15 less common malignant tumors and cutaneous metastases from other tumors. The most frequent benign lesions were melanocytic nevus, dermatofibroma, epidermal cysts, actinic and seborrheic keratoses. Each type of skin lesion had specific imaging features. Most lesions (87.6%) were located in the dermis, 267 (92.9%) were hypoechoic, 245 (84.5%) had homogeneous echotexture, 209 (72.1%) were well-defined, and 146 presented some degree of vascularization (50.3%). All malignant lesions were visualized at UHF ultrasound. In B-mode, benign and malignant lesions appeared as variable shapes with no statistically significant differences between the two groups in these criteria; the main difference was observed in Doppler mode. Vascularization was more frequent in malignant lesions, being the most relevant ultrasonographic parameter for differentiating malignant and benign lesions.

### CONCLUSION

UHF ultrasound proved useful in assessing skin tumors, supporting diagnosis, staging, assessing therapeutic response, and surveillance. However, it's still not possible to differentiate the main skin tumors based only on sonographic criteria. Therefore, the correlation between dermoscopy and histology is necessary for a definitive diagnosis.

### CLINICAL RELEVANCE/APPLICATION

Ultra-high-frequency ultrasound, particularly at 24 MHz or higher, is a valuable tool in the assessment of skin tumors. It aids in the diagnosis process, helps in cancer staging, response evaluation to therapy, and assists in follow-up after treatment.

## R5B-SPNMMI-1 THE PROGNOSTIC VALUE OF EARLY TREATMENT RESPONSE ASSESSMENT WITH 177LU-PSMA WHOLE-BODY-SCINTIGRAPHY IN COMPARISON TO INTERIM PSMA-PET

Kambiz Rahbar (*Abstract Co-Author*) Nothing to Disclose
David Ventura (*Abstract Co-Author*) Nothing to Disclose
Philipp Schindler, MD (*Abstract Co-Author*) Nothing to Disclose
Wolfgang Roll (*Presenter*) Nothing to Disclose

### PURPOSE

PSMA-PET is an essential tool for patient selection prior to radioligand therapy (RLT), interim staging and follow up to monitor therapy. The value of post therapeutic whole-body scans (WBS) after injection off 177Lu-PSMA is underestimated. The aim of this study was to compare early response to treatment as assessed by post-therapeutic WBS with interim staging by PSMA-PET after 2 cycles to predict overall survival (OS)

### METHODS AND MATERIALS

Patients with metastatic castration resistant prostate cancer, who received at least two cycles of RLT, and interim PSMA-PET were retrospectively evaluated. The PROMISE V2 framework was used to categorise PSMA expression and assess response to treatment. Response was defined as either disease control in responders (DCR) or disease progression in those failing to respond.

### RESULTS

A total of 188 men treated with RLT between February 2015 and December 2021 were included. The comparison of various imaging modalities showed a robust and statistically significant correlation, as determined by the Cramer V test: e. g. response on WBS during second cycle compared to first interim PET (cf = 0.888, $P < 0.001$, n = 188). The median follow-up time was 14.7 months (range: 3-63 months; 125 deaths occurred). Median OS was 14.5 months (95% CI: 11.9-15.9). Early response assessment was associated with a significantly better OS: e.g. DCR of second cycle WBS (24 vs 13 months, $P < 0.001$) with a HR of 2.81 ($P < 0.001$) or DCR of interim PET after 2 cycles (24 vs 11 months, $P < 0.001$) with a HR of 3.5 ($P < 0.001$). A decline of at least 50% in PSA levels after two cycles of RLT also indicates a significantly lower likelihood of death (26 vs 17 months, $P < 0.001$) with a HR of 1.92 ($P = 0.001$).

### CONCLUSION

Routinely acquired WBS after RLT with 177Lu-PSMA can be used for interim analysis with comparable results to PSMA-PET and can identify patients at risk of poor outcomes.

### CLINICAL RELEVANCE/APPLICATION

Response prediction and early response assessment is warranted during radioligand therapies to prevent patients from unnecessary treatment related side effects and radiation exposure. Routinely acquired whole body scans after injection of 177Lu-PSMA provide comparable results to more cost-intensive PSMA-PET.

We describe the framework and data characteristics for establishing body region- and clinical indication-based diagnostic reference levels (DRL) and achievable doses (AD) for pediatric CT in the Middle East and North Africa (MENA).

### METHODS AND MATERIALS

Our project in partnership with Middle East Federation of Organizations of Medical Physics included 34 imaging sites from 17 countries in the MENA region, who contributed following data on 7917 pediatric patients (<19 years; F:M, 3168:4749) who had head (n=2979), chest (n=1770), abdomen-pelvis (AP, n=1943) or chest-abdomen-pelvis (CAP; n=1225) CT: patients' age, sex, weight, clinical indication for CT, CT scanner information, scan factors (tube current and potential), and radiation doses [volume CT dose index (CTDIvol) and dose length product (DLP)]. We estimated overall and site-specific 50th (AD) and 75th (DRL) percentile CTDIvol and DLP separately for each body region and clinical indication. Non-normal data were compared using the Kruskal-Wallis test.

### RESULTS

Most CT exams in children regardless of age groups were single phase acquisition without or with intravenous contrast (head CT 92%; chest CT 86%-91%; AP-CT 76%-85%) as opposed to 50% multiphase CAP-CT in all age groups. There was a significant variation in CTDIvol and DLP between the participating sites for body regions and clinical indications in all age groups (p=0.001). The protocol- and age group-matched MENA protocol-based ADs and DRLs were significantly higher (more than 50%) than the US levels. The head, chest, and AP-CT DLP DRLs were higher than the corresponding DLP DRLs in the US for 23/34 (68%), 21/34 (62%) and 23/34 (68%) of participating sites. There were significant differences in radiation doses across different CT scanner vendors (p<0.001). The low-income countries (LICs) had higher doses compared to middle- and high-income countries (HMIC): head (median LIC CTDIvol: 50 vs 40mGy for HMIC), chest (median LIC CTDIvol: 6 vs 4mGy for HMIC), AP (median LIC CTDIvol: 6.24 vs 4.9mGy for HMIC), CAP (median LIC CTDIvol: 51 vs 40mGy for HMIC) CT exams (p=0.001)

### CONCLUSION

Economic disparities and scanner distribution have a profound effect on the variations and use of higher radiation doses across the MENA regions with several-fold higher radiation doses for children scanned in low-income countries as compared with the high- and middle-income countries.

### CLINICAL RELEVANCE/APPLICATION

Socioeconomic factors resulting in higher radiation doses in MENA region warrant efforts on radiation dose education with incorporation of clinical indication-based protocols and upgrade of CT technology.

## R5B-SPNPM-2 CHANGING GADOLINIUM-BASED CONTRAST AGENTS TO PREVENT RECURRENT ADVERSE DRUG REACTIONS: PROPENSITY-MATCHED 6-YEAR COHORT STUDY

Ah Young Kim, MD (*Abstract Co-Author*) Nothing to Disclose

Minwoo Han (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the preventive effect of changing the previous gadolinium-based contrast agents (GBCAs) for reducing the recurrence of GBCA-associated acute adverse drug reactions (ADRs).

### METHODS AND MATERIALS

This retrospective, observational, single-center study included patients who underwent GBCA-enhanced MRI examinations from January 2016 to December 2021, and had a history of acute GBCA-associated ADRs in the examination. Baseline participant characteristics, generic profile of GBCA, administration of premedication, history of prior ADR to iodine contrast agent, and symptoms of GBCA-associated acute ADRs were retrospectively analyzed. Multivariable logistic regression with generalized estimating equations and propensity score matching were used to adjust for selection bias.

### RESULTS

Among 238,743 examinations, 1,042 acute ADRs (0.44%; 95% CI: 0.41%-0.46%) were reported. Among them, a total of 373 patients who underwent 1,412 follow-up GBCA-enhanced MRI examinations were included. The overall recurrence rate was 31.9% (119/373). Multivariable logistic regression analysis revealed that the ADR recurrence rate was significantly lower in the GBCA change group (adjusted OR, 0.31; 95% CI: 0.12-0.77; P=0.012). After adjustment with propensity score matching, the recurrence rate was significantly lower in the GBCA change group than the GBCA non-change group (14.3% [6/42] vs. 36.9% [31/84], respectively; OR, 0.29 [95% CI: 0.11-0.77]; P=0.003). A history of ADR to iodinated contrast media (OR, 1.14; 95% CI: 0.68-1.90; P=0.62) and premedication (adjusted OR, 2.05; 95% CI: 0.92-4.58; P=0.081) did not significantly influence GBCA-associated ADR recurrence. In per exam analysis, multivariable logistic regression analysis also revealed that the ADR recurrence rate was significantly lower in the GBCA change group (adjusted OR, 0.36; 95% CI: 0.17-0.79; P=0.011). Subgroup analyses for recurrent hypersensitivity reactions demonstrated similar results.

### CONCLUSION

Changing the previous GBCA can effectively reduce the rate of recurrence of GBCA-associated adverse drug reactions, as shown with propensity-score-matched analysis.

### CLINICAL RELEVANCE/APPLICATION

Changing the previous gadolinium-based contrast agents (GBCA) is effective for lowering the recurrence rate of GBCA-associated adverse drug reactions, and the result was consistent after propensity score matching.

## R5B-SPNR-1 ATLAS OF LOCATION-PROGNOSIS CORRELATION IN IDH WILD-TYPE GLIOBLASTOMA: UNVEILING INSIGHTS THROUGH A VOXEL-WISE COX REGRESSION ANALYSIS WITH OPEN-SOURCE DATASETS

Yukio Miki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Natsuko Atsukawa (*Abstract Co-Author*) Nothing to Disclose
Hiroyuki Tatekawa, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The impact of the glioblastoma's location on prognosis remains insufficiently explored, despite its potential importance in prognostic prediction. This study examined the correlation between tumor location and prognosis in cases of glioblastoma, employing MRI of IDH wild-type glioblastoma from The Cancer Imaging Archive.

### METHODS AND MATERIALS

A total of 769 subjects with IDH wild-type glioblastoma from the UCSF-PDGM and UPENN-GBM datasets were included for survival analysis. Patient/tumor demographics such as age, sex, MGMT methylation status, and tumor volume were used for the covariates of the subsequent analysis. After registration of every tumor ROI to the MNI standard space, a voxel-wise Cox regression analysis was conducted to create a hazard ratio (HR) map indicating the association of the tumor's presence or absence with prognosis in each voxel, adjusting for the covariates. Voxels that showed statistically significant were visualized. To validate the voxel-wise Cox regression model, subjects were classified into two groups based on whether the tumor ROIs of each subject overlapped the high/low HR regions to differentiate short- and long-term overall survival (OS) using the log-rank test.

### RESULTS

The HR map revealed that tumors in the medial frontobasal region and around the third to fourth ventricles were associated with worse prognosis in both datasets, underscoring the challenges in complete resection and treatment accessibility in these areas. Conversely, tumors located in the right temporal and occipital lobes exhibited favorable impact on prognosis, likely due to the potential for more extensive resection in the non-dominant hemisphere. Subjects whose tumor ROIs overlapped high HR regions showed significantly shorter OS in both datasets (both $p < 0.05$), while subjects whose tumor ROIs overlapped low HR regions showed significantly longer OS in UPENN-GBM dataset ($p = 0.002$). The log-rank test supported the results of the voxel-wise Cox regression model.

### CONCLUSION

This study represents a substantial step forward in our understanding of IDH wild-type glioblastomas, especially regarding the influence of tumor location on prognosis. Subjects with glioblastomas located in the medial frontobasal region and around the third to fourth ventricle were identified to have a poor prognosis, whereas subjects with glioblastomas in the right temporal and occipital lobes had a favorable prognosis.

### CLINICAL RELEVANCE/APPLICATION

This study highlights the correlation between tumor location and prognosis in IDH wild-type glioblastoma, revealing areas associated with better or worse outcomes. These insights can guide clinicians in tailoring treatment plans, potentially improving glioblastoma patient management.

## R5B-SPNR-11 MACHINE LEARNING ALGORITHMS WITH MAGNETIC RESONANCE IMAGING FOR DIAGNOSING IDIOPATHIC PARKINSON'S DISEASE: A DIAGNOSTIC ACCURACY META-ANALYSIS

Ahmed Benghatnsh (*Abstract Co-Author*) Nothing to Disclose
Abdelmohimen Adel M Elkhadar (*Abstract Co-Author*) Nothing to Disclose
Muhammed Elhadi (*Abstract Co-Author*) Nothing to Disclose
Ahmed Msherghi, MBBCh (*Presenter*) Nothing to Disclose

### PURPOSE

Idiopathic Parkinson's disease (IPD) is a common neurodegenerative disorder with a gradual onset and varying progression. Diagnosis relies solely on clinical criteria, often resulting in many cases remaining undiagnosed during the prodromal phase until the motor phase appears. Magnetic Resonance Imaging (MRI) has traditionally been used to exclude other diagnoses in suspected IPD cases. Recent advancements in MRI technology have sparked discussions on its potential role in IPD diagnosis. While some studies have explored Artificial Integration (AI) integration in MRI scans for of diagnosing IPD, a conclusive meta-analysis of its accuracy and practicality is needed.

**METHODS AND MATERIALS**

A systematic search was conducted in PubMed, EMBASE, Web of Science, and IEEE from inception to April 2024, focusing on the application of AI-integrated MRI for diagnosing IPD. Statistical analysis was carried out using R software (version 4.0.3) with the mada package. The analysis will explore sensitivity, specificity, false-positive rates, diagnostic odds ratio, and both positive and negative Likelihood Ratios (LRs), each with a 95% Confidence Interval (CI).

**RESULTS**

This analysis included 12 studies involving 3765 participants, with 2375 confirmed cases of IPD. The pooled sensitivity and specificity of AI-integrated MRI scans for identifying brain features of IPD were determined to be 83% (95% CI: 69-92%, I2=98.6%) and 85% (95% CI: 81.3-88.2%, I2=73.5%), respectively. The false-positive rate was reported as 15% (95% CI: 11.8-18.7%). The diagnostic odds ratio was calculated as 27.9 (95% CI: 10.60-73.41). The positive and negative Likelihood Ratios were found to be 5.57 (95% CI: 4.02-7.73) and 0.20 (95% CI: 0.10-0.39), respectively.

**CONCLUSION**

This study demonstrated the accuracy of AI-based algorithms in diagnosing Idiopathic Parkinson's disease through MRI scans.

**CLINICAL RELEVANCE/APPLICATION**

This study suggests that AI could be a beneficial addition in diagnosing Idiopathic Parkinson's disease. However, given the variability between studies, additional longitudinal large-scale studies are necessary to evaluate the practicality in clinical environments.

## R5B-SPNR-12 T1 PRE- AND POST-CONTRAST DELTA HISTOGRAM PARAMETERS IN PREDICTING THE GRADE OF MENINGIOMA AND THEIR RELATIONSHIP TO KI-67 PROLIFERATION INDEX

Hong Liu (*Abstract Co-Author*) Nothing to Disclose
Tao Han (*Abstract Co-Author*) Nothing to Disclose
Liu Xianwang (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the feasibility of delta histogram parameters (including absolute delta histogram parameters (AdHP) and relative delta histogram parameters (RdHP)) in predicting the grade of meningioma and to further investigate whether delta histogram parameters correlate with the Ki-67 proliferation index.

**METHODS AND MATERIALS**

Ninety-two patients with meningioma who underwent MRI examination (including T1-weighted (T1) and contrast-enhanced T1-weighted images (T1C)) were enrolled in this retrospective study. A total of 46 low-grade cases formed the low-grade group (grade 1, LGM), and a total of 46 high-grade cases formed the high-grade group (38 grade 2, 8 grade 3, HGM). Histogram parameters (HP) of T1 and T1C were extracted. Subsequently, morphological MRI features, AdHP (AdHP=T1CHP-T1HP), and RdHP (RdHP=(T1CHP-T1HP)/T1HP) were recorded and compared, respectively. Binary logistic regression analysis was used to obtain the combined performance of the significant parameters. Diagnostic performance was identified by ROC. Spearman's correlation coefficients were taken to assess the relationship between delta histogram parameters and the Ki-67 proliferation index.

**RESULTS**

In morphological MRI features, HGM is more prone to lobulation and necrosis/cystic changes (all $p<0.05$). In delta histogram parameters, HGM exhibits a higher mean, Perc.01, Perc.25, Perc.50, Perc.75, Perc.99, SD, and variance of AdHP, maximum, mean, Perc.25, Perc.50, Perc.75, and Perc.99 of RdHP, compared with LGM (all $p<0.00357$). The optimal predictive performance was obtained by combining morphological MRI features and delta histogram parameters with an AUC of 0.945. Significant correlations were observed between significant delta histogram parameters and the Ki-67 proliferation index (all $p<0.05$).

**CONCLUSION**

Delta histogram parameter is a promising potential biomarker, which may be helpful in noninvasive predicting the grade and proliferative activity of meningioma.

**CLINICAL RELEVANCE/APPLICATION**

Non-invasive prediction of the grade and proliferative activity of meningioma is of great clinical importance. Delta histogram parameter is a potential biomarker for the assessment of meningioma. Both AdHP and RdHP help predict the grade and proliferative activity of meningioma. The combined variable integrating conventional MRI features and delta histogram parameters yielded optimal diagnostic performance.

## R5B-SPNR-14 SIMULTANEOUS NEUROMELANIN AND NIGROSOME1 IMAGING USING A SINGLE 3D MULTI-ECHO GRE SEQUENCE

Hwan Heo, MENG (*Abstract Co-Author*) Nothing to Disclose
Jeongwon Jo (*Abstract Co-Author*) Nothing to Disclose
Aleum Lee, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Sung-Min Gho, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

We proposed a single 3D multi-echo GRE sequence for simultaneous neuromelanin (NM) and nigrosome1 (N1) imaging. This method utilizes product sequences without requiring any sequence modifications, and can be executed within a practically acceptable scan time (~5 min). Additionally, deep learning based analyses are applied to differentiate Parkinson's disease (PD) patients from controls, detect and segment the loss of the swallow tail sign, and identify changes in NM signal.

**METHODS AND MATERIALS**

Data acquisition We modified the previously proposed N1 imaging protocol to simultaneously obtain NM contrast by incorporating two spatial saturation pulses available in the product sequences of all vendors for magnetization transfer weighting. In total, 25 datasets (non-PD:16 PD: 9) were acquired using the scan protocol on 3T MRI scanners. Image processing analysis For N1 contrast, susceptibility map weighted images (SMWI) were reconstructed using data from the last three echoes. For NM contrast, magnitude images from the first echo were utilized. We quantified N1 and NM using models based on convolutional neural networks. A segmentation model was developed for the substantia nigra (SN), and a parcellation model was created for the spatial normalization of NM images. Additionally, we trained a model to locate and detect abnormalities in N1. For idiopathic PD (IPD), the reference standard was derived from 18F-FP-CIT PET findings.

**RESULTS**

The images from the non-PD display clearer NM contrasts compared to those from the IPD patients. The measured NM volume/Intracranial volume values were 3.04 and 2.54, respectively, indicating that NM volumes are relatively larger in non-PDs compared to IPD patients. Additionally, the comparative results of the N1 diagnostic performance, based on the 18F-FP-CIT PET scan results, show a sensitivity of 90%, specificity of 93%, positive predictive value of 90%, negative predictive value of 93%, and an accuracy of 92%. Clear swallow tail signs were observed in the non-PDs. However, the loss of the swallow tail sign was detected in the IPD patients on both sides.

**CONCLUSION**

We demonstrated that the proposed method for simultaneous NM and N1 imaging provides reliable estimates of NM-related volumes of the SN and detects the N1 regions within a practically acceptable scan time (~5 min). Our method, which is based on product sequences, will be easily compatible with equipment from most MRI vendors.

**CLINICAL RELEVANCE/APPLICATION**

Our proposed method has clinical significance as it allows for the simultaneous acquisition of images with two types of contrast (i.e. NM N1) in a reasonable scan time, which is particularly advantageous for PD patients who generally cannot undergo long scan times.

## R5B-SPNR-16 QUANTITATIVE ASSESSMENT OF MENINGIOMA CONSISTENCY USING SYNTHETIC MRI

Osamu Togao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kousei Ishigami, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Koji Yamashita, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kazufumi Kikuchi, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Preoperative prediction of meningioma consistency is important for surgical planning. The purpose of this study was to determine whether the quantitative assessment using synthetic MRI (SyMRI) can predict meningioma consistency.

**METHODS AND MATERIALS**

Eighteen patients with meningioma (3 men and 15 women, median age 63 years) were included in the study. SyMRI was performed using 3T MRI with a 2D multi-dynamic multi-cho sequence. The SyMRI software (version 11.3) was used to acquire various quantitative maps, and regions of interest were placed in all slices of the tumor. The evaluation parameters were T1-, T2-values, and proton density. For comparison with the conventional method, mean values of tumor-to-thalamus signal intensity ratio on T1-weighted image (T1R), on T2-weighted image (T2R), and ADC generated from b-values 0 and 1000 s/mm2 of the DWI were also evaluated. The 10th, 25th, 50th, 75th, 90th percentiles, and the mean were calculated as histogram analysis. The consistency of meningiomas was evaluated intraoperatively by neurosurgeons using a 5-point scale according to the grading method of Zada et al. Meningiomas with a score of 3 or more were classified as hard, while those with a score of 1 or 2 were classified as soft. Statistical analysis was performed using the Mann-Whitney U test and receiver operating characteristic (ROC).

**RESULTS**

Soft meningiomas showed significantly longer T1 and T2 relaxation times and higher proton density compared to hard meningiomas (T1: 2701 ms vs. 1721 ms in the 90th percentile, P = 0.0007; T2: 111 ms vs. 94 ms in the mean, P = 0.0266; proton density: 92% vs. 85% in the 25th percentile, P = 0.0059). On ROC analysis, the 90th percentile value of T1 showed the best diagnostic performance (area under the curve 0.94). No significant differences were found in the other parameters.

**CONCLUSION**

Quantitative assessment using SyMRI could predict meningioma consistency.

**CLINICAL RELEVANCE/APPLICATION**

Preoperative assessment using synthetic MRI can optimize the surgical plan, including reducing bleeding and shortening operative time for patients with meningioma.

## R5B-SPNR-18 DIAGNOSTIC PERFORMANCE OF RADIOMICS IN PREDICTION OF KI-67 INDEX STATUS IN MENINGIOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Hamed Ghorani, MD (*Abstract Co-Author*) Nothing to Disclose
Mohammad Mohammadi (*Abstract Co-Author*) Nothing to Disclose
Sina Zakavi (*Abstract Co-Author*) Nothing to Disclose
Houman Sotoudeh, MD (*Abstract Co-Author*) Nothing to Disclose
Nima Broomand Lomer, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The Ki-67 marker serves as an indicator of tumor proliferation and is associated with the prognosis of meningiomas. Radiomics demonstrates potential in predicting both the grades of meningiomas and the status of Ki-67 index. Our meta-analysis aims to assess the diagnostic performance of radiomics in predicting Ki-67 index status within meningiomas.

**METHODS AND MATERIALS**

Following a systematic exploration of databases including Web of Science, PubMed, Embase, and Scopus, coupled with rigorous screening procedures, eligible studies underwent meticulous data extraction and evaluation of bias risk utilizing QUADS-2, RQS, and METRICS checklists. Sensitivity analysis was conducted employing the leave-one-out method, while assessment of publication bias involved contour-enhanced funnel plots and the trim and fill method. Pooled sensitivity, specificity, positive likelihood ratios (PLR), negative likelihood ratios (NLR), and diagnostic odds ratio (DOR) were computed. The summary receiver operating characteristic (SROC) curve was generated to assess overall accuracy. Subgroup analyses were performed to identify potential sources of heterogeneity.

**RESULTS**

The meta-analysis comprised eight studies, yielding pooled sensitivity and specificity estimates of 69% (95% CI [60%, 76%], I2 = 39%, p = 0.12) and 85% (95% CI [80%, 89%], I2 = 42%, p = 0.1), respectively. Correspondingly, the DOR, PLR, and NLR were computed as 13.01 (95% CI [8.40, 20.14]), 4.31 (95% CI [3.23, 5.77]), and 0.39 (95% CI [0.31, 0.50]), respectively. Notably, no indication of publication bias was detected (p = 0.565), and sensitivity analysis revealed no outliers. The median RQS score was 17.5 (48.6%), while the mean METRICS score stood at 78%. Employing the

QUADAS-2 tool, four studies were classified as low risk, and an equal number were categorized as high risk. Subgroup analysis delineated the superior performance of multiparametric MRI sequences in contrast to single sequences.

**CONCLUSION**

Radiomics exhibits considerable promise in predicting the Ki-67 index status among meningioma patients, thus potentially serving as a valuable instrument to enhance clinical decision-making and the management of meningioma cases.

**CLINICAL RELEVANCE/APPLICATION**

Radiomics analysis emerges as a pivotal tool in managing meningioma patients, predicting Ki-67 index status and enhancing prognostic evaluations. Multiparametric MRI sequences outperform single-sequence approaches, suggesting potential for refining imaging protocols and improving diagnostic accuracy and treatment stratification.

## R5B-SPNR-4 DEEP LEARNING-BASED QUANTIFICATION OF T2-FLAIR MISMATCH SIGN: EXTENDING IDH MUTATION PREDICTION IN ADULT-TYPE DIFFUSE LOWER-GRADE GLIOMA

Sun Won Park, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyu Sung Choi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Young Hun Jeon (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the predictive value of quantitative T2-FLAIR mismatch ratio (qT2FM) using fully automated tumor segmentation in adult-type diffuse lower-grade glioma (LGG).

**METHODS AND MATERIALS**

This single-center retrospective study included 218 consecutive patients (mean age, 47 years ± 15 [SD]; 125 male) diagnosed with adult-type diffuse LGG (WHO grade 2 and 3) from January 2011 to August 2021. The cohort was classified into three molecular subtypes: IDH wildtype (IDHwt), IDH mutant and 1p/19q codeletion (IDHmut-Codel), and IDH mutant and no 1p/19q codeletion (IDHmut-Noncodel). Tumor masks for quantitative T2FM analysis were obtained via deep learning-based tumor segmentation of pre- and post-contrast T1-weighted, T2-weighted, and FLAIR images. The qT2FM was calculated as the difference in normalized signal intensity ratios between T2 and FLAIR images at the tumor and normal-appearing white matter (NAWM). Multivariate logistic regression was used to identify significant predictors for distinguishing IDHmut-Noncodel from other molecular subtypes and for assessing IDH mutation status. Correlation analyses were conducted between qT2FM, vT2FM, and median apparent diffusion coefficient (ADC) value. Diagnostic performance was evaluated using the area under the receiver-operating characteristic curve (AUC).

**RESULTS**

The IDHmut-Noncodel group exhibited a higher qT2FM (0.37 ± 0.38, P = .004), compared to the other two groups, with IDHmut-Codel and IDHwt (0.24 ± 0.39 and 0.07 ± 0.62, respectively). Multivariate logistic regression revealed qT2FM as the only significant imaging predictor for distinguishing IDHmut-Noncodel from other groups (odds ratio [OR] 3.43, 95% CI; 1.30-9.05, P = .01). Additional significant predictors of IDH mutation included younger age, frontal lobe location, cortical involvement, and higher qT2FM. Significant correlations were observed between qT2FM and vT2FM (rpb = 0.214, P = .003) as well as median ADC value (R = 0.339, P < .001). The combined AUC of qT2FM and vT2FM provided superior diagnostic performance in identifying both IDHmut-Noncodel (AUC, 0.77, P = .005) and IDH mutation status (AUC, 0.77, P = .004), compared to using each parameter alone.

**CONCLUSION**

Quantification of T2-FLAIR mismatch ratio, derived from deep learning-based tumor segmentation, provides valuable predictive information for identifying IDH mutation and diagnosing IDHmut-Noncodel in patients with adult-type diffuse LGGs.

**CLINICAL RELEVANCE/APPLICATION**

The integration of qT2FM into clinical protocols may enhance diagnostic accuracy and influence treatment strategies, emphasizing the growing relevance of advanced imaging techniques in neuro-oncology.

## R5B-SPNR-6 PERFUSION TO THE RESCUE! DISTINGUISHING HIGH-GRADE AND LOW-GRADE GLIOMAS USING PERCENTAGE SIGNAL RECOVERY

Rohin Sharma, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Conventional MRI provides anatomic information about brain tumors however it does not provide information about their microstructure, such as microvasculature, neoangiogenesis, or cellularity. Perfusion MRI acts as a surrogate marker for tumor angiogenesis and addresses these drawbacks. The commonly used perfusion parameters include Cerebral blood volume (CBV) and flow (CBF), which are a measure of the neovascularization of malignant tissue. Percentage signal recovery (PSR) is a novel perfusion parameter that assesses the percentage drop of signal intensity post-contrast administration and is a measure of a multitude of factors; rate of flow of blood, amount of extravascular space, and leakage of contrast through the neovessels, and hence, unlike CBV/CBF, it assesses capillary permeability.There is a dearth of literature on the utility of PSR on a 3T scanner to distinguish high and low-grade gliomas.

**METHODS AND MATERIALS**

24 adults with primary intracranial gliomas were assessed with perfusion MRI on a 3T scanner and classified into high or low-grade based on the perfusion findings. The results were ultimately compared with the final histopathological grade. Classification of tumors based on PSR was compared with that of conventional perfusion parameters CBV and CBF, and their values relative to normal brain parenchyma.

**RESULTS**

Histopathologically, 15 out of 24 were proven high-grade and 9 were low-grade gliomas. Amongst conventional MRI parameters, only diffusion restriction could significantly differentiate high-grade from low-grade gliomas.Percentage signal recovery was found to be the best parameter to distinguish high-grade gliomas from low-grade, with a sensitivity and specificity of 100% and AUC of 1 at a cut-off of 78%. This was followed by rPSR with a diagnostic accuracy of 88%. rCBV and rCBF had diagnostic accuracies of 79% each while CBV had an accuracy of 71%. CBF could not statistically significantly distinguish the two groups.

**CONCLUSION**

Amongst the various perfusion MRI parameters, PSR fared better than conventional MRI and other perfusion MRI parameters in distinguishing high-grade from low-grade gliomas, with a diagnostic accuracy of 100% at a cut-off value of 78%.

**CLINICAL RELEVANCE/APPLICATION**

Perfusion MRI and percentage signal recovery may be considered for preoperative assessment and grading of primary intracranial gliomas in a non-invasive manner which can help in better patient management and operative planning.

## R5B-SPNR-7 UTILIZING MACHINE LEARNING TECHNIQUES ON MRI RADIOMICS TO IDENTIFY PRIMARY TUMORS IN BRAIN METASTASES

Weilin Yang (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to create a machine learning-based model, utilizing both clinical and radiomics data, to predict the primary origin of brain metastases using multiparametric magnetic resonance imaging (MRI).

**METHODS AND MATERIALS**

A retrospective analysis of 202 patients (87 males, 115 females) with a total of 439 brain metastases was conducted. Patients were categorized into training sets (brain metastases originating from lung cancer [BMLC] n=194, brain metastases originating from breast cancer [BMBC] n=108, brain metastases originating from gastrointestinal tumors [BMGiT] n=48) and test sets (BMLC n=50, BMBC n=27, BMGiT n=12). Quantitative image features (3404 in total) were extracted via semi-automatic segmentation from MRI scans (T1WI, T2WI, FLAIR, and T1-CE). Inter-rater reliability was assessed using the intra-class correlation coefficient (ICC). Radiomics features were selected employing analysis of variance (ANOVA), recursive feature elimination (RFE), and Kruskal-Wallis test. Three machine learning classifiers were utilized to construct the radiomics model, which was validated through five-fold cross-validation on the training set. A combined model incorporating both radiomics and clinical features was developed, and its diagnostic performance was assessed using area under the curve (AUC) and evaluated in an independent test set.

**RESULTS**

The radiomics model accurately differentiated BMGiT from BMLC (13 features, AUC = 0.915 ± 0.071) or BMBC (20 features, AUC = 0.954 ± 0.064). However, classification between BMLC and BMBC was less satisfactory (11 features, AUC = 0.729 ± 0.114). Nevertheless, the combined model improved predictive performance, achieving AUC values of 0.965 for BMLC vs. BMBC, 0.991 for BMLC vs. BMGiT, and 0.935 for BMBC vs. BMGiT.

**CONCLUSION**

The machine learning-based radiomics model exhibits promising capabilities in discerning the primary sites of brain metastases, potentially aiding in the identification of the primary tumor in cases where the history of the primary tumor is unavailable but brain metastasis is suspected.

**CLINICAL RELEVANCE/APPLICATION**

- Machine learning radiomics models offer predictive insights into brain metastasis tumor types.
- Quantitative features extracted from multiparametric MR images can serve as valuable biomarkers for tumor classification.
- Integration of clinical features with radiomics models enhances diagnostic accuracy.

## R5B-SPNR-8 ASSOCIATION OF GYMPHATIC SYSTEM DYSFUNCTION WITH SLEEP DISORDERS IN PARKINSON'S DISEASE

Teng Zhang (*Abstract Co-Author*) Nothing to Disclose
Yuting Li (*Presenter*) Nothing to Disclose

**PURPOSE**

Parkinson’s disease (PD) is a prevalent neurodegenerative disease characterized by abnormal deposition of a-syn proteins, which is closely associated with the glymphatic system dysfunction. During sleep period, the glymphatic system is more effective, and thus is susceptible to sleep disorders. Sleep disorders are considered as most common complications in PD. However, the relationship between sleep disorders and glymphatic system dysfunction in PD patients remains unknown. This study aims to investigate the impact of sleep disorders on glymphatic system in PD using a non-invasive imaging technique called diffusion tensor image analysis along the perivascular space (DTI-ALPS).

**METHODS AND MATERIALS**

A total of 123 PD patients and 55 healthy controls (HCs) underwent sleep questionnaires and MRI examinations as part of data collection from the Parkinson’s Progression Markers Initiative cohort. ALPS indices were compared between PD patients and HCs, as well as between PD patients with and without sleep disorders. Correlation was assessed between ALPS index and clinical characteristics. Furthermore, a 2-year follow-up analysis was performed to explore longitudinal impact of sleep disorders on glymphatic system function and disease progression.

**RESULTS**

PD patients showed significantly decreased ALPS indices compared with HCs (P=0.042). Within PD patients, ALPS index negatively correlated with duration (P=0.030), GDS (P=0.023), SCOPA-AUT (P=0.010), and MDS-UPDRS Total Score (P=0.007). PD patients with sleep disorders showed slightly decreased ALPS index compared with those with normal sleep (P=0.262). During follow-up, 10 patients transitioned from having normal sleep to experiencing sleep disorders, showing significant decreased ALPS index compared to baseline (P=0.028). In these patients, ?ALPS/T was negatively correlated with ?MOCA/T (P=0.004). In contrast, patients who maintained normal sleep showed no significant difference in ALPS index between baseline and follow-up (P=0.74).

**CONCLUSION**

Sleep disorders may contribute to dysfunction of glymphatic system and disease progression in PD patients, as indicated by ALPS index. Therefore, more attention should be devoted to addressing sleep disorders in order to prevent disease progression of PD.

**CLINICAL RELEVANCE/APPLICATION**

This study revealed the pathway of “sleep disorder-glymphatic system dysfunction-disease progression” in PD patients by employing the ALPS index. These findings emphasized the significance of addressing sleep disorders in treatment of PD.

## R5B-SPPD-1 STUDY OF MALE AND FEMALE DIFFERENCES IN IRON CONTENT IN NORMAL NEWBORN BRAIN BASED ON QUANTITATIVE SUSCEPTIBILITY MAPPING (QSM)

Xueyan Zhang (*Abstract Co-Author*) Nothing to Disclose
Shumeng Zhu (*Abstract Co-Author*) Nothing to Disclose
Yi Zhu (*Abstract Co-Author*) Nothing to Disclose
Xing Li (*Presenter*) Nothing to Disclose

### PURPOSE

Iron plays a crucial role in brain development, influencing cognitive and motor functions. This study utilizes Quantitative Susceptibility Mapping (QSM) to examine magnetic susceptibility in various nuclear clusters of male and female neonates. By investigating gender differences in brain iron content during the neonatal period, this research seeks to enhance our understanding of gender-specific neurodevelopmental pathways.

### METHODS AND MATERIALS

In this prospective study, 28 healthy neonates (16 males, 12 females) were scanned using a 3.0T scanner with a 32-channel head and neck coil. The magnetic-sensitive images for QSM were obtained through a Functool post-processing workstation. Seven brain regions were analyzed: bilateral globus pallidus, putamen, caudate nucleus head, dorsal thalamus, red nucleus, substantia nigra, and dentate nucleus of the cerebellum. The independent samples t-test was utilized to analyze the differences in magnetic susceptibility values between male and female neonates. Pearson correlation analysis was employed to investigate the relationships between the magnetic susceptibility values and age metrics.

### RESULTS

The susceptibility value of the left TH of male neonates was higher than that of female neonates, while the susceptibility value of the left DN was lower than that of female neonates, and the difference was statistically significant (t=3.251, P=0.003; t=-2.618, P=0.015). There was no correlation between the susceptibility value of each nucleus and the age.

### CONCLUSION

The study reveals significant gender-specific differences in the magnetic susceptibility values of certain brain nuclei in neonates, which may impact early neurodevelopment. Specifically, higher susceptibility in the male left dorsal thalamus suggests enhanced motor and decision-making skills, while elevated values in the female left dentate nucleus correlate with superior balance and cognitive abilities. Additionally, due to the limited age range of subjects, no age-related trends in susceptibility were observed in this study.

### CLINICAL RELEVANCE/APPLICATION

This study highlights the importance of considering gender in the neonatal brain. Understanding these differences could provide insights into the neurodevelopmental processes and help tailor early interventions based on gender-specific needs.

## R5B-SPPD-2 IMPROVING SPECIFIC ABSORPTION RATE MANAGEMENT SAFETY AND IMAGE QUALITY BY USING A HIGH DIELECTRIC CONSTANT PAD IN FETAL MRI AT 3.0T

Ming Li (*Abstract Co-Author*) Nothing to Disclose
Xin Zhang (*Abstract Co-Author*) Nothing to Disclose
Bing Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Chenchen Yan, MD (*Abstract Co-Author*) Nothing to Disclose
Zhengyang Zhu, MD (*Presenter*) Nothing to Disclose

### PURPOSE

As the static magnetic field strength increases, elevated specific absorption rate (SAR) value and dielectric artifacts are the two main technical challenges in fetal MRI at 3.0T. The elevated local temperature caused by radiofrequency induced current during the scanning may result in adverse impacts on fetal development. We aim to assess the potential of high dielectric constant (HDC) pad in increasing image quality and decreasing SAR in fetal MRI at 3.0T.

### METHODS AND MATERIALS

A total of 168 pregnant women were enrolled in this study, of which 128 subjects underwent bSSFP sequence and 40 subjects underwent SSFSE with and without HDC pad. Qualitative and quantitative image analysis were performed in each case. Qualitative analysis: A 5-point scale was used to score the images acquired with and without HDC pad by two pediatric radiologists. Quantitative analysis: firstly, the overall radiofrequency SAR values of the

images obtained with and without HDC pad were read on United Imaging software workstation. Secondly, four regions of interest (ROI) of frontal lobe, temporal lobe, thalamus and occipital lobe were placed on the standard level of each fetal brain. The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated for each of the four ROIs. Wilcoxon test was used to analyze the differences between the image quality scores with and without HDC pad. Paired sample t-test or paired rank sum test was used to analyze the differences in SAR, SNR and CNR values with and without HDC pad. Spearman correlation test was used to detect correlations between image quality variable changes and patient clinical characteristics, such as gestational age, abdominal circumference, amniotic fluid index, body mass index and fetal presentation.

**RESULTS**

After adding HDC pad, image quality score, SNR and CNR was significantly higher ($p<0.001$) and whole-body SAR decreased significantly ($p<0.001$). For bSSFP sequence, there was 41.45% increase in SNR, 54.05% increase in CNR, and 32.6% decrease in whole-body SAR after adding HDC pad. For SSFSE sequence, there was 258.75% increase in SNR, 459.55% increase in CNR and 15.40% decrease in whole-body SAR after adding HDC pad. There was no significant correlation between image quality variable changes and patient clinical characteristics ($p>0.05$).

**CONCLUSION**

Adding HDC pad can reduce or eliminate the inhomogeneous dielectric artifacts in fetal MRI at 3.0T, resulting in significant increase of image quality. HDC pad can also lower SAR values, promoting fetal and maternal safety during 3.0T MRI scanning.

**CLINICAL RELEVANCE/APPLICATION**

HDC pad demonstrated significant potential for improving patient safety and imaging quality of fetal MRI at 3.0T, regardless of GA, AFI, AC, BMI and fetal presentation.

## R5B-SPPD-3 ADVANCING PAEDIATRIC BRAIN MAPPING: AN AI-DRIVEN ADAPTIVE FUNCTIONAL MRI PIPELINE FOR MAPPING OF FUNCTIONAL BRAIN NETWORKS

Radha Kumari (*Abstract Co-Author*) Nothing to Disclose
Akshay Kumaar M (*Abstract Co-Author*) Nothing to Disclose
Sachin Patalasingh (*Abstract Co-Author*) Nothing to Disclose
Malavika Ganesh (*Abstract Co-Author*) Nothing to Disclose
Rimjhim Agrawal, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Resting-state functional MRI (rs-fMRI) provides valuable insights into intrinsic brain functional organisation. However, in paediatric cases, developmental changes present challenges such as differences in head size, grey-white matter distribution, and myelination, rendering adult templates unsuitable for analyses. This complicates clinical problem-solving, hampering the understanding and treatment of neurodevelopmental disorders and conditions like epileptic lesions or brain tumours. This study introduces a novel adaptive pipeline for mapping brain networks in paediatric rs-fMRI for effective clinical management and understanding paediatric brain function.

**METHODS AND MATERIALS**

The raw resting-state functional MRI (N=50) underwent canonical reorientation, motion artefact correction, despiking, skull stripping, anatomical coregistration, and denoising. Normalisation was then applied using a paediatric MRI template. Resting state networks were extracted via Independent Component Analysis (ICA), with the best-fit ICA selected using a self-supervised neural network pretrained on adult networks and fine-tuned for paediatric data (N=10).

**RESULTS**

Leveraging the proposed framework, the Visual, Sensorimotor, Language, and Default Mode networks were mapped successfully using paediatric rs-fMRI. The fine-tuned neural network achieved an accuracy of ~96% in identifying the networks from the independent components of paediatric data post ICA.

**CONCLUSION**

In conclusion, this study introduces an innovative adaptable pipeline and proves the efficacy in mapping functional brain networks in paediatric rs-fMRI, marking a significant advancement in paediatric neuroimaging. Further refinement and validation of this pipeline may extend its utility to extract additional resting state networks. This study holds great potential for improving our comprehension of neurodevelopmental disorders and guiding treatment approaches for paediatric neurological conditions.

**CLINICAL RELEVANCE/APPLICATION**

This study explores the potential of paediatric resting-state fMRI in understanding the underlying mechanisms of various developmental disorders, including epilepsy, tumours, and traumatic brain injury. By mapping the functions of the brain, this method could change how paediatric patients are cared for, making diagnoses and treatments more accurate leading to better patient outcomes.

## R5B-SPPH-1 QUANTITATIVE LUNG IMAGING WITH CZT-BASED PHOTON-COUNTING CT: BENEFITS OF ULTRA HIGH-RESOLUTION IMAGING AND DEEP-LEARNING RECONSTRUCTION

Richard Thompson, PhD (*Abstract Co-Author*) Employee, Canon Medical Research, USA
Steven Ross, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhou Yu, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Amir Pourmorteza, PhD (*Abstract Co-Author*) Nothing to Disclose
Shobhit Sharma, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the combined benefits of ultra high-resolution imaging capabilities of CZT-based photon-counting CT (PCCT) and deep-learning reconstruction (DLR) for quantitative lung imaging.

### METHODS AND MATERIALS

A lung phantom (COPDGene2), with 3 reference foams (20-lb, 12-lb, and 4-lb with HU120kVp of -703, -824, and -937) and polycarbonate airways (inner diameter (ID): 2.5-6 mm, wall thickness (WT): 0.4-1.5 mm), was used. The phantom was scanned in axial mode on a prototype CZT-based PCCT at 120 kV using a 0.4x0.5 mm focal spot and exposures of 50, 100, and 200 mAs (CTDIvol = 3.2, 6.4, and 12.8 mGy, respectively). All scans were reconstructed in ultra high-resolution (UHR) mode using 3 different methods: (1) filtered-back projection (FBP), (2) FBP w/ iterative denoising (dnFBP), and (3) DLR. All images were reconstructed using a lung kernel (FC52) with a pixel size (PS) of 0.25 mm and slice thickness (ST) of 0.2 mm. To evaluate benefits of UHR with DLR, the following were quantified: (1) contrast and contrast-to-noise ratios (CNRs) for ground-glass nodules (GGNs) and emphysema (ES) (ST = 3.0 mm), and (2) measurement error in wall area percentage (WA%) for airways (ST = 1.2 mm). The 20-lb and 4-lb foams were used as surrogates for GGN and ES, while the 12-lb foam was used for normal lung tissue. CNRs for GGN and ES were computed as: CGGN,ES= |HUGGN,ES-HULung|; CNRGGN,ES=CGGN,ES/sLung. For airways, a custom code for estimating ID and WT based on peak analysis of airway intensity profiles was used, and WA% was computed as: WA% = (OD2 - ID2)/OD2 × 100, with OD = ID + (2 × WT).

### RESULTS

Noise for DLR was 79.9/76.6/70.1% lower than FBP and comparable to dnFBP at 50/100/200 mAs. CGGN, ES were higher for DLR with mean improvements for GGN/ES across all exposures of 4.3/9.9 and 3.0/10.1 HU over dnFBP and FBP, respectively. Consequently, CNRGGN, ES for DLR was comparable to dnFBP and much higher than FBP with mean improvements over all exposures of 326.5%/377.6% for GGN/ES. Mean errors in WAP% across all airways were lower for DLR at 4.1/4.1/3.0% compared to both dnFBP at 5.6/5.7/4.7% and FBP at 5.2/5.6/4.0% at 50/100/200 mAs, with benefits of DLR especially apparent for smaller airways.

### CONCLUSION

DLR in UHR imaging with CZT-based PCCT improves noise and preserves spatial resolution, as indicated by CNRs much higher than FBP and comparable to dnFBP at all exposures, while maintaining superior accuracy for WA% measurements. These benefits have potential for improvements in quantitative lung imaging while allowing for valuable reductions in patient dose.

### CLINICAL RELEVANCE/APPLICATION

The ability to accurately characterize changes in airway walls while reducing patient dose is crucial for monitoring progression of lung diseases such as COPD and pulmonary fibrosis.

## R5B-SPPH-10 IMPACT OF DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM ON CT RADIOMIC FEATURES IN PATIENTS WITH PULMONARY NODULES

Zhiming Xiang (*Abstract Co-Author*) Nothing to Disclose
Kun Ma (*Abstract Co-Author*) Nothing to Disclose
Zhijuan Zheng (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the effects of deep learning image reconstruction (DLIR) algorithm on radiomic features of patients with pulmonary nodules compared to adaptive statistical iterative reconstruction-V (ASIR-V) algorithm in ultra-low-dose computed tomography (ULD-CT).

### METHODS AND MATERIALS

Patients with pulmonary nodules underwent standard-dose computed tomography (SDCT) (4.30±0.36 mSv) and ULD-CT (0.33±0.04 mSv) plain scans. The SDCT was reconstructed with 50%ASIR-V, and ULD-CT with 50%ASIR-V, DLIR-M, and DLIR-H. Pulmonary nodules were segmented using artificial intelligence software (LungDoc 5.7) and 102 radiomic features (shape, first order, and texture features) were extracted from SDCT and ULD-CT images. The intraclass correlation coefficient (ICC) was employed to describe the reproducibility of radiomic features between ULD-CT and SDCT.

### RESULTS

A total of 89 participants (52 years ± 12) with 160 nodules were included in the study, consisting of 120 solid nodules and 40 pure ground-glass nodules. The ICC of radiomic features improved from 0.73±0.18 for 50%ASIR-V to 0.77±0.13 and 0.78±0.13 for DLIR-M and DLIR-H between ULD-CT and SDCT (P=0.013). In different reconstruction algorithms, the shape feature demonstrated the highest ICC value among all radiomic feature classes (the mean ICC=0.95), followed by first order feature (the mean ICC>0.85), while the texture feature displayed the lowest reproducibility (the mean ICC=0.75). Of the 102 radiomic features considered, 52.94% (54 of 102), 55.88% (57 of 102), and 67.65% (69 of 102) were reproducible (ICC = 0.75) for 50%ASIR-V, DLIR-M, and DLIR-H, respectively. In 50%ASIR-V, DLIR-M, and DLIR-H, 84.21% (16 of 19) of the first order features and 100% (8 of 8) of the shape features demonstrated reproducibility, while the reproducibility of the texture features was only 40.00% (30 of 75), 44.00% (33 of 75), and 60.00% (45 of 75), respectively.

### CONCLUSION

The majority of the radiomic feature classes of pulmonary nodules have a high level of reproducibility between ULD-CT and SDCT. Among them, the shape and first order features are highly reproducible between ULD-CT and SDCT. Compared with ASIR-V, DLIR can improve the reproducibility of texture features in ULD-CT.

### CLINICAL RELEVANCE/APPLICATION

DLIR technology can improve the reproducibility of radiomic features in ULD-CT scans. This improvement in reproducibility has important clinical significance. It means doctors can more reliably and accurately assess pulmonary nodules, whether using ultra-low-dose CT or standard-dose CT scan.

## R5B-SPPH-11 ENHANCING RELIABILITY OF BRAIN VOLUMETRIC ANALYSIS WITH DEEP LEARNING-BASED MRI DENOISING

Hackjoon Shim (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Seong Kyu Jeon (*Abstract Co-Author*) Nothing to Disclose
Jin Woo Kim (*Abstract Co-Author*) Nothing to Disclose
Juho Kim (*Abstract Co-Author*) Nothing to Disclose
Junhyung Kim (*Abstract Co-Author*) Nothing to Disclose
Chuluunbaatar Otgonbaatar, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hei-Jung Jang (*Abstract Co-Author*) Nothing to Disclose
Won Beom Jung (*Abstract Co-Author*) Nothing to Disclose
Jaekyun Ryu, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Brain MRI plays a crucial role in diagnosing neurodegenerative diseases by revealing structural changes. Accurate volumetric analysis of brain structures is pivotal for assessing disease progression. However, conventional image reconstruction techniques often compromise between signal-to-noise ratio (SNR) and scan duration, hindering optimal image quality within a reasonable acquisition time. Deep learning-based image reconstruction (DLR) using deep convolutional neural networks (DCNN) presents a promising solution to this challenge. Here, we evaluate the utility of DLR in brain MRI for volumetric analysis, comparing it with conventional methods.

### METHODS AND MATERIALS

We acquired structural MRI data from ten healthy subjects (M/F = 6/4; aged 25-50 years) using a 3T MRI scanner (Canon Medical Systems, Vantage Galan STD) with a 16-channel head and neck coil. T1-weighted structural MR images were obtained using a 3D magnetization-prepared rapid gradient-echo (MPRAGE) sequence. Three image sets were acquired per subject: original unfiltered images (NEX = 1, scan time = 5 mins 58 secs), images reconstructed using DLR (Advanced Intelligent Clear-IQ Engine, AiCE), and high SNR images (NEX = 3, scan time = 17 mins 54 secs). DLR was based on a DCNN trained with low and high SNR MR image pairs. For whole-brain voxel-based morphometry (VBM), we utilized the CAT 12 toolbox integrated into SPM12 software. The images were normalized to the standard MNI space, segmented into gray matter (GM), white matter (WM), and cerebrospinal fluid (CSF) using DARTEL, and smoothed with a 6-mm FWHM Gaussian kernel. Volumetric parcellations of subcortical GM regions were obtained using the Neuromorphometrics atlas.

### RESULTS

Figure 1 illustrates the efficacy of DLR in reducing non-uniform noise without loss of structural information. VBM analysis revealed significant volume reductions in specific brain regions with low SNR images compared to high SNR and DLR-enhanced images (Fig. 2). Subcortical volumetry corroborated these findings, highlighting the impact of image quality on quantitative measures (Fig. 3).

### CONCLUSION

Quantitative brain MRI analysis is increasingly valuable in clinical practice. Our study demonstrates that image noise affects tissue segmentation and volumetric measurements, crucial for detecting neurodegenerative diseases. DLR presents a viable approach to enhance the reliability of brain volumetric analysis without additional scan time, potentially improving clinical decision-making.

### CLINICAL RELEVANCE/APPLICATION

DLR allows for increased SNR and more equivocal brain volumetric measurements with fast scanning times compared to conventional imaging.

## R5B-SPPH-2 IMPACT OF CLINICAL TREATMENT PLANNING METHODOLOGY FOR YTTRIUM 90 RADIOEMBOLIZATION PATIENT DOSIMETRY

Stephanie Leon, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Dante E. Roa, PhD (*Abstract Co-Author*) Nothing to Disclose
Edmond Olguin, PhD (*Abstract Co-Author*) Nothing to Disclose
Oliver Paucar (*Abstract Co-Author*) Nothing to Disclose
Andres Gonzales Galvez (*Abstract Co-Author*) Nothing to Disclose
Terrance Moretti, PhD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

For glass microspheres used in Yttrium-90 Transarterial Radioembolization (TARE), the manufacturer-recommended dosimetry method is the partition model, which assumes a uniform distribution of activity in each compartment (liver, tumor, and lungs) and lack of cross-irradiation between compartments. However, more detailed imaging-based dosimetry models may result in differing calculated tumor and organ doses than treatment planning.

**METHODS AND MATERIALS**

IRB approval was acquired to acquire imaging and treatment planning data for ten patients who received TARE for hepatocellular carcinoma. Three Monte Carlo (MC) voxelized source models were developed for each of them: one based on their pre-treatment Tc99m SPECT/CT, one based on their post-treatment Y90 bremsstrahlung SPECT/CT, and one approximating the assumptions of the partition model (equal distribution of activity through the perfused areas of the liver and entire visible lung volume), referred to as the uniform perfused model. Using a Y90 source, simulations were performed for each of these models, and doses were assessed for the treated volume, healthy liver, and lungs. These were compared to the nominal doses from treatment planning. Dose-volume histograms (DVH) for these volumes were generated for each source model to evaluate differences in 3D dose distribution.

**RESULTS**

Mean doses within the tumor typically, but not always, matched the values predicted by the partition model. For patients undergoing lobectomy, differential uptake in the tumor resulted in higher doses than when the entire lobe was considered. Simulated lung doses did not always agree with those calculated during treatment planning, mainly due to tumor proximity to the lungs. Pretreatment SPECT/CT dose generally agreed with doses calculated during treatment planning. The bremsstrahlung images consistently resulted in lower doses within the tumor and healthy liver, which may have been the result of differing biodistribution or poor image quality. The partition model-based source term generated DVH's which had a more uniform and spread-out dose throughout the perfused liver. Depending on model, planned dose and calculated dose may differ by up to 86%.

**CONCLUSION**

The MC architecture in this work is appropriate for assessment of dose-volume effect for patients undergoing TARE. Continued use of the partition model is appropriate for mean doses within the perfused liver, but can cause miscalculation of doses to certain organs, particularly the lungs.

**CLINICAL RELEVANCE/APPLICATION**

The currently-used TARE partition model can overestimate or underestimate dose to tumor, normal liver, and lungs in ways that affect treatment planning. Use of a more detailed imaging-based model could help mitigate these inaccuracies.

## R5B-SPPH-3 AUTOMATED ORGAN-SPECIFIC CT RECONSTRUCTION USING A TUNABLE MULTI-AGENT ARCHITECTURE

John M. Hoffman, PhD (*Abstract Co-Author*) Nothing to Disclose
Joshua Genender, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

When reading CT images, clinicians zoom into organ systems necessary to reach a diagnosis; however, the spatial resolution of these zoomed images is limited by parameters chosen at the scanner. To address this, we developed a pipeline that dynamically reconstructs CT images to organ-specific fields-of-view (FOVs), allowing for high-quality visualization of patient anatomy.

**METHODS AND MATERIALS**

Our dataset included projection data of 15 chest CT scans from the TCIA LDCTPD collection. Our pipeline used a multi-agent blackboard architecture that iteratively generated reconstructions based on patient anatomy. Reconstructions were generated through the interplay of three agents: (1) a CT reconstruction agent, which outputs reconstructed image series; (2) a segmentation agent, which performs organ segmentation (lungs, heart, aorta); and (3) a parameter tuning agent, which guides the reconstruction volume for the next iteration. Agreement between segmentations and semantic anatomical knowledge was used as a stopping criterion for the reconstruction loop. The image matrix size was doubled between iterations when necessary. Once the stopping criterion was satisfied, a final set of organ-specific reconstructions was generated from organ bounding boxes. To compare the spatial resolution of automated versus manually-zoomed images, we extracted an aortic calcification from one scan and computed the full width at half-maximum (FWHM) of the pixel intensity profile. Reconstructions were generated using the FreeCT tool and segmentations by an active contours model and TotalSegmentator.

**RESULTS**

Our pipeline successfully reconstructed images with the expected organ-specific FOVs for each case in our dataset. The FWHM for the automated calcification was 0.4 mm (21%) narrower than the manually zoomed calcification, suggesting improved spatial resolution. Intermediate results showed the system progressively narrowed its focus to the desired FOV, explained by its use of contextual information in low-quality images (early iterations) and fine details in high-quality images (late iterations).

**CONCLUSION**

The automated organ-specific reconstruction pipeline identified and limited reconstruction FOVs to patient anatomy with improved spatial resolution. This pipeline shows potential for use in complex CT quantitative imaging systems, particularly those with multiple interacting analysis components.

**CLINICAL RELEVANCE/APPLICATION**

This tool provides high-quality views of anatomy that would otherwise be generated by a technician or zoomed-in from a rib-to-rib image. Our tunable multi-agent architecture demonstrates cognitive AI methodologies in CT reconstruction, which we believe could allow for advanced quantitative imaging systems.

## R5B-SPPH-4 DEEP LEARNING-BASED MULTI-MODALITY MODEL FOR ACCURATE GROSS TUMOR VOLUME SEGMENTATION IN NASOPHARYNGEAL CARCINOMA RADIOTHERAPY

Le Lu (*Abstract Co-Author*) Nothing to Disclose
Jia Ge (*Abstract Co-Author*) Nothing to Disclose
Ying Chen (*Abstract Co-Author*) Nothing to Disclose
Zi Li (*Abstract Co-Author*) Nothing to Disclose
Xianghua Ye (*Abstract Co-Author*) Nothing to Disclose
Dakai Jin, MS (*Presenter*) Nothing to Disclose

## PURPOSE

In nasopharyngeal carcinoma (NPC) radiation therapy, clinicians must outline the primary gross tumor volume (GTV) precisely on the planning computed tomography (pCT) for accurate radiation dose delivery. Due to the limited contrast between NPC tumors and many adjacent normal tissues, oncologists need to manually delineate GTV with the help of diagnostic CT or MRI in clinical practice. In this study, we develop a series of multi-modality NPC GTV deep segmentation models using multi-center datasets.. The quantitative segmentation performance is evaluated on the internal test set and one independent external dataset.

## METHODS AND MATERIALS

We collected and curated an in-house dataset from the hospital for deep segmentation model development, which consisted 145 NPC patients with pCT, enhanced diagnostic CT, and diagnostic MRI (T1 T2 phases). Diagnostic CT and MRI were registered to pCT using affine and deformable transformation (DEEDS). Additionally, we collected and curated one publicly available dataset (SegRap2023) as external validation, containing 98 no-contrast pCT and enhanced CT. GTV annotations of all datasets were examined and edited by two experienced radiation oncologists following the international GTV delineation consensus guideline. We developed three deep segmentation models: the first model used pCT as input; the second used pCT and enhanced diagnostic CT as input; and the third took pCT, enhanced diagnostic CT with random masked MRI scans as input. We used nnUNet as the deep segmentation network. For evaluation, 20% of the in-house dataset was randomly selected as the internal testing set and the curated SegRap2023 was used as the external testing dataset.

## RESULTS

The quantitative NPC GTV segmentation performance is summarized in Table 1. In internal testing, the model using pCT alone achieved reasonably high performance with a 76.6% Dice score. When enhanced diagnostic CT were incorporated, the segmentation model slightly improved the performance by 0.3% Dice score. Further incorporating the masked MRI scans seemed not help with the performance. Regarding the external testing, pCT model experienced significant performance drop (76.6% to 60.3%) Yet, pCT + diagnostic CT model led to a much stable external testing result (63.1%), demonstrating the strength of enhanced CT in determining NPC GTV.

## CONCLUSION

We developed and tested a series of multi-modality deep-learning model for segmenting GTV in NPC patients. The model achieves high quantitative segmentation performance, which is evaluated on the internal test set and one independent external dataset.

## CLINICAL RELEVANCE/APPLICATION

It can be potentially used in radiotherapy practice to standardize the NPC GTV segmentation and reduce the workloads of radiation oncologists.

# R5B-SPPH-6 ENHANCING INTRA-OPERATIVE GUIDANCE FOR NEUROVASCULAR INTERVENTIONS OF INTRACRANIAL ANEURYSMS USING EPIPOLAR 3D RECONSTRUCTION FROM TWO VIEWS

Ciprian N. Ionita, PhD (*Abstract Co-Author*) CEO, QAS.AI;Grant, Canon Medical Systems Corporation

Ahmad Rahmatpour, PhD (*Abstract Co-Author*) Nothing to Disclose
Parisa Naghdi, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyle Williams, BS (*Presenter*) Nothing to Disclose

## PURPOSE

This study investigates the application of a rule-based epipolar 3D reconstruction algorithm to enhance intra-operative guidance during neurointerventional procedures for intracranial aneurysms. By using only two angiographic views our approach eliminates the need for multiple cone beam CT (CBCT) acquisitions to reflect intra-operative changes.

## METHODS AND MATERIALS

Our study employed three patient-specific ICA aneurysm models obtained from clinical CT angiography reconstructions. We used computational fluid dynamics (CFD) simulations to generate detailed virtual angiograms of these aneurysms, including a 1.5-second iodine injection to simulate the contrast material dynamics during actual angiographic procedures. For the imaging simulations, we utilized the ASTRA Toolbox to create cone beam projection geometries that mimic those of standard clinical biplane C-arm systems. Angiographic data was simulated for two standard views (AP and lateral) which are routinely used during neurovascular interventions. These simulated high-resolution biplane x-ray images were inputs to our epipolar reconstruction algorithm. This algorithm efficiently reconstructs three-dimensional vascular geometries from only two planar images, eliminating the need for additional imaging exposures or complex co-registration processes. We quantified the accuracy of our 3D reconstructions using DICE coefficients, which provided a quantitative comparison between our reconstructed geometries against the original high-fidelity patient-specific aneurysm models.

## RESULTS

The epipolar reconstruction reported DICE = 0.734 ± 0.027 among the three models. Reconstruction errors were primarily observed above the carotid bifurcation. The results suggest epipolar reconstruction may prove useful for 3D quantitative angiography.

## CONCLUSION

The performance of our epipolar reconstruction algorithm suggests its potential to provide 3D neurointerventional imaging without high dose CBCT. The method efficiently recovers 3D vascular geometries from biplane angiographic views, with an estimated 83.3% reduction in cumulative air kerma, thus reducing radiation risk to the patient. Further refinement could improve its sensitivity and specificity, reinforcing its utility in real-time intra-operative guidance.

## CLINICAL RELEVANCE/APPLICATION

This epipolar reconstruction algorithm enhances neurointerventional accuracy by providing 3D vascular geometries from standard biplane angiographic views. Its ability to deliver precise, real-time visuals intraoperatively could improve surgical decision-making and patient outcomes in treating intracranial aneurysms.

## R5B-SPPH-7 TRAINING A DEEP-LEARNING-BASED NOISE REDUCTION METHOD TO REDUCE HALLUCINATED STRUCTURES IN ULTRA-LOW-DOSE CT

### PURPOSE

In ultra-low-dose (ULD) CT with strongly increased image noise, deep learning-based noise reduction (DLR) methods tend to generate artificial structures without appropriate training. The purpose of this work was to develop a DLR method using a training strategy dedicated to ULD CT to reduce hallucinated structures.

### METHODS AND MATERIALS

A deep neural network for ULD CT denoising (ULD-NET) was trained by mapping the synthesized noisy CT images to high quality target CT images. The target images were obtained by iterative reconstruction (IR) of routine dose (RD) projection data with slice thickness/interval of 2.0/0.5 mm and a sharp kernel (Qr68). The training inputs were synthesized by superimposing noise maps on the target images, where the noise maps were generated by subtracting the 25% dose (QD) filtered back projection (FBP) images from the corresponding RD FBP images, both with a thin slice thickness (0.8 mm). The QD images were reconstructed from QD projection data simulated by a projection noise insertion method. A U-Net architecture was adopted as the backbone of ULD-NET. The trained ULD-NET was applied to the original thin slice and sharp kernel FBP images. By using more realistic noise maps and cleaner target images, this training strategy was expected to reduce hallucinated structures compared to an existing model (GARNET) previously trained and clinically validated. The performance was evaluated in a pilot study including 5 pediatric thoracic CT cases scanned on a PCD-CT scanner (Alpha, Siemens) at ULD (CTDIvol < 0.1 mGy). Two pediatric radiologists evaluated 3 conditions: (1) IR, (2) GARNET, (3) ULD-NET in terms of spatial resolution, noise, hallucination in lung parenchyma (1-5, 1=widespread fake structures, 5=no fake structures), and overall diagnostic confidence (1-4, 4=high confidence).

### RESULTS

ULD-NET received the highest ratings in spatial resolution/noise/diagnostic confidence (3.81±0.37/3.75±0.46/3.75±0.46) compared to GARNET (3.12±0.69/2.38±0.35/3.13±0.44) and IR (2.63±0.52/2.19±0.59/3.06±0.62). In terms of hallucination, no significant difference was found between ULD-NET and IR (4.25±0.71 vs. 4.25±1.04, p=1), both higher than GARNET (2.12±0.83, p<0.01), demonstrating a significant reduction of hallucinated structures by ULD-NET.

### CONCLUSION

Using a training strategy dedicated to ULD, the proposed ULD-NET method improved the overall diagnostic image quality without introducing hallucinations that were significant in a prior denoising method.

### CLINICAL RELEVANCE/APPLICATION

DLR tends to generate hallucinated structures when the noise in input images is high. Our proposed ULD-NET has the potential to significantly alleviate the hallucination problem, allowing for more routine use of ULD-CT.

## R5B-SPPH-8 IS THERE A THRESHOLD LIMIT FOR BRAIN TUMOR TARGET SIZE AND OFF AXIS DISTANCE FROM ISOCENTER FOR HYPER ARC RADIOSURGERY USING MILLENNIUM 120 MLC?

Sumit Varadhan (*Abstract Co-Author*) Nothing to Disclose
Dharmin Desai, PhD (*Abstract Co-Author*) Nothing to Disclose
Ryan Malmin (*Presenter*) Nothing to Disclose

### PURPOSE

Stereotactic Radiosurgery (SRS) using standard Millennium 120 leaf MLC is the most commonly used radiosurgery platform. However, in the era of HyperArc SRS, that employs automated delivery and treatment planning, the minimum target size that can be effectively treated using a Millennium 120 MLC as well as how far away off axis from the isocenter the target can be accurately treated remains a question of interest. The goal of this study is to characterize a minimum threshold target size and off axis distance from isocenter for high precision SRS using a measurement guided approach.

### METHODS AND MATERIALS

To test the hypothesis, we created incrementally decreasing pair of targets of sizes 10mm, 8mm, 5mm and 3mm in the Standard imaging LUCYR EA head phantom. The location of the first target was at the origin at isocenter (0, 0, 0). The second target was placed at (1, 1, 0) to (5 ,5, 0) coordinates (cm) in 1cm increments from the Z=0 coronal plane. Thus the smallest pair of targets treated was 3mm in diameter and the largest distance from the isocenter was 7.1 cm when the second target was at (5cm, 5cm, 0cm) location. The location of targets was chosen such that all the targets are encompassed in the 7.7 cm2 X 7.7 cm2 diode array when the verification plan is delivered to the SRS MapCHECK in a StereoPHAN phantom. A dose of 15 Gy in 1 fraction using 6FFF photons was planned and delivered using HyperArc SRS. All the targets received 100% dose to the target volume using Acuros XB 16.1 algorithm. Thus, a total of 25 HyperArc SRS plans of incrementally decreasing target size (10mm to 3mm) and increasing off axis distance (14 mm to 71 mm) was delivered to SRS MapCHECK. Further, the impact of rotational set up errors on delivered dose was investigated. This was done by intentionally moving the 6DOF couch in 0.5 degree increments in each of the rotational axis (roll, pitch and yaw) and the accuracy of delivered dose was ascertained with measurements on high resolution diode array

### RESULTS

All plans passed the SRS MapCHECK quality assurance with > 97% Gamma pass rate using a strict 2%/1mm criteria. With the introduction of 0.5, 0.7 and 1.0 degree rotational errors in roll, pitch and yaw axis, the pass rates were 91.6%, 85.1 % and 76.4% respectively.

### CONCLUSION

Brain tumors as small as 3mm in diameter and 70 mm away from each other can be accurately treated with Millennium 120 MLC in Hyper Arc SRS. 0.5 degree is the threshold rotational error in each of the rotational axis for accurate off axis delivery of HyperArc SRS for small targets.

### CLINICAL RELEVANCE/APPLICATION

High precision SRS using HyperArc technology can be used to treat targets as small as 3mm in size and as far away as 70mm off axis, using regular Millennium 120 MLC obviating the need for other approaches and expensive capital expenditures.

## R5B-SPVA-1 VARIATIONS IN THE UTILIZATION OF INTRAVASCULAR ULTRASOUND (IVUS) IN THE MEDICARE POPULATION FROM 2013-2022

Richard E. Sharpe JR, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Aditya Khurana, MD (*Abstract Co-Author*) Nothing to Disclose
Jumana Baldawi, MD (*Abstract Co-Author*) Nothing to Disclose
Mustafa Al-Ogaili, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate utilization rate and geographical distribution of intravascular ultrasound (IVUS) among the Medicare population.

### METHODS AND MATERIALS

All IVUS CPT codes as classified by the NITOS system (a validated imaging CPT classification tool) were extracted from the Part B POSPUF database for the years 2013-2022. State locales were determined by cross referencing the Medicare administrator code (MAC) with the corresponding state the claim was billed in. Compound annual growth rates (CAGR) and absolute differences were calculated.

### RESULTS

The total number of IVUS grew from 16396.0 in 2013 to 204989.0 in 2022, for a CAGR of 32.4% The utilization rate of IVUS per 10,000 Medicare enrollees grew from 5.0 in 2013 to 69.9 in 2022, for a CAGR of 34.1% The three states with the highest gain in IVUS utilization were District of Columbia (1045.8 per 10,000 Medicare enrollees; 32.2 to 1078.0), California (177.5 per 10,000 Medicare enrollees; 5.8 to 183.3), and Connecticut (142.4 per 10,000 Medicare enrollees; 2.6 to 145.0)The three states with the lowest gain/greatest decrease were Nebraska (-7.9 per 10,000 Medicare enrollees; 24.6 to 16.7), West Virginia (-4.7 per 10,000 Medicare enrollees; 9.9 to 5.3), and Idaho (-1.5 per 10,000 Medicare enrollees; 4.4 to 2.8).

### CONCLUSION

IVUS is a newer sophisticated technology that is increasingly utilized by US Medicare beneficiaries over the past decade. The identification of significant state level variations raises potential concern for overutilization in some states, underutilization in others, and potential differences in patient access to emerging technologies.

### CLINICAL RELEVANCE/APPLICATION

IVUS allows for better periprocedural planning and may be useful in a variety of surgical and interventional procedures in the Medicare population.

## S3A-SPBR-1 MRI-BASED RADIOMICS ANALYSIS TO PREDICT THE LEVEL OF TUMOR-INFILTRATING LYMPHOCYTES (TILS) IN BREAST CANCE

Xiaomei Li (*Abstract Co-Author*) Nothing to Disclose
Guijing Jia (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the relationship between the level of tumor infiltrating cells (TILs) in breast cancer and its clinical, pathological and MRI-based radiomics features, and establish radiomics machine learning model to predict TILs level in breast cancer

### METHODS AND MATERIALS

This study included a total of 132 patients pathologically diagnosed as breast cancer. The clinical, pathological and MRI features of patients were collected, and divide patients into high TILs and low TILs groups based on pathology. The two groups were compared by two-sample t test or Chi-square test, and the features with statistical significance were selected for clinical model construction. Radiomics features were extracted from the early stage of DCE enhancement(DCE2), late DCE enhancement(DCE6) and T2 sequence. A least absolute shrinkage and selection operator regression was used to screen features and construct machine learning classification models (including random forest and support vector machine models). Three single-phase models and a multi-sequence radiomics model were constructed, and a combined radiomics-clinical model were further constructed. AUC, DCA and calibration curve were used to compare the efficacy of different models

### RESULTS

Low TILs group (n=65) and highTILs group (n=67) showed differences in Ki-67, triple-negative breast cancer, and ADC value ($p<0.05$). Compared with the low TILs group, the high TILs group had lower ADC value(789±130 VS 842±118 *10-6mm2/s), higher proportion of triple negative breast cancer (23.9% VS 9.2%) and higher proportion of Ki-67 hyperexpression(49.3% VS 29.7%). The three clinical features were used to construct a model and the AUC of the training set(TS) and validation set(VS) were 0.687 and 0.573. The radiomics features of the patients were extracted and screened from DCE2, DCE6 and T2 sequence.The model which constructed from 7 radiomics features in DCE2 performs the best among Three single-phase models , with AUC of 0.998 and 0.732 in the TS and VS . The RF model was obtained by fusion features of the three-stage sequence, and the AUC of the TS and VS were 0.972 and 0.935 . Finally, a combined radiomics-clinical model was constructed, and the AUC of the TS and VS were 0.973 and 0.931. DCA and calibration curves showed that the predictive efficiency of combined radiomics-clinical mode was higher than clinical model

### CONCLUSION

The MRI-based radiomics prediction model has a good performance in the classification of TILs levels, which is expected to be used as a non-invasive TILs level evaluation method to provide assistance for clinical practice

### CLINICAL RELEVANCE/APPLICATION

The machine learning model based on DCE-MRI has excellent capabilities in non-invasive evaluation of cancer TILs.

## S3A-SPBR-10 HIGH AI SCORE ON SCREENING MAMMOGRAMS BUT NO BREAST CANCER: A BLINDED CONSENSUS REVIEW OF 382 CASES

Solveig S. Hofvind (*Abstract Co-Author*) Nothing to Disclose
Henrik Koch, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Retrospective and prospective studies using artificial intelligence (AI) to analyze screening mammograms for cancer detection, have shown promising results. However, less attention has been given to cases with high AI score, but no cancer detected - a false positive AI alarm. In this retrospective review study, we explored mammographic features in screening mammograms with high AI score, but no breast cancer detected in the actual or two next screening rounds.

### METHODS AND MATERIALS

Mammograms from 69,165 women who participated in BreastScreen Norway 2010-2022 were analyzed with a commercially available AI system (Transpara, ScreenPoint Medical). An AI score from 1 to 10 indicated the suspiciousness of malignancy where 1 indicated low risk and 10 high risk. We selected cases with an AI score of 10 followed by two biennial, negative screening examinations. Of the 2,124 examinations matching these criteria, we selected 382 random examinations for a blinded consensus review. Three experienced breast radiologists reviewed the cases and classified

mammographic features (density, distortion, density with calcification, calcification, mass, spiculated mass), interpretation score (1; negative, 2; probably benign, 3; intermediate suspicion of malignancy, 4; probably malignant, 5; high suspicion of malignancy) and BI-RADS mammographic breast density (a-d). For cases with calcification, distribution and morphology of the calcification was recorded.

**RESULTS**

For all 382 cases, 91% (348/382) were given an interpretation score of 1 (negative) by the reviewing radiologists. All cases (26/26) classified as BIRADS density d were given an interpretation score of 1 (negative). For all cases, 31% (117/382) was classified as density, 1% (3/382) as distortion, 29% (112/382) as density with calcification, 39% (115/382) as calcification, 9% (34/382) as mass and 0% (1/382) as spiculated mass. Out of the 115 cases with calcification, 79% (91/115) were classified as benign (morphology), 77% (89/115) as cluster (distribution) and 62% (71/115) as a benign cluster.

**CONCLUSION**

The majority of cases with high AI score but no cancer detected, were easily dismissed as negative in the review, and would likely not be recalled for further assessment in a real screening setting.

**CLINICAL RELEVANCE/APPLICATION**

This knowledge is important to understand reasons for high AI scores on negative cases. The knowledge may help maintain and potentially even decrease the rate of false positive recalls when AI is implemented as part of the screening interpretation procedure.

## S3A-SPBR-2 MULTI-INSTITUTIONAL EVALUATION OF BACKGROUND PARENCHYMAL ENHANCEMENT CLASSIFICATION USING DEEP LEARNING

Susanne D. Diekmann, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Robert Grimm, MD (*Abstract Co-Author*) Employee, Siemens AG;Stockholder, Siemens AG
Hendrik O. Laue, PhD (*Abstract Co-Author*) Nothing to Disclose
Markus Wenzel, PhD (*Abstract Co-Author*) Nothing to Disclose
Heinrich von Busch (*Abstract Co-Author*) Employee, Siemens AG;Stockholder, Siemens AG;Stockholder, Koninklijke Philips NV
Hans Meine (*Abstract Co-Author*) Nothing to Disclose
Kai Geisler, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

This study presents an automated method for Background Parenchymal Enhancement (BPE) in breast magnetic resonance imaging (MRI). The method is based on deep learning and validated on a multi-institutional dataset according to the BI-RADS BPE classification.

**METHODS AND MATERIALS**

The dataset consists of 3000 patients collected retrospectively from seven clinical institutions located in Europe and eastern Asia. The class distribution is 53.6%, 28.4%, 13.3% and 4.7% for minimal, mild, moderate and marked BPE. Convolutional neural networks are trained to segment the breast tissue and the fibroglandular tissue (FGT) on 200 and 96 volumes, respectively. As indicator for BPE, the area under the cumulative histogram over the relative enhancement of voxels inside the FGT mask is computed. The pre-contrast image and the post-contrast image closest to 130 seconds after contrast-agent injection areused to compute the relative enhancement. 60% of the cases are used to compute thresholds on the BPE indicator and 40% are used for evaluation against BPE classifications from the different clinical sites. We compute the thresholds once across all sites and once for each site individually.

**RESULTS**

We asses the ROC-AUC for classifying BPE into low (minimal or mild) versus high (moderate or marked) BPE. It is 0.7656 when evaluated over all sites together. When evaluated for each site individually it ranges between 0.6606 and 0.8750 with a median of 0.8489. The four-class accuracy evaluated over all test cases equates to 48.18% when the thresholds are defined globally. When defining the thresholds per site this accuracy rises to 55.20%.

**CONCLUSION**

We observe that automatic classification of BPE in multi-institutional settings based on quantifying the enhancement in the fibroglandular tissue generalizes to a certain degree between institutions. However, the classification accuracy can be improved by calibrating the classification thresholds for each site individually. Reasons for this are differences in MRI acquisition protocols, contrast agents and patient cohort characteristics.

**CLINICAL RELEVANCE/APPLICATION**

BPE is assessed as part of BI-RADS reporting for breast cancer diagnostic in MRI. It is associated to breast cancer risk and the diagnostic accuracy of breast MRI readings, while being subject to very high inter-reader variability. This creates a need for robust observer-independent methods to estimate BPE.

## S3A-SPBR-4 PREDICTION OF BREAST LESIONS WITH CALCIFICATION USING RADIOMICS MODELS FROM ULTRASONIC IMAGES

Xinyi Wang, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate radiomics models to predict benign and malignant breast lesions with calcifications based on ultrasonic (US) images.

**METHODS AND MATERIALS**

Retrospective data from 490 patients undergoing breast US examinations from January to September 2021 yielded 508 breast lesions (334 malignant, 170 benign). Lesions with calcifications on both US and mammography were included. Pathological findings established the gold standard for lesions requiring biopsy, while lesions without biopsy underwent a minimum 24-month follow-up for benign diagnosis. The clearest US image displaying calcifications was selected for each lesion, with separate markings for calcifications and lesions. Radiomics models were developed based on calcification regions of interest (ROIs) and whole-lesion ROIs through feature extraction, selection, and machine learning modeling, utilizing Support Vector Machine, Logistic Regression, Decision Tree (DT), Multi-layer Perceptron, and Random Forest models. Performance evaluation included decision curve analysis and calculation of area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity on internal and external test sets.

**RESULTS**

Models built solely on calcification ROIs exhibited higher AUCs on the internal test set but decreased significantly on the external test set. Models constructed using whole-lesion ROIs showed better AUCs on the internal test set, with variable performance on the external test set. The DT model demonstrated notable classification performance (AUC = 0.769), with an accuracy, sensitivity, and specificity of 0.800, 0.870, and 0.680, respectively, on

the internal test set, and 0.790, 0.860, and 0.570, respectively, on the external test set. Decision curve analysis indicated higher net income for the DT model at prediction probabilities < 89.2% and < 86.9% on the internal and external test sets, respectively.

**CONCLUSION**

Models based solely on calcification ROIs showed limited predictive efficacy. However, the DT model built on whole-lesion ROIs demonstrated promise in diagnosing breast lesions with calcifications on US images.

**CLINICAL RELEVANCE/APPLICATION**

Advancements in US technology allow high-frequency instruments to reveal subtle structures, including breast calcifications. While US may not fully display all calcifications like mammography, it can detect most within a lesion. Radiomics leverages extensive image features, providing decision support through quantitative analysis. This study demonstrates the potential of radiomics models, particularly the DT model, in predicting benign and malignant lesions containing calcifications, offering valuable clinical implications in breast lesion diagnosis.

## S3A-SPBR-5 REFINING MICROCALCIFICATION DETECTION IN FULL-FIELD DIGITAL MAMMOGRAPHY USING GENERATIVE AI: ENHANCED ACCURACY AND REDUCED FALSE POSITIVES

Manisha Bahl, MD, MPH (*Abstract Co-Author*) Consultant, Lunit Inc;Expert Advisory Committee, 2nd.MD
Synho Do, PhD, MS (*Abstract Co-Author*) Nothing to Disclose
Kyungsu Kim, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Calcifications on mammography may indicate ductal carcinoma in situ (Stage 0 breast cancer). This study aims to develop a novel deep learning (DL) solution that reduces false positives while maintaining high sensitivity to assist radiologists in detecting calcifications.

**METHODS AND MATERIALS**

We developed a DL network to segment calcifications on full-field digital mammograms, trained with the European Radiology dataset (81 mammograms) featuring pixel-level calcification masks. Despite excellent sensitivity (98.0%), the high false positive rate (PPV 3.2%) prompts us to explore refinement techniques for the DL mask. We evaluated two standard signal processing (SP) approaches (Gaussian difference and Top-Hat transform) and our novel Generative AI model. This model processes the baseline DL mask, transforming calcification-positive pixels into calcification-free areas, and generates a refined mask by subtracting the original pixels from the newly generated pixels. It was trained using our institutional dataset of 1121 mammograms, annotated for calcification-free regions, and validated using the external InBreast dataset (126 mammograms). To assess performance specific to tissue density, we catergorized the densities within and around each calcification as either interior or exterior.

**RESULTS**

Our Generative AI model improved PPV from 3.2% to 7.3% (a 2.3-fold increase) while maintaining a sensitivity above 95%. It significantly outperformed standard SP approaches in detecting calcifications, particularly in patients with small calcifications, enhancing detection accuracy by more than 1.3 times in calcifications smaller than 50 pixels, by over 1.9 times in those with low-interior density, and by more than 2.2 times in high-exterior density scenarios.

**CONCLUSION**

Our Generative AI model significantly reduces false positives and enhances sensitivity in detecting calcifications on mammography, particularly effective in complex cases involving small calcifications of varying densities.

**CLINICAL RELEVANCE/APPLICATION**

Our Generative AI model generates precise virtual normal mammograms, which when aligned with the original abnormal images, facilitate pixel-level difference analysis, assisting radiologists in the early detection of breast cancer.

## S3A-SPBR-6 AI SOFTWARE PERFORMANCE IN UNILATERAL MAMMOGRAPHY: SIMULATING TOTAL MASTECTOMY SCENARIOS

Jung Min Chang, MD (*Abstract Co-Author*) Research Consultant, Genoray Co, Ltd
Jung Oh Lee, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Janie M. Lee, MD, MSc (*Abstract Co-Author*) Research Grant, General Electric Company;Investigator, General Electric Company
Jiyeong An, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The contribution of contralateral breast information to the diagnostic accuracy of artificial (AI) algorithms for breast cancer detection on screening mammograms is poorly understood. Whether AI algorithms developed in training sets of bilateral mammograms perform comparably for unilateral mammograms in women who have undergone mastectomy is not yet established. This study aimed to evaluate the performance of commercially available AI software in unilateral mammogram simulating postmastectomy surveillance, compared with AI software used in bilateral mammograms from the same patients serving as controls.

**METHODS AND MATERIALS**

A retrospective database search identified consecutive patients who underwent breast cancer surgery between January 2021 and December 2021. A commercially available AI software application (Lunit INSIGHT MMG) was applied to the mammogram immediately preceding the breast cancer diagnosis in two modes: bilateral and unilateral analysis, with each unilateral mammogram replicating the conditions of contralateral mastectomy. AI outputs were reviewed and sensitivity, specificity, and number of marks per breast were compared between bilateral and unilateral analysis. Interobserver agreement of the maximum abnormality scores in cancer cases for each of the CC and MLO views between the two modes were assessed using the intraclass correlation coefficient (ICC).

**RESULTS**

A total of 694 women (mean age, 55.2 ± 10.8 years) with unilateral or bilateral breast cancer contributed mammograms for analysis; each breast was then separately evaluated in the unilateral post-mastectomy simulation (n=1388), of which 730 had breast cancer (52.6%) (mean invasive size = 1.1 cm) and compared with bilateral mammography analysis. The sensitivity of unilateral analysis was not inferior to that in the bilateral analysis (78.5% vs. 76.6%), with a difference of 1.9%. The specificity of unilateral analysis (81.3%; 95% CI: 78.1, 84.1) was inferior to that in the bilateral analysis (81.3% vs. 91.8%), with a difference of -10.5% being lower than the non-inferiority margin. The average number of marks per breast in both modes was 0.94. The maximum abnormality scores of cancers in bilateral and unilateral analysis showed excellent agreement (intraclass correlation coefficient: 0.985).

**CONCLUSION**

AI software performance in simulated unilateral mammography analysis demonstrated non-inferior sensitivity and inferior specificity compared to bilateral mammography.

**CLINICAL RELEVANCE/APPLICATION**

Non-inferior sensitivity of AI software in unilateral mammography compared to bilateral mammography supports use of AI software in the setting of surveillance mammography in patients treated with mastecomy.

## S3A-SPBR-7 THE DIAGNOSTIC VALUE OF MULTIMODAL IMAGING BASED ON MR COMBINED WITH ULTRASOUND IN BENIGN AND MALIGNANT BREAST DISEASES

Zhiqun Wang (*Abstract Co-Author*) Nothing to Disclose
Dong Bai (*Presenter*) Nothing to Disclose

**PURPOSE**

We aimed to construct and validate a multimodality MRI combined with ultrasound based on radiomics for the evaluation of benign and malignant breast diseases.

**METHODS AND MATERIALS**

The preoperative enhanced MRI and ultrasound images of 131 patients with breast diseases confirmed by pathology in Aerospace Center Hospital from January 2021 to August 2023 were retrospectively analyzed, including 73 benign diseases and 58 malignant diseases.Ultrasound and 3.0T multiparameter MRI scans were performed in all patients. Then, all the data were divided into training set and validation set in a 7:3 ratio.Regions of interest (ROI) were drawn layer by layer based on ultrasound and MR enhanced sequences to extract radiomics features. The optimal radiomic features were selected by the best feature screening method. Logistic Regression classifier was used to establish models according to the best features, including ultrasound model, MRI model, ultrasound combined with MRI model. The model efficacy was evaluated by the area under the curve(AUC) of the ROC(receiver operating characteristic), sensitivity, specificity, and accuracy.

**RESULTS**

The F-test based on ANOVA was used to screen out 20 best ultrasonic features, 11 best MR Features, and 14 best features from the combined model.Among them, texture features accounted for the largest proportion, accounting for 79%.The ultrasound combined with MR Image fusion model based on Logistic Regression classifier had the best diagnostic performance. The AUC of the training group and the validation group were 0.92 and 091, the sensitivity was 0.80 and 0.67, the specificity was 0.90 and 0.94, and the accuracy was 0.84 and 0.79, respectively.It was better than the simple ultrasound model (AUC of validation set was 0.82) or the simple MR model (AUC of validation set was 0.85).

**CONCLUSION**

Compared with the traditional ultrasound or magnetic resonance diagnosis of breast diseases, the multimodal model of MRI combined with ultrasound based on radiomics can more accurately predict the benign and malignant breast diseases, thus providing a better basis for clinical diagnosis and treatment.

**CLINICAL RELEVANCE/APPLICATION**

Multi-modality imaging methods make up for the shortcomings of single examination methods, and combine radiomics to avoid the mistakes of manual judgment, so as to make more accurate judgment of diseases.

## S3A-SPBR-9 DEVELOPMENT OF A DEEP LEARNING SYSTEM FOR PREDICTING ER-NEGATIVE, ER-LOW POSITIVE, AND ER-HIGH POSITIVE BREAST CANCER BASED ON MAGNETIC RESONANCE IMAGING

Guanxun Cheng, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhenwei Shi, PhD (*Abstract Co-Author*) Nothing to Disclose
Zaiyi Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Yi Dai, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate a dynamic contrast-enhanced (DCE)-MRI based deep learning system capable of discriminating different ER expressing statuses (ER-negative, ER-low positive, and ER-high positive) in breast cancer.

**METHODS AND MATERIALS**

This retrospective diagnostic study has been approved by the local institutional review board, and patient consent was waived. Pretreatment DCE-MRI data was collected from patients with breast cancer of six centers between February 2016 and August 2023. Patients were categorized into ER-negative, ER-low positive, and ER-high positive groups based on pathologic examination. Tumor segmentation was performed on the DCE image with peak enhancement using an automated deep learning algorithm. Four DCE-MRI based models were developed to discriminate between ER negative vs. ER-low/high positive, ER negative vs. ER-low positive, ER negative vs. ER-high positive, and ER-high positive vs. ER-low positive breast cancers. The model performance was evaluated using the area under the receiver operating characteristic curve (AUC).

**RESULTS**

A total of 3500 breast cancer patients from six institutions were retrospectively studied. One thousand eight hundred and sixty-two patients from Center 1 and 2 were included in the training dataset (mean [SD] age, 49 [11] years); 1638 patients from Center 3-6 formed the external test dataset (A-D) (mean [SD] age, 50 [11] years, 47 [8] years, 47 [10] years and 51 [10] years, respectively). The AUCs of the models yielded by the training set and the external test sets A-D were 0.759-0.827 for differentiating between ER negative versus -low/high tumors, 0.779-0.936 for ER negative versus -low positive, 0.765-0.842 for ER negative versus ER-high positive and 0.661-0.787 for ER-high positive versus ER-low positive, respectively.

**CONCLUSION**

These findings suggest that a DCE-MRI based deep learning system may have the potential to preoperatively predict ER statuses in breast cancer patients, with therapeutic implications.

## CLINICAL RELEVANCE/APPLICATION

The DCE-MRI based deep learning system could be used to noninvasively identify the new three-classification of ER expressing status in breast cancer, which is helpful to the decision-making for endocrine therapies.

## S3A-SPCA-1 IMPACT OF CORONARY ATHEROSCLEROSIS ON LEFT VENTRICULAR FUNCTION IN ESSENTIAL HYPERTENSION: CORRELATION BETWEEN MYOCARDIAL STRAIN AND GENSINI SCORE

Xin Tang, MD (*Abstract Co-Author*) Nothing to Disclose
Li Jiang, MD (*Abstract Co-Author*) Nothing to Disclose
Jin Wang (*Abstract Co-Author*) Nothing to Disclose
Yining Jiang (*Abstract Co-Author*) Nothing to Disclose
Wei-Feng Yan, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Coronary arterial atherosclerosis (CAS) significantly impacts morbidity and mortality in patients with hypertension (HTN). The extent of CAS's influence on left ventricular (LV) dysfunction in hypertensive patients remains unclear. This study explores the effects of CAS on LV systolic and diastolic functions in this population.

### METHODS AND MATERIALS

A total of 115 hypertensive patients clinically suspected of having coronary artery disease underwent cardiac MRI and digital subtraction angiography (DSA) assessments. Of these, 87 were confirmed to have coronary arterial sclerosis (CAS) while 28 did not. We assessed LV structure and function, global strains (including peak systolic and diastolic strain rates in radial, circumferential, and longitudinal orientations), and Gensini scores. Patients with HTN CAS+ were categorized into two subgroups based on the median Gensini score of 12. Multivariable linear regression analysis was used to identify factors influencing reduced LV strain.

### RESULTS

Compared to normal controls, hypertensive patients showed increased LV end-diastolic (160.9±43.7 vs. 130.9±27.6, P<0.01) and end-systolic volumes (83.2±44.7 vs. 47.7±14.6, P<0.01), along with reduced global peak strains (Radial: 26.6±12.5 vs. 36.9±9.2; Circumferential: 17.1±6.1 vs. 21.0±2.8; Longitudinal: 10.3±4.8 vs. 14.5±2.4, all P<0.05). HTN CAS+ patients exhibited a lower ejection fraction compared to healthy controls (53.0±18.4 vs. 63.8±7.16, P<0.01). A progressive reduction in all global peak strains and peak diastolic strain rates was observed from normal controls through those with a Gensini score =12 to those with a score >12. Gensini score independently affected global circumferential and longitudinal peak strains (GCPS, ß=0.28, P<0.05; GLPS, ß=0.38, P<0.05) after adjusting for confounding factors in hypertensive patients.

### CONCLUSION

CAS exacerbates LV dysfunction in hypertensive patients, particularly impairing diastolic function in early stages. There is a significant association between reductions in LV myocardial strain and increases in Gensini score.

### CLINICAL RELEVANCE/APPLICATION

This study highlights the significant role of cardiac MRI in evaluating the impact of coronary atherosclerosis on left ventricular function in hypertensive patients with concurrent coronary artery disease. By correlating myocardial strains measured by MRI with Gensini scores from DSA, we demonstrate that cardiac MRI provides critical insights for the precise management of patients with coronary artery disease.

## S3A-SPCA-2 HOW THE COMBINATION OF CONVENTIONAL FACTORS AND THE RADIOMICS SIGNATURE OF CORONARY PLAQUE TEXTURE COULD IMPROVE CARDIAC RISK PREDICTION

Stefan O. Schoenberg, MD, PhD (*Abstract Co-Author*) Research agreement, Siemens AG
Matthias F. Froelich, MD (*Abstract Co-Author*) Consultant, Smart Reporting GmbH;Consultant, Guerbet SA
Sandy Engelhardt (*Abstract Co-Author*) Nothing to Disclose
Theano Papavassiliu (*Abstract Co-Author*) Nothing to Disclose
Jannik Kahmann (*Abstract Co-Author*) Nothing to Disclose
Isabelle Ayx, MD (*Presenter*) Research Consultant, AstraZeneca PLC

### PURPOSE

High-risk plaques (HRP) have an elevated risk of causing cardiovascular events through plaque rupture or erosion. Changes in epicardial adipose tissue (EAT) are connected to cardiovascular disease (CVD) and HRP. Radiomics analysis could help understand the association between plaque texture, EAT, and cardiovascular risk. Photon-counting CT (PCCT) exhibits enhanced feature stability, offering the potential to further advance radiomics analysis.

**METHODS AND MATERIALS**

Coronary plaques were manually segmented in this retrospective, single-centre study and radiomic features were extracted using pyradiomics. The study population was divided into groups according to the presence of HRP, plaques with at least 70%, respective 50% stenosis, or triple-vessel disease. A combined group with patients exhibiting at least one of these risk factors was formed. Random forest feature selection identified differentiating features for the groups. EAT thickness and density were measured and compared with feature selection results.

**RESULTS**

306 plaques from 61 patients (13 female, mean age 61 years) were analysed. Plaques of patients with HRP features or relevant stenosis demonstrated a higher presence of texture heterogeneity through various radiomics features compared to patients with only an intermediate stenosis degree. While EAT thickness did not significantly differ, affected patients showed higher mean densities in the 50%, HRP, triple-vessel, and combined groups, but not in the 70% group.

**CONCLUSION**

The combination of a higher EAT density and a more heterogeneous plaque texture might offer an additional tool in identifying patients with an elevated risk of cardiovascular events.

**CLINICAL RELEVANCE/APPLICATION**

Cardiovascular disease is until today the leading cause of mortality in the world. Plaque composition and changes in the epicardial adipose tissue are connected to cardiac risk and MACE rate. A better understanding of the interrelation of these risk indicators can lead to improved cardiac risk prediction and early personalized therapy.

## S3A-SPCA-3 LEVERAGING AI FOR OPPORTUNISTIC SCREENING: IDENTIFYING CORONARY ARTERY CALCIFICATION ON NON-ECG GATED LUNG CANCER SCREENING CHEST CT

Kevin Pham, DO (*Abstract Co-Author*) Nothing to Disclose
Akash Dadlani (*Abstract Co-Author*) Nothing to Disclose
Ava Wexler (*Abstract Co-Author*) Nothing to Disclose
Devon A. Klein, MD, MBA (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate non-contrast lung cancer screening chest CT scans for coronary artery calcification (CAC) to identify cardiovascular risk. Our goal is to improve early detection strategies using commercially available artificial intelligence (AI) technology.

**METHODS AND MATERIALS**

A retrospective analysis was conducted applying Nanox AI's cardiac solution to non-contrast, non-ECG gated chest CTs in two phases. The study comprised two cohorts: the first included 497 adult non-contrast chest CTs, and the second consisted of 492 low-dose lung cancer screening CTs. In Phase 1, 382 (77%) were successfully analyzed by the software. The results were independently verified by an experienced radiologist. In Phase 2, 431 (87.6%) of the lung cancer screening studies were analyzed by the software. Phase 1 focused on validation of the AI solution, and Phase 2 emphasized reproducibility of results while revealing incidence of undocumented CAD in at-risk patients. The study population had a mean age of 67 years (SD = 5.8), with a range of 52 to 78 years. Among the patients (n=171), 70% were male (n=120) and 30% were female (n=51).

**RESULTS**

Phase 1: 41.62% (159) of the analyzed scans exhibited moderate to severe CAC; 30.1% had a CAC Score > 400 and 11.52% had a CAC Score from 100 to 400. Phase 2: 39.68% (171) demonstrated moderate to severe CAC; 23.4% had a CAC Score > 400 and 16.2% had a CAC Score from 100 to 400. 40% (68) had no history of CAD. 31% (53) patients with moderate to severe disease were unknown. No significant relationship was observed between Lung-RADS (13% (22); score =3 considered significant).

**CONCLUSION**

AI-driven CAC screening in lung cancer patients can lead to detection of moderate to severe CAC, prompting early intervention and improving outcomes.

**CLINICAL RELEVANCE/APPLICATION**

Atherosclerotic cardiovascular disease (ASCVD) is prevalent in the general population and can result in myocardial infarction and stroke. CAC scoring predicts mortality and informs ASCVD risk assessment, guiding management for primary prevention. Asymptomatic adults who are intermediate to high ASCVD risk are screened with dedicated ECG-gated CT scans. Incidental CAC can be identified on non-gated chest CT scans performed for other reasons. The Society of Cardiovascular Computed Tomography and Society of Thoracic Radiology recommend reporting CAC presence and severity in all non-contrast chest CTs. This would be clinically impactful in patients without known CAD who would not otherwise be screened. This AI-driven solution allows for consistent CAC reporting with a quantified measure of CAC severity using the Agatston score.

## S3A-SPCA-6 PREDICTION OF RADIATION THERAPY INDUCED CARDIOVASCULAR TOXICITY FROM PRETREATMENT CT IMAGES IN PATIENTS WITH THORACIC MALIGNANCY VIA AN OPTIMALBIOMARKER APPROACH

Steven J. Feigenberg (*Abstract Co-Author*) Nothing to Disclose
Caiyun Wu (*Abstract Co-Author*) Nothing to Disclose

Bonnie Ky (*Abstract Co-Author*) Nothing to Disclose
Nicholas Poole (*Abstract Co-Author*) Nothing to Disclose
Jennifer (Wei) Zou, PHD (*Abstract Co-Author*) Nothing to Disclose
Mujun Long (*Abstract Co-Author*) Nothing to Disclose
Mostafa Alnoury, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Cardiovascular toxicity is a well-known complication of thoracic radiation therapy (RT), potentially leading to increased morbidity and mortality in cancer patients, but existing techniques for prediction of cardiovascular toxicity have limitations. There is growing interest in the identification of predictive

biomarkers of cardiovascular toxicity to maximize patient oncologic and cardiovascular outcomes. In this work, an optimal biomarker (OBM) method is designed and tested to perform cardiotoxicity prediction from pre-treatment CT images.

**METHODS AND MATERIALS**

Manual segmentations of 10 cardiovascular objects of interest (heart, left ventricular myocardium, left atrium, right atrium, left ventricle, right ventricle, ascending aorta, aortic arch, descending thoracic aorta, and thoracic aorta) were performed on pre-treatment non-contrast-enhanced CT simulation images in 125 patients with thoracic malignancy (41 who developed cardiotoxicity and 84 who did not develop cardiotoxicity after RT based on reference standard serial echocardiography), and 1078 image-based features were extracted from these objects. The top 5 features in a specific combination that were maximally independent among themselves and with respect to all other features and that showed the best class-discriminative ability among the 1078 features were determined. A prediction model based on an SVM classifier utilizing these 5 features was designed and tested.

**RESULTS**

The number of data sets used for training, validation, and testing were 75, 25 and 25, respectively. The best 5-feature combination consisted of CT intensity-based and texture-based features derived from the left ventricle which yielded a testing prediction accuracy of 0.88. Several other combinations of 3 and 4 features derived from the heart, left atrium, thoracic aorta, and descending thoracic aorta yielded an accuracy of 0.84.

**CONCLUSION**

It is feasible to predict the future development of cardiotoxicity with high accuracy in individual patients with thoracic malignancy from available pre-treatment CT images acquired prior to the initiation of RT via advanced machine learning methods.

**CLINICAL RELEVANCE/APPLICATION**

The proposed method has the potential for personalized RT planning, risk prediction, and management of patients with malignancy, which may ultimately optimize oncologic and cardiovascular outcomes for each individual patient.

## S3A-SPCA-7 MYOCARDIAL EXTRACELLULAR VOLUME QUANTIFICATION IN CARDIAC CT: COMPARISON OF THE EFFECTS OF DEEP LEARNING RECONSTRUCTION AND ITERATIVE RECONSTRUCTION ALGORITHMS WITH MRI AS A REFERENCE STANDARD

Jianlin Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Hao Woo (*Abstract Co-Author*) Nothing to Disclose
Zhaoguo Cui (*Abstract Co-Author*) Nothing to Disclose
YAN WANG (*Abstract Co-Author*) Nothing to Disclose
Dong Yang, BMedSc, MMEd (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the effects of deep learning reconstruction- advanced intelligent clear-IQ engine (DLR-AiCE) and two different iterative reconstruction that incorporates myocardial extracellular volume (ECV) quantification by cardiac CT using MRI as a reference standard.

**METHODS AND MATERIALS**

In this prospective study Patients who underwent cardiac CT and MRI were collected., Paired CT image sets were reconstructed using DLR-AiCE, model-based iterative reconstruction (MBIR) and hybrid iterative reconstruction (HIR). Subtraction techniques were used to obtain subtraction images which used for calculation of CT-ECV. T1 mapping were used to evaluate the MR-ECV. We calculated correlations between the CT-ECV and MR-ECV via Pearson correlation analysis.

**RESULTS**

In the mid anterior wall of the left ventricle, there is a good correlation between the CT-ECV results calculated by DLR-AiCE, MBIR, and HIR compared to MR-ECV ($r=0.645$, $r=0.723$, $r=0.604$, $P<0.05$). In the mid anteroseptal wall of the left ventricle, there is also a good correlation between the CT-ECV results calculated by DLR-AiCE, MBIR, and HIR compared to MR-ECV ($r=0.633$; $r=0.668$; $r=0.627$, $P<0.05$). In the anterior lateral and inferior septal wall of the left ventricle, only CT-ECV results calculated by DLR-AiCE show a correlation with MR-ECV ($r=0.614$, $r=0.672$, $P<0.05$). In the inferior lateral and inferior walls of the left ventricle, none of CT-ECV resulted calculated by three reconstruction methods show a correlation with MR-ECV ($P>0.05$).

**CONCLUSION**

DLR-AiCE can improved accuracy of myocardial ECV quantification when compared with iterative reconstruction using MRI as a reference standard.

**CLINICAL RELEVANCE/APPLICATION**

Because of the lengthy acquisition time, the numerous contraindications and complexity associated with the scanning process, the prevalence of CMR is limited. Cardiac CT, on the other hand, is widely used due to its ease of access and quick acquisition times. Therefore, CT-ECV quantification derived from DLR-AiCE may represent a useful non-invasive alternative for assessing ischemic and non-ischemic cardiomyopathies.

## S3A-SPCA-9 RADIOMICS SIGNATURE OF AGING MYOCARD IN CARDIAC PHOTON COUNTING COMPUTED TOMOGRAPHY

Stefan O. Schoenberg, MD, PhD (*Abstract Co-Author*) Research agreement, Siemens AG
Isabelle Ayx, MD (*Abstract Co-Author*) Research Consultant, AstraZeneca PLC
Mustafa Kuru (*Abstract Co-Author*) Nothing to Disclose
Abhinay Krishna Vellala (*Abstract Co-Author*) Nothing to Disclose
Alexander Hertel, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon-counting computed tomography (CT) offers improved spatial and temporal resolution, allowing for detailed texture analysis in cardiovascular imaging. As cardiovascular diseases primarily affect individuals over 65, this technology could detect structural changes in the ageing left-ventricular myocardium. Identifying these changes may help establish an imaging-based cardiovascular profile that indicates premature biological ageing and the associated elevated risk of major cardiovascular events, providing crucial insights into the progression of coronary heart disease.

**METHODS AND MATERIALS**

This IRB-approved retrospective study examined 90 patients undergoing clinically indicated electrocardiography (ECG)-gated contrast-enhanced cardiac CT with a first-generation whole-body dual-source photon-counting detector CT (NAEOTOM Alpha, Siemens Healthcare GmbH). Patients were selected who had a similar Agatston score (between 0-100) and were then split into two age groups: 50-60 years and 70-80 years. The left ventricular myocardium was segmented and radiomics features extracted. Epicardial adipose tissue (EAT) density and thickness, along with other clinical parameters,

such as diabetes, hypertension, smoking, hyperlipidemia and more, were also recorded. The statistical analysis was conducted using R statistics and a Python-based random forest (RF) classifier.

## RESULTS

There were no significant differences between the recorded clinical parameters and the measured EAT density, as well as the right ventricular thickness, between the two age groups. This enabled a homogeneous comparison. The RF classifier was able to differentiate between the two age groups with a test accuracy of 0.74 and a train accuracy of 0.95. Several important features were identified.

## CONCLUSION

The radiomics texture features of the left ventricular myocardium demonstrated superior performance in differentiating between the two age groups, outperforming conventional parameters such as EAT density and thickness. This suggests that radiomics analysis of the left ventricular myocardium may serve as a potential imaging biomarker of myocardial aging.

## CLINICAL RELEVANCE/APPLICATION

Radiomics analysis of left ventricular myocardium offers a unique opportunity to visualize changes in myocardial texture during aging.

Pauline Pannenbecker, MD, BA (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the impact of novel ultra-high resolution (UHR) photon-counting detector (PCD) CT on image quality and reader confidence in spectral CT pulmonary angiographies (CTPA) compared to standard resolution dual-energy CTPA with energy-integrating detector (EID) CT.

### METHODS AND MATERIALS

Between February and April of 2024, 32 CTPAs were acquired with a high-pitch UHR scan protocol on a PCD CT and retrospectively compared to 32 CTPAs performed with a standard resolution dual-energy protocol on a dual-source EID CT. For both protocols, 50ml of iodinated contrast medium were injected (flow rate 4ml/s). Pitch was set at 3.2 in the PCD group and at .55 in the EID group (default setting). Objective image quality was assessed with ROI-based measurements (CT attenuation, contrast-to-noise and signal-to-noise ratio (CNR, SNR)) within pulmonary vessels. Based on a five-point rating scale, four readers (R1-4) assessed CTPA images reconstructed in a medium soft kernel based on minimal slice thickness images (PCD group: 0.4mm, EID group: 0.6mm) and iodine maps with regard to overall image quality, assessability of pulmonary vessels and self-reported confidence in the diagnosis of pulmonary embolism.

### RESULTS

No difference in CT attenuation was ascertained for PCD and EID CTPAs (all $p > 0.05$). CNR and SNR in lobar arteries were higher in the UHR PCD group, e.g. median CNR 26.7 [21.1 - 42.8] vs. 22.7 [16.1 - 28.4] in the right lower lobe (PCD vs. EID, $p < 0.05$). Subjective image quality for UHR PCD CTPAs was rated higher by three of four readers with 81.25% of CTPAs rated as excellent (R1/R2/R3/R4) as opposed to 8.3%, 13.9% 8.3% of EID CTPAs (R1/R2/R3, $p < 0.05$). Iodine maps were rated higher in the UHR group by all readers (e.g. excellent image quality in 62.5% of PCD maps vs. 0% of EID maps (R1), all $p < 0.001$). In UHR PCD CTPAs, assessability of pulmonary vessels ranked higher with assessability down to peripheral subsegmental levels in 78.1%, 75.0%, 78.1% and 65.6% of PCD CTPAs vs. 3.1%, 6.2%, 3.1% and 25% of EID CTPAs (R1/R2/R3/ R4, $p < 0.01$). Self-reported diagnostic reader confidence was higher for UHR PCD CTPAs with highest confidence levels attributed in 78.1%, 84%, 71.9% and 65.6% of cases vs. 0%, 18.8%, 0% and 37.5% of EID CTPAs (R1/R2/R3 $p < 0.01$, R4 $p < 0.05$).

### CONCLUSION

UHR PCD CTPA allows for superior objective and subjective image quality and increased reader confidence in the diagnosis of pulmonary embolism compared to standard dual-energy EID CTPA.

### CLINICAL RELEVANCE/APPLICATION

PCD CTPA at UHR settings enables assessment of both anatomic images, as well as the full spectral dataset in the form of iodine maps. An improved image quality and therefore increased self-reported diagnostic confidence of readers is of potentially high relevance for patient safety and diagnostic accuracy.

## S3A-SPCH-3 PREDICTIVE MODELING FOR RECURRENT PULMONARY EMBOLISMS WITH DEEP LEARNING BASED ON COMPUTED TOMOGRAPHIC PULMONARY ANGIOGRAPHY AND CLINICAL DATA

Shreyas Kulkarni, BS (*Abstract Co-Author*) Nothing to Disclose
Michael K. Atalay, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Scott Collins, RT (*Abstract Co-Author*) Nothing to Disclose

Zhusi Zhong (*Abstract Co-Author*) Nothing to Disclose
Vineethsubbu Somasundaram (*Presenter*) Nothing to Disclose

**PURPOSE**

Pulmonary embolisms (PE) pose a significant threat to public health in the United States, with high mortality rates despite available treatments. Recurrent PE episodes further compound the severity of the condition and exacerbate mortality risk. We aimed to develop a deep learning model leveraging computed tomographic pulmonary angiography (CTPA) and clinical data to predict recurrence in PE patients. We hypothesize that this deep learning model will outperform PE Severity Index (PESI) in predicting PE recurrence.

**METHODS AND MATERIALS**

An internal database of 3978 CTPA scans were collected from 927 patients (163 deceased, median age 64, range 13-99, 52% female) who have experienced a PE via retrospective review across three institutions. From this population, 418 patients had follow-up CTPA scans and 128 were diagnosed with at least one case of a persisting or recurrent PE. Data from one institution were randomly split 7:1:2 into training, validation, and internal testing sets. Data from the two remaining institutions were used as an external testing set. Imaging features extracted from PEnet and clinical data (PESI variables) were used to train Random Survival Forest models. Performance was evaluated with concordance index (c-index) and compared to PESI predictions with the Wilcoxon signed-rank test. Kaplan-Meier analysis was performed by stratifying patients into high- and low-risk groups based on the combined imaging and clinical model prediction.

**RESULTS**

Models based on (a) imaging, (b) clinical, (c) combined imaging and clinical data, and (d) combined imaging, clinical data, and PESI achieved c-index values of 0.587, 0.682, 0.678, and 0.695, respectively, on the internal testing set. The complete fusion model achieved a c-index value of 0.621 on the external testing set. For both the internal and external data sets, the combined model outperformed PESI (0.508 and 0.531, respectively, $p<0.001$). When stratifying patients into high- and low-risk groups, recurrence outcomes were significantly different for both the internal dataset and external dataset ($p<0.05$).

**CONCLUSION**

Deep learning models based on combined CTPA features and clinical data outperform other models and PESI for recurrence risk prediction in PE. The addition of imaging to clinical features mostly improves performance compared to clinical features alone, however the addition of PESI does not. The next steps will involve integrating additional data and implementing a foundational model to enhance performance on external datasets.

**CLINICAL RELEVANCE/APPLICATION**

This study addresses the pressing need for improved risk stratification in post-treatment PE management, ultimately enhancing patient outcomes and reducing the burden of PE-related complications.

## S3A-SPCH-7 AUTOMATIC VIRTUAL CONTRAST-ENHANCED CT SYNTHESIS USING DUAL-ENERGY CT AND RESIDUAL U-NET WITH ATTENTION MODULE FOR DETECTING HILAR LYMPH NODES

Jung Han Woo (*Abstract Co-Author*) Nothing to Disclose
Myung Jin Chung, MD (*Abstract Co-Author*) Research Consultant, Samsung Electronics Co, Ltd;Research Consultant, Pharmex Advanced Laboratories, SL;Research Grant, Lunit Inc;Research Grant, VUNO Inc
JAEMO KOO (*Abstract Co-Author*) Nothing to Disclose
Uju Jeon, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To propose an automatic virtual contrast-enhanced chest computed tomography (CT) synthesis using dual-energy CT and a Residual U-Net with an attention module to detect clinically significant hilar lymphadenopathy.

**METHODS AND MATERIALS**

We conducted a retrospective analysis of 2,082 patients who underwent dual-energy chest CT scans. Our approach utilized a Residual U-Net combined with a Convolutional Block Attention Module (CBAM) to transform non-contrast CT images into virtual contrast-enhanced CT images. We evaluated the effectiveness of our method through quantitative and qualitative analyses and an observer study involving thoracic radiologists, focusing on the detection of significant hilar lymph nodes.

**RESULTS**

Our method achieved an average peak signal-to-noise ratio (PSNR) of 25.082, a structural similarity index (SSIM) of 0.833, and mutual information (MI) of 1.568. The mean absolute error (MAE), mean squared error (MSE), and root mean squared error (RMSE) were reported as 0.040, 0.023, and 0.102, respectively. Compared to other methods, our proposed approach demonstrated superior performance across all evaluation metrics. In the observer study, our method exhibited a higher diagnostic accuracy for detecting hilar lymphadenopathy (69.2%) compared to the Residual U-Net-based GAN with CBAM (53.7%).

**CONCLUSION**

The integration of dual-energy computed tomography (DECT) with a Residual U-Net framework augmented by CBAM presents a highly effective technique for generating synthetic contrast-enhanced chest CT images. This novel approach significantly enhances the detection of clinically significant hilar lymphadenopathy, underscoring its potential clinical utility.

**CLINICAL RELEVANCE/APPLICATION**

The integration of dual-energy CT and a Residual U-Net enhanced by the Convolutional Block Attention Module (CBAM) significantly improves the detection of hilar lymphadenopathy, offering clear benefits in clinical settings. This approach reduces the need for contrast media, which is particularly advantageous for patients with contraindications such as renal insufficiency or allergies, thereby minimizing associated risks and operational costs.

## S3A-SPCH-9 INITIAL CLINICAL EXPERIENCES OF A NOVEL PHOTON COUNTING SYSTEM COMBINING CADMIUM ZINC TELLURIDE DETECTORS AND SUPER-HIGH RESOLUTION DEEP-LEARNING IMAGE RECONSTRUCTION

Luuk J. Oostveen, DIPLPHYS (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation

Pieternel Van Der Tol (*Abstract Co-Author*) Nothing to Disclose
Mirte Simmelink (*Abstract Co-Author*) Nothing to Disclose
Ewoud J. Smit, MD, PhD (*Presenter*) Speakers Bureau, Canon Medical Systems CorporationResearch Grant, Canon Medical Systems Corporation

## PURPOSE

To assess the quality of chest images acquired with a photon counting CT (PCCT) scanner that combines cadmium zinc telluride (CZT) detectors with super-high resolution deep-learning image reconstruction (SHR-DLR).

## METHODS AND MATERIALS

The first 18 patients who underwent imaging of the chest for various indications on a prototype PCCT scanner (Canon Medical Systems, Tokyo, Japan) were analyzed in this study. Scans were reconstructed as normal resolution images (NR; 0.62 mm sections, 512 matrix, hybrid iterative reconstruction, lung kernel) and as super-high-resolution images (SHR-DLR; 0.21 mm sections, 1024 matrix, deep learning reconstruction, lung kernel). Exposure dose (CTDIvol and DLP) were recorded. All images were reviewed by an experienced chest radiologist for image quality (IQ) in a random manner. Images were scored for overall IQ, sharpness, detail visibility, noise and artifacts, all on a 5-point scale (poor, moderate, good, very good, excellent). Image noise was measured over a homogeneous region in the left ventricle. The number of bronchial branching generations were counted in the upper right (1R), upper left (5L) and right lower lobe (10R). Bronchus volumes were automatically calculated. A signed rank test with a p-value below 0.05 indicated a significant difference.

## RESULTS

Exposure dose in this initial patient group was 5.4 (IQR 1.4-5.4) mGy CTDIvol and 188 (IQR 56-231) mGy.cm DLP. The SHR-DLR images were rated to have higher overall image quality (4.7 vs 3.4), image sharpness (4.7 vs 3.1), detail visibility (4.4 vs 3.3) and lower perceived image noise (4.1 vs 3.2) compared to the NR images (all $p<0.01$). No artifacts were seen in either reconstruction (both 4.0). Image noise was 36.5 (IQR 35.5-37.4) HU with SHR-DLR compared to 36.8 (IQR 31.7-39.6) HU with NR, but with finer noise texture on the SHR-DLR images. On average, 1.2 more peripheral bronchial branches could be assessed with SHR-DLR ($p<0.01$). Bronchial volume from automatic segmentation was higher for the DLR-SHR images with 54.1 mL compared to 47.2 mL for the NR images ($p<0.01$).

## CONCLUSION

Initial results show that PCCT combining CZT detectors and SHR-DLR reconstruction provides superior spatial resolution and excellent depiction of the bronchial system while keeping image noise low.

## CLINICAL RELEVANCE/APPLICATION

Photon counting CT systems with SHR-DLR providing low-noise super-high-resolution images of the chest may push diagnostic abilities past their current limits.

## S3A-SPER-1 USING EXPLAINABLE ARTIFICIAL INTELLIGENCE (XAI) ASSISTED SYSTEMS TO ENHANCE THE RESCUE PROCESS FOR PATIENTS WITH CEREBRAL HEMORRHAGE IN RURAL HOSPITALS

Chih-Hsing Tang (*Presenter*) Nothing to Disclose

### PURPOSE

In modern times, the shortage of various medical personnel and the need for them to multitask due to harsh medical environments require the immediate establishment of a rapid and effective response model. Deep learning models are often questioned as "black boxes." To overcome these challenges, we have decided to introduce an explainable AI assisted system to aid in medical decision-making.

### METHODS AND MATERIALS

1.Our AI assisted diagnostic system utilizes convolutional neural networks for data training and model construction, followed by validation of explainability using the occlusion sensitivity map method. 2.After patients undergo brain CT scans, images are simultaneously transmitted to the PACS system and AI interpretation system. When the AI system detects positive bleeding cases, it sends alert SMS messages via the FHIR protocol to the attending and reporting physicians' phones, prompting prioritized interpretation or intervention.

### RESULTS

1.After explainability validation, errors were observed in images affected by motion artifacts, brain implants, and incomplete skull structures. Excluding these types, the system exhibited a sensitivity of 0.95 ($P < 0.05$) and accuracy of 0.94 ($P < 0.05$). 2.Improving Work Efficiency: The average completion time for emergency head CT reports has been reduced by 67%, with a 60% decrease in the median time. This reduction has alleviated pressure on employees, allowing each person to save an average of 10.6 hours per year in report writing. Based on an average hourly wage of $158 for radiologists, this translates to an annual savings of $1680 per person in labor costs. 3.Near miss incidents occurred with a success rate of approximately 1.47%, where rescue physicians failed to report minor brain bleeds. 4.Enhancing patient care efficiency: Medical decision-making time decreased from within 30 minutes to 20 seconds, a 90% speed increase, and reduced mortality rates associated with ongoing bleeding. 5.Reducing the time from emergency admission to surgical treatment: Due to timely SMS reminders, the proportion of patients undergoing surgery within an hour increased from 14% to 45%.

### CONCLUSION

The use of an explainable AI assisted diagnostic system improved the quality and efficiency of medical care. The AI system's ability to promptly notify results reduced physician workload. These results demonstrate the value and potential of enhancing human intelligence (HI) with artificial intelligence (AI), especially in small to medium-sized hospitals with limited resources, highlighting its significant value.

### CLINICAL RELEVANCE/APPLICATION

AI serves as an assistant rather than a replacement, and when used correctly and strategically, AI assisted systems can generate substantial benefits for healthcare quality.

## S3A-SPER-2 ASSESSMENT OF AN AI AID IN DETECTION OF ADULT APPENDICULAR SKELETAL FRACTURES, JOINT DISLOCATION AND JOINT EFFUSION BY EMERGENCY RADIOLOGISTS

Raquel Cano Alonso, MD (*Abstract Co-Author*) Nothing to Disclose
Vicente Martinez de Vega, PhD (*Abstract Co-Author*) Nothing to Disclose
Ana Fernandez Alfonso (*Abstract Co-Author*) Nothing to Disclose
Julia Lopez Alcolea, MD (*Abstract Co-Author*) Nothing to Disclose
David Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Alejandro Diaz Moreno, MD (*Presenter*) Nothing to Disclose

### PURPOSE

We hypothesized that our Artificial intelligence (AI) applied to the reading of urgent bone X-rays could successfully detect fractures, joint dislocations and joint effusion with high sensitivity (Sens) and specificity (Spec) rates. Thus, the objectives of our study are: 1. To determine Sens and Spec rates of our AI software in the detection of bone fractures, joint dislocations and elbow-joint effusion on radiographs as compared to Gold Standard (GS). 2. To evaluate the concordance rate between the reading of radiographs by AI and Radiology residents (RR). 3. To determine and compare the proportion of doubtful results by AI and RR, as well as the rates that were confirmed by GS.

## METHODS AND MATERIALS

We designed an observational, transversal double-blind descriptive and retrospective study to evaluate all adult Bone X-rays (BXR) referred from the Emergency Department at our center from October to November 2022, obtaining a sample of 792 BXR, which was divided into three groups: large joint, small joint and long-flat bones. Our AI is trained to detect three variables (fractures, joint dislocations and elbow effusion) and provide a result as positive, negative or doubtful. We compared the diagnostic performance of AI and RR against a senior radiologist with more than ten years of experience (considered as GS).

## RESULTS

Our study sample population's median age was 48 years; 48,6% were male. Most radiological examinations included 2 projections (90.2%) and their quality was considered optimal for diagnostic purposes in the vast majority of cases (97.2%). Statistical analysis showed Sens=90.6%, and Spec=98% for fracture detection by RR and 95.8% and 97.6% by AI. RR achieved higher Sens (77.8%) and Spec (100%) for joint dislocation detection than AI. The Kappa Coefficient between RR and AI was 0.797 for fractures in the group of large joints; for all other variables and groups, the concordance rate was acceptable. Moreover, we described the frequency of doubtful cases in every category and how many of them were considered positive by GS.

## CONCLUSION

We designed a study to evaluate the impact of AI in a real working environment, comparing AI diagnostic performance vs radiologists (in training and senior). AI achieved high Sens, Spec and AUC in the diagnosis of bone fractures. Our study also demonstrated a high concordance rate between AI and RR performance. To conclude, AI could be a helpful screening method because it can reduce the rate of missed diagnosis in a real-life environment.

## CLINICAL RELEVANCE/APPLICATION

Radiography is the first-line imaging modality for the diagnosis of traumatic skeletal injuries. Our study evaluates an AI software diagnostic performance on bone fractures, joint dislocations and elbow-joint effusion detection in a real working environment.

## S3A-SPGI-1 BASED ON CLINICAL AND CT RADIOMICS TO PREDICT THE EARLY RESPONSE OF CHEMOTHERAPY IN COLORECTAL CANCER LIVER METASTASIS

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Long Yuan (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to evaluate the predictive value of a combined model constructed with clinical, pathological and CT radiomics features in predicting the chemotherapy response in patients with colorectal cancer liver metastases (CRLMs).

### METHODS AND MATERIALS

A retrospective analysis was conducted on 169 patients with CRLMs in our hospital, including clinical, pathological and enhanced CT images.One liver metastasis (n=169) was randomly selected from each patient, including 75 responsive and 94 unresponsive.The lesions were randomly divided into a training set (n=118) and the validation set (n=51) at a 7:3 ratio. Radiomics features were extracted from portal venous phase CT images in the training set. And optimal radiomics features were selected using Select Percentile univariate analysis, Spearman correlation analysis, and the LASSO algorithm. The logistic regression (LR) classifier was used to construct the radiomics model and calculate the radiomics score (Radscore). Moreover, the clinical and pathological features were identified by t test, U test and chi-square test. Based on these features, clinical-pathological models and a combined model of both were developed. The predictive performance of the models were evaluated using receiver operating characteristic (ROC) curves. A nomogram was constructed based on the predictors of the combined model.

### RESULTS

A total of 9 radiomics and 3 clinical, pathological features were identified in this study, including liver metastasis type, CEA levels, and RAS gene status.In both training and validation sets, the efficacy of the combined model to predict chemotherapy response of CRLMs (AUC=0.896, 0.798) was similar to the radiomics model (AUC=0.895, 0.786), and the difference was not statistically significant (Z=-0.082, 0.548, P=0.935, 0.584). The efficacy of the combined model in predicting chemotherapy response of CRLMs in the training set was higher than that of the clinical-pathological model (AUC=0.681, Z= -4.346, P < 0.001), but there was no significant difference between the two models in the validation set (AUC=0.680, Z=1.536, P=0.125).

### CONCLUSION

The pre-chemotherapy CT radiomics features can effectively predict the chemotherapy response in CRLMs. Furthermore, combining clinical and pathological features can imporve the predictive performance of the model, but the value is limited.

### CLINICAL RELEVANCE/APPLICATION

This study presents a nomogram using clinical and CT texture features to early predict response of chemotherapy in CRLM, offering a basis for personalized treatment plans and patient prognosis evaluation, with potential application in clinical practice.

## S3A-SPGI-10 MACHINE LEARNING-BASED PREDICTION MODEL FOR KIRSTEN RAS (KRAS) MUTATION IN RECTAL CANCER USING RADIOLOGICAL FEATURES AT MR IMAGING

Sang Soo Shin, MD (*Abstract Co-Author*) Nothing to Disclose
Chung-Man Moon (*Abstract Co-Author*) Nothing to Disclose
Seong Woo Cho, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the association of Kirsten Ras (KRAS) mutation with radiological characteristics of rectal cancer at MR imaging to build a machine learning (ML)-based prediction model for diagnosis and clinical decision-making.

### METHODS AND MATERIALS

Three hundred one consecutive patients diagnosed with rectal cancer by endoscopic biopsy were included in this study. KRAS genotyping was performed after curative surgical resection. Qualitative MR image analysis was performed through consensus between two radiologists. The relationship between rectal MR imaging analysis and KRAS mutation was assessed using the univariate analysis. To build a KRAS mutation prediction model, radiological characteristics were confirmed through Random Forest (RF) and Linear Discriminant Analysis (LDA). Receiver operating characteristic curve (ROC) analysis was performed to prove the effectiveness of the ML model.

**RESULTS**

One hundred forty-seven patients had KRAS mutations, while 154 patients had no mutation (wild type). In univariate analysis, KRAS mutant tumors were associated with extramural vascular invasion, circumferential configuration, extramural mass formation, polypoid growth pattern, tumor signal intensity (SI) on T2-weighted images, tumor-to-muscle T2 SI ratio, and tumor-to-muscle T1 SI ratio among all 23 features ($P < 0.05$). Based on the optimal features identified by the RF and LDA methods, the area under the curve (AUC) of the ROC of the model was 0.757 (accuracy = 0.756) and 0.756 (accuracy = 0.754), respectively.

**CONCLUSION**

The diagnostic prediction model showed fair diagnostic accuracy for preoperative identification of KRAS mutations in rectal cancer.

**CLINICAL RELEVANCE/APPLICATION**

The diagnostic prediction model based on MR imaging findings can help clinical decision-making in patients with rectal cancer by providing KRAS mutation information in rectal cancer.

## S3A-SPGI-2 DEVELOPMENT OF A NON-INVASIVE DIAGNOSTIC MODEL FOR HIGH-RISK ESOPHAGEAL VARICES BASED ON RADIOMICS OF SPLEEN CT

Cheng Yan (*Abstract Co-Author*) Nothing to Disclose
Liqin Zhao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance of radiomic models derived from multi-phase spleen CT for HREV in cirrhotic patients.

**METHODS AND MATERIALS**

als between September 2019 and September 2023, with one serving as an external validation cohort. Non-contrast (NCP) and contrast-enhanced CT scans and endoscopic evaluations were performed. Patients were categorized into HREV and non-HREV groups based on endoscopy. Radiomic features were extracted from spleen CT images in NCP, arterial (AP), and portal venous phases (PVP). Feature selection was conducted using lasso regression and Pearson's correlation. Ten machine learning models were developed to diagnose HREV, assessed by AUC. Statistical significance was determined by the Kruskal-Wallis H test and Bonferroni-corrected Mann-Whitney U test ($p < 0.05$).

**RESULTS**

Among 233 patients, 11, 6, and 11 features were selected from NCP, AP, and PVP images, respectively. The AP models demonstrated the highest AUC values:0.8149 (CI: 0.8011, 0.8293) for the internal test set and 0.7703 (CI: 0.7558, 0.7794) for the external validation set. The NCP models revealed AUC values of 0.7095 (95% CI: 0.6889-0.7268) and 0.6540 (95% CI: 0.6335-0.6689) for the internal and external sets, respectively. The PVP models demonstrated AUCs of 0.7458 (95% CI: 0.7250-0.7632) and 0.7166 (95% CI: 0.7036-0.7311) for the same cohorts. Significant differences in AUC values were observed across phases ($p < 0.05$).

**CONCLUSION**

Radiomic models based on splenic CT, particularly those utilizing arterial phase imaging, demonstrate high diagnostic accuracy for HREV, enabling potential early detection and timely intervention.

**CLINICAL RELEVANCE/APPLICATION**

This study introduces a non-invasive method through multi-phase spleen CT, notably employing an arterial-phase spleen model, to more accurately diagnose high-risk esophageal varices and reduce reliance on invasive techniques, thereby enhancing maneuverability in clinical radiology.

## S3A-SPGI-3 THE FEASIBILITY OF A LOW-DOSE THREE-PHASE LIVER CT PROTOCOL (ULTRA-LOW-DOSE CT OF 60KVP TUBE VOLTAGE AT THE PORTAL VENOUS PHASE) FOR LIVER CANCER SCREENING AND FOLLOW-UP OF LIVER METASTASES

Zhen Li, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Qiuxia Wang (*Abstract Co-Author*) Nothing to Disclose
Hao Tang (*Abstract Co-Author*) Nothing to Disclose
Youfa Tang (*Presenter*) Nothing to Disclose

**PURPOSE**

The objective of this study is to validate the feasibility of a low-dose three-phase liver CT protocol (ultra-low-dose CT of 60kVp tube voltage at the portal venous phase) for liver cancer screening in high-risk populations and follow-up of liver metastases in cancer patients.

**METHODS AND MATERIALS**

68 participants with suspected liver cancer and metastases scheduled to undergo abdomen dynamic CT were enrolled during the accrual period of 2023 to 2024.The portal venous phase (PVP) of 60 kVp series(tube voltage 60kVp and tube current 500mAs)was obtained 12s after the AP scan, and the portal venous phase (PVP) of 120 kVp series(tube voltage 120kVp and automatic tube current modulation range, 90-500 mAs)was obtained 18s after 60 kVp series. The mean CT values and image noise were measured in the liver parenchyma, liver lesions, portal vein. The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. The overall image quality, the visibility of the peripheral branches of hepatic vessels and the confidence in the diagnosis was rated on a 5-point scale.

**RESULTS**

1) The image noise and overall image quality were significantly worse in the 60kVp series than in the 120 kVp series. However, no image in the 60kVp series was less score of 3,which meant an image quality meeting routine clinical practice. And the 60kVp series had higher CNR in liver lesions than that of 120 kVp series. 2) DLP, and ED for reduced-dose group were significantly lower than those for standard-dose group(lower 24%).The sensitivity of readers 1, 2, and 3 was 85.0%, 80.6%and 84.8% for standard-dose group, respectively, 97.0%, 97.2%and 97.0% for reduced-dose group; the specificity was 97.0%, 97.2%and 97.3% for standard-dose group, respectively, 97.0%, 97.2%and 97.3% for reduced-dose group.

**CONCLUSION**

The reduced-dose three-phase liver CT group(60kvp series at PVP) demonstrated the specificity comparable and the sensitivity better to that of the standard-dose three-phase liver CT group(120kvp series at PVP)for liver lesions, indicating that the low-dose liver three-phase CT protocol (ultra-low-

dose CT at 60kVp tube voltage at the portal venous phase) has high clinical application potentiality for liver cancer screening in high-risk populations and follow-up of liver metastases in cancer patients

**CLINICAL RELEVANCE/APPLICATION**

a novel low-dose three-phase liver CT protocol (ultra-low-dose CT at 60kVp tube voltage at the portal venous phase) that maintains diagnostic performance while minimizing radiation exposure, might be a preferable option for liver cancer screening in high-risk populations and follow-up of liver metastases in cancer patients.

## S3A-SPGI-4 ASSESSING THE EFFICACY OF MACHINE LEARNING MODELS IN PREDICTING IMMUNOTHERAPY SURVIVAL FOR ADVANCED HEPATOCELLULAR CARCINOMA

Bang Bin Chen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study assesses the effectiveness of machine learning models in predicting the survival outcomes of patients with advanced hepatocellular carcinoma (HCC) undergoing immunotherapy.

**METHODS AND MATERIALS**

This retrospective analysis involved data from 143 patients with advanced hepatocellular carcinoma (HCC) who underwent immunotherapy between 2015 and 2022. Three machine learning models—Gradient Boosting Machine (GBM), Kaplan-Meier, and Cox regression—were developed using variables such as patient demographics, hepatitis etiology, liver function reserve, tumor stage, Barcelona Clinic Liver Cancer (BCLC) stage, alpha-fetoprotein (AFP) levels, extent of tumor involvement, and CT scan characteristics. Follow-up for patients continued until December 31, 2022, with both progression-free survival (PFS) and overall survival (OS) being recorded. Model performance was evaluated using cross-validation metrics.

**RESULTS**

The median follow-up period was 36.3 months (95% CI, 29.1-43.5 months). The median PFS and OS were 4.8 months (95% CI, 3.5-6.1) and 16.5 months (95% CI, 10.1-22.9), respectively. For PFS, both the GBM and Cox regression models demonstrated similar discrimination power, while the Kaplan-Meier model exhibited better calibration. Among these, the GBM model showed the highest accuracy, achieving a concordance index (c-index) of 0.598. For OS, all three models displayed comparable discrimination power, and again, the Kaplan-Meier model showed superior calibration. The GBM model also achieved the highest accuracy for OS, with a concordance index of 0.651.

**CONCLUSION**

Machine learning models effectively predict the survival of patients with advanced HCC undergoing immunotherapy, providing valuable insights for personalized treatment planning.

**CLINICAL RELEVANCE/APPLICATION**

The integration of machine learning models into clinical settings can potentially refine the precision of immunotherapy for HCC, thereby enhancing patient outcomes and optimizing treatment strategies. Future studies should focus on incorporating real-time data and refining these models to further aid clinical decision-making.

## S3A-SPGI-5 MACHINE LEARNING-BASED PREDICTION OF HEPATIC DECOMPENSATION APPLYING COMBINED TOPOLOGICAL AND RADIOMICS SIGNATURES DERIVED FROM BODY COMPOSITION MODELS

Yashbir Singh, PhD, MEng (*Presenter*) Nothing to Disclose

**PURPOSE**

This research aims to address traditional imaging biomarkers' limitations in detecting hepatic decompensation, a crucial phase in liver disease progression that requires timely intervention. Our study introduces an innovative approach employing deep learning-based body composition models. By integrating topological and radiomics signatures derived from CT images, we strive to enhance the predictive accuracy for hepatic decompensation, potentially revolutionizing early detection and management strategies.

**METHODS AND MATERIALS**

Our study cohort comprised 277 patients diagnosed with Primary Sclerosing Cholangitis (PSC), each having undergone an abdomen CT scan in the portal venous phase. A deep-learning algorithm was developed in-house for the segmentation of Subcutaneous Adipose Tissue (SAT), Skeletal Muscle (SKM), Visceral Adipose Tissue (VAT), and Intermuscular Adipose Tissue (IMAT). The extraction of radiomics features was facilitated using the PyRadiomics platform, and topological features were derived from persistence images. These extracted features were then combined into a singular input vector, which served as the basis for a logistic regression classifier. The model underwent validation through a 5-fold cross-validation process and was additionally tested on an external dataset to ensure its robustness and applicability.

**RESULTS**

The logistic regression model demonstrated significant predictive capabilities, achieving an average AUC of 0.8 in the 5-fold cross-validation, indicating its robustness. When applied to an external validation dataset, the model maintained its performance, with a peak AUC of 0.8 on the ROC curve. These results underscore the model's potential effectiveness in predicting hepatic decompensation.

**CONCLUSION**

This study showed a novel machine learning-based methodology that effectively combines topological and radiomics features to predict hepatic decompensation from CT images. Our method opens new pathways for the early detection and intervention of hepatic decompensation, potentially improving patient outcomes.

**CLINICAL RELEVANCE/APPLICATION**

The clinical implications of this research are far-reaching, offering a promising tool for healthcare professionals in the early identification and management of patients at risk of hepatic decompensation. By providing a more accurate predictive model, clinicians can tailor interventions more effectively, thereby potentially reducing the morbidity and mortality associated with advanced liver disease. This study sets the groundwork for future clinical applications and underscores the importance of integrating advanced machine-learning techniques in medical diagnostics.

## S3A-SPGI-6 DEEP LEARNING-BASED PREDICTION OF HEPATIC DECOMPENSATION USING VARIOUS ANATOMIC REGIONS IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS VIA COMPUTED TOMOGRAPHY

Yashbir Singh, PhD, MEng (*Presenter*) Nothing to Disclose

**PURPOSE**

To study the efficacy of a deep learning model in predicting hepatic decompensation among patients with Primary Sclerosing Cholangitis (PSC) using Computed Tomography (CT) imaging to enhance early diagnosis and management strategies.

**METHODS AND MATERIALS**

This retrospective cohort study included 277 adult patients diagnosed with large duct PSC, all of whom underwent abdominal CT scans. The portal venous phase images were utilized as inputs for a 3D Densenet121 model, trained via five-fold cross-validation to classify hepatic decompensation. A deep learning approach was taken by training the model on various sections of the 3D CT images, including the right, left, anterior, posterior, inferior, and superior halves, to ascertain the contribution of each anatomic region to the model's predictive accuracy. AUROC performance was conducted for each section and the entire scan.

**RESULTS**

Over a median follow-up of 1.5 years (interquartile range 142-1318 days post-CT), hepatic decompensation was observed in 128 patients. The deep learning model demonstrated high predictive performances with a baseline mean AUROC of 0.89 ± 0.04. The analysis of individual anatomic sections yielded mean AUROC values of 0.83 ± 0.03 (left, right), 0.82 ± 0.09 (anterior), 0.79 ± 0.02 (posterior), 0.78 ± 0.02 (superior), and 0.76 ± 0.04 (inferior).

**CONCLUSION**

The deep learning model, particularly the 3D Densenet121 applied to CT imaging, shows significant potential in predicting hepatic decompensation in PSC patients. This study highlights the importance of leveraging advanced imaging analysis techniques for better clinical outcomes in chronic liver diseases.

**CLINICAL RELEVANCE/APPLICATION**

The findings underscore the value of deep learning in refining the predictive accuracy of medical imaging, offering a promising tool for clinicians to identify and manage patients at risk of hepatic decompensation in the context of PSC. This approach could pave the way for personalized treatment strategies and improved patient care.

## S3A-SPGI-7 PERFORMANCE OF RADIOLOGISTS IN CHARACTERIZING AND DIAGNOSING HEPATIC LESIONS USING DYNAMIC CONTRAST-ENHANCED CT WITH AND WITHOUT ARTIFICIAL INTELLIGENCE

Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Masahiro Yanagawa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shoji Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akinori Hata, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Nakamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hiromitsu Onishi, MD, PhD (*Abstract Co-Author*) Research Grant, General Electric Company;Speakers Bureau, General Electric Company
Takahiro Tsuboyama, MD (*Abstract Co-Author*) Nothing to Disclose
Daiki Nishigaki, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the performance of radiologists in characterizing and diagnosing hepatic lesions with and without the assistance of artificial intelligence (AI).

**METHODS AND MATERIALS**

This retrospective study included 83 nodules/masses from 69 patients who underwent dynamic contrast-enhanced CT of the liver. Image assessments were conducted by 20 radiologists grouped according to their level of experience (10 senior and 10 junior). Each radiologist determined the probability of eight characteristics based on enhancement patterns and the diagnosis with and without an AI which consists of convolutional neural networks to analyze 3-dimentional image data. Their results were compared with a reference standard determined by two board-certified abdominal radiologists and area under the receiver operating characteristic curves (AUCs) were analyzed using the multireader multicase method.

**RESULTS**

For 69 patients, 47 were male and the mean age was 63 ± 16 [SD] years. Using AI improved AUCs for the characterization of enhancement (without AI, 0.90 [95% CI 0.86, 0.93], with AI, 0.92 [95% CI 0.88, 0.96]; P = .018), nonperipheral washout (without AI, 0.89 [95% CI 0.83, 0.94], with AI, 0.91 [95% CI 0.86, 0.96]; P = .031), and delayed enhancement (without AI, 0.83 [95% CI 0.77, 0.89], with AI, 0.87 [95% CI 0.81, 0.93]; P = .005), and the diagnosis of hepatocellular carcinoma (without AI, 0.81 [95% CI 0.75, 0.88], with AI 0.83 [95% CI 0.77, 0.89]; P = .043). Improvements in AUCs for the characterization were observed in both the senior (enhancement, expansion and coalescence of enhancing areas, and delayed enhancement) and junior (delayed enhancement) groups.

**CONCLUSION**

Using AI improved the radiologists' performance in characterizing and diagnosing hepatic lesions. In terms of their capacity to assess imaging characteristics, improvements were observed regardless of their level of experience.

**CLINICAL RELEVANCE/APPLICATION**

The use of an AI system resulted in improved assessment of imaging features and more accurate diagnoses by radiologists, which is expected to improve the clinical care and prognosis of patients.

## S3A-SPGI-8 PREOPERATIVE PREDICTION OF LIVER REGENERATION FOLLOWING HEMIHEPATECTOMY USING MACHINE LEARNING MODEL

Qingqing Chen (*Abstract Co-Author*) Nothing to Disclose
Hongjie Hu, MD (*Abstract Co-Author*) Nothing to Disclose
Fang Wang (*Abstract Co-Author*) Nothing to Disclose
Dan Cao (*Presenter*) Nothing to Disclose

**PURPOSE**

The inadequate remnant liver regenerative capacity may directly lead to liver failure and even death for patients who underwent hemihepatectomy. The aim of this study is to explore the potential ability of machine learning model for preoperatively predicting the remnant liver regeneration in patients

following hemihepatectomy.

## METHODS AND MATERIALS

A total of 213 patients who underwent hemihepatectomy were retrospectively included. We semi-automatically segmented the future remnant liver from preoperative CT. The volume of future remnant liver (LVpre) was measured, and radiomics features were extracted from the future remnant liver in portal venous phase. The volume of postoperative remnant liver (LVpost) was measured on follow-up CT. The regeneration index (RI) was calculated by the following equation: (LVpost - LVpre)/LVpre) × 100 (%). The machine-learning model was developed by the Ada Boost analysis in the training cohort (n=121), the internal validation cohort (n=52) and the external validation cohort (n=40). The AUC, sensitivity, specificity, accuracy and F1 score were employed to evaluate the diagnostic efficiency of the machine-learning model for preoperative prediction of the remnant liver regenerative capacity.

## RESULTS

We developed a machine learning model that excellent prediction performance of the remnant liver regenerative capacity in the training cohort, the internal validation cohort and the external validation cohort, with AUC of 0.88 (95%CI: 0.81-0.96), 0.80 (95%CI: 0.65-0.95) and 0.85 (95%CI: 0.67-1.00) (Fig.1). The diagnostic sensitivity, specificity, accuracy and F1 score of the model in the training cohort were 0.79, 0.88, 0.85 and 0.79. In the internal validation cohort, the sensitivity, specificity, accuracy and F1 score of the model were 0.63, 0.86, 0.79 and 0.65. In the external validation cohort, the sensitivity, specificity, accuracy and F1 score of the model were 0.82, 0.83, 0.83 and 0.72 (Fig.2). A further analysis between radiomics features and remnant liver regenerative capacity indicated that the high radiomics scores were associated with high RI (Fig.3).

## CONCLUSION

The new machine learning model based on radiomics features may serve as a potential preoperative predictor of remnant liver regeneration capacity for patients who underwent hemihepatectomy.

## CLINICAL RELEVANCE/APPLICATION

The insufficient remnant liver regenerative capacity may lead to postoperative liver insufficiency and even liver failure for patients who underwent hemihepatectomy. The newly developed machine-learning model based on radiomics features may serve as a potential preoperative predictor of remnant liver regeneration capacity to ensure the safety of hepatectomy and improve prognosis.

## S3A-SPGU-1 ASSESSING THE FEASIBILITY OF MAGNETIC RESONANCE IMAGING COMPILATION FOR DETERMINING THE TREATMENT STRATEGIES AND PREDICTING THE RECURRENCE RISK FACTORS AND SHORT-TERM EFFICACY IN CERVICAL CANCER

Wenzheng Li, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Liu M. Hui I, MD (*Abstract Co-Author*) Nothing to Disclose
Yigang Pei, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaorong Ou (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the feasibility of using Magnetic Resonance Imaging Compilation (MAGiC: sy-T2WI; sy-T1, sy-T2, and sy-PD maps) to determine treatment plan and to predict recurrence risk factors (RRF) and short-term treatment efficacy (STE) in cervical cancer (CC) patients using high-resolution T2WI (hr-T2WI)and DWI as reference standards.

### METHODS AND MATERIALS

The study protocol was approved by the local Research Ethics Committee. Informed consent was obtained from all subjects. 194 patients suspected of CC were enrolled and undergone MAGiC, hr-T2WI and DWI (the parameter presented in Table 1) on 3.0T GE MRI (Fig 1a). The subjective evaluation of image quality and tumor staging using sy-T2WI and hr-T2WI were conducted. The accuracy, sensitivity and specificity of sy-T2WI were analyzed for making treatment plan (staging IB-IIA: surgery; IIB-IVA: CCRT) (Fig 1b). RRF was assessed by surgery (RRF and no-RRF groups) for staging IB-IIA (Fig 1c) and STE was evaluated by a repeat MRI at 2 months (complete response (CR) and no-CR groups) after concurrent chemoradiotherapy (CCRT) for IIB-IVA CC patients (Fig 1d). The area under the curve (AUC) was used to objectively predict RRF and STE using the quantitative sy-T1, T2, PD maps, their combinations and apparent diffusion coefficient (ADC).

### RESULTS

119 out of 194 CC patients were included, including 50 patients with surgery and 69 subjects with CCRT. For the image quality, sy-T2WI was no significant differences compared with hr-T2WI in four aspects (All $P>0.05$; Table 2, Fig 2). The accuracy, sensitivity and specificity of sy-T2WI was 0.908, 0.908 and 0.999, and an excellent agreement was found between sy-T2WI and hr-T2WI for differentiating IB-IIA from IIB-IVA ($k = 0.935$; $p < 0.001$) (Table 3, Fig 3). For the quantitative synthetic images, T2, T1 and ADC had a significant difference to identified RRF from no-RRF, CR from no-CR group respectively ($P < 0.05$) but PD ($P > 0.05$; Table 4). For RRF, the diagnostic performance of T2 (AUC: 0.908) and T1 (AUC: 0.854) were similar to ADC (AUC: 0.776; all $P > 0.05$) (Table 5, Fig 4). For STE, the predictive performance of T2 was superior to ADC (AUC: 0.902 vs. 0.737; $p = 0.030$) but T1 (AUC: 0.877; $p = 0.081$) (Table 5, Fig 5). Furthermore, T1+T2 was superior to ADC for predicting RRF (AUC: 0.980 vs 0.776; $p = 0.005$) and STE (AUC: 0.982 vs. 0.737; $p < 0.001$) (Table 5, Fig 4-5).

### CONCLUSION

MAGiC is a promising technique for deciding therapeutic plan and predicting RRF and STE in CC patients, which is similar and even superior to hr-T2WI and DWI.

### CLINICAL RELEVANCE/APPLICATION

MAGIC is a reliable technique for facilitating the synthetic morphologic images and quantitative synthetic images, which should be as an alternative strategy of hr-T2WI and DWI for deciding treatment plan and predicting RRF and STE in CC patients.

## S3A-SPGU-10 A REAL-WORLD COMPREHENSIVE ASSESSMENT OF SPACEOAR HYDROGEL EFFICACY, CLINICAL APPLICATIONS, AND COMPLICATIONS

### PURPOSE

Radiation is the standard therapy for prostate cancer. However, it may cause damage to the surrounding organs including rectum. SpaceOAR hydrogel, is an FDA approved spacer, which increases the distance between the rectum and prostate, reducing rectal radiation exposure. However, it has some complications including suboptimal placement or migration of the hydrogel. This study aims to quantify the increased recto-prostatic distance after SpaceOAR placement and to assess the frequency of SpaceOAR related complications.

### METHODS AND MATERIALS

We conducted a search using the keyword of "SpaceOAR" among MRI pelvis reports in our department radiology reports search engine, "Montage, mPower Nuance". A total of 700 patients were found of which 181 patients MRI performed prior to and after SpaceOAR placement. A board-certified radiologist measured the distance between prostate and rectum (PRD) in nine different planes including one centimeter superior to the apex and inferior to the base and at the level of mid gland on sagittal views and one centimeter to the left, right, and midline of the prostate on axial views. The SpaceOAR related complications were also recorded. Microsoft Excel was used for data recording and analysis.

### RESULTS

The average PRD was significantly different before and after SpaceOAR placement at all locations ($p<0.001$). The mean PRD increased throughout the entire prostate (ranging from 0.8± 0.3 cm at base to 1.2±1.4 cm at the apex). Although the averages where significantly different, SpaceOAR was not observed in recto prostatic space among 12/181 (7%) patients, due to suboptimal placement. Asymmetric distribution of the SpaceOAR was noted, with no increase in PRD among 37/181 (20%) of patients at the apex level (up to 82/181 in left apex), 20/181 (11%) at the base (up to 46/181 in right base), and 10/181 (5%) at mid-prostate level. SpaceOAR related complications were noted in 23/181 of patients (12.7%) with infiltration into rectal wall as the most frequent one resulting in fistula formation in one patient.

### CONCLUSION

The PDR did not increase at the apex in a large proportion of patients following SpaceOAR placement. SpaceOAR related complications were noted in 13% of patients.

### CLINICAL RELEVANCE/APPLICATION

Although SpaceOAR increases the mean PRD, some portions of rectum may be spared due to asymmetric distribution of the SpaceOAR, predominantly in apex. This may increase the risk of radiation exposure to the rectum at this location. Additionally, the most common complications related to SpaceOAR placement includes rectal wall infiltration.

## S3A-SPGU-2 ARTIFICIAL INTELLIGENCE ASSISTANCE FOR PROSTATE MRI ANALYSIS : TOWARDS INCREASED TUMOR DETECTION SPECIFICITY

Roberto Ardon (*Abstract Co-Author*) Employee, AXA Venture Partners
Leo Alberge (*Abstract Co-Author*) Nothing to Disclose
Chloe Adam, PhD (*Abstract Co-Author*) Employee, Incepto Medical SAS
Maria Elena Laino, MD (*Abstract Co-Author*) Nothing to Disclose
Luc Beuzit (*Abstract Co-Author*) Nothing to Disclose
Guillaume Herpe (*Abstract Co-Author*) Medical Officer Incepto-France Grant, Guerbet
Martin Charachon (*Abstract Co-Author*) Nothing to Disclose
Gaspard d'Assignies, MD, PhD (*Presenter*) Founder, Incepto Medical SAS;Employee, Incepto Medical SAS;Stockholder, Incepto Medical SAS

### PURPOSE

To evaluate the impact of artificial intelligence (AI) models on diagnostic performances of a panel of readers in detecting clinically significant prostate cancer (csPCa) (ISUP = 2) on ProstateX dataset.

### METHODS AND MATERIALS

An evaluation dataset consisted of curated 202 prostate MR from a public dataset ProstateX (mean age 66, including 76 csPCa MRI, 36 of which are in the peripheral zone, 40 in the transition zone). Gold standard diagnosis for csPCa was established by histology and/or expertise.4 general radiologists (100 to 150 prostate MRI reading per year) were asked to review 202 examinations each without the help of the AI, and the same randomly shuffled dataset after a one month wash-out period assisted by the AI. One expert radiologist (> 400 prostate MRI reading per year) reviewed the 202 examinations without AI. A case-level PI-RADS score according to PI-RADS V2.1 was provided for each examination.The AI model was trained on a database of 5,000 MRI scans from 10 clinical sites, independent of the dataset explored here, providing lesion detection and a case level suspicion of malignancy in two grades, moderate or high.Readers' and AI performances at the exam-level were evaluated using sensitivity/specificity, and accuracy by considering the cut-off PI-RADS >=3.Interreader reproducibility was evaluated using Kappa score on PI-RADS 2.1 scores.Chi-square testing was used for statistical significance of performance comparisons.

### RESULTS

General radiologists performances (without/with AI) values were respectively sensitivity (.94,CI.95[.92,.97]/.94,CI.95[.91,.96], p=0.20), specificity (.34,CI.95[.31,.38]/.50,CI.95[.46,.54], p<0.001 ), accuracy (.55,CI.95[.52,.58] / .65,CI.95[.62,.68],p<0.001). Expert performances (without AI) were respectively sensitivity (.96,CI.95[.91,1.00]), specificity (.69CI.95 [.61,.78]), accuracy (.78,CI.95[.72,.84]). Standalone performances of the AI solution were respectively sensitivity (.91,CI.95[.84,.97]), specificity (.64,CI.95[.56,.72], accuracy (.73 CI.95[.67,.79]). Cohen's Kappa score on PI-RADS scores was .30 before AI and reached .60 after.

### CONCLUSION

AI assistance led to a significant increase of diagnostic performances,+9% for accuracy, of the general radiologists, as well as standardization of the PI-RADS scorings. But this study raises two remarks: firstly AI standalone performances were higher than the general radiologist aided by AI questioning the willingness for AI. Secondly, expert reading remains the most performant, assessing the continuous need for training.

### CLINICAL RELEVANCE/APPLICATION

AI improves and overcome significantly general radiologist diagnostics specificity and accuracy for prostate cancer detection in MRI.

## S3A-SPGU-3 AI DETECTS MISSED SMALL RENAL MASSES ON SINGLE PHASE CT

Masoom A. Haider, MD (*Abstract Co-Author*) Nothing to Disclose
Satheesh Krishna, MD (*Abstract Co-Author*) Nothing to Disclose
Antonio Finelli (*Abstract Co-Author*) Nothing to Disclose
Girish Kulkarni, MD (*Abstract Co-Author*) Nothing to Disclose
Kristen McAlpine (*Abstract Co-Author*) Nothing to Disclose
Nikhil S. Mirajkar, MBChB, FRCR (*Presenter*) Nothing to Disclose

**PURPOSE**

Radiologists can miss incidental small renal masses (SRM's) on a single-phase CT. The purpose of this study was to evaluate the performance of a UNet based lesion segmentation model on SRM's missed by radiologists.

**METHODS AND MATERIALS**

We trained nnUNet v2 model on 1155 (radiologist annotated portal or nephrographic phase images) of which 489 were from the public domain C4KC-KiTs training set from the Cancer Imaging Archive and the rest were from our centre. The model was a cascade of a low-resolution 3D followed by a 3D full resolution classifier with 5-fold cross-validation. We retrospectively reviewed a dataset of 222 small renal masses to identify cases that had prior imaging with a missed SRM, and a prediction was run on these cases. This retrospective study was approved by our research ethics board and informed consent was waived.

**RESULTS**

Eleven cases (5% miss rate 11/222) were identified where a radiologist missed an SRM. Our model missed four cases (2% miss rate 4/222) equating to a 64% reduction (p value = 0.02) in miss rate. On lesion level analysis, 14 lesions were missed by the radiologist. Our model missed only 4 lesions, with a sensitivity of 71% (10/14). Lesions missed by our model included 3 SRM's incorrectly categorised as cysts and one tiny 6 mm central endophytic lesion. The model detected an additional 3 lesions which were not SRM's. The 3 false positive lesions were subcentimeter cysts that demonstrated long term stability. Average time interval between the baseline CT where the lesion was missed by the radiologist and follow up imaging where the lesion was first reported was 23 months. The average interval size change of the SRMs during this period was 0.8 cm/year. 3 patients had SRMs that rapidly increased in size within a short time interval with a significant delay in their diagnosis. The model detected all 3 of these high-risk masses on the baseline CT.

**CONCLUSION**

Our study demonstrates that a UNet model can detect missed SRM's with a sensitivity of 71%. The model reduces the miss rate of incidental SRM's from 5% (11/222) to 2% (4/222), a 64% reduction (p value = 0.02). Further multicentre data set testing on missed SRM's is planned.

**CLINICAL RELEVANCE/APPLICATION**

A UNet classifier shows strong potential to help reduce observational miss rates for incidental small renal masses.

## S3A-SPGU-5 3D V-NET-BASED SEGMENTATION OF ADRENAL GLANDS

Xiaodong Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Yaofeng Zhang (*Abstract Co-Author*) Nothing to Disclose
Yuanchong Chen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To establish a 3D V-Net-based segmentation model of adrenal glands on CT.

**METHODS AND MATERIALS**

Retrospectively collecting CT image series of adrenal glands for the training of adrenal segmentation model. Inpatient abdominal CT examinations with normal adrenal glands and no diagnosed adrenal diseases upon discharge were retrospectively collected in the normal adrenal dataset (N = 3861). The abnormal adrenal glands dataset consists of the portal venous phase image series from contrast-enhanced CT examinations of patients diagnosed with adrenal adenoma or adrenal metastasis clinically or pathologically (N = 1799). All these datasets (N = 5660) were used to train the segmentation model of adrenal gland after being annotated by radiologists. Then, two groups of health check-up patients from the same institution (N = 6126) and another institution (N = 931) were included whose chest CT images were used for model validation. Indicators including Sụrensen-Dice similarity coefficient (DSC) were used to evaluate the efficacy of the model.

**RESULTS**

The DSC of the test set of left and right adrenal segmentation models were 0.910 (0.890 - 0.930) and 0.920 (0.890 - 0.930), respectively. The DSC in external validation datasets were 0.816 (0.744 - 0.866) (left adrenal gland), 0.819 (0.743 - 0.865) (right adrenal gland) and 0.752 (0.666 - 0.820) (left adrenal gland), 0.747 (0.673 - 0.812) (right adrenal gland), from the same institution and another institution, respectively.

**CONCLUSION**

The 3D V-Net-based adrenal segmentation model can achieve considerable segmentation efficacy that can be used in both abdomen and chest CT images.

**CLINICAL RELEVANCE/APPLICATION**

The 3D V-Net-based adrenal segmentation model with high internal validity as well as considerable external validity can lay the groundwork of automated imaging diagnosis of adrenal glands.

## S3A-SPGU-6 AI-ASSISTED COMPRESSED SENSING IMPROVES IMAGE QUALITY OF PROSTATE T2-WEIGHTED IMAGING

Hui Xu (*Abstract Co-Author*) Nothing to Disclose
Liting Shen (*Abstract Co-Author*) Nothing to Disclose
Wei Jie (*Abstract Co-Author*) Nothing to Disclose
Ying Yuan, BEng,BEng (*Abstract Co-Author*) Nothing to Disclose
Zhenghan Yang (*Abstract Co-Author*) Nothing to Disclose
Dan YU (*Abstract Co-Author*) Nothing to Disclose
Qian Liao (*Abstract Co-Author*) Nothing to Disclose
Liang Wang, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the image quality, lesion delineation abilities, and Prostate Imaging Reporting and Data System (PI-RADS) scoring performance of prostate T2-weighted imaging (T2WI) based on AI-assisted compressed sensing (ACS).

**METHODS AND MATERIALS**

The prospective study was conducted with forty adult male patients from urology department requiring prostate MRI. Each participant underwent three consecutive prostate MRIs in sagittal, coronal, and axial planes using both parallel imaging (PI) and ACS using two different reconstruction programs (T2WIPI, T2WIACS1 and T2WIACS2). Two radiologists performed quantitative and qualitative evaluations. Quantitative analysis included metrics such as signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), the slope profile and widest diameter of the largest or most suspicious lesion, and the edge rise distance (ERD) of the dorsal prostate capsule in the axial plane. Qualitative assessment employed a five-point Likert scale (from 1 = nondiagnostic to 5 = excellent) to rate image quality. T2WI and PI-RADS scores were assessed for the largest or most suspicious lesions. Statistical analysis involved one-way ANOVA with post hoc Tukey or Tamhane tests for continuous variables, and the Friedman test with Bonferroni post hoc adjustments for discrete variables. The intraclass correlation coefficient (ICC) measured the reliability of qualitative data.

**RESULTS**

The total acquisition time for three-plane T2WIACS1 and T2WIACS2 were reduced by 47% and 53%, respectively, compared to T2WIPI. CNR improvements were significant in sagittal T2WIACS1, sagittal T2WIACS2 and axial T2WIACS1 over T2WIPI ($P < 0.05$). Sagittal plane analysis revealed significant enhancements in overall image quality, image sharpness, PZ and TZ boundary clarity, artifacts, and lesion delineation for T2WIACS1 with T2WIACS2 showing notable artifact reduction ($P < 0.05$). In the coronal plane, T2WIACS1 demonstrated superior lesion delineation compared to both T2WIPI and T2WIACS2 ($P < 0.05$). The axial plane analysis indicated significant improvements in overall image quality and PZ and TZ boundary clarity for T2WIACS1 over T2WIPI ($P < 0.05$). No significant differences were observed in slope profile, widest diameter, and ERD ($P > 0.05$). And no significant differences were observed in T2WI and PI-RADS scores across the groups ($P > 0.05$) with excellent agreement (ICC: 0.83-0.95).

**CONCLUSION**

ACS significantly reduces prostate T2WI scanning times by at least half, while maintaining or enhancing image quality and diagnostic performance.

**CLINICAL RELEVANCE/APPLICATION**

This advancement demonstrates clinical efficiency without affecting clinical decision-making and possesses great application potential.

## S3A-SPGU-7 APPLICATION VALUE OF CT LYMPHANGIOGRAPHY IN CLINICAL GRADING OF PRIMARY CHYLURIA

Qi Hao (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of CT lymphangiography (CTL) in the staging of primary chyluria.

**METHODS AND MATERIALS**

The clinical and CTL imaging data of 77 patients diagnosed with primary chyluria were collected retrospectively.All 77 patients underwent DLG and CTL. CTL was performed on patients with a Siemens Sensation 16 or Philips Brilliance iCT spiral CT machine 20 min to 2 h after DLG with a combined chest and abdomen CT scan from the inferior border of the thyroid cartilage in the neck to the inferior border of the pubic symphysis. Scan parameters: tube voltage 80-120 kV, tube current 250-300 mA, layer thickness 5 mm, layer interval 5 mm, and pitch 1. After completion of the scan, the raw data were transferred to the EBW workstation for transverse thin-layer reconstruction with 2 mm layer thickness and 1.8 mm layer interval, and 3D reconstruction was performed.Referring to the clinical grading criteria,seventy-seven patients were divided into mild and severe groups, and CTL indexes were recorded separately for each group.CTL indexes include: Abnormal deposition of lipiodol in the urinary system, chest, abdomen and pelvis.The CTL image findings of the two groups were statistically analyzed. ?2 test was used for counting data.,$P < 0.05$ was considered statistically significant.

**RESULTS**

Among 77 cases of primary chyluria, 27 cases were in mild group and 50 cases were in severe group. In the two groups,CTL showed abnormal lipiodol deposition in renal parenchyma in 10 cases (37.0%) and 25 cases (50.0%) respectively, and in bladder in 6 cases (22.2%) and 23 cases (46.0%) respectively.The difference of abnormal lipiodol deposition in renal parenchyma between the two groups was statistically significant ($P=0.031$), and the incidence of severe group (50.0%) was higher than that of mild group (37.0%).The difference of abnormal lipiodol deposition in bladder between the two groups was statistically significant ($P=0.040$), and the incidence in the severe group (46.0%) was higher than that of mild group (22.2%).There was no significant difference in abnormal lipiodol deposition in chest and abdomen, bone and thoracic duct between the two groups ($P > 0.05$).

**CONCLUSION**

CTL can be used for imaging diagnosis and evaluation according to the distribution of abnormal lipiodol deposition in abnormal lymphatic vessel in patients with primary chyluria, among which the suprhilar type and the whole kidney type can effectively indicate the clinical grade of primary chyluria.

**CLINICAL RELEVANCE/APPLICATION**

CTL can provide an important image basis for the diagnosis and treatment of primary chyluria.

## S3A-SPGU-9 AI-DRIVEN RADIOMICS MODEL TO PREDICT RESIDUAL TERATOMA/SEMINOMA IN METASTATIC NONSEMINOMATOUS GERM CELL TUMORS(MNSGCTS)

Neda Abdalvand (*Abstract Co-Author*) Nothing to Disclose
Ren Yuan, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Patients with mNSGCTs with retroperitoneal disease often have residual lesion(s) after chemotherapy. Some residuals contain teratoma or viable cancer requiring surgery; around 50% consist of necrotic or fibrotic tissue. Current guidelines recommend post-chemotherapy retroperitoneal lymph node dissection (PC-RPLND) for residual lesions >1 cm in the short axis, which leads to overtreatment in many cases. Accurate surgical patient selection is essential to avoid unnecessary harm, while it's challenging when differentiating teratoma/seminoma from benign residual masses, as the tumour markers are all normal. We propose an AI-radiomics approach using post-PC pre-RPLND CT images can help differentiate residual teratoma/seminoma from benign tissue.

**METHODS AND MATERIALS**

We retrospectively included 53 patients (19-58 years) with mNSGCT who received cisplatin-based chemotherapy, then normal serum tumor markers before RPLND, had residual lesions over 1 cm on pre-RPLND enhance CT, and detailed pathology reports of the RPLND (96 lesions: 56 teratomas, 22 fibrosis/necrosis, 18 viable seminomas). CT radiomics features of residual lesions were extracted using 3D slicer. Recursive Feature Elimination with Cross-Validation was used for feature selection. The data were randomly divided into 80% vs 20% for training and testing. 5-fold cross-validation was

applied to train the model. We trained prediction models using Random Forest (RF), Gradient Boosting (GB), and Support Vector Machine (SVM) algorithms. Model performance was assessed with the receiver operating characteristic (ROC) curve and Brier scores to select the best model.

## RESULTS

The three models all excel in discrimination (i.e., AUC/Sensitivity/Specificity: 0.84, 0.76, 0.79 for RF vs 0.75, 0.71, 0.69 for GB vs. 0.81,0.81,0.78 for SVM), while RF exhibited the highest AUC (0.84) and the lowest Brier score (0.1630), indicating superior discrimination and better calibration of predicted probabilities, respectively, compared to GB and SVM.

## CONCLUSION

The pilot study showed that in patients with mNSGCTs who received chemotherapy with residual retroperitoneal lesions, an ML model using CT images of radiomic features can distinguish teratoma/seminoma from benign pathology in the residual lesions.

## CLINICAL RELEVANCE/APPLICATION

The ML-radionics model has the potential to assist the decision-making of RPLND in avoiding unnecessary surgeries in patients with mNSGCTs who received chemotherapy and had residual lesions but normal tumor markers.

## S3A-SPHN-1 CONTRAST-ENHANCED 3D T1 VIBE OUTPERFORMS MPRAGE FOR INTRACAVERNOUS CRANIAL NERVE VISUALIZATION IN DIPLOPIA

Dawon Jung, MD (*Abstract Co-Author*) Nothing to Disclose
Eunhee Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hongseok Ko, MD (*Abstract Co-Author*) Nothing to Disclose
Hyeji Lee (*Presenter*) Nothing to Disclose

### PURPOSE

We aimed to compare the visual conspicuity of contrast-enhanced 3D T1 volume-interpolated breath-hold examination (VIBE) and magnetization-prepared rapid-acquisition gradient-echo (MPRAGE) for assessment of intracavernous cranial nerve (CN) III, V1, V2 and VI in patients with diplopia.

### METHODS AND MATERIALS

We retrospectively included 74 patients who had undergone contrast-enhanced diplopia MRI from May 2023 to April 2024 in a single center. Contrast-enhanced 3D T1 VIBE and MPRAGE images with fat suppression were acquired in the coronal plane with a slice thickness of 1.5 mm. A neuroradiologist evaluated degree of cavernous sinus enhancement and visualization of bilateral intracavernous CN III, V1, V2 and VI (figure 1, 2). Cavernous sinus enhancement was scored using a three-level scale as follows: coarse granular enhancement as grade 1, mild granular enhancement as grade 2, avid homogenous enhancement as grade 3. The visual conspicuity of CN was scored using a five-level scale and defined as the identifiable proportion of the total cavernous segment of each CN. If less than 50% of the length of the intracavernous CN was identified, it was classified as grade 1, 50% to less than 75% as grade 2, 75% to less than 100% as grade 3, 100% as grade 4, and neural enhancement as grade 5 (pathologic status). Wilcoxon signed-rank test was used to compare the visualization scores between VIBE and MPRAGE.

### RESULTS

In 55 out of 74 patients (mean age 51.6 years; 26 females), all intracavernous CNs were found to be normal. Analysis using the Wilcoxon signed-rank test indicated that the median scores for cavernous sinus enhancement and visual conspicuity of all CNs were either equal to or higher on VIBE compared to MPRAGE (table 1). Among the 110 normal bilateral CNs evaluated, 105 CN IIIs were fully identified on VIBE (95%), while only 75 (68%) were identified on MPRAGE. For CN V1, 76 (69%) and 9 (5%) were graded as 4 on VIBE and MPRAGE, respectively. CN V2 was identified as grade 4 in 72 (65%) on VIBE and 44 (40%) on MPRAGE. For CN VI, 82 (74%) were identified as grade 4 on VIBE and 23 (20%) on MPRAGE.

### CONCLUSION

Our study demonstrates that contrast-enhanced 3D T1 VIBE MRI provides superior conspicuity of intracavernous CNs III, V1, V2 and VI compared to MPRAGE in patients with diplopia. This finding was evident in both the degree of cavernous sinus enhancement and the ability to identify the entire course of each CN within the cavernous sinus.

### CLINICAL RELEVANCE/APPLICATION

The contrast-enhanced coronal 3D T1 VIBE sequence with fat suppression represents the optimal sequence for assessing intracavernous CNs, providing uniform and robust enhancement of cavernous sinus. 3D T1 VIBE MRI may be the preferred neuro-ophthalmic imaging modality for evaluating intracavernous CNs in patients with diplopia.

## S3A-SPHN-2 CLINICAL TEMPORAL BONE IMAGING AT 0.55T: COMPARISON OF ANATOMIC EVALUATION TO 1.5/3T MRI AND HIGH-RESOLUTION CT

Nicole Seiberlich, PhD (*Abstract Co-Author*) Royalties, Siemens AG;Research support, Siemens AG
Mohannad Ibrahim, MD (*Abstract Co-Author*) Nothing to Disclose
Jayapalli R. Bapuraj, MD (*Abstract Co-Author*) Nothing to Disclose
Shruti Mishra, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Masotti (*Abstract Co-Author*) Nothing to Disclose
Ashok Srinivasan, MD (*Abstract Co-Author*) Nothing to Disclose
Radhika Rajeev, MD (*Abstract Co-Author*) Nothing to Disclose
Eric A. Liao, MD (*Abstract Co-Author*) Nothing to Disclose
Lauren Kelsey, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Reduced susceptibility artifacts at 0.55T may be advantageous for MRI of the temporal bone compared to 1.5/3T (high field; HF). This study aims to compare evaluation of normal temporal bone anatomy at 0.55T to HF by comparing visibility of key anatomic structures and clinically-relevant cochlear measurements, using high-resolution temporal bone computed tomography (HRCT) as a gold-standard.

**METHODS AND MATERIALS**

In this IRB-approved retrospective study, 10 patients (4M, 6F; avg. age 59 yrs.) who underwent internal auditory canal (IAC) imaging on Siemens Healthineers Magnetom Free.Max 0.55T with a comparison HRCT and IAC protocol 1.5/3T MRI (n=6 1.5T; n=4 3T) were included. The 3D T2w sampling perfection and application-optimized contrasts using flip angle resolution (3D T2w SPACE) sequence from the 0.55T protocol was used; one normal ear was selected from each study. At high-field, the comparison high-resolution 3D T2w sequence varied between T2w SPACE and vendor-specific gradient-recalled echo techniques. Exams were anonymized and reviewed independently by three board-certified neuroradiologists. Readers scored visualization of anatomic structures on a 4-point Likert scale (1=not visible, 4=well visualized), measured the length and width of the cochlea (oblique coronal view), and the width of the IAC porus acousticus (axial view). Readers also rated IQ (1=non-diagnostic, 4=excellent) for the MRIs.

**RESULTS**

One reader rated IQ of the 0.55T T2w SPACE lower compared to the HF sequence (p=0.03); there was no significant difference in IQ for the other two readers. For one measurement for one reader (cochlear width, R3), the 0.55T measurement was closer to HRCT (no sig.difference) compared to HF vs HRCT (p=0.002). One measurement for two readers (IAC width; R1, R3) was similar between 0.55T and HF, with both demonstrating significant differences to CT. No anatomic structure had significantly improved visibility at 0.55T compared to HF. One or more readers rated improved visibility at HF compared to 0.55T for the following structures: cochlear apical and middle turns (R2, R3), facial nerve (R2), vestibular nerve (R2), cochlear nerve (R2). Other relationships were not significantly different. All readers scored visualization of the vestibular aqueduct higher on CT compared to both HF and 0.55T.

**CONCLUSION**

Clinically-relevant temporal bone anatomy can be comparably evaluated at 0.55T using the 3D T2w SPACE sequence versus 1.5/3T MRI. Quantitative evaluation with clinically-relevant cochlear measurements was similar or better at 0.55T compared to 1.5/3T when using HRCT as the gold standard.

**CLINICAL RELEVANCE/APPLICATION**

Temporal bone imaging may represent a use-case where evaluation at 0.55T may be similar to conventional field strengths of 1.5/3T.

## S3A-SPHN-3 A COMPARATIVE STUDY OF 3D-FLAIR AND 3D-IR-REAL MR SEQUENCES FOR EVALUATION OF ENDOLYMPHATIC HYDROPS

Guixun Hong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

3D-FLAIR and 3D-IR-Real MR sequences have been used to for the visualization of endolymphatic hydrops (EH) in Ménière disease (MD). The purpose of this study was to compare the clinical value of high-resolution 3D-FLAIR and 3D-IR-Real MRI sequences for the evaluation of EH.

**METHODS AND MATERIALS**

3D-FLAIR and 3D-IR-Real MR sequences were performed 8 hours after intratympanic gadolinium (Gd) perfusion through auripuncture. Two experienced radiologists reviewed the image quality of both sequences. The EH grades of vestibular, cochlear, and semicircular canals were evaluated using visual grading to compare the SNR and CNR of the 3D-FLAIR and 3D-IR-Real sequences. Paired t-test was used to compare the SNR and CNR of the two sequences. Cohen kappa test was used to evaluate the subjective score of image quality and the EH severity of the two sequences.

**RESULTS**

The image quality reliability between the two radiologists was excellent (0.7 < kappa < 0.9). The image quality difference between 3D-IR-Real and 3D-FLAIR sequences was statistically significant (P<0.001). The SNR of the 3D-IR-Real sequence (132.26±28.86) was higher than that of 3D-FLAIR (34.96±15.52), and the difference was statistically significant (t=-43.64, P<0.001). The CNR of the 3D-FLAIR sequence (22.09±14.15) was higher than that of the 3D-IR-Real (12.38±9.07), and the difference was statistically significant (t=11.92, P<0.001). More severe hydrops was detected with 3D-IR-Real sequences than with 3D-FLAIR sequences in the cochlear and vestibular hydrops (P < 0.001).

**CONCLUSION**

Compared with the 3D-FLAIR sequence, the high-resolution 3D-IR-Real sequence showed higher image quality and more sensitive to the detection of endolymphatic hydrops.

**CLINICAL RELEVANCE/APPLICATION**

3D-IR-Real sequence combined with visual evaluation has more advantages than 3D-FLAIR sequence for MR evaluation of EH. The 3D-IR-Real sequence is also superior to the 3D-FLAIR sequence in its ability to show details of cochlear and vestibular endolymphatic hydrops.

## S3A-SPIN-1 MEDICARE REIMBURSEMENT FOR DIAGNOSTIC MRI: AN ANALYSIS OF THE 2020-2021 PUBLIC USE FILE

Hussein Alhashemy, MD (*Abstract Co-Author*) Nothing to Disclose
Kevin R. Carter, DO (*Abstract Co-Author*) Nothing to Disclose
Zain Hussain, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to analyze the variation in Medicare reimbursement for diagnostic MRI procedures from 2020 to 2021, examining changes in reimbursement valuation and the implications of policy updates.

### METHODS AND MATERIALS

We utilized the '2020 and 2021 National Provider and Supplier Aggregate Report' from CMS, focusing on six MRI HCPCS codes across different anatomical sites. Inflation adjustment was applied using the CPI inflation rate from the U.S. Bureau of Labor Statistics. Compound Annual Growth Rates (CAGR) were calculated and compared across years.

### RESULTS

Inflation-adjusted reimbursement amounts showed significant declines across all examined procedures from 2020 to 2021. Overall, these procedures exhibited negative CAGR values ranging from -8.42% to -5.37%, indicating a consistent trend of decreasing Medicare reimbursement. There was a significant increase in the number of services performed in office settings as compared to facility settings. The MRI scans of the brain, both with and without contrast, demonstrated the highest decrease in reimbursement rates.

### CONCLUSION

Even after accounting for inflation, our findings reveal a concerning decline in Medicare reimbursement for commonly used MRI procedures, particularly for brain MRI. The decrease in reimbursement rates for MRI scans may affect the financial sustainability of providers and access to diagnostic imaging for Medicare beneficiaries. The shift towards more procedures being performed in office settings might reflect changes in practice patterns influenced by economic pressures.

### CLINICAL RELEVANCE/APPLICATION

Understanding the trends in MRI reimbursement is crucial for radiologists and healthcare administrators to adapt to economic changes and ensure the sustainability of diagnostic imaging services. The findings highlight the need for ongoing adjustments in Medicare reimbursement policies to keep pace with inflation and healthcare dynamics.

## S3A-SPIN-2 GENERATIVE AI-BASED FACE ANONYMIZATION METHOD ON HEAD MRI SCANS

Takafumi Nemoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kohei Yamamoto (*Abstract Co-Author*) Nothing to Disclose
Changhee Han (*Presenter*) Nothing to Disclose

### PURPOSE

Recently, the increasing demand for enhanced privacy has highlighted the need for a stringent yet non-detrimental method of anonymizing faces for AI model training and validation. This is particularly important given that Volume Rendering (VR) from head CT or MRI scans can reveal facial contours, potentially serving as visual cues for patient identification. Traditional anonymization methods, which typically involve removing the facial regions often compromise data quality and can cause domain shifts during AI model training and validation. We propose a novel generative AI-based method that effectively anonymizes faces in head MRI scans, while preserving the quality and continuity of the image in 2D.

### METHODS AND MATERIALS

The dataset comprised 195 brain MRI cases, with 156 allocated for training and 39 for validation. We utilized Large Mask Inpainting (LaMa), a Generative Adversarial Network (GAN)-based model for conditional image generation, to restore 2D MRI slices that had randomly-missing regions, ensuring continuity between adjacent slices. For validation, we employed a rule-based method to identify the facial regions and generate corresponding mask images. The areas missing from these masks were then fed into the trained model to regenerate the patients' facial areas. For visual assessment, we reconstructed the facial regions using VR.

### RESULTS

Figure 1 presents a comparison between a traditional anonymization method (Deficit) and our method (Generated) in axial view. The Deficit method significantly altered the visual appearance from the original state (Before) by removing the face front. In contrast, the Generated result, achieved by omitting the mask area before image generation, closely resembled the Before state. Figure 2 displays VR-based reconstruction results of the Before, Deficit, and Generated images. The Generated method achieved sufficient anonymization without compromising image quality. Although setting the mask to be thin results in more realistic images, it also makes it easier to identify individuals, so we used a thicker mask.

### CONCLUSION

We demonstrated that our generative AI-based method can effectively anonymize faces in head MRI scans without degrading 2D image quality.

### CLINICAL RELEVANCE/APPLICATION

Developing accurate medical AI models requires vast amounts of multi-institutional data. In this context, face anonymization is crucial for the safe usage of data. However, conventional anonymization methods often lead to considerable image quality degradation, which could result in accuracy drops in AI models due to data removal and domain shifts. This study offers a fundamental solution to this issue, and we plan to verify the AI model accuracy drops caused by conventional methods compared to our model.

## S3A-SPIN-3 DEVELOPING SYNTHETIC TUMORS IN LIVER, PANCREAS, AND KIDNEY USING GENERATIVE AI

Qi Chen (*Abstract Co-Author*) Nothing to Disclose
Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to generate synthetic tumors that can be generalized to detect and segment real tumors across various organs from CT volumes, encompassing a broad spectrum of patient demographics, imaging protocols, and healthcare facilities.

### METHODS AND MATERIALS

We observe that early-stage tumors tend to have similar imaging characteristics in computed tomography (CT), whether they originate in the liver, pancreas, or kidneys. Leveraging this observation, we introduce a novel framework, termed DiffTumor, that can learn the common imaging characteristics of tumors across various organs. The development of DiffTumor has three stages. (1) Training an Autoencoder Model on 9,262 unlabeled three-dimensional CT volumes. The use of large, diverse datasets can enhance the model's ability to generalize across CT volumes of different patient demographics and reduce the need for annotated tumor volumes for training Diffusion Models in the subsequent stages. (2) Training a Diffusion Model using latent features and tumor masks as conditions. Once trained, this model can generate features necessary for reconstructing CT volumes with tumors based on arbitrary shapes. (3) Training a Segmentation Model using synthetic tumors and their corresponding masks. With a large repository of healthy CT volumes, DiffTumor can produce a vast array of synthetic tumors, varying in location, size, shape, texture, and intensity, improving AI models for tumor detection/segmentation.

### RESULTS

Radiologists #1 (3-year experience) and #2 (7-year experience) only achieved a mean specificity of 30.3% (liver: 31.7%, pancreas: 22.5%, and kidney: 36.7 %) and 38.1% (39.2%, 34.2%, and 40.8%), respectively. Senior Radiologist #3 (10-year experience) and Radiologist #4 (13-year experience) achieved mean specificity of 50.8% (53.3%, 44.2%, and 55.0%) and 45.4% (45.8%, 38.8%, and 51.7%), respectively. In early tumor detection, AI models training with our synthetic tumors achieve Sensitivity of 82.2%, 71.4%, and 78.6%. In all-stage tumor segmentation, AI models training with our synthetic tumors achieve DSC of 70.9%, 64.8%, and 84.2% for liver, pancreatic, and kidney tumors, respectively.

### CONCLUSION

We explored the potential of generative AI for tumor synthesis, which requires minimal annotations, creating synthetic tumors in real-time, augmenting large-scale datasets of healthy organs, and improving tumor detection/segmentation.

### CLINICAL RELEVANCE/APPLICATION

Synthetic data showed promise to improve AI models in detecting early-stage tumors (radius < 2cm) and segment all-stage tumors. Larger-scale external validation (N=30,000) has been launched in collaboration with City of Hope (TGen) and UCSF to con& 7;rm the performance and robustness of these AI models.

## S3A-SPIN-4 PATIENT PRIVACY LEAKS IN LARGE LANGUAGE MODELS AFTER FEDERATED TRAINING ON MEDICAL REPORTS

Klaus Maier-Hein (*Abstract Co-Author*) Nothing to Disclose
Ralf Floca (*Abstract Co-Author*) Nothing to Disclose
Andres Martinez Mora (*Abstract Co-Author*) Nothing to Disclose
Benjamin Hamm (*Abstract Co-Author*) Nothing to Disclose
Dimitrios Bounias, MSc (*Abstract Co-Author*) Nothing to Disclose
Maximilian Zenk (*Abstract Co-Author*) Nothing to Disclose
Santhosh Parampottupadam, PhD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Transformer-based Large Language Models (LLMs), like ChatGPT, have seen remarkable progress in extracting insights from text datasets, including radiology reports. LLMs could maximize their impact by accessing large quantities of radiological reports from different sites. However, data protection laws (like HIPAA) impose strict regulations on data sharing, given the high sensitivity of these data. Federated Learning (FL) emerges as a promising solution for multi-institution environments, as it allows for training using robust datasets without data ever leaving the institution. However, if FL systems are not adequately protected against attacks, reconstruction techniques could leak data from model parameters. In this work, we show how report data from a public radiology dataset could be recovered from transformer models in a simulated FL setup, underscoring the need for proper privacy protection.

### METHODS AND MATERIALS

A transformer-based language AI model was trained on radiological reports from the public dataset Dischargesum, composed of 250k+ diagnosis reports and 68k+ discharge reports. The models were trained with a GPT-2 tokenizer, vocabulary size 50257, and sequences of length 32. Training data were distributed at random to six virtual clients to simulate an FL setup. Data was reconstructed by a malicious central server using gradients shared by the clients. By targeting specific clients, the server exploited scaled versions of the input data from the model's adjustments, applying adjustments in model biases to reconstruct effectively the original input data. The original client report data was compared to the reconstructed data by the server for evaluation. Reconstruction capabilities were assessed by measuring the accuracy of the number of sentences recovered from the original data.

### RESULTS

In the FL setup, a server successfully reconstructed 36% to 42% of the sentences from the diagnosis and discharge datasets. These results, obtained from batches of 64, 128, and 256 tokens, were averaged across ten experiments.

### CONCLUSION

In this work, we showcase how transformers, the backbone for popular LLMs, could expose training data from radiological reports. This is possible even in a FL environment, where patient privacy should be a priority. Consequently, if reports are to be used for AI model training, there is a need for robust privacy-preserving measures.

### CLINICAL RELEVANCE/APPLICATION

This proof-of-concept study underscores the need for robust privacy measures in training Large Language Models through federated learning, particularly as multi-institution collaborations in healthcare increase. The goal is to prevent the leakage of patient data from radiology reports while complying with stringent data protection regulations.

## S3A-SPIN-5 IS YOUR DE-IDENTIFIED RADIOGRAPH TRULY DE-IDENTIFIED?

Bradley J. Erickson, MD, PhD (*Abstract Co-Author*) Board of Directors, VoiceIt Technologies, LLC;Stockholder, VoiceIt Technologies, LLC;Board of Directors, FLOWSIGMA Inc;Officer, FLOWSIGMA Inc;Stockholder, FLOWSIGMA Inc;Officer, Yunu Inc;Stockholder, Yunu Inc
Cody Wyles, MD (*Abstract Co-Author*) Nothing to Disclose

Shahriar Faghani, MD (*Abstract Co-Author*) Nothing to Disclose
Michael Taunton, MD (*Abstract Co-Author*) Consulting, DJO Global, Inc;Royalties, DJO Global, Inc
Pouria Rouzrokh, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

De-identifying (or anonymizing) medical imaging data is crucial for ensuring patient privacy during research endeavors, data transfers, and the development of artificial intelligence (AI) models. For radiographs, the two most common strategies for de-identification are: 1) the removal or substitution of tags containing protected health information (PHI) in the DICOM metadata, and 2) altering pixel values in areas containing PHI markers on the image itself (e.g., by covering them with a black box). Considering these strategies, we hypothesized that specialized AI models might still detect PHI "fingerprints" from imaging features, potentially revealing patient identities.

### METHODS AND MATERIALS

After obtaining institutional review board approval, we collected 661,124 anterior-posterior (AP), lateral, and oblique hip and pelvis radiographs from our institutional total joint arthroplasty registry. We de-identified them using the aforementioned strategies. The data were then split into training, validation, and test folds at the patient level. We trained a ConvNeXt (v2) model to encode each input radiograph into a one-dimensional vector of size 768. The model was designed to increase the cosine similarity between encoded vectors of imaging pairs belonging to the same patient, regardless of view and time distance, and to decrease it for other pairs. After training, we identified a cosine similarity cutoff threshold for distinguishing the output vectors for a pair of radiographs as belonging to similar or different patients by plotting the Receiver Operating Characteristic (ROC) curve of that prediction on our validation set. We then applied this threshold to our test set and also leveraged t-SNE plots and integrated gradient maps (IGMs) to elucidate the model's performance.

### RESULTS

The comparison of cosine similarity between encoded vectors for radiographic pairs against the calibrated threshold successfully detected true identity relationships in 94% of all possible pairs in the test set. The pipeline had reliable performance even across pairs that contained radiographs of different views and with years of time distance between them. IGMs highlighted the contour of the bones as the most prominent features learned by the model (Figure).

### CONCLUSION

Despite de-identifying radiographs by both of the two most common methods to protect PHI, a self-supervised AI model demonstrated the capability to reidentify them with 94% accuracy.

### CLINICAL RELEVANCE/APPLICATION

Relying solely on DICOM metadata alteration and pixel value changes in radiographs may not sufficiently de-identify them. Medical systems need more robust de-identification and anonymization strategies for highly sensitive data access situations.

## S3A-SPIN-7 UNLOCKING THE INFINITE DATA STREAM: CONTINUAL LEARNING FOR DYNAMIC MULTI-ORGAN AND TUMOR SEGMENTATION

Yu-Cheng Chou, BSc (*Abstract Co-Author*) Nothing to Disclose
Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop an efficient training strategy that enables artificial intelligence (AI) algorithms to learn from massive medical datasets (i.e., 8.5 million images) for multi-organ and multi-tumor segmentation.

### METHODS AND MATERIALS

We developed AI algorithms that can learn from massive computed tomography (CT) data by storing the most significant data in the Replay Buffer (RB). New data comes in and gets added to the RB, which has a defined memory size. When it is full, we discard the oldest data first. At the same time, mini batches are generated through random sampling from the buffer at a defined sampling rate. This ensures efficiency while maintaining the integrity of medical information. To make sure we only keep the most distinctive CT scans from different hospitals, we introduced a Data Pruning (DP) mechanism that computes the cosine similarity among all pairs of data within the RB, and then discard the ones with highest similarity. Furthermore, we formulated a Structure Uncertainty Prioritization (SUP) strategy that keeps data with the top K uncertainty to maintain a buffer focused on the most diagnostically challenging samples. We measure the uncertainty by assigning a weighted entropy based on the ratio of each class's annotation size to the total annotation size. Our experimental evaluation utilized two extensive abdominal CT datasets, one proprietary dataset comprising 15 organ classes split into 2,101 and 516 for training testing, and an assembled dataset consisting of 16 partially labeled sub-datasets offering 32 classes with 2,100 training cases and 583 testing cases. Notably, we maintained a consistent data flow without shuffling in any of our experiments.

**RESULTS**

The single-pass RB approach achieved a Dice Similarity Coefficient (DSC) of 82.22% on the proprietary dataset, closely matching the performance of traditional 100-epoch training (DSC of 82.60%) and significantly outperforming conventional training methods in varied data distributions, with a DSC of 47.22% on the assembled dataset compared to 0.65% with conventional methods. Notably, our approach demonstrated enhanced capability in detecting small structures like the Adrenal Gland, with a DSC of 55.34%.

**CONCLUSION**

Our study demonstrates a significant advancement in AI training for medical imaging, effectively managing large, continuous data flows and mitigating catastrophic forgetting, a common challenge in dynamic clinical environments.

**CLINICAL RELEVANCE/APPLICATION**

This training strategy significantly improves the efficiency and accuracy of AI models in medical image analysis, particularly in detecting intricate structures (e.g., adrenal gland) in massive datasets, enhancing the diagnostic capabilities of radiologists in high-volume clinical settings.

## S3A-SPIN-8 CHARACTERIZING THE IMPACT OF GPCI-ADJUSTMENT ON DIAGNOSTIC ULTRASOUND REIMBURSEMENT DISPARITIES: AN RVU-BASED ANALYSISOF BUDGET NEUTRALITY

Maryamnaz Falamaki, MD (*Abstract Co-Author*) Nothing to Disclose
Talha Ayaz, MD (*Abstract Co-Author*) Nothing to Disclose
Zain Hussain, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the efficacy of Medicare’s Geographic Practice Cost Indices (GPCI) adjustments in mitigating regional disparities in ultrasound reimbursement among diagnostic radiologists with regards to practice setting, provider gender and exam type.

**METHODS AND MATERIALS**

Using the 2021 Medicare Public Use File, we assessed claims for the following procedures: Ultrasound of the abdomen, complete (76700); Ultrasound of the head and neck (76536); Ultrasound of one breast, complete (76641); Ultrasound of the pelvis, complete, not related to pregnancy (76856); and Transvaginal ultrasound pelvis (76830). Data were standardized using the CMS Physician Fee Schedule Look-Up Tool and adjusted for inflation via the U.S. Department of Labor's CPI. Statistical analyses included univariable and multivariable linear regressions with generalized estimating equations to identify factors influencing Relative Value Units (RVUs) per beneficiary.

**RESULTS**

In 2021, 1,814,182 ultrasound services were provided to 2,160,804 Medicare beneficiaries across various regions and settings. The most frequently performed study was “ultrasound of the head and neck (CPT 76536)” with a total of 559,003 exams, followed by “ultrasound of the abdomen, complete (CPT 76700)” totaling 529,549 exams. After adjusting for inflation, statistical analyses showed that significant regional differences persist after controlling for GPCI, particularly with regards to facility settings consistently yielding lower RVUs than office settings. For example, the Midwest's coefficient shifted from -0.349 in the unadjusted model to -0.054 in the adjusted model. Similarly, the South's effect decreased from -0.268 to -0.002 (all $p<0.05$). When all three GPCI metrics were incorporated into the multivariable final risk model, the R squared value increased by approximately 1.3%, indicating GPCI partially mediates for regional disparities in RVUs per beneficiary.

**CONCLUSION**

This study illustrates that despite GPCI adjustment, some regional disparities in RVUs per beneficiary for diagnostic ultrasound reimbursement persist. This suggests that revision of reimbursement valuations is necessary to better reflect the true costs and needs across different regions.

**CLINICAL RELEVANCE/APPLICATION**

Findings from this study are crucial for policymakers and healthcare administrators, highlighting the necessity for refined Medicare reimbursement strategies to ensure equitable distribution of healthcare resources and quality care across the United States.

## S3A-SPIR-1 EMBOLOTHERAPY FOR PULMONARY ARTERIOVENOUS MALFORMATIONS IN PEDIATRIC POPULATION WITH HEREDITARY HEMORRHAGIC TELANGIECTASIAS - A RETROSPECTIVE CASE SERIES

Haraldur Bjarnason, MD (*Abstract Co-Author*) Nothing to Disclose
Nadir Demirel (*Abstract Co-Author*) Nothing to Disclose
Vivek Iyer (*Abstract Co-Author*) Nothing to Disclose
Sanjay Misra, MD (*Abstract Co-Author*) Support, Cardinal Health, Inc
Emily C. Bendel, MD (*Abstract Co-Author*) Nothing to Disclose
Haseeb Mukhtar, MBBS, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To document the role of embolotherapy for pulmonary arteriovenous malformation (pAVM) management, and investigate factors associated with pAVM persistence after embolotherapy in pediatric patients with hereditary hemorrhagic telangiectasia (HHT).

### METHODS AND MATERIALS

Pediatric HHT patients who received embolotherapy for pAVMs at our institute were retrospectively identified from January 1st, 1999, to January 31st, 2024. Cases with adequate clinical and imaging follow-up and without prior pAVM treatment at another institute were included. Demographic, clinical, and procedural data were obtained from the electronic health record. Categorical variables were reported as count with percentage, while continuous variables were reported as median with range. Univariate Cox proportional hazard models were used to determine factors associated with primary pAVM persistence. Multivariate analysis could not be done due to the small sample size.

### RESULTS

Twenty-one patients (median age=15 years) were treated for 65 different pAVMs in 40 distinct procedures (Median follow-up time=7.56 years). ENG was the most common genetic mutation (84.6%). One major procedural complication occurred (coil embolization to the right middle cerebral artery). Persistence occurred in 15 out of the 65 treated pAVMs (23.1%). The cumulative probability of persistence at 5 years was 25.0% (95% CI: 63.7% - 84.8%). Recanalization was the most common cause of primary persistence (73.3%). Age below the median cutoff of 15 years (p=0.0436) and greater maximum diameter of the plug/coil (p=0.0106) were significantly associated with primary persistence on univariate analysis.

### CONCLUSION

Embolotherapy is an effective option for pAVM management in the pediatric population with HHT. The risk of primary persistence was associated with age below 15 years, and the use of larger diameter plugs/coils.

### CLINICAL RELEVANCE/APPLICATION

Data on pAVM embolotherapy specifically in pediatric HHT patients is limited. This study therefore sheds further light on this important subject and demonstrates the efficacy and safety of embolotherapy in this subgroup of patients.

## S3A-SPIR-2 CORRELATION BETWEEN VASCULAR ANATOMIC VARIANT OF PROSTATIC ARTERY AND CLINICAL EFFICACY OF PROSTATIC ARTERIES EMBOLIZATION

Maria A. Cova, MD (*Abstract Co-Author*) Nothing to Disclose
Michele Pontello (*Abstract Co-Author*) Nothing to Disclose
Manuel Belgrano, MD (*Abstract Co-Author*) Nothing to Disclose
Michelangelo Digregorio, MD (*Presenter*) Nothing to Disclose

### PURPOSE

the aim of this study is to correlate anatomical variations of the prostatic artery with short-term clinical efficacy.

### METHODS AND MATERIALS

this is a single-center retrospective study involving 132 patients with benign prostatic hyperplasia symptoms who underwent prostatic artery embolization from February 2016 to February 2023. Technical success is defined as embolization of the prostatic artery on at least one pelvic half. Short-term clinical efficacy is defined as the absence of symptoms requiring surgery within 12 months.

**RESULTS**

out of 132 patients, 95 (72%) underwent bilateral embolization, 28 (21.2%) underwent unilateral embolization, and 9 (6.8%) did not undergo embolization due to vessel non-visualization or particularly unfavorable vascular anatomy. The procedure was technically successful in 93,2% of cases. A total of 218 prostatic arteries were embolized. Type I variant was found 104 times (47.7%), type II variant was found 39 times (17.9%), type III variant was found 51 times (23.4%), and type IV variant was found 24 times (11%). Out of 123 technically successful procedures, surgery within 12 months was necessary in 13 cases (10.5%). 2 out of these 13 patients were treated with unilateral prostatic artery embolization, while the remaining 11 were treated with bilateral embolization. Type I variant was found at least on one side 10 times; Type II variant was found at least on one side 3 times; Type III variant was found at least on one side 1 time; and Type IV variant was found at least on one side 3 times. Type I variant on at least one pelvic half is associated with a short-term clinical efficacy rate of 90.4%. Type II variant on at least one pelvic half is associated with a short-term clinical efficacy rate of 92.3%. Type III variant on at least one pelvic half is associated with a short-term clinical efficacy rate of 98%. Type IV variant on at least one pelvic half is associated with a short-term clinical efficacy rate of 87.5%.

**CONCLUSION**

although the small size of the study population severely limits statistical significance, the type III variant seems to be associated with the highest short-term efficacy rate, while the type IV variant seems to be associated with the lowest short-term efficacy rate.

**CLINICAL RELEVANCE/APPLICATION**

the type of vascular anatomic variant of the prostatic artery could represent an additional variable to consider in patient selection.

## S3A-SPIR-3 CLINICAL AND IMAGING OUTCOMES OF DOXYCYCLINE EXCHANGE SCLEROTHERAPY FOR LYMPHATIC MALFORMATIONS

Prateek C. Gowda, BS (*Abstract Co-Author*) Nothing to Disclose

Tushar Garg, MD (*Abstract Co-Author*) Conference Travel, Siemens Healthineers
William Morefield (*Abstract Co-Author*) Nothing to Disclose
Dana A. Schaar (*Presenter*) Nothing to Disclose

**PURPOSE**

Evaluate serial doxycycline exchanges (SDEs) for lymphatic malformations (LMs).

**METHODS AND MATERIALS**

We performed a retrospective, single-center chart review of patients undergoing LM sclerotherapy with SDE at our large, tertiary care academic institution from April 2003 through March 2023. Change in patient symptoms between pre- and post-treatment clinical notes was the primary outcome measure, which was assessed based on the resolution of patient-specific presenting symptoms. Secondary outcomes were percent change in lesion volume measured from imaging studies, evaluated using three-dimensional ellipsoidal approximation, and 30-day adverse events.

**RESULTS**

Forty-six patients (25 of 46 [54.3%] male) received an average of 1.9 (±1.0) treatments with 4.8 (±2.3) exchanges per treatment including the initial instillation in the interventional radiology suite. Patients presented at a mean age of 14.83 years (±21.65 years). Swelling (28/46; 60.9%) and discomfort (8/46; 17.4%) were the most prevalent initial symptoms. Of the 46 patients, 24 (52.2%) had one SDE admission, 14 (30.4%) had 2 separate admissions, and 8 (17.4%) had at least 3 separate admissions. Patients presented for additional treatment predominantly because of inadequate resolution of their initial presenting symptoms. Eight adverse events were observed, characterized as 4 mild, 3 moderate, and 1 severe. Of the 46 patients, 44 had appropriate follow-up to assess clinical change. Of the 44 patients, 4 (9.1%) experienced full clinical remission, 27 (61.4%) experienced improved clinical symptoms, and 13 (29.5%) experienced either unchanged or increased symptoms. LM size was reduced by a median of 63.4% (interquartile range [IQR] 63.9) after 1 series of exchanges and by an additional 64.4% (IQR 69.5) after a second series. Of 34 patients, 27 (79.4%) experienced a reduction in mean lesion size after all treatments, and 7 (20.6%) experienced an increase.

**CONCLUSION**

The majority of patients experienced improved clinical symptoms and a reduction in LM size at the conclusion of SDE therapy.

**CLINICAL RELEVANCE/APPLICATION**

SDE therapy is a safe and effective treatment of LMs that allows for multiple sessions of sclerotherapy with a single fluoroscopic procedure.

## S3A-SPIR-4 RELATIONSHIP BETWEEN PROPORTION OF ADENOMYOSIS AND EFFICACY OF UTERINE ARTERY EMBOLIZATION

Gyeong Sik Jeon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hyewon Yang (*Presenter*) Nothing to Disclose

**PURPOSE**

Uterine artery embolization (UAE) is a well-established treatment option for uterine fibroids and adenomyosis. The existing literature suggests that UAE efficacy is lower for patients with adenomyosis. Many patients present with concomitant uterine fibroids and adenomyosis, but few studies have addressed this patient population. The purpose of this study was to assess whether the proportion of adenomyosis affected treatment success and recurrence rates.

**METHODS AND MATERIALS**

This single-center retrospective study evaluated patients between March 1st, 2011 to June 30th 2023 undergoing UAE for adenomyosis. The patient's clinical characteristics and magnetic resonance imaging findings were analyzed. Patients were sorted into three groups based on proportion of adenomyosis: (a) Pure adenomyosis, (b) Mixed - myoma dominant (c) Mixed - adenomyosis dominant.Clinical symptoms were evaluated using the Uterine Fibroid Symptom and Quality of Life (UFS-QOL) questionnaire. UAE was considered successful when patients reported a decreased level of

symptom severity. Symptoms leading to a secondary surgical procedure or intervention was considered symptom recurrence. Descriptive statistics was used to evaluate clinical success rates and symptom recurrence between these three groups.

**RESULTS**

102 patients (mean age, 41 ± 5.4 years) with varying degrees of adenomyosis underwent UAE. 52 patients had only adenomyosis and 50 patients had concomitant uterine fibroids and adenomyosis. Of the latter, 24 patients had an adenomyosis volume larger than twice the summative volume of fibroids and were considered mixed - adenomyosis dominant. Average clinical follow-up was 9.4 months (range 1-65 months). Clinical success rates were 94.23% for the pure adenomyosis group (49/52), 92.31% for the myoma dominant group (24/26), and 91.67% for the adenomyosis dominant group (22/24) (p=0.9019). Symptom recurrence occurred in 40.82% (20/49), 29.17% (7/24), and 31.82% (7/22) (p=0.5633), respectively. There was no statistically significant difference between the three groups.

**CONCLUSION**

Our clinical experience suggests that treatment success and symptom recurrence in patients treated with UAE is not affected by proportion of adenomyosis.

**CLINICAL RELEVANCE/APPLICATION**

In patients with concomitant adenomyosis and uterine fibroids, the proportion of adenomyosis should not be a deterrent for treatment with uterine artery embolization.

## S3A-SPIR-5 PREDICTING THE THERAPEUTIC TEMPERATURE OF TRANSCRANIAL MRGFUS BASED ON MULTILAYER PERCEPTRON NETWORK

Mingliang Yang (*Abstract Co-Author*) Nothing to Disclose
Yan Li (*Abstract Co-Author*) Nothing to Disclose
Xin Lou, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Haoxuan Lu (*Abstract Co-Author*) Nothing to Disclose
Yongqin Xiong (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a prediction model for predicting the treatment temperature of transcranial magnetic resonance-guided focused ultrasound with preset parameters, to quantitatively assess the accuracy of the predicted temperature, and to analyze the efficacy of different predictors on the predicted temperature.

**METHODS AND MATERIALS**

The authors retrospectively analyzed consecutive participants with essential tremor or Parkinson's disease who received MRgFUS treatment between January 2019 to June 2023 at their center. The average maximum temperature at the target were obtained for each sonication by using MR thermometry. The magnitude of the effect of 5 different predictors (e.g., energy per sonication) or combinations of predictors on the efficacy of the multilayer perceptron focused ultrasound temperature network (Fust-Net) for target temperature prediction at the target site was analyzed and tested.

**RESULTS**

A total of 90 participants (799 sonications; mean age, mean age, 64.00 years [SD, 9.27 years]; 67 male participants) were included in the study. Fust-Net obtained the best predictive performance from the combination of Skull Density Ratio (SDR), planned energy, planned duration, head size, and mean skull area predictors, achieving the prediction of the mean maximum temperature (mean absolute error 1.976, effective prediction temperature 91%), with test sets of 18 participants with 199 sonications data for each sonication. The sub-predictor importance was verified by ablation experiments for planned energy, SDR, planned duration, head size and average skull area, respectively.

**CONCLUSION**

A multilayer perceptron prediction model that predict the therapeutic temperature of MRgFUS treatment shows promise in setting the treatment parameters and improving the success rate and safety of treatment.

**CLINICAL RELEVANCE/APPLICATION**

A multilayer perceptron-based MRgFUS treatment temperature prediction model was developed which holds the potential to simplify MRgFUS treatment protocols, and improve patient's safety by enabling more accurate and facile temperature control during MRgFUS procedures.

## S3A-SPIR-6 SAFETY AND EFFICACY OF VENOUS COIL-EMBOLIZATION OF DO'S TYPE IIA PELVIC ARTERIOVENOUS MALFORMATIONS

Sang Yub Lee (*Abstract Co-Author*) Nothing to Disclose
Young Soo Doo (*Abstract Co-Author*) Nothing to Disclose
Lyo Min Kwon (*Abstract Co-Author*) Nothing to Disclose
Gwanghyun Kim, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the safety and efficacy of coil embolization of venous segments in patients with Do's type IIa pelvic arteriovenous malformations (AVM).

**METHODS AND MATERIALS**

A retrospective analysis from March 2017 to February 2023 was performed in 13 patients (mean age 42.2 ± 14.2 years, 7 males) who underwent transvenous coil embolization for type IIa pelvic AVM (AVM with multiple arterioles shunting to focal venous segments of the draining vein) without using additional liquid embolic agents. Treatment outcomes were analyzed based on clinical findings, post-angiography findings, and follow-up computed tomography (CT) scans to evaluate technical success, clinical success, and complete remission rates.

**RESULTS**

Of the 13 patients, 12 received single treatment with coil embolization [transvenous access (n=9) and direct puncture (n=3)]. In one patient, a transvenous approach was initially attempted but failed because of the untraceable draining vein, and successful embolization was performed in the second session with direct puncture. The technical success rate was 92.8% (13/14). All symptomatic patients experienced symptom improvement and asymptomatic patients remained symptom-free, resulting in a clinical success rate of 100% (13/13). Follow-up CT imaging in nine of the 12 patients showed complete occlusion of the AVM without recurrence. One minor complication, a small amount of retroperitoneal hemorrhage that resolved spontaneously, was observed in one patient; no major complications were observed.

### CONCLUSION

Coil embolization of the draining vein segment without the additional use of liquid embolic agents is safe and effective for managing type IIa pelvic AVM.

### CLINICAL RELEVANCE/APPLICATION

Type II pelvic AVMs can be managed safely and effectively through embolization using a coil only, without the additional use of the liquid embolic agent ethanol.

## S3A-SPIR-8 SUPERIOR HYPOGASTRIC NERVE BLOCK AS AN ADJUNCT TO UTERINE FIBROID EMBOLIZATION: A RETROSPECTIVE COHORT STUDY EVALUATING OPIOID-SPARING EFFECTS

Ali N. Harb, MD (*Abstract Co-Author*) Nothing to Disclose
Arif Musa, MD, MS (*Abstract Co-Author*) Research Grant, Stryker Corporation;Contract, WebMD Health Corp (WebMD, Inc)
Jawad Muayad (*Abstract Co-Author*) Nothing to Disclose
Zain Hussain, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to evaluate the efficacy of Uterine Fibroid Embolization (UFE) with versus without Superior Hypogastric Nerve Block (SHPB) in reducing opioid use post-procedure, further addressing the paucity of data on opioid-sparing strategies in the management of uterine fibroids.

### METHODS AND MATERIALS

A retrospective cohort study utilized TriNetX data, analyzing opioid usage among women diagnosed with uterine leiomyomas who underwent UFE alone (CPT 37243) and UFE with SHPB (CPT 64517) within the 90-day post-operative period. Propensity score matching adjusted for demographics and comorbidities, ensuring balanced comparison across cohorts. Time-to-event analyses were conducted using Cox Proportional hazards modeling and Kaplan-Meier analysis.

### RESULTS

After matching, our study included two cohorts of 112 patients each. Within 90-days after surgery, the UFE with SHPB group showed a statistically significant reduction in opioid use post-procedure, with a Risk Difference of -13.393% (95% CI: -26.328%, -0.458%), Risk Ratio of 0.746 (95% CI: 0.558, 0.996), and Hazard Ratio of 0.673 (95% CI: 0.455, 0.995, p=0.0095) compared to the UFE alone group.

### CONCLUSION

UFE with SHPB is associated with significant reduction in opioid consumption in the postoperative period compared to UFE alone, highlighting the benefits of integrating SHPB as a pain management strategy in minimally invasive fibroid treatment.

### CLINICAL RELEVANCE/APPLICATION

These findings suggest that incorporating SHPB in UFE procedures can enhance postoperative recovery by minimizing opioid use, thus offering a potentially preferable treatment alternative for women with symptomatic uterine fibroids. This approach may reduce opioid-related side effects and improve overall patient outcomes.

## S3A-SPIR-9 COMPARATIVE PERI- AND POST-OPERATIVE COMPLICATIONS IN WOMEN AFTER UTERINE ARTERY EMBOLIZATION VERSUS HYSTERECTOMY FOR FIBROIDS AND ADENOMYOSIS

James B. Spies, MD (*Abstract Co-Author*) Nothing to Disclose
Stephen Bush (*Abstract Co-Author*) Nothing to Disclose
Frank Annie (*Abstract Co-Author*) Nothing to Disclose
Amy R. Deipolyi, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Uterine fibroids and adenomyosis are common women’s health issues that often require intervention. Despite prior studies showing the efficacy of uterine artery embolization (UAE), it is rarely performed compared with hysterectomy. This observational study used TriNetX, a multi-institution database of anonymous health information gleaned from electronic medical records, to compare large cohorts of women with fibroids and adenomyosis who underwent either UAE or hysterectomy, focusing on peri- and post-procedure complications.

### METHODS AND MATERIALS

All 141,119 consecutive women with fibroids and/or adenomyosis who underwent hysterectomy or UAE from 1/1/2016-1/1/2024 in US institutions participating in TriNetX were included. Demographic (age, race, location) and clinical (comorbidities) patient characteristics and adverse outcomes including pelvic floor prolapse, bowel obstruction, peri-procedure blood transfusion, and length of stay, were recorded. Hysterectomies were categorized as open or laparoscopic, and as transabdominal or transvaginal. A propensity score matching (PSM) analysis compared all UAE patients to subgroups of women who underwent different types of hysterectomy, matched by race, age, and medical comorbidities.

### RESULTS

139,621 women underwent hysterectomy whereas 1,498 (1%) underwent UAE. UAE utilization was more likely among women who were black (2.2 v. 0.6%; P<0.01) and younger (44±9 v. 50±11 years; P<0.01). Hysterectomy was associated with more frequent periprocedural blood transfusions (4.3 v. 0.7%, P<0.01), longer post-procedure hospitalizations (10 v. 1 day, P=0.01), and higher rates of intestinal obstruction (4.9 v. 1.7%, P<0.01) and pelvic floor prolapse (5.3 v. 1.2%, P<0.01) within 5 years. PSM analysis showed that abdominal hysterectomy had the longest hospitalizations (5 days) and highest blood transfusion rate (3%); vaginal hysterectomy had the highest rate of pelvic floor prolapse (17%). After UAE, there was a 3% reintervention rate and 17% pregnancy rate.

### CONCLUSION

Hysterectomy is associated with more perioperative blood transfusions, longer hospitalizations, and increased rates of intestinal obstruction and pelvic floor prolapse.

### CLINICAL RELEVANCE/APPLICATION

As a minimally invasive therapy, UAE may be superior to hysterectomy in the treatment of fibroids and adenomyosis, avoiding potential complications including pelvic floor prolapse and bowel obstruction.

## S3A-SPMK-1 MRI FEATURES OF PLANTAR VEIN THROMBOSIS

Durval D. Santos, MD (*Abstract Co-Author*) Nothing to Disclose
Atul K. Taneja, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Ariadne Obrigon (*Abstract Co-Author*) Nothing to Disclose
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Adham A. Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Alexandre L. Santos (*Abstract Co-Author*) Nothing to Disclose
Frederico C. Miranda, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Plantar vein thrombosis (PVT) is an underdiagnosed condition that affects the deep plantar veins, presenting a challenging clinical diagnosis, due to its non-specific symptoms that often resemble other foot pathologies.The goal of this study was to evaluate the magnetic resonance imaging (MRI) findings in patients diagnosed with plantar venous thrombosis and to enhance the understanding of this condition.

### METHODS AND MATERIALS

Comprehensive analysis was conducted on a substantial data which includedage (years), sex (male, female), weight (kg), height (m), symptoms (acute pain, chronic pain, trauma, asymptomatic), body mass index (BMI), time between the onset of pain and carrying out an MRI exam (days). This analysis encompassed data from 112 anonymized patients, with a total of 130 MRI exams (86 of the forefoot and 44 of the ankle) showing imaging findings of PVT.

### RESULTS

Upon evaluating all the veins of the foot, we observed a higher frequency of involvement of the lateral plantar veins (53.1%) when compared to the medial veins (3.8%). In the forefoot, the most affected vascular segments were the plantar metatarsal veins (45.4%), the plantar venous arch (38.5%), and the plantar communicating veins (25.4%). MRI revealed consistent findings, including perivascular edema (100%), muscular edema (86,2%), venous ectasia (100%), perivascular enhancement (100%), and venous filling defects (97,7%).

### CONCLUSION

This study evaluated the findings of PVT diagnosed by MRI, describing the frequency of the most affected veins. When considering the entire foot or just the ankle, the lateral plantar vein was most frequently affected (53.1% and 97.7%, respectively). In the forefoot, the plantar metatarsal veins were most commonly involved (68.6%). As for the imaging findings, venous ectasia, edema and perivascular enhancement were present in 100% of the cases, followed by filling defect, which was observed in 97.7% of the cases. In the assessment of painful conditions of the foot, it is crucial to consider PVT as a potential diagnosis. PVT appears to be a less common variant of a more proximal deep venous thrombosis, which is a more prevalent condition, sharing similar risk factors. However, mechanical load and stress appear to be a unique risk factor specifically associated with PVT.

### CLINICAL RELEVANCE/APPLICATION

As we enhance awareness of this condition and the corresponding MRI findings, it may become easier to recognize and accurately diagnose this pathology.

## S3A-SPMK-2 DEVELOPMENT OF DEEP LEARNING MODEL FOR DETECTING LOW BONE MINERAL DENSITY IN THE FEMORAL NECK AND LUMBAR VERTEBRAE USING CHEST RADIOGRAPHS

Takahiro Ideta (*Abstract Co-Author*) Nothing to Disclose
Takayuki Ishida, PhD (*Abstract Co-Author*) Nothing to Disclose
Kouichi Yamamoto (*Abstract Co-Author*) Nothing to Disclose

Hiroaki Matsuzawa (*Abstract Co-Author*) Nothing to Disclose
Takao Ichida, RT (*Abstract Co-Author*) Nothing to Disclose
Yukino Ohta (*Presenter*) Nothing to Disclose

### PURPOSE

Artificial intelligence (AI) technologies can detect overall osteoporosis on chest radiographs with high accuracy. Bone loss can appear in various body parts based on individuals' lifestyle and body shape, it is necessary to detect low bone mineral density (BMD) in each part to alert patients and enable early

treatment. Therefore, we developed two types of deep learning models to detect and differentiate low BMD in the femoral neck and lumbar vertebrae, and evaluated their effectiveness and characteristics.

**METHODS AND MATERIALS**

We used chest radiographs and BMD values, measured using dual-energy X-ray absorptiometry, of 2728 female examinees who underwent health examinations. Chest radiographs were categorized into low BMD (n=1358) and normal (n=1370) based on the BMD of the femoral neck. In addition, the radiographs were also classified into low BMD (n=562) and normal (n=2166) based on the BMD of the second to the fourth lumbar vertebrae. A deep learning model was developed to detect low BMD in the femoral neck and another to detect low BMD in the lumbar vertebrae. They were trained using whole chest radiographs, and 10-fold cross-validation method was used for training. The sensitivity, specificity, overall accuracy, and area under the curve (AUC) were used to evaluate the performance of the deep learning models. To get visual explanations in the images used by the deep learning models for classification, average heatmaps were generated using Explainable AI.

**RESULTS**

For detecting low BMD in the femoral neck, the sensitivity, specificity, overall accuracy, and AUC were respectively 75.4 %, 75.2 %, 75.3 % and 0.82. For detecting low BMD in the lumbar vertebrae, they were respectively 89.5 %, 89.1 %, 89.3 % and 0.96. The overall accuracy for the lumbar vertebrae was 14.0 % higher than that for the femoral neck. The heatmap distributions were near the distal ends of clavicle and cardiac shadow for the detection of low BMD in the femoral neck, whereas they were observed around the proximal ends of clavicle and upper thoracic vertebrae for the detection of low BMD in the lumbar vertebrae.

**CONCLUSION**

The proposed deep learning model could detect low BMD from chest radiographs and distinguish low BMD parts. Detecting low BMD in the femoral neck yielded moderate performance, whereas in the lumbar vertebrae yielded high performance. Detecting low BMD in the femoral neck was more challenging. Regions showing characteristics of low BMD in each part were respectively identified on the images.

**CLINICAL RELEVANCE/APPLICATION**

This model can detect low BMD, which is the early stage of osteoporosis, and identify parts with bone loss from chest radiographs. This enables simple screening and may be effectiveness for appropriate prevention and treatment depending on the bone loss parts.

## S3A-SPMK-3 RADIOMICS-BASED ARTIFICIAL INTELLIGENCE MODEL DIFFERENTIATING LIPOMA FROM ATYPICAL LIPOMATOUS TUMOR

Luz Moran (*Abstract Co-Author*) Nothing to Disclose
Rut Bernal Leon (*Abstract Co-Author*) Nothing to Disclose
Alberto Ramirez Garcia-Mina, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a Radiomics-based Machine Learning model able to distinguish between lipoma and atypical lipomatous tumor (ALT) on MRI and evaluate its performance.

**METHODS AND MATERIALS**

A total of 59 patients with a lipomatous soft tissue tumor were included from August 2015 to December 2023 retrospectively in a single institution. All patients had an MRI study including T1-weighted, T2-weighted, and PD SPAIR-weighted sequences and a core needle biopsy with the determination of MDM2 gene amplification by FISH. The lesion that had no MDM2 amplification was considered a lipoma, and the lesion with MDM2 amplification was defined as ALT. There were 42 lipomas (mean age, 60.2; sex ratio, 19:23) and 17 ALTs (mean age, 64.4; sex ratio, 9:8). A 3D segmentation was performed for each lesion in the three sequences using the software MM Radiomics (syngo.via Frontier v. 1.4.0). 854 radiomic features were extracted from each ROI from the original images (first-order, shape, and texture features) and the images obtained by applying Wavelet filter using MM Radiomics.Different Machine Learning models (support vector machine, K-nearest neighbors, decision trees, and neural network) were developed using Classification Learner in MATLAB. SMOTE (Synthetic Minority Oversampling Technique) was applied for handling imbalanced data, as ALTs were a minority class in the study population. The performance of the different models (ROC AUC score, accuracy, sensitivity, specificity, and F1-score) was evaluated using five-fold stratified cross-validation.

**RESULTS**

The best performance was achieved with a neural network model using only the T1-weighted images: accuracy, 94%; AUC-ROC, 0.97; sensitivity, 95.2%; specificity, 92.9%. Using the T2 or PD SPAIR-weighted images did not add value to the performance of the models. The best combined model with T1, T2, and PD SPAIR-weighted images was a support vector machine algorithm: accuracy, 92.9%; AUC-ROC, 0.94; sensitivity, 95.2%; specificity, 90.5%.

**CONCLUSION**

Machine learning based radiomics analysis using MR imaging can differentiate lipoma from atypical lipomatous tumor.

**CLINICAL RELEVANCE/APPLICATION**

Machine learning based radiomics analysis may help in more accurate identification of lipoma and atypical lipomatous tumor, with the potential to improve the diagnostic workflow of these lesions.

## S3A-SPMK-4 DIAGNOSTIC ACCURACY OF MULTIPLE FAST DEEP LEARNING-BASED MRI PROTOCOLS IN DIAGNOSING STRUCTURAL INJURIES OF THE KNEE: COMPARISON WITH STANDARD MRI PROTOCOL

Fabio Lombardo, MD (*Abstract Co-Author*) Nothing to Disclose
Alessandro Spezia (*Abstract Co-Author*) Nothing to Disclose
Emanuele Quartuccio (*Abstract Co-Author*) Nothing to Disclose
Giovanni Foti, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Calculating the diagnostic accuracy of multiple deep learning (DL) protocols with decreasing acquisition times in identifying structural knee injuries, in comparison to standard magnetic resonance imaging (MRI) protocol.

**METHODS AND MATERIALS**

This prospective institutional review board-approved study included consecutive patients studied between June 2023 and March 2024. All patients underwent standard MRI knee protocol, including multiplanar 3 mm T1 (TR 671; TE 9.8), STIR (TR 3590; TE 46.4) and DP fat-saturated (TR 1706; TE

37.9) sequences (acquisition time 20 minutes) and commercially available DL protocols characterized by a reduction in acquisition times by 2, 4, and 6 times (acquisition time 10, 5 and 3 minutes) the same day. Four radiologists (21, 16, 13 and 5 years of experience, respectively), blinded to standard MRI protocol, evaluated the presence of meniscal, tendon, ligament tears, bone marrow or chondral lesions on DL protocols. Standard MRI images served as standard of reference. For each patient, 12 zones were considered. Diagnostic accuracy values of DL protocol (qualitative assessment) were calculated on a per-injury basis using a multi-reader multi-case analysis. Inter-observer agreement was calculated with Kendall coefficient. A value of $p<0.05$ was considered statistically significant.

**RESULTS**

100 patients (58 males, mean age 55 years) were enrolled, with 1200 zones evaluated. Standard MRI revealed the presence of structural abnormality in 344/1200 zones (29%). Sensitivity and specificity of two-fold, four-fold and six-fold reduced DL protocols were 99% (340/344) and 99% (854/856), 98% (336/344) and 99% (849/856), 78% (268/344) and 80% (681/856). Kendall's tau-b coefficient was calculated as 0.92, 0.91 and 0.77, for the two-fold, four-fold and six-fold reduced DL protocols, respectively.

**CONCLUSION**

The two-fold and four-fold reduced DL protocols of the knee showed high diagnostic accuracy values, with respect to standard MRI protocol. A drop in accuracy was achieved by using the six-fold protocol.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning two-fold and four-fold DL MRI protocols allowed to reduce the acquisition time with respect to standard MRI protocol, without any loose of diagnostic accuracy. DL sequences could be employed in clinical practice to reduce the acquisition time and the risk of motion artifacts.

## S3A-SPMK-5 MR T2 MAPPING ANALYSIS OF TALAR CARTILAGE IN THE ANKLE: INVESTIGATING CORRELATIONS WITH TRAUMA MECHANISMS

Jang Gyu Cha, MD (*Abstract Co-Author*) Nothing to Disclose
Yu Sung Yoon, MD (*Abstract Co-Author*) Nothing to Disclose
Eun Kyung Khil, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the physiological and functional characteristics of talar cartilage in ankle trauma patients through MRI T2 mapping analysis, delineating cartilage changes based on ankle trauma mechanisms.

**METHODS AND MATERIALS**

In this retrospective study, a total of 78 adult patients with ankle trauma underwent ankle MRI with T2 mapping between January 2021 and October 2022. Trauma mechanisms were classified using the Lauge-Hansen classification, dividing patients into supination (S group) and pronation (P group) groups. Patients were also categorized based on posterior malleolar (PM) involvement. T2 values of talar cartilage were quantitatively measured in six anatomical regions using MRI T2 mapping sequence protocols. Interobserver and intraobserver reliability of T2 mapping measurements were assessed by two experienced musculoskeletal radiologists. Comparative analyses of T2 mapping values in each anatomical region of the talus were conducted between the two groups stratified by trauma mechanism. Furthermore, comparisons were made based on PM involvement status within each group.

**RESULTS**

Among 78 patients (mean age: 38.62 ± 14.82 years; 60.3% male, 39.7% female), 53 were in the S group and 25 in the P group, with 53 having PM involvement. The P group exhibited significantly higher T2 values in the entire lateral portion of talar cartilage compared to those in the S group ($p < 0.001$). Conversely, individuals in the S group showed significantly higher T2 values in the entire medial portion ($p < 0.001$). Furthermore, PM involvement correlated with elevated T2 values in the posterior portion of talar cartilage (medial, lateral and bilateral compartments, $p= 0.005$, 0.011, 0.001, respectively). Interobserver and intraobserver reliability of T2 mapping measurements were 0.70-0.89 and 0.66-0.89, respectively.

**CONCLUSION**

Our study highlights significant T2 value discrepancies linked to trauma mechanisms and PM involvement. These findings underscore the clinical relevance of T2 mapping in ankle injury assessment and treatment guidance.

**CLINICAL RELEVANCE/APPLICATION**

Understanding regional talar cartilage alterations using T2 mapping could aid in assessing ankle trauma severity, guiding treatment decisions, and predicting patient prognosis, thereby improving clinical management strategies for ankle injuries.

## S3A-SPMK-6 MULTIPARAMETRIC MR IMAGING OF MORPHEA (LOCALIZED SCLERODERMA): DISEASE DISTRIBUTION AND IMAGING FINDINGS

Sarah Attia, BS (*Abstract Co-Author*) Nothing to Disclose
Avneesh Chhabra, MD, MBA (*Abstract Co-Author*) Consultant, ICON plc;Consultant, Treace Medical Concepts, Inc;Author with royalties, Wolters Kluwer nv;Author with royalties, Jaypee Brothers Medical Publishers Ltd;Speaker, Siemens AG;Medical Advisor, ImageBiopsy Lab;Research Grant, ImageBiopsy Lab
Alireza Eajazi, MD (*Abstract Co-Author*) Nothing to Disclose
Flavio Duarte Silva (*Abstract Co-Author*) Nothing to Disclose
Alex Iancau, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Morphea has only been described on conventional MRI. To illustrate the spectrum of findings on multiparametric MRI (MPMRI) in clinically proven Morphea cases and assess disease extent and activity.

**METHODS AND MATERIALS**

In this cross-sectional IRB-approved study, electronic medical records were reviewed to identify patients diagnosed with morphea who underwent MPMRI screening over an 10-year period. The protocol included multiplanar T1W, fluid-sensitive 2D and 3D imaging, DWI, perfusion imaging, and delayed post-contrast 3D T1W imaging. MSK fellowship-trained radiologist evaluated all cases, assessing imaging quality, and categorizing the lesion’s compartmental depth and activity. Two other MSK readers were recruited to do inter-reader analysis.

**RESULTS**

Of the 49 patients with a diagnosis of Morphea, 37 (76%) were females, and 12 (24%) were males, with a mean age of 39.04 years (±16.12). The Morphea types were: linear (20/49), generalized (13/49); En coup de Sabre (5/49); Parry Romberg (4/49); plaque (2/49); eosinophilic fasciitis (3/49); and not otherwise specified (2/49). Among them, 14/49, 23/49, 11/49, and 1/49 affected the upper extremity, lower extremity, face, and torso, respectively. All MRI scans exhibited good quality with minimal motion artifacts. 32/49 (65%) and 17/49 (34%) were superficial and deep lesions, respectively, with 11/17 (65%) of deep lesions exhibiting muscle edema. Skin thickening and thinning were noted in 71% (35/49) and 20% (10/49) of scans, respectively. Fat atrophy and hypertrophy were observed in 71% (35/49) and 2% (1/49) of scans, respectively. Additionally, bone/joint involvement was detected in 4% (2/49) of cases. 28 active, 15 inactive, and 6 patients had undetermined disease activity based on clinical diagnosis. Out of the 28 patients who were clinically active with morphea, 19/28 (68%) scans had increased perfusion, with 4 of those scans missing perfusion in the MRI protocol ($P<0.001$). There were also 23/28 (82%) scans of patients with clinically active morphea who exhibited increased delayed post-contrast enhancement ($P<0.001$). Patients with clinically active lesions exhibited an average Apparent Diffusion Coefficient (ADC) of 1.27 (±0.63), while inactive lesions had an average ADC value of 0.74 (±0.63) ($P<0.05$).

**CONCLUSION**

In conclusion, MPMRI is valuable in assessing morphea lesions, depth of involvement, and activity- both qualitatively and quantitatively.

**CLINICAL RELEVANCE/APPLICATION**

The findings of this study emphasize the practical utility of MPMRI in improving morphea diagnosis, with high-resolution qualitative and quantitative markers, which can be used for tailored treatment strategies and track patient outcomes.

## S3A-SPMK-7 MONITORING CHANGES OF TIBIAL TALAR JOINT CARTILAGE IN AMATEUR MARATHON ATHLETES BY ULTRA-SHORT ECHO TIME MAGNETIC RESONANCE IMAGING: A PRELIMINARY STUDY

Shaolin Li, PhD (*Abstract Co-Author*) Nothing to Disclose
Yijie Fang (*Abstract Co-Author*) Nothing to Disclose
DANTIAN ZHU (*Abstract Co-Author*) Nothing to Disclose
Yiyin Hu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of ultra-short echo time magnetic resonance imaging (UTE-MT) magnetization transfer in identifying cartilage alterations in the tibial talar joint before and following long-distance running in amateur marathon runners.

**METHODS AND MATERIALS**

The Institutional Ethics Committee Review Board approved the study, and before the study, subjects gave written agreement. Twenty-seven amateur long-distance runners underwent magnetic resonance examinations of the tibial talar joint joints bilaterally pre-run, 48 hours post-run, and 4 weeks post-run. MRI scans were performed using the UT-MT sequences, and the UTE-MT ratio (UTE-MTR) was measured for tibial talar joint cartilage at three time points. One UTE slice each on the medial and lateral sides of the tibial talar joint was selected for data analysis. Each region was subdivided into 6 regions of interest (ROI): the front, the middle, and the rear tibial/talar cartilage (Fig. A). Changes in MTR values for each ROI at the three time points were compared and differences in values for each region were analyzed. Additionally, the inter-rater reliability and sequence reproducibility were examined. Two-way mixed intraclass correlation coefficient (ICC) was used to assess the reproducibility and inter-rater reliability of the UTE-MT.

**RESULTS**

The UTE-MTR measurements showed good reproducibility [ICC: 0.903 (0.882 - 0.924)] and inter-rater reliability [ICC: 0.944 (0.927 - 0.956)]. For most subregions of cartilage, the UTE-MTR values decreased 48 h post-run and increased after 4 weeks of rest (Fig. B). UTE-MTR values in rear tibial and talar cartilage showed a significant decrease at 48 h post-run compared to the other two time points ($P < 0.05$).

**CONCLUSION**

MR UTE-MT sequence can be used to quantitatively analyze the early changes of cartilage composition in the tibiotalar joint after long-term physical training, in which the cartilage microstructure of rear talar cartilage is more prone to change.

**CLINICAL RELEVANCE/APPLICATION**

UTE-MTR is a promising method for the detection of dynamic changes in tibial talar joint cartilage after long-distance running.

Yoshifumi Noda, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Fuminori Hyodo, PharmD (*Abstract Co-Author*) Nothing to Disclose
Akio Ito, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the impact of deep-learning 3D camera on workflow and patients' positioning in CT examinations by comparing to manual positioning by radiographers.

### METHODS AND MATERIALS

This prospective study included 596 participants (median age, 71 years; 364 men) who underwent unenhanced chest-abdomen-pelvis CT between October 2023 and January 2024 by either manual positioning (manual group) or automatic positioning using deep-learning 3D camera (camera group). The scan parameters used in the two groups were completely matched. The CT-room time, from entering to leaving CT scan room, was compared between the two groups. Additionally, off-center distance that is range difference between table height and scanner isocenter, CT dose-index volume (CTDIvol), dose-length product (DLP), and the standard deviation of the CT attenuation of the abdominal aorta at the midpoint of scan range as background noise were compared between the two groups.

### RESULTS

The median CT-room time was shorter in the camera group than in the manual group (223 s vs. 255 s; $P < .001$). No difference was found in median off-center distance (13 mm vs. 14 mm; $P = .30$), CTDIvol (5.4 mGy vs 5.5 mGy; $P = .58$), DLP (416 mGy*cm vs. 410 mGy*cm; $P = .64$), and the background noise (9 HU vs. 9 HU; $P = .19$) between the two groups.

### CONCLUSION

Patients' positioning with a deep-learning 3D camera improved workflow in CT examinations compared to manual positioning by radiographers.

### CLINICAL RELEVANCE/APPLICATION

A deep-learning 3D camera could improve workflow compared to manual positioning by radiographers.

## S3A-SPMS-2 REFERENCE VOLUMETRIC DATA OF ABDOMINAL SKELETAL MUSCLE AND ASSESSMENT OF CUT-OFF VALUES FOR THE DIAGNOSIS OF SARCOPENIA BY CT SCAN IN A HEALTHY KOREAN POPULATION

Bohyun Kim, MD (*Abstract Co-Author*) Nothing to Disclose
Sung Eun Rha, MD (*Abstract Co-Author*) Nothing to Disclose
Seo Yeon Youn, MD (*Abstract Co-Author*) Nothing to Disclose
Soon Nam Oh, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate appropriate reference values for abdominal skeletal muscle volumetric data obtained from abdominal CT scans in a healthy Korean population for the diagnosis of sarcopenia

### METHODS AND MATERIALS

This study included 1129 healthy kidney donors (479 men and 650 women) aged 19 to 72 years who underwent abdominal CT examinations over a 10-year period from 2014 to 2023. Body composition assessment was conducted using an automated segmentation technique with commercial AI-based software. Sex-specific distributions of abdominal skeletal muscle volume (SMV) from T12-L4 were analyzed along with skeletal muscle area (SMA) and skeletal muscle index (SMI). Cutoff values for SMA and SMI to determine sarcopenia were defined as values at two standard deviations (SDs) below the

mean reference value in the young age group (20-44 years). Candidate cutoff values of abdominal SMV, including the 25th percentile (Q1), 5th percentile, and 2SDs values, were analyzed in the sex-specific young age group (20-44 years).

**RESULTS**

The cutoff values for SMA and SMI were 115.40 cm2 and 38.76 cm2/m2, respectively, in men, and 74.44 cm2 and 28.28 cm2/m2, respectively, in women. The mean, Q1 value, 5th percentile, and -2SDs values of abdominal SMV were 2420.2 cm3, 2176.1 cm3, 1787.4 cm3, and 1705.6 cm3, respectively, in men, and 1493.3 cm3, 1363.5 cm3, 1145.0 cm3, and 1043.1 cm3, respectively, in women of reference age.

**CONCLUSION**

We provide a set of cadidates for sex-specific cutoff values for abdominal SMV measured by AI-based CT acquisition in a healthy Korean population, which may aid in identifying sarcopenia and prognostic correlations with various diseases in this population.

**CLINICAL RELEVANCE/APPLICATION**

SMA and SMI values measured at the L3 level on abdominal CT scans are recognized as relatively accurate methods for diagnosing sarcopenia. The recent integration of AI enables volumetric measurement of abdominal skeletal muscle, offering more comprehensive and precise information on muscle mass. However, there are few studies on reference values in a healthy population. This study aims to find out which value in skeletal muscle volumetric data can be used as a cutoff for diagnosing sarcopenia, which can be used for prognostic correlation of various diseases.

## S3A-SPNMMI-1 ENHANCING LOW-DOSE PET: A VALIDATION STUDY OF DEEP LEARNING APPROACH ON LIST-MODE SIMULATED DATA AND A NOVEL ATTENTION-MODEL UTILIZING MR ANATOMICAL STRUCTURE

Lei Xiang (*Abstract Co-Author*) Nothing to Disclose
Hongping Meng (*Abstract Co-Author*) Nothing to Disclose
Min Zhang (*Abstract Co-Author*) Nothing to Disclose
Xinrui Zhan (*Presenter*) Nothing to Disclose

### PURPOSE

The primary purpose of this combined study is twofold: firstly, to verify whether deep learning models trained on list-mode simulated low-dose PET data can enhance image quality in real-world low-dose scenarios; and secondly, to explore the utility of MR anatomical information and attention mechanisms in improving PET/MR image quality using a newly collected dataset of list-mode simulated data. This approach aims to reduce radiation exposure to patients while maintaining or enhancing image clarity, which is crucial for accurate disease detection and management.

### METHODS AND MATERIALS

The study utilized PET/MR images from a total of 84 cases: 30 from the first study collected using SOC procedure but compared low-dose due to various real-world factors, and 54 from the follow up study collected with list-mode scanning and low-dose PET data from 30s to 150s was reconstructed. All are captured using a Siemens Biograph mMR scanner with PSF-OP-OSEM. The datasets included multiple tracers: 20 68Ga-DOTATATE, 4518F-FDG, 368Ga-FAPI, and 1618F-FDG Deep learning enhancements were applied using an improved UNET model, incorporating MR anatomical structure attention to ensure effective feature integration from both PET and MR modalities. Model's performance will be evaluated with SNR and CNR on first study data and PSNR and SNR on second study data.

### RESULTS

Presented in Table 1 and Table 2, across the first 30 cases, there was an average SNR enhancement of 14.5% (Random-area), 6.8% (Liver), and 20.1% (Lung), while CNR showed improvements of 18.1% (Random-area), 7.9% (Liver), and 12.6% (Lung). On follow-up 54 list-mode dataset, there was an average SNR enhancement of 35.44±6.43% (18F-FDG), 43.27±9.05%(18F-PSMA-1007), and 53.54±20.40%(68Ga-DOTATATE). There was an average PSNR enhancement of 18.05±7.15% (18F-FDG), 21.157±9.45%(18F-PSMA-1007), and 53.54±20.40%(68Ga-DOTATATE).

### CONCLUSION

Deep-learning models trained on list-mode simulated data consistently enhance image quality in low-dose PET scans, aiding lesion detection and reducing false negatives in PET/MRI applications. As shown in Figure 1, noise reduction clarifies lesion visibility, improving diagnostic accuracy. Incorporating MR anatomical information and attention mechanisms has significantly advanced noise reduction and image fidelity, enhancing clinical utility.

### CLINICAL RELEVANCE/APPLICATION

This study confirms that deep learning, particularly using list-mode simulated data and attention mechanisms, improves PET imaging quality at lower doses. These advancements promise to enhance patient outcomes by reducing radiation exposure and refining the diagnostic process in clinical settings.

## S3A-SPNMMI-2 QUANTITATIVE COMPARISON OF NUCLEAR MEDICINE IMAGING WITH C-11 PITTSBURGH COMPOUND B AND F-18 FLUTEMETAMOL, AND TC-99M HMDP IN ATTR-CARDIAC AMYLOIDOSIS

Yoshihiro Nishiyama, MD (*Abstract Co-Author*) Nothing to Disclose
Yukito Maeda (*Abstract Co-Author*) Nothing to Disclose
Yuka Yamamoto, PhD (*Abstract Co-Author*) Nothing to Disclose
Takahisa Noma (*Abstract Co-Author*) Nothing to Disclose
Yasukage Takami (*Abstract Co-Author*) Nothing to Disclose
Takashi Norikane, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Bone scintigraphy using 99m-Tc hydroxy methylene diphosphonate (HMDP) and other radioactive tracers has been an important noninvasive diagnostic modality in the diagnosis of ATTR cardiac amyloidosis (ATTR-CA). Amyloid PET using C-11 Pittsburgh compound B (PiB), F-18 flutemetamol (FMM) and other radioactive tracers are also emerged as important PET tracers used in the detection of amyloid deposition. Although these radioactive tracers are considered as useful for diagnosing ATTR-CA, there are no studies comparing the accumulation of these tracers in detail. The purpose of this study was to compare the accumulation pattern of PiB, FMM and HMDP in patients with ATTR-CA.

## METHODS AND MATERIALS

A total of 17 ATTR-CA patients were included in this study. PET data was acquired in list mode using a 10 min table time and the acquisition was started 10 mins after the administration of both PIB and FMM. Chest SPECT images are obtained 3 hours after HMDP administration. For quantitative analysis, 17 segment polar map images were generated of all 3 images. On polar map images, the mean activity was measured for the whole heat and for each 17 segments. Relative uptake (RU) was calculated for each segment using the mean whole heart activity as a reference. The formula for calculating RU is defined as follows: RU= mean segment activity/mean whole heart activity. For PET data, myocardial-to-blood pool ratio of each segment (MBR-Seg) was also calculated as a reference of blood pool activity in the left ventricle.

## RESULTS

In the RU assessment, linear regression analysis showed a good correlation between PiB and FMM, PiB and HMDP, and FMM and HMDP accumulation (PiB vs FMM: $p<0.001$, ?=0.704, PiB vs HMDP: $p<0.001$, ?=0.634, FMM vs HMDP: $p<0.001$, ?=0.690, respectively). The Bland-Altman plot indicated no evidence of a fixed bias or a proportional bias. In the assessment radioactive tracer accumulation pattern, the one-way ANOVA revealed significant differences in RU per segment ($p<0.001$), with segment 17 demonstrating the lowest values (PiB: 0.93±0.05, FMM: 0.91±0.03, HMDP: 0.81±0.07, respectively) and segment 9 exhibiting the highest values (PiB: 1.09±0.05, FMM: 1.10±0.07, HMDP: 1.17±0.06, respectively) in all 3 images. The mean ± SD of MBRmax in PiB (1.90 ± 0.58) was significantly higher that in FMM (1.41 ± 0.26) ($p<0.001$). Linear regression analysis also showed a good correlation between PiB MBR and FMM MBR ($p<0.001$, ?=0.764).

## CONCLUSION

In conclusion, these preliminary results indicated that PiB, FMM, and HMDP demonstrated comparable accumulation patterns in patients with ATTR-CA.

## CLINICAL RELEVANCE/APPLICATION

PiB, FMM, and HMDP demonstrated comparable accumulation patterns in patients with ATTR-CA.

## S3A-SPNPM-1 DIAGNOSTIC IMAGING UTILIZATION ASSOCIATED WITH PRIMARY CARE TELEMEDICINE AND IN-PERSON VISITS IN A LARGE INTEGRATED HEALTH SYSTEM

Michael Gould (*Abstract Co-Author*) Nothing to Disclose
Peter Huynh (*Abstract Co-Author*) Nothing to Disclose
Rebecca Hill (*Abstract Co-Author*) Nothing to Disclose
Lee Barton (*Abstract Co-Author*) Nothing to Disclose
Ahmad Alach, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This study examines how primary care visit formats (in-person, telephone, or video) influence the rate of imaging orders for the common medical concerns of back pain, knee pain, and abdominal pain. We hypothesized that imaging orders would be more common during telephone or video visits due to limitations in conducting physical exams.

### METHODS AND MATERIALS

In this retrospective cohort study, we analyzed health records from Kaiser Permanente Southern California to compare imaging orders during primary care visits for back pain, knee pain, or abdominal pain. Exclusions were made for visits with multiple diagnoses or prior diagnoses of the conditions. The study was approved by the institutional review board with a waiver of informed consent.

### RESULTS

The study analyzed 1,262,249 non-pregnant adult primary care visits from March 2018 to March 2022. Patients had a mean age of 49.7 years. 58.1% of patients were female. 43.2% of patients were Hispanic. Back pain was the most frequent diagnosis (41.9%), followed by abdominal pain (33.6%). Family Medicine physicians conducted 71.6% of visits, while internists conducted 28.4%.Most visits (74.8%) were in person, while 22.2% were over the phone. Only 3.1% were done via video call. 61.4% of visits were conducted prior to mid-March 2020, 38.8% were conducted after. Imaging tests were ordered in 32.3% of visits, mostly after in-person visits (86.2%), and especially among female patients (57.6%). Knee pain visits had the highest imaging order rate (54.0%), compared to 23.0% for back pain and 28.1% for abdominal pain.Compared to in-person visits, patients were less likely to receive an imaging order after either a telephone visit (OR 0.30; 95% CI [0.29-0.31]; p<.001) or a video visit (OR 0.42; 95% CI [0.42-0.44]; p<.001). Back pain (OR 0.27; 95% CI [0.26-0.28]; p<.001) or abdominal pain (OR 0.36; 95% CI [0.35-0.37]; p<.001) were less likely to result in imaging compared to knee pain. Similarly, Black (OR 0.81; 95% CI [0.79-0.82]; p<.001) or Hispanic (OR 0.91; 95% CI [0.90-0.92]; p<.001) patients were less likely to receive imaging than non-Hispanic white patients. Internists were more likely than family medicine physicians to order imaging (OR 1.12; 95% CI [1.08-1.17]; p<.001).

### CONCLUSION

In this retrospective cohort study, telemedicine visits did not yield more imaging for evaluation of back, knee, or abdominal pain. Imaging orders were also affected by other variables such as race, diagnosis, time of visit, and provider specialty.

### CLINICAL RELEVANCE/APPLICATION

In the evolving world of virtual care, it is vital to understand how telemedicine influences clinical decision-making and imaging usage. Our findings are significant for informing and expanding upon telemedicine practice across the country.

## S3A-SPNPM-2 WORKFLOW EFFICIENCY IN OUTPATIENT MR ABDOMINAL IMAGING: COMPARISON OF OPTIMIZED AND CONVENTIONAL FACILITY DESIGNS

James A. Brink, MD (*Abstract Co-Author*) Board of Directors, Accumen Inc
Onofrio A. Catalano, MD (*Abstract Co-Author*) Research Grant,Bayer AG;Consultant, IBM Corporation;

Wei-Ching Lo (*Abstract Co-Author*) Employee, Siemens AG

Andrew Sharp, MS (*Abstract Co-Author*) Nothing to Disclose
Alexander J. Herold, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to assess the outpatient workflow efficiency of an optimized MRI facility in comparison to a conventional facility for abdominal examinations, while also evaluating the impact of workflow optimization efforts over a specified time period.

**METHODS AND MATERIALS**

A retrospective analysis was conducted, encompassing 2,122 contrast-enhanced MRI examinations of the prostate (n=1,353) and liver (n=769) between January 2021 and December 2023. The study compared an optimized facility (OF), equipped with three scanner bays, each of which includes a pair of dockable scanner tables, and a total of four dedicated preparation bays, to a reference facility (RF) utilizing a traditional single-scanner/single-table setup. All scans were performed on 3T scanners (MAGNETOM Vida, Siemens Healthineers, Forchheim, Germany). Efficiency metrics, including Total Gradient Time, Table Turnover Time, Table Preparation Time, Arrival to Begin Time, and Exam Turnaround Time, were derived from MRI scanner logs. Statistical analysis, including three-way ANOVA and chi-square tests, assessed the impact of facility, body region, and time on efficiency metrics.

**RESULTS**

The OF's innovative design facilitated the use of shorter patient time slots relative to RF (30 vs. 45 minutes, $p<0.001$). Table Turnover Time was significantly shorter at OF compared to RF for both liver and prostate exams ($p<0.001$), resulting in reduced Exam Turnaround Time by 3.9 minutes (11.5%, $p<0.001$) for liver and 4.4 minutes (12.3%, $p<0.001$) for prostate exams. OF also exhibited a higher proportion of exams with Table Turnover Time =3 minutes (57.4% vs. 3.2%, $p<0.001$). Arrival to Begin Time was significantly lower at OF ($p<0.001$). Over the study period, RF experienced significant reductions in Total Gradient Time and Table Turnover Time for both liver and prostate exams ($p<0.001$), while OF showed improvements in Total Gradient Time and a decrease in Table Turnover Time mainly for prostate exams ($p<0.05$).

**CONCLUSION**

The optimized MRI facility demonstrated superior workflow efficiency, particularly in Table Turnover Times, compared to the traditional facility for contrast-enhanced abdominal examinations. Moreover, both facilities experienced improvements over time, highlighting the effectiveness of workflow optimization efforts.

**CLINICAL RELEVANCE/APPLICATION**

Optimized MRI Facility design may increase scanner throughput and potentially improve cost-effectiveness and patient experience.

## S3A-SPNPM-3 BEYOND INTUITION: THE ROLE OF METACOGNITION IN RADIOLOGIC ACCURACY AND EFFICIENCY

Rakefet Ackerman (*Abstract Co-Author*) Nothing to Disclose
Eyal Bercovich, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to delve into cognitive dynamics to enhance diagnostic accuracy and patient care outcomes. We examine the role of metacognitive processes, including confidence and thinking time allocation, during medical imaging diagnosis.

**METHODS AND MATERIALS**

Metacognitive processes are hypothesized to be pivotal for decision-making efficacy. In our study, 30 radiologists interpreted 48 bone radiographs, which included a high rate of challenging cases. We tracked each radiologist's diagnostic accuracy, confidence ratings, decision times, and choice of a next step: submit, consult a senior, or ask for additional tests. We analyzed the relationships among these metacognitive components and their impact on diagnostic accuracy and efficiency.

**RESULTS**

Preliminary findings indicate a pivotal metacognitive effect on diagnostic accuracy. High confidence (90.85%) paralleled high accuracy (91.67%) in easier images, while more challenging images revealed a disparity between confidence (80.39%) and lower accuracy (47.14%). This discrepancy suggests overconfidence amidst complexity. Notably, the challenging cases, where success rates approach chance (50%), consume most of the radiologists' time. Response divisions by presence/absence of abnormalities and by the recommended next step shed light on the particular cases prone to confidence bias and waste of thinking time.

**CONCLUSION**

Identifying cases particularly prone to confidence bias and inefficient use of time holds potential for enhancing metacognitive awareness and optimizing radiologist work quality and efficiency. The study underscores the critical need for further research focused on medical decision-making, emphasizing metacognition as a key tool for understanding and improving diagnostic accuracy.

**CLINICAL RELEVANCE/APPLICATION**

Acknowledging Metacognitive pitfalls may enhance radiologists' ability to accurately assess their own knowledge and decision-making. By fostering metacognitive awareness, radiologists can better identify their diagnostic biases, particularly in complex cases.

### PURPOSE

Head CT perfusion (CTP) is critical in treating acute cerebral infarction. It requires a 60-70 second imaging window to capture the 4D contrast dynamics from arrival to washout in the brain parenchyma. During "code stroke," accurately determining cardiac output (CO), which affects contrast agent kinetics, is challenging for physicians, complicating protocol selection. This study aims to assess whether a simplified 65 second fixed scan protocol achieves similar success rates compared to a more complex multi-protocol workflow.

### METHODS AND MATERIALS

We retrospectively analyzed 316 head CTP cases from January 2023 to April 2024 using a 256 row CT. Cases were excluded if they had cardiac devices or an arterial input function (AIF) peak < 100 HU. Three protocols were compared: 56 seconds (normal), 70 seconds (low CO), and 65 seconds (fixed). Contrast was injected at 4 ml/s with a total volume of 40 ml. The normal and fixed protocols had 20 phases, while the low CO protocol had 23. In the first half of the study period, physicians chose between normal and low CO protocols, while in the second half, all patients underwent the fixed protocol. Success rates and radiation exposure were evaluated. The time density curve (TDC) from automatic CTP analysis software extracted key time points for contrast agent arrival, AIF peak, venous output function (VOF) peak, and VOF plateau. Failure was defined as contrast arrival before scanning or if the venous plateau was absent. Additional data were collected, including age, gender, BMI, cardiothoracic ratio (CTR), and imaging protocol instructions. Multiple regression analysis identified factors affecting each timing in the TDC, while multivariable logistic regression was used to determine predictors for scans requiring more than 60 seconds.

### RESULTS

Among the 296 cases (median age 76 years [IQR 62-82], 147 females), 78 used the normal, 120 used the low CO, and 98 used the fixed protocol. The success rate was 98% across both halves of the study period. The average CTDIvol in the first half was 136 mGy, while it was 124 mGy in the latter half, resulting in an 8% reduction in radiation exposure ($P < .001$). Age, gender, BMI, and CTR significantly influenced each timing in the TDC. However, no significant factors could predict cases requiring more than 60 seconds, even when including physician protocol instructions.

### CONCLUSION

Switching from a complex multi-protocol workflow to a more straightforward 65 second fixed-time protocol yielded similar scan success rates and an 8% reduction in radiation exposure.

### CLINICAL RELEVANCE/APPLICATION

The 65 second fixed time CTP offers consistent success rates with reduced radiation exposure. This simplification can streamline acute stroke workflows, leading to quicker diagnosis and improved patient safety.

## S3A-SPNR-10 WHITE MATTER MICROSTRUCTURE ALTERATIONS OF COGNITIVE IMPAIRMENT IN AMYOTROPHIC LATERAL SCLEROSIS: A SYSTEMATIC REVIEW

Mahan Shafie (*Abstract Co-Author*) Nothing to Disclose
Mahsa Mayeli, MD,MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease primarily affecting upper and lower motor neurons, leading to muscle weakness and paralysis. Despite the traditional perception of ALS as solely a motor disorder, more than half of ALS patients experience cognitive and behavioral symptoms, often resembling those seen in frontotemporal dementia (FTD). This systematic review aims to study microstructural white matter (WM) biomarkers of cognitive and behavioral impairment in ALS exploring whether diffusion tensor imaging (DTI) metrics alterations could identify the cognitive and behavioral profile of ALS patients.

**METHODS AND MATERIALS**

A systematic search on PubMed, Scopus, and Web of Science was conducted following PRISMA guidelines to identify relevant studies published up to Jan 2024. Studies reporting DTI findings in patients with ALS spectrum were included. Data extraction and quality assessment were performed independently by two reviewers.

**RESULTS**

A total of 27 studies met the inclusion criteria. Data from these studies, comprising 1,865 ALS patients, were reviewed. DTI investigations revealed that the corpus callosum (CC), uncinate fasciculus (UF), cingulum, corticospinal tract (CST), and superior longitudinal fasciculus (SLF) were the most frequently investigated WM tracts in ALS patients with cognitive impairment. DTI metrics of these tracts were associated with various cognitive domains.

**CONCLUSION**

DTI studies have identified consistent associations between WM tract alterations and cognitive impairment in ALS. However, the causal relationship between WM damage and cognitive impairment in ALS remains unclear. Further interventional and longitudinal studies with more inclusive sample sizes are needed to definitively establish this connection.

**CLINICAL RELEVANCE/APPLICATION**

Understanding the relationship between WM tract changes and cognitive dysfunction in ALS can aid in the early detection and monitoring of cognitive decline in these patients. Moreover, the identified associations between specific WM tracts and cognitive domains may provide valuable insights for the development of targeted therapeutic interventions aimed at preserving cognitive function in ALS. Consequently, DTI could serve as a valuable tool for assessing cognitive status and guiding clinical management strategies in ALS patients.

## S3A-SPNR-11 EVALUATION OF RADIOLOGIST REPORTING TIMES AND TREATMENT TIMES FOR PATIENTS PRESENTING VIA THE MOBILE STROKE TREATMENT UNIT

Bruno Hochhegger, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Abheek Raviprasad, MD (*Abstract Co-Author*) Nothing to Disclose
Evelyn Y. Anthony, MD (*Abstract Co-Author*) Nothing to Disclose
Mohammadreza Hosseini-Siyanaki (*Abstract Co-Author*) Nothing to Disclose
Keith R. Peters, MD (*Abstract Co-Author*) Nothing to Disclose
Hakki S. Sagdic, MD (*Abstract Co-Author*) Nothing to Disclose
Reza Forghani, MD, PhD (*Presenter*) Consultant, General Electric Company;Research Grant, General Electric Company;Research Grant, Intel Corporation;Research Grant, Toronto-Dominion Bank;Research Grant, McGill University Health Centre Foundation;President, Montreal Imaging Experts Inc

**PURPOSE**

Randomized trials have demonstrated that mobile stroke treatment units (MSTU) increase stroke thrombolysis rates and reduce onset-to-treatment times. We evaluated the radiologist CT/CTA reporting times and treatment times in patients presenting via the MSTU with suspected stroke.

**METHODS AND MATERIALS**

Patients who presented to the emergency department via the MSTU and received a non-contrast CT (NCCT) or CTA head on a MSTU were included. NCCT and CTAs were initially reviewed by the stroke neurologist on call and automatically uploaded to each patient's EMR and PACS. Formal CT interpretation was then produced by a board-certified neuroradiologist or by radiology resident prior to final review by neuroradiologist. For every case, a log file was retrieved from the PACS, containing timestamps of every moment the study was modified. Examinations were considered positive if there was evidence of ICH, LVO, M2 and M3 segment occlusion, or acute large territory infarct.

**RESULTS**

184 consecutive patients who presented with stroke-like symptoms via the MSTU were included. The average time from exam start to image availability in PACS was 18 ± 15 min (interquartile range (IQR) 10-22). The average time from exam start to formal radiologist interpretation was 67 ± 50 min (IQR 33-86). In 126 cases, a radiology resident provided a preliminary interpretation. The average time from exam start to preliminary resident report was 42 ± 29 min (IQR 23-49). In some cases, image transfer times were noted to result in a significant delay in interpretation.27 patient examinations were positive for either ischemic or hemorrhagic infarcts. 22 patients received Tenecteplase on board the MSTU, with time from initial patient evaluation to administration time averaging 17 ± 7 min (IQR 12-21). Nine patients underwent endovascular thrombectomy, with time from initial patient evaluation to groin stick averaging 51 ± 4 min (IQR 47-55). All groin punctures occurred within 1 hour of evaluation by the MSTU.

**CONCLUSION**

MSTU allowed the neurologist to receive actionable radiology report within 60 minutes in a large proportion of suspected stroke cases. Treatment with thrombolysis or endovascular thrombectomy occurred in shorter times compared to previous studies evaluating patients presenting to the emergency department.

**CLINICAL RELEVANCE/APPLICATION**

Treatments for stroke, including thrombolysis and mechanical thrombectomy, are time-sensitive and MSTU equipped with CT scanners can enable expedited diagnosis and care in the prehospital setting. However, optimal set up of these systems should also take into account essential infrastructure, including internet connectivity and bandwidth, for optimal operational and time benefits.

## S3A-SPNR-12 USING MR FINGERPRINTING IN NORMAL PRESSURE HYDROCEPHALUS TO PREDICT RESPONSE TO CSF DRAIN TEST

Doksu Moon (*Abstract Co-Author*) Nothing to Disclose
Sean Nagel (*Abstract Co-Author*) Nothing to Disclose
Mark A. Griswold, PhD (*Abstract Co-Author*) Research support, Siemens AG;Royalties, Siemens AG;Contract, Siemens AG;Royalties, General Electric

Company
Stephen E. Jones, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Normal pressure hydrocephalus (NPH) is a neurodegenerative syndrome occurring in late life, comprising difficulties with memory, walking, and urinary incontinence. A characteristic is markedly enlarged ventricles not caused by any obstruction. NPH is treatable in a subset of patients by removal of CSF, usually by a neurosurgically implanted shunt catheter. A major drawback to date is no reliable non-invasive method to predict who will benefit. Thus, there remains an unmet need to develop a reliable non-invasive method to predict neurosurgical success.We hypothesize that treatable vs non-treatable NPH is related to a global disarray of water properties in brain tissue, without focal abnormality, and that this can be detected using whole brain quantitative measurements. We propose using whole-brain quantitative numbers from MR Fingerprinting (MRF) to detect subtle changes in water properties (specifically representative T1 and T2 relaxation times) before and after large volume drain, and relate those changes to clinical outcomes.

**METHODS AND MATERIALS**

20 NPH patients with a scheduled large volume CSF drain test were scanned before and after with MRF, using a 2D WIP obtained over 15-20 slices, in addition to a volumetric T1. Brain and ventricular volumes were obtained from FreeSurfer. Custom software using IDL fitted whole brain T1 T2 histograms to a log-normal two-gaussian fit, in both the white matter and grey matter. The peak of each fit formed two metrics representing brain water properties, and these could be compared normative data. Standard clinical assessment included 10m walking test (for time and the number of steps), and clinician assessment.

**RESULTS**

Of 20 NPH patients 11 showed response to CSF drain trial. All pre-treatment MRI metrics (for GM and WM; and T1 and T2), showed at least some ability to distinguish those who responded to treatment versus those who did not (AUCs between 0.756 and 0.839). Most of the patients who responded to treatment had lower T1 time (WM and GM average) post-treatment (8/9 = 89%). Similarly, most of the patients who did not respond to treatment had higher T1 time (WM and GM average) post-treatment (7/9 = 78%). T2 time was lower after treatment for most patients, regardless of their clinical response.

**CONCLUSION**

Whole brain T1 and T2 relaxation times using MRF in 20 NPH patients helped predict clinical response to large volume CSF drain trial.

**CLINICAL RELEVANCE/APPLICATION**

MR Fingerprinting offers promise as a non-invasive technique to predict neurosurgical success of a large volume CSF drain trial. This method easily addresses an unmet need and can have high clinical impact.

**PURPOSE**

Assessing and reporting on brain metastases (BM) over time is critical in determining the treatment course. However, the workflow is laborious. This study investigated utility of PACS-integrated artificial intelligence-enabled Lesion Tracking Tool (AI-LTT) for monitoring BMs longitudinally, focusing on workflow efficiency gains and accuracy in comparison to fully manual workflow on post Gamma Knife radiosurgery (GKR) patients.

**METHODS AND MATERIALS**

In this retrospective study, follow-up images of patients with BM who underwent GKR at our institution were examined on a research instance of our PACS (AI Accelerator, Visage Imaging, Inc.). In manual workflow, two board-certified neuroradiologists displayed up to eight studies of each patient and measured orthogonal lesion diameters manually. In AI-LTT workflow introduced at RSNA2023, a custom hanging protocol automatically selected, displayed, and 3D registered T1 gadolinium-enhanced MR sequences in up to eight studies. A nnU-Net validated on 158 post-GKR studies automatically detected and 3D segmented BMs from which the maximum diameters are extrapolated per RANO-BM criteria and presented in a chart. This enhanced report can be imported into the free-text MRI report as a CSV file, containing the longitudinally tracked lesions, the related image series, orthogonal diameters, and the percentage change of each brain tumor compared to the prior study. The neuroradiologists revised the AI measurements as needed. We recorded time and number of mouse clicks for both workflows from study open until completion of lesion measurement. We analyzed inter-observer variability of the reader`s manual measurements based on the BM evaluation by a third neuroradiologist.

**RESULTS**

Compared to manual measurements involving 50 studies of ten patients, the AI-LTT demonstrated a significant reduction of mean time (678.5vs.366.0 seconds, $P<0.01$; 103.6vs.52.1 seconds per lesion, $P<0.01$) and mean clicks (201.5vs.62.9 clicks, $P<0.01$; 29.2vs.9.0 clicks per lesion, $P<0.01$) across two neuroradiologists; intra-class and Spearman correlation coefficients of manual diameter measurements were 0.922 and 0.881, respectively. Mean Dice coefficient of nnU-Net segmentations was 0.704±0.311 and sensitivity and F1-score of correctly identified lesions (=5mm) were 0.816 and 0.855, respectively.

**CONCLUSION**

The AI-LTT allowed for a substantially faster workflow while maintaining accuracy. The planned translation of AI-LTT into clinical practice can enable lesion-specific treatment response monitoring and reporting.

### CLINICAL RELEVANCE/APPLICATION

Due to inter-observer variability and effort of manual longitudinal BM measurements in MRI reports, standardized and automated measurements are critically needed.

## S3A-SPNR-15 COMPARTMENTALIZATION OF SUBARACHNOID HEMORRHAGE ON CT SUGGESTING FIRST IN-VIVO VISUALIZATION OF THE SUBARACHNOID LYMPHATIC-LIKE MEMBRANE (SLYM)

Khaled Almohaimede, MD (*Abstract Co-Author*) Nothing to Disclose
Pejman Jabehdar Maralani, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Chinthaka C. Heyn, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Anish Kapadia, MD (*Abstract Co-Author*) Nothing to Disclose
Yusuf Alibrahim, BMedSc, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In this study, we aim to investigate the existence of a recently discovered fourth meningeal layer called the subarachnoid lymphatic-like membrane (SLYM) using imaging techniques. The SLYM potentially divides the subarachnoid space into superficial and deep compartments and acts as a barrier. By examining how subarachnoid hemorrhage compartmentalizes within the subarachnoid space at different degrees of hemorrhage, we can gain insight into the potential role of SLYM in this compartmentalization.

### METHODS AND MATERIALS

A retrospective analysis was conducted including examining medical records and CT scans from 97 patients who experienced acute aneurysmal subarachnoid hemorrhage (aSAH). The distribution of subarachnoid blood into superficial and deep subarachnoid spaces was classified based on proximity to the dural or pial surfaces, respectively, as seen on multiplanar CT head. Statistical analysis was performed to compare the observed blood distribution patterns with the severity of hemorrhage, as determined by the modified Fisher Scale.

### RESULTS

The study revealed interesting differences in blood distribution within the subarachnoid space between patients with low-grade and high-grade modified Fisher scores. In cases with lower MFS of 1-2, the blood distributes primarily towards the deeper or pial-adjacent subarachnoid space. We also observed that if SAH is positive in the deeper subarachnoid compartment at a certain level along the brainstem, it will be positive in the same compartment at different levels suggesting compartmental continuity. Conversely, patients with higher MFS of 3-4 are more likely to have SAH abutting both pial and dural surfaces.

### CONCLUSION

SAH appears to compartmentalize within the subarachnoid space with preferential involvement of the deep, pial adjacent compartment. We suspect this is related to the newly discovered SLYM. In higher grade SAH, there is an increased likelihood of involvement of the superficial, dural adjacent compartment. This may be due to displacement or rupture of the presumed SLYM.

### CLINICAL RELEVANCE/APPLICATION

Understanding the function of the SLYM could have significant implications for the pathophysiology, diagnosis, and treatment of aSAH and various neurological disorders. By elucidating its influence on CSF circulation, such research might shed light on related pathologies. Future studies based on these findings could lead to the development of improved diagnostic tools and potentially even novel therapeutic strategies targeting the SLYM function and integrity to manage certain neurological conditions.

## S3A-SPNR-16 GADOQUATRANE: DOSE-RESPONSE ASSESSMENT IN MR ANGIOGRAPHY FOR THE NOVEL TETRAMERIC MACROCYCLIC GBCA IN COMPARISON TO GADOBUTROL OR GADOTERATE IN A NON-CLINICAL AND A CLINICAL SETTING

Mark Klemens, MD (*Abstract Co-Author*) Employee, Bayer AG
Petra Palkowitsch (*Abstract Co-Author*) Nothing to Disclose
Gregor Jost, PhD (*Abstract Co-Author*) Employee, Bayer AG
Gesine Knobloch, MD (*Abstract Co-Author*) Nothing to Disclose
Birte M. Hofmann, DVM, PhD (*Presenter*) Employee, Bayer AG

### PURPOSE

The purpose of the investigations was to assess the signal enhancement (SE) properties of the novel macrocyclic GBCA gadoquatrane in vessels (MR Angiography) at different doses vs gadobutrol/gadoterate administered at the standard dose. Gadoquatrane has a unique tetrameric structure with high stability and high relaxivity, expected to enable a lower dose for CE-MRI compared to established macrocyclic GBCAs.

### METHODS AND MATERIALS

A non-clinical and a clinical cross-over study using time-resolved MRA (TWIST) were conducted using 1.5T clinical MR scanners with quantitative SE measurements in vessels. In the non-clinical setting, six Göttingen minipigs received two doses of gadoquatrane (0.025 and 0.03 mmol Gd/kg), gadobutrol and gadoterate (both 0.1 mmol Gd/kg) in 4 sessions. With the exception of gadoterate (volume 0.2 mL/kg, injection rate (2 mL/s) doses were administered at the same volume (0.1 mL/kg) and injection rate (1 mL/s). Thoracoabdominal vessels were analyzed by regions of interest measurements in 6 arteries (aorta and branches) and 2 veins (inferior vena cava, portal vein). In the clinical study, the dose-response relationship of gadoquatrane was assessed in healthy participants (N=43, 18-50 years) receiving gadoquatrane (0.01, 0.03, 0.06 mmol Gd/kg; 0.033, 0.1, 0.2 mL/kg) and gadobutrol (0.1 mmol Gd/kg; 0.1 mL/kg) intravenously (injection rate 1 mL/s) in randomized order. Immediately after injection, time-resolved MRA of the carotid arteries (aortic arch to skull base) was performed. SE within the carotid arteries was measured over approx. 2 minutes. Peak-SE and time-to-peak were determined to characterize the SE-profile of the bolus.

### RESULTS

Non-clinically, the vascular signal-time curves for each region showed similar bolus shapes and peak-SE for both doses of gadoquatrane and comparators (e.g., SE ascending aorta after mmol Gd/kg: gadoquatrane 0.025: 154 (SD 5.1); 0.03: 173 (SD 20.4); gadoterate 0.1: 160 (SD 11.7); gadobutrol 0.1: 182 (SD 16.5)). Clinically, peak-SE increased with increasing gadoquatrane dose. With 0.03 mmol Gd/kg, gadoquatrane reached a similar peak-SE (381, CV%20.1) as gadobutrol (371, CV%25.9) with 0.1 mmol Gd/kg bw. Time-to-peak of 0.03 mmol Gd/kg gadoquatrane was similar to gadobutrol injected at the same volume of 0.1 mL/kg.

### CONCLUSION

No relevant differences in SE kinetics and peak-SE were observed in the non-clinical or clinical study between gadoquatrane at a dose of 0.03 mmol Gd/kg and the approved GBCAs injected at a 70% higher Gd dose.

### CLINICAL RELEVANCE/APPLICATION

Gadoquatrane is a novel, tetrameric macrocyclic GBCA currently in development for MRI and MRA. It aims to substantially reduce not only the Gd per contrast enhanced MR procedure but due to the tetrameric structure also the molecule dose.

## S3A-SPNR-17 PREVALENCE OF ALZHEIMER DISEASE PATHOLOGY IN STUDIES OF MEMORY AND AGING

Nicole S. McKay, PhD (*Abstract Co-Author*) Nothing to Disclose
Molly Beatty (*Presenter*) Nothing to Disclose

### PURPOSE

Preclinical Alzheimer disease (AD) describes a period prior to symptom onset during which pathology begins to accumulate. Recent development of neuroimaging- and biofluid- measures of AD pathology has allowed for in vivo quantification of preclinical pathological burden. Prior work estimated that by age 85, only one third of older adults remain free of amyloid and AD-related atrophy. Using complementary multimodal biomarkers of AD pathology, we aimed to reproduce and extend these estimates of preclinical AD prevalence in a cohort of cognitively unimpaired (Clinical Dementia Rating (CDR) = 0) older adults.

### METHODS AND MATERIALS

Neuroimaging-derived measures of amyloid and neurodegeneration (cortical amyloid, cortical thickness, summary tau) as well as biofluid-derived measures of non-specific AD pathology (amyloid42:40, phosphorylated-tau217, neurofilament light) were drawn from the Knight Alzheimer Disease Research Center database. Gaussian mixture modelling defined the cutoff threshold for each modality, establishing biomarker positivity. Participant data corresponding with CDR of 0 was used when assessing probability of positivity, which we examined as a function of age.

### RESULTS

Our results reproduce and extend prior estimates of AD pathology in cognitively unimpaired older adults, confirming in our independent sample that AD pathology is present in cognitively unimpaired individuals. Cerebrospinal fluid-derived measures of amyloid peaked at a rate near 60%, but all measures of amyloid and neurodegeneration were observed to rise to be present in at least 40% of cognitively unimpaired older adults. Unsurprisingly, tau was observed at the lowest rate, potentially reflecting its close association with cognitive impairment. It is important to note that cohorts examining sporadic AD recruit individuals with family histories of AD and therefore have higher rates than average populations of apolipoprotein-variant carriers, which may influence the rates of AD pathology.

### CONCLUSION

Characterizing the prevalence of preclinical AD is critical for understanding the pathophysiology of AD, may inform the design of clinical trials or interventions, and may also provide important context for furthering our understanding of cognition across older adulthood. Ultimately, creating an awareness of preclinical AD among researchers is essential for future work surrounding aging and memory.

### CLINICAL RELEVANCE/APPLICATION

As adults in the U.S over 65 are predicted to outnumber children under the age of 18 in 2034, AD is a condition that will only increase in significance alongside an aging population, especially as we enter into the future realm of AD prevention.

## S3A-SPNR-19 ALTERED REGIONAL HOMOGENEITY AND FUNCTIONAL CONNECTIVITY IN PATIENTS WITH EARLY PARKINSON'S DISEASE

Wei Wei (*Abstract Co-Author*) Nothing to Disclose
Xipeng Yue (*Abstract Co-Author*) Nothing to Disclose
Yu Shen (*Abstract Co-Author*) Nothing to Disclose
Kaiyue Ding (*Abstract Co-Author*) Nothing to Disclose
Yan Bai (*Abstract Co-Author*) Nothing to Disclose
Meiyun Wang (*Abstract Co-Author*) Nothing to Disclose
Jiapei Xie (*Abstract Co-Author*) Nothing to Disclose
Xinhui Wang (*Presenter*) Nothing to Disclose

### PURPOSE

Parkinson's disease (PD) is a neurodegenerative disorder that primarily affects movement and significantly impacts patients' quality of life. Despite this, the underlying pathophysiological mechanism of the disease remain unclear. This study aims to investigate changes in regional homogeneity (ReHo) and functional connectivity (FC) in early PD patients using resting-state functional magnetic resonance imaging (rs-fMRI) to better understand the mechanism behind of the disease.

### METHODS AND MATERIALS

Rs-fMRI data using a 3-T system (MAGNETOM Prisma, Siemens Healthcare, Erlangen, Germany) equipped with a 64-channel head/neck coil were collected from 49 early PD patients and 57 age- and gender-matched healthy controls (HCs) in this study. The RESTplus software was utilized to analyze rs-fMRI data and compare ReHo differences between early PD patients and HCs. Brain regions exhibiting significant ReHo differences were then selected as regions of interest (ROIs), and the strength of functional connections between these ROIs and other areas of the brain were calculated to identify changes between early PD and HCs.

### RESULTS

Compared with HCs, the early PD patients showed a significant decrease in regional homogeneity in the sensorimotor network (Precentral_R, Postcentral_L and Postcentral_R). The functional connectivity analysis in which the three regions described above were used as ROIs revealed decreased

functional activity between the sensorimotor network (Precentral_R, Postcentral_L and Postcentral_R) and visual network(Occipital_Mid_L, Occipital_Inf_L, Occipital_Sup_R, Occipital_Mid_R, Lingual_R, Cuneus_R, Fusiform_R, Temporal_Mid_L, Temporal_Mid_R, Temporal_Inf_R).

**CONCLUSION**

The pathophysiological mechanism of early PD patients may be related to abnormal spontaneous neuronal activity patterns with weak synchronization of sensorimotor network, and the decreased connectivity of the sensorimotor network with the visual network.

**CLINICAL RELEVANCE/APPLICATION**

Abnormal spontaneous neuronal activity patterns in early PD patients may be related to the onset of the disease. These findings could help us better understand the underlying pathophysiological mechanisms of PD and potentially identify therapeutic targets for neuroregulation in PD patients.

## S3A-SPNR-3 ALTERED BRAINNETWORK AND MODULAR INTERACTIONSIN PEDIATRIC PATIENTS WITH COMPLETE SPINAL CORD INJURY(CSCI) : A RESTING-STATE FUNCTIONAL MRI(RS-FMRI)STUDY

Haotian Xin (*Abstract Co-Author*) Nothing to Disclose
Beining Yang (*Abstract Co-Author*) Nothing to Disclose
Yu Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate functional network and modular interactions changes and find the possible impact in children with CSCI.

**METHODS AND MATERIALS**

69 subjects were recruited, including 33 right-handed pediatric complete spinal cord injury (CSCI) patients(age range, 6-12 years; mean age, 9.15±1.922 y; 5 males, 28 females) and 36 age- and gender- matched healthy controls(HCs). All patients were evaluated for motor and sensory scores, injury level, age at injury, and time since injury. A single gradient echo-planar imaging sequence was conducted to capture rs-fMRI images of all participants using a 3T magnetic resonance system (Siemens, Erlangen, Germany). The functional network was constructed using a graph-theory method, resulting in a 90 × 90 matrix. Three scales of metrics in global, modular and nodal were obtained to investigate the alterations of the overall functional network organization and modular interactions. Two-sample independent t-tests, chi-squared test, permutation test, and Partial correlation were used in statistical analysis. Statistical significance was set at $P < 0.05$, and a False Discovery Rate(FDR) method was applied for multiple comparison correction.

**RESULTS**

Compared with HCs, pediatric CSCI patients showed a significant decrease in both nodal centralities and nodal efficiency of bilateral thalamus. For modular interactions, patients demonstrated increased connectivity between the default mode network(DMN) and attention network(AN) but reduced connections between the DMN and subcortical network(SN ), DMN and visual network(VN), AN and SN respectively. Besides, a reductive within-module connectivity was found in DMN. Moreover, decreased participant coefficient(Pc) were observed in the left thalamus and TPOmid, and the Pc values in left thalamus positively correlated with the time since injury. As for modular organizations divided based on algorithm, there exhibited 5 modules in HCs while 6 modules in CSCI patients, in which the main changes occurs in Module III (AN), where part of its area is functionally transformed to DMN and part is divided into a new Module VI. However, no significant differences were found in global metrics(small-worldnesss, Eloc, Eg).

**CONCLUSION**

The reorganization of brain functions after CSCI in children took place mainly in higher cognitive-related regions such as DMN, AN and SN, rather than in sensorimotor areas.

**CLINICAL RELEVANCE/APPLICATION**

This study reveals alterations in psychological and cognitive areas following spinal cord injury, indicating the necessary to ensure the cognitive, emotional, and psychological well-being of pediatric patients with CSCI for their integration into social life.

## S3A-SPNR-4 THE DIAGNOSTIC VALUE OF CONTRAST ENHANCEMENT VESSEL WALL MRI IN NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

Yu Murakami (*Abstract Co-Author*) Nothing to Disclose
Koichiro Futatsuya (*Abstract Co-Author*) Nothing to Disclose
Takatoshi Aoki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuta Yoshimatsu (*Abstract Co-Author*) Nothing to Disclose
Yoshiya Tanaka, MD (*Abstract Co-Author*) Nothing to Disclose
Yuya Fujita (*Abstract Co-Author*) Nothing to Disclose
Satoru Ide, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Neuropsychiatric systemic lupus erythematosus (NPSLE) is a severe complication of SLE that is associated with neuroinflammation. Vessel wall imaging (VWI) can visualize the cerebral arterial wall and assess active inflammation using contrast agents, making it potentially useful in evaluating neuroinflammation. In NPSLE, cerebral vascular issues include vasculitis, non-inflammatory vasculopathy, atherosclerotic plaques, vascular spasms, and arterial dissection. Although contrast-enhanced (CE) -VWI is considered useful for evaluating these conditions, detailed studies on its effectiveness in diagnosing NPSLE are scarce. This study aims to evaluate the efficacy of CE-VWI in distinguishing NPSLE from non-NPSLE.

**METHODS AND MATERIALS**

Patients clinically suspected of having NPSLE who underwent MRI at our institution between March 2019 and October 2022 were included in this prospective study. Each participant underwent a 3T MRI with 3D T1WI-CUBE, featuring a spatial resolution of 0.7×0.8×0.9 mm and a scan time of 4 minutes. We evaluated vessel wall lesions (VWLs) across 15 intracranial artery segments (from internal carotid artery and basilar artery to 2nd segment of each cerebral artery), scoring them as positive or negative, and whether the lesion was enhanced. The VWL score counts segments with wall thickening, and the CE-VWL score counts those showing enhancement. Additional assessments included brain lesions, and stenotic lesions via MR angiography. We conducted intergroup comparisons on MRI findings, used multivariate analysis to identify factors linked to NPSLE, and assessed the diagnostic capability of VWI using ROC analysis.

**RESULTS**

According to the proposed criteria, 47 patients were classified as NPSLE and 55 as non-NPSLE, with mean ages of 44.3 (range 19-74) and 44.0 (range 16-80), respectively. Key differences included: 11% of NPSLE patients had large perforator infarctions compared to none in non-NPSLE ($p=0.01$). NPSLE

patients had higher median VWL score (11 vs. 6, p<0.001) and CE-VWL score (2 vs. 0, p<0.001). Stenosis on MRA was also more common in NPSLE (40% vs. 9%, p<0.001). Multivariate analysis revealed the CE-VWL score as the sole significant factor linked to NPSLE (OR 1.91; 95% CI 1.19-3.07; p=0.007). ROC analysis indicated an AUC of 0.78 for CE-VWL score, with a specificity of 91% and an odds ratio of 13.5 at the optimal cutoff value of 2.

**CONCLUSION**

CE-VWI is useful for differentiating NPSLE from non-NPSLE, particularly since CE-VWLs are characteristic of NPSLE.

**CLINICAL RELEVANCE/APPLICATION**

CE-VWI with 3D-CUBE could diagnose NPSLE, confirming VWL enhancement with high specificity. Its brief 4-minute scan can be readily incorporated into the clinical workflow for NPSLE assessments, enhancing practicality and accuracy.

## S3A-SPNR-6 FROM CYTOARCHITECTURE TO MRI BIOMARKERS: A PIPELINE TO INFORM AUTOMATIC SEGMENTATION OF THE MEDIAL TEMPORAL LOBE STRUCTURES WITH ANATOMICAL BOUNDARIES DERIVED FROM HISTOLOGY

**PURPOSE**

The medial temporal lobe (MTL) is targeted by both primary and concomitant molecular pathologies in Alzheimer's disease (AD). For the past two centuries, the complex anatomy of the MTL has been the subject of extensive research. However, current PET and MRI AD biomarkers use often crude parcellations of the MTL, lacking sufficient validation against anatomical ground truth. Here we use a unique dataset of finely annotated serial histology, ex vivo MRI and antemortem 3T in vivo MRI of the MTL from 17 brain donors to train and evaluate an automatic MTL subregion segmentation algorithm. To our knowledge, this is the most comprehensive attempt to infuse MRI biomarkers with cytoarchitectural reference annotations.

**METHODS AND MATERIALS**

A team of neuroanatomists annotated the boundaries of 27 MTL subregions on over 2000 serial Nissl histological sections from 17 brain donors. These boundaries were mapped to 9.4T ex vivo MRI (proton density, 0.2x0.2x0.2mm3) and, subsequently, to 3T in vivo MRI (T2-weighted, ~0.4x0.4x2.6mm3) using deformable registration. After each registration step, extensive manual editing was performed to correct for registration errors and ensure 3D continuity and smoothness. Deep learning method nnU-Net was trained on the resulting in vivo MRI annotations to automatically segment a set of major subregions (formed by merging smaller subregions). Surface-based registration between an MTL template and the output of nnU-Net was used to parcellate major subregions into the original 27 smaller subregions. Segmentation accuracy was assessed by five-fold cross-validation with the Dice Similarity Index (DSI).

**RESULTS**

The segmentation accuracy of the 10 major subregions varied considerably with the DSI ranging from 0.32 to 0.75. While accuracy is not as high as in some previous MTL subregion segmentation approaches, this is not surprising because the anatomical variability of cytoarchitecture-based ground truth annotations in our approach is likely much higher than in prior approaches where ground truth was generated by applying heuristic/geometric rules.

**CONCLUSION**

It is feasible to leverage cytoarchitecturally defined anatomical boundaries for automatic in vivo MRI segmentation. However, high variability in the location of cytoarchitectural borders poses clear limitations on MTL segmentation accuracy.

**CLINICAL RELEVANCE/APPLICATION**

Cytoarchitecturally defined anatomical boundaries for automatic segmentation of in vivo MRI scans opens avenues for more accurate and early detection of neurodegenerative diseases.

## S3A-SPNR-7 SLOWING OF APERIODIC NEUROPHYSIOLOGICAL ACTIVITY IN CONCUSSED ADOLESCENT FOOTBALL PLAYERS

Christopher T. Whitlow, MD, PhD (*Abstract Co-Author*) Consultant, Biogen Idec Inc
Joel Stitzel (*Abstract Co-Author*) Nothing to Disclose
Leonardo G. Bezerra (*Abstract Co-Author*) Nothing to Disclose
Joseph A. Maldjian, MD (*Abstract Co-Author*) Consultant, BioClinica, Inc;

Elizabeth M. Davenport, PhD (*Abstract Co-Author*) Nothing to Disclose

Laura Flashman (*Abstract Co-Author*) Nothing to Disclose
Kevin C. Yu (*Presenter*) Nothing to Disclose

**PURPOSE**

American tackle football is associated with high concussion rates, leading to neurophysiological disturbances and debilitating symptoms. Previous investigations of concussion using magnetoencephalography (MEG) have largely ignored aperiodic (i.e., arrhythmic) neurophysiological activity. We examined whether concussion during a season of high school football is related to changes in aperiodic activity, as well as whether any such changes are associated with clinical outcomes and co-localize with regions dense in specific neurotransmitter systems.

**METHODS AND MATERIALS**

Pre- and post-season resting state MEG data were collected from 91 high school football players, of whom 10 were diagnosed with concussion. Data were source-imaged, frequency-transformed, and parameterized using specparam. Linear mixed models were used to examine effects of concussion on pre-to-post-season changes in neurophysiological activity. Co-localization of the resulting beta-weight maps with 19 neuromaps atlases was conducted using autocorrelation-preserving null permutations. Scores on the Post-Concussive Symptom Inventory were correlated with pre-to-post-season physical, cognitive and behavioral symptoms to determine clinical relevance.

**RESULTS**

Concussion was associated with increased aperiodic exponents in superior-frontal cortices, and this aperiodic slowing mediated concussion effects on delta and gamma power. Aperiodic slowing was also associated with higher post-concussion symptoms across participants. The concussion-aperiodic relationship was strongest in brain regions with high normative densities of cholinergic and noradrenergic neurotransmitter systems.

**CONCLUSION**

We find that concussion is associated with increased aperiodic exponents in superior-frontal cortices, potentially accounting for concussion-related delta increases and gamma decreases in similar regions, and the strength of this slowing effect is associated with higher symptom report. Neurochemical contextualization suggests possible involvement of noradrenergic and cholinergic systems implicated in the neuropathophysiology of concussion, suggesting targets for future pharmacotherapeutic studies.

**CLINICAL RELEVANCE/APPLICATION**

Greater concussion-related aperiodic neurophysiological slowing may be associated with increased symptoms, potentially supporting its use as a clinical marker.

## S3A-SPNR-8 FUNCTIONAL MRI FINDINGS OF TRANSCRANIAL MAGNETIC STIMULATION IN PATIENTS WITH OBSESSIVE-COMPULSIVE DISORDER: A SYSTEMATIC REVIEW

Mahan Shafie (*Abstract Co-Author*) Nothing to Disclose
Mahsa Mayeli, MD,MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

Obsessive-compulsive disorder (OCD) is a chronic condition, which is believed to involve structural and functional abnormalities in the brain. As pharmacological treatments often yield inadequate responses in OCD patients, recent attention has turned to brain stimulation targeting these neural regions as safe therapeutic interventions. Despite the promising treatment efficacy of transcranial magnetic stimulation (TMS), the fundamental neural mechanisms underlying its effects remain understudied. This systematic review aims to evaluate functional MRI (fMRI) findings associated with TMS in OCD patients, exploring the potential impact of TMS and identifying predictors of intervention outcomes based on neuroimaging.

**METHODS AND MATERIALS**

A systematic search on PubMed, Scopus, and Web of Science was conducted following PRISMA guidelines to identify relevant studies published up to Feb 2024. Studies reporting fMRI findings in patients with OCD who underwent TMS were included. Data extraction and quality assessment were performed independently by two reviewers.

**RESULTS**

A total of eight studies met the inclusion criteria. Resting-state fMRI investigations revealed changes in functional connectivity (FC) between various brain regions following TMS treatment, with significant alterations observed in the dorsomedial prefrontal cortex (dmPFC) and its connections. Task-based fMRI studies identified neural correlates associated with symptom improvement and treatment response, particularly in regions such as the pre-supplementary motor area (preSMA), orbitofrontal cortex (OFC), and dorsolateral prefrontal cortex (dlPFC).

**CONCLUSION**

The findings of this systematic review suggest that TMS may modulate neural circuits implicated in OCD pathophysiology. Our comprehensive analysis of fMRI data after TMS in OCD patients concludes that there is an intricate interaction between brain connection patterns, target regions, and stimulation procedures. Targeting several brain regions, such as the dmPFC, dlPFC, SMA, and OFC, has shown promise in reducing OCD symptoms by modifying functional connectivity within the cortico-striato-thalamo-cortical circuit, despite the heterogeneity seen among studies. These results support the hypothesis that the pathophysiology of OCD is caused by abnormal connections within this circuitry.

**CLINICAL RELEVANCE/APPLICATION**

Understanding the neural mechanisms underlying TMS in patients with OCD is crucial for the development of targeted therapeutic interventions. This systematic review provides insights into the fMRI changes associated with TMS in OCD patients, highlighting its potential as a treatment modality and paving the way for more effective and personalized therapeutic approaches for OCD.

## PURPOSE

Obesity in midlife is a contributor to Alzheimer disease later in life. Adiposity in the liver and muscles are associated with increased systemic inflammation, insulin resistance and impaired cognition. In this study, we aimed to investigate the relationship between MRI-derived Positron Density Fat Fraction (PDFF) and thigh fat-to-muscle ratio (FMR), insulin resistance, systemic inflammation, and brain histology using Diffusion Basis Spectrum Imaging (DBSI) in cognitively normal midlife individuals.

## METHODS AND MATERIALS

In total, 67 cognitively normal middle-aged participants (Age: 50.02 years, female: 65.7%, obesity:53.7%, BMI: 31.72kg/m2) underwent brain, abdominal, and thigh MRI and metabolic assessment. Homeostatic Model Assessment for Insulin Resistance (HOMAIR) and serum IL-6, IL-10, and TNF-alpha were measured. The hepatic PDFF maps were derived from liver chemical shift encoded MR images followed by segmentation using a CNN model. After N4ITK bias correction on mid-thigh slices, thigh total fat (subcutaneous, inter-, and intra-muscular fat combined), and muscle volumes were segmented, and total thigh FMR was calculated. After eddy current and movement correction, DBSI maps including fractional anisotropy (overall integrity), axial diffusivity (axonal injury), radial diffusivity (myelin loss), restricted fraction (inflammation cellularity), hindered fraction (extracellular edema), and fiber fraction (axonal density) were calculated using an in-house MATLAB script. Voxel-wise analyses were performed using tract-based spatial statistics (TBSS) pipeline based on matrices contrasting PDFF, thigh FMR, HOMAIR, IL-6, IL-10, and TNF-alpha with age and sex as covariates, and a 0.05 false-discovery rate.

## RESULTS

There was a significant association between HOMAIR and PDFF ($p<0.001$) but not thigh FMR. No association was found between PDFF and thigh FMR with systemic inflammation markers. Obese individuals showed higher PDFF ($p=0.02$) but not HOMAIR ($p=0.12$) or FMR ($p=0.08$). We observed a significant positive association between PDFF and restricted fraction in widespread areas. There was no significant association between HOMAIR, systemic inflammatory markers, or thigh FMR and DBSI measures.

## CONCLUSION

Our results indicate the role of hepatic fat, but not thigh fat or insulin resistance in increased inflammation-related cellularity in the brain in cognitively normal midlife individuals. These findings suggest that excess hepatic fat may increase the risk for Alzheimer disease and cognitive impairment through promoting neuroinflammation.

## CLINICAL RELEVANCE/APPLICATION

Modifying hepatic fat and preventing fatty liver disease can act as a proxy for reducing neuroinflammation.

## S3A-SPOB-2 DEVELOPMENT OF AN ARTIFICIAL INTELLIGENCE-BASED SUPPORT SYSTEM FOR FETAL CARDIAC ULTRASOUND SCREENING

Kazuki Iwamoto (*Abstract Co-Author*) Nothing to Disclose
Naoaki Harada (*Abstract Co-Author*) Nothing to Disclose
Ryuji Hamamoto, MD (*Abstract Co-Author*) Research Grant, FUJIFILM Holdings Corporation
Ryu Matsuoka (*Abstract Co-Author*) Nothing to Disclose
Akihiko Sekizawa (*Abstract Co-Author*) Nothing to Disclose
Reina Komatsu (*Abstract Co-Author*) Nothing to Disclose
Masaaki Komatsu, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Fetal cardiac ultrasound screening is generally performed on all fetuses, however, the global prenatal detection rate for congenital heart disease (CHD) is still insufficient due to technical differences among examiners. Here, we have developed an artificial intelligence (AI)-based support system for this ultrasound screening toward clinical application.

### METHODS AND MATERIALS

We enrolled fetal cardiac ultrasound videos of 262 normal cases and 38 CHD cases who underwent fetal cardiac ultrasound screening in the second trimester. This dataset included 3 vendors; Voluson® P8/E8/E10/Expert22 (GE Healthcare, Chicago, IL, US), Aplio® i700/i900 (Canon Medical Systems, Otawara, Tochigi, Japan), and Arietta® 70 (Fujifilm Healthcare, Tokyo, Japan). The correct positions of 18 cardiac substructures were annotated with bounding boxes. The time-series information of these detection results was displayed using barcodes and detection rate graphs. First, the diagnostic accuracy of the automatic normal substructure detection was assessed. Then, we attempted to verify whether our AI system could enhance the screening performance of examiners. A comparative study was performed on the screening performance of 50 examiners (6 experts, 30 fellows, and 14 residents) with and without the AI system. In each situation, the examiners were given 60 randomly numbered videos of the normal and CHD cases and determined normal or abnormal. The multiplicity of statistical analyses was controlled by a fixed sequence procedure.

### RESULTS

The sensitivity for the normal substructure detection was 93.5%, showing superiority to the sensitivity threshold of 80% based on preliminary test results ($p < 0.001$). The specificity was 95.9%, indicating superiority to the specificity threshold of 80% ($p < 0.001$). In the subgroup analyses, both the sensitivity and specificity for the normal substructure detection of every vendor and machine achieved over 90%. Furthermore, the sensitivity of the screening of unskilled doctors (fellows and residents) using the AI system was 78.4%, showing superiority over the sensitivity of the examiner alone ($p = 0.005$). The specificity was 86.5%, showing superiority to the specificity of the examiner alone ($p < 0.001$). On the other hand, the screening performance of experts showed no significant difference with and without the AI system.

### CONCLUSION

Our AI system demonstrated sufficient accuracy in the automatic normal substructure detection and could enhance the screening performance of unskilled doctors in fetal cardiac ultrasound screening.

### CLINICAL RELEVANCE/APPLICATION

This system aims to support fetal cardiac ultrasound screening in a clinical scenario.

## S3A-SPOB-3 3D CRANIOFACIAL FETAL MRI: FORMALISATION OF A LANDMARKING AND MEASUREMENT PROTOCOL IN TRISOMY 21 AND HEALTHY CONTROL SUBJECTS

Christina Malamateniou, PhD, MA, BSC, MEd (*Abstract Co-Author*) Nothing to Disclose
Lisa Story, MBBS (*Abstract Co-Author*) Nothing to Disclose

Aysha Luis, MBBS (*Abstract Co-Author*) Nothing to Disclose
Jo Hajnal (*Abstract Co-Author*) Nothing to Disclose
Jana Hutter (*Abstract Co-Author*) Nothing to Disclose
Jacqueline Matthew, BSc, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

To assess initial experiences of novel automated MRI biometrics using slice-to-volume registration fetal MRI.

## METHODS AND MATERIALS

A systematic literature review was performed to define anatomical landmarks appropriate for MRI in 3D space. The final protocol was agreed by consensus with 3 fetal MRI radiologists (fig 1 c.). Landmarks were propagated to subjects from a template atlas (31 weeks GA) using classical affine+non-rigid registration (fig1 b.). The centroid data of points was used to calculate biometrics, using 3D vector formulae. Biometric comparisons were made between cohorts and 10 random cases measured manually.

## RESULTS

108 control (mean GA=31+6) and 24 T21 subjects (mean GA=32+4) were assessed (MRI=1.5 or 3T). An analysis of variance between subject groups found differences in biometry for skull base, skull/midface length and nasopharyngeal areas (total 17/31 biometrics) correlating with known dysmorphology in T21 phenotypes (ANOVA, $p < 0.05$, see fig 1d.). The time to manually label 10 random cases was an average of 22mins/case versus 5mins/case to inspect automated labels. The manual versus automated biometry had a mean relative error of more than 5% in 8/35 biometrics and manual measurements were not possible for 22/350 measures due to variable image quality.

## CONCLUSION

Automated methodologies can assist in rapid quantitative craniofacial assessment for deep phenotyping. Since measurement error reduces precision, future work will focus on optimising MRI sequences, deep learning methods and validation in syndromic cohorts.

## CLINICAL RELEVANCE/APPLICATION

This work highlights the potential for quantitative 3D characterisation of craniofacial features with reconstructed fetal MRI, traditionally a subjective assessment using 2D raw data. Paired with our previously published MRI-based 3D surface rendering techniques (fig 1a), there are new opportunities for prenatal phenotyping to complement equivocal prenatal ultrasound exams.

## S3A-SPPD-1 EXTRACTION AND EVALUATION OF FEATURES OF PRETERM PATENT DUCTUS ARTERIOSUS IN CHEST X-RAY IMAGES USING DEEP LEARNING WITH HUMAN GUIDED TRAINING

Hyeonsung Choi (*Abstract Co-Author*) Nothing to Disclose
Jimin Lee (*Abstract Co-Author*) Nothing to Disclose
Hyun Ho Kim (*Abstract Co-Author*) Nothing to Disclose
Phillip Chang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to identify specific chest x-ray (CXR) features associated with preterm patent ductus arteriosus (PDA) using deep learning image analysis and to quantitatively assess these features.

### METHODS AND MATERIALS

We collected 17488 neonatal CXR images from 4617 echocardiogram cases in NICU, labeled based on PDA diagnosis. A subset of 463 randomly chosen images was isolated into a test group to evaluate a PDA prediction model. Our approach involved the 'human-guided easy learning' method we developed, where a non-pediatrician doctor was first shown 173 PDA positive and negative CXR images three times to identify PDA-specific features. Subsequently, the trained doctor diagnosed 4654 unlabeled CXR images. Of these, 3349 images that were correctly identified by the doctor were then used to train a deep learning model to predict PDA probability. Post-training, we applied GradCAM++ to identify critical predictive features.

### RESULTS

The deep learning model showed a specificity of 0.91, sensitivity of 0.33 and an ROC-AUC of 0.72 in the test group. GradCAM++ highlighted significant features in the upper thorax, left lower heart, and right lower lung areas. Based on the GradCAM++ analysis, we selected four critical radiologic features and identified significant differences in three features between PDA positive and negative images: the mean ratio of the upper heart width to the maximum heart width was 0.45 (95% CI, 0.44-0.47) in PDA positive versus 0.54 (0.53-0.54) in negative; the cardiothoracic ratio was 0.57 (0.57-0.58) versus 0.55 (0.55-0.55); the ratio of the upper heart width to the thorax width was 0.27 (0.26-0.28) versus 0.30 (0.30-0.31). The z-test p-value for each of these features were all less than 0.001. However, the mean normalized brightness of the lung fields was 0.51 (0.50-0.52 versus 0.51-0.52) for both groups, with a p-value of 0.48.

### CONCLUSION

Our trained deep learning model effectively identified key radiologic features for diagnosing PDA. The ratios of the upper heart width to both the maximum heart width and the thorax width, along with the cardiothoracic ratio, differed significantly between PDA positive and negative images.

### CLINICAL RELEVANCE/APPLICATION

PDA is common in preterm infants and typically diagnosed with echocardiograms, which require specialized pediatric expertise. Meanwhile, plain CXR imaging, favored for its convenience and minimal radiation exposure, is frequently used in NICU. The radiologic features identified by our study can serve as auxiliary diagnostic tools for PDA, particularly valuable when echocardiographic resources are limited. Additionally, our methodology could be applicable to other diseases lacking defined objective radiologic criteria but known to exhibit specific imaging features.

## S3A-SPPD-2 ENHANCING RHEUMATIC HEART DISEASE DETECTION IN LOW-RESOURCE SETTINGS WITH UNCERTAINTY-BASED ACTIVE LEARNING

Marius G. Linguraru, DPhil, MSc (*Abstract Co-Author*) Co-founder, PediaMetrix Inc
Andrea Beaton (*Abstract Co-Author*) Nothing to Disclose
Emmy Okello (*Abstract Co-Author*) Nothing to Disclose
Kelsey Brown (*Abstract Co-Author*) Nothing to Disclose
Craig A. Sable (*Abstract Co-Author*) Nothing to Disclose
Taylor Gloria Broudy (*Abstract Co-Author*) Nothing to Disclose

Holger R. Roth, PhD (*Abstract Co-Author*) Employee, NVIDIA Corporation;Researcher, NVIDIA Corporation
Joselyn Rwebembera (*Abstract Co-Author*) Nothing to Disclose
Pooneh Roshanitabrizi (*Presenter*) Nothing to Disclose

**PURPOSE**

We introduce a new automated system to detect rheumatic heart disease (RHD)—a critical health issue in low-resource settings—using point-of-care color Doppler echocardiograms. This system combines active learning (AL), a type of machine learning technique, and uncertainty assessment to enhance diagnostic precision with minimal data annotation, utilizing an uncertainty-generating mechanism for improved functionality.

**METHODS AND MATERIALS**

We analyzed 1,022 color Doppler echocardiography cine-loops (parasternal and apical views) from 511 children with mitral regurgitation (mean age 12±2 years; range 5 to 17 years) in Uganda. Echocardiograms, obtained with a GE VIVID Q or IQ portable echocardiography machine using a 5 MHz transducer, were reviewed by expert cardiologists to determine the presence or absence of RHD. Of the children studied, 229 were deemed normal and 282 were diagnosed with RHD. The research received IRB approval. Our automated detection method includes selecting echocardiogram views and systolic frames using a DenseNet-121 neural network, RHD detection from two views with a 3D residual neural network, and uncertainty estimation for AL using test-time augmentation and Monte Carlo dropout techniques.

**RESULTS**

Using 411 training datasets, our method attained an RHD detection accuracy of 85%, sensitivity of 79%, and specificity of 92% across 100 test datasets. Notably, our AL framework achieved comparable results with only 43% of the training datasets (i.e., 178 training datasets), yielding an accuracy of 77%, sensitivity of 73%, and specificity of 81%. The p-value of 0.15, calculated using the McNemar test at a significance level of 0.05, suggests that the differences between the full and reduced dataset performances are not statistically significant. This level of performance is akin to that of specialized cardiologists, whose agreement typically falls within the range of 66% to 83%.

**CONCLUSION**

The study underscores the efficiency of our approach in drastically reducing annotation efforts, which are expensive and impractical due to the specialized human skills required.

**CLINICAL RELEVANCE/APPLICATION**

This approach could enhance RHD detection in low- and middle-income countries, potentially saving lives in regions where RHD annually causes over 300,000 deaths.

## S3A-SPPD-3 UTILITY OF DILUTED CONTRAST MATERIALS FOR PEDIATRIC PATIENTS WITH CONGENITAL HEART DISEASE DURING THE COMPUTED TOMOGRAPHY ANGIOGRAPHY

Tomoyasu Sato (*Abstract Co-Author*) Nothing to Disclose
Atsushi Ono (*Abstract Co-Author*) Nothing to Disclose
Kazuo Awai, MD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation;Research Grant, Hitachi, Ltd;Research Grant, Fujitsu Limited;Research Grant, Nemoto Kyorindo co, Ltd;Research Grant, FUJIFILM Holdings Corporation
Yoshinori Funama, PhD (*Abstract Co-Author*) Nothing to Disclose
Takeshi Nakaura, MD (*Abstract Co-Author*) Nothing to Disclose
Takanori Masuda, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Diluted contrast material is useful, contrast material reduction can be achieved using it in combination with lower-voltage scan on children with congenital heart disease. To investigate the contrast material dilution rates at varying tube voltages and compare the contrast enhancement and contrast material dose between undiluted 120 kVp and diluted 80 kVp protocols in clinical settings.

**METHODS AND MATERIALS**

Contrast material solution was diluted across a range of 2-1024 times using physiological saline. The injected iodine dose in undiluted 120 kVp protocol (n = 46) and doubly diluted 80 kVp protocol (n = 48) was 600 mg/kg (injection volume was body weight × 2.0 mL) and 300 mg/kg (injection volume was body weight × 2.0[1.0 mL CM + 1.0 mL saline]) during 12 s injection duration. The study included median computed tomography number for ascending aorta and pulmonary artery, image noise, contrast noise ratio, and radiation dose between two groups.

**RESULTS**

Comparable hounsfield unit (HU) values were achieved by diluting ~2 times at 80 kVp compared to 120 kVp. Under the doubly diluted 80 kVp protocol, contrast material dose was reduced by ~50% compared with undiluted 120 kVp protocol. No significant disparities were observed in median HU values for the ascending aorta and pulmonary artery between two protocols (p = 0.95 and 0.82).

**CONCLUSION**

Analogous range of HU values was attained using dilution factor of ~2 at 80 kVp compared to 120 kVp. Doubly diluted 80 kVp protocol curtailed the contrast material dosage by ~50% compared to undiluted 120 kVp protocol while preserving vessel enhancement.

**CLINICAL RELEVANCE/APPLICATION**

No detailed study revealing why the use of diluted CM increases contrast enhancement on CTA has been performed. Based on our study, we anticipate that utilizing diluted contrast material within a pediatric patient cohort would effectively elevate CT values on CTA examinations.

Dazhou Guo (*Abstract Co-Author*) Nothing to Disclose
Qinji Yu (*Abstract Co-Author*) Nothing to Disclose
Dakai Jin, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Lymph node (LN) detection in CT is essential for cancer diagnosis, staging and treatment planning. Previous statistical learning-based or deep learning-based works concentrated on detecting LNs in a single body region, such as the chest or abdomen, and typically yield limited recall and high false positives (FPs) even for enlarged LNs = 10mm (e.g., 60.9% recall at 6.1FPs per patient for the chest region, and 73.9% at 9FPs for abdomen). In this study, using the latest transformer-based detector, we propose a LN DEtection TRansformer (LN-DETR) that can effectively tackle the challenging yet clinically important LN detection task across major body sections.

### METHODS AND MATERIALS

We collected and curated data from 7 institutions including 1067 patients with 10,000+ annotated LNs including various body parts (neck, chest, and upper abdomen) and different diseases (head neck cancer, esophageal cancer, lung cancer, COVID, and other diseases). Built upon a latest transformer-based object detection framework (Mask DINO), we first design an efficient multi-scale 2.5D fusion scheme to incorporate the 3D LN context across consecutive input slices. Then location debiased query selection and contrastive query learning were further proposed to enhance the representation ability of LN queries, important to increase the LN detection sensitivity and reduce FPs. We use five out of seven datasets to develop and internally test the LN detection performance (70% training, 10% validation, and 20% testing), and report the sensitivity at 1, 2, 4 FPs per patient/CT-volume. The left two institutional datasets are used for independent external testing.

### RESULTS

The proposed LN-DETR achieves an average recall of 70.90% and 64.63% for LNs = 7mm across 1 to 4 FPs/patient in the internal and external testing, significantly outperforming the leading CNN-based method (MULAN) by 4.90% and 5.24%, respectively. It is also noted that for the subgroup of enlarged LNs (= 10mm), LN-DETR reports a recall of 83.5% at 4FPs per patient and an average recall of 80.43% across 1 to 4 FPs/patient.

### CONCLUSION

The LN-DETR model significantly enhances lymph node detection performance and shows strong generalizability across different body parts and diseases.

### CLINICAL RELEVANCE/APPLICATION

The proposed algorithm can detect lymph nodes of multiple body parts in CT scans with high precision, potentially assisting in the clinical workflow of radiology and radiation oncology.

## S3A-SPPH-10 CRANIOCAUDAL CYCLIC LOAD IMPROVE RISK ASSESSMENT OF LUMBAR PEDICLE SCREW LOOSENING:FINITE ELEMENT ANALYSIS BASED ON QUANTITATIVE COMPUTER TOMOGRAPHY

Huishu Yuan (*Abstract Co-Author*) Nothing to Disclose
Chenyu Jiang (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to investigate influence of craniocaudal cyclic load on pedicle screw fixation strength by computed tomography (QCT) based finite element analysis (FEA) and we examined predict ability in pedicle screw loosening (PSL).

### METHODS AND MATERIALS

12 clinical PSL cases (7 men, 5 women) and 12 age- and sex-matched controls were enrolled for CT based FEA. Simple axial pullout load and axial pullout load with preset craniocaudal cyclic load (100 times cycle) were applied to each model respectively, and the ultimate pullout force under both conditions is calculated as the fixed strength and compared. Besides, average HU values of screw trajectory and the bone mineral density (vBMD) of vertebral trabeculae were measured. The ultimate pullout force and HU value were compared between PSL and controls cases.

### RESULTS

The cyclic load remarkably reduce the pullout force of pedicle screws (906.2±180.2 N vs. 729.3±172.3 N, $p<0.0001$) by CT based FEA. No significant difference between the PSL and the control group in the simple axial pull-out force and vBMD of vertebral trabeculae. But the pullout force with preset cyclic load (639.2±169.4 N vs. 819.4±125.1 N, $p=0.072$) and the HU value of the screw trajectory (177.5±43.8 vs. 217.2±29.6, $p=0.016$) in the PSL group is significantly lower than that in the control group. Area under receiver operating characteristic curve (ROC) revealed pullout force with preset cyclic load slightly better predicted PSL than HU value of the screw trajectory (AUC = 0.798 vs. 0.750).

### CONCLUSION

The craniocaudal cyclic load significantly reduces the screw fixation strength which may be related to the declining HU value of screw trajectory. The pullout force with preset cyclic load by QCT based FEA are helpful for the clinical prediction of PSL.

### CLINICAL RELEVANCE/APPLICATION

The FEA pipeline proposed in this study is effective for the evaluation of PSL. Based with QCT-FEA, the craniocaudal cyclic load significantly reduces the screw pullout force by progressively accumulating bone tissue failure around the screw, which may relate with bone mass loss around the screw trajectory.

## S3A-SPPH-11 AUTOMATIC LIVER TUMOR DIAGNOSIS IN CONTRAST-ENHANCED CT SCANS WITH VARIABLE INPUT PHASES

Yu Shi, MD (*Abstract Co-Author*) Nothing to Disclose
Ling Zhang (*Abstract Co-Author*) Nothing to Disclose
Xu Han (*Abstract Co-Author*) Nothing to Disclose

Chunli Li (*Abstract Co-Author*) Nothing to Disclose
ZHANG XIAOMING (*Presenter*) Nothing to Disclose

### PURPOSE

We present a novel network dubbed LIDIA (LIver tumor DIAgnosis network), crafted for the differential diagnosis of eight liver tumor types through the analysis of multi-phase contrast-enhanced computed tomography (CECT) scans.

### METHODS AND MATERIALS

LIDIA features an iterative fusion module, which can effectively extract features from either a 4-phase sequence (non-contrast, arterial, venous, and delayed phases, NAVD) or a 3-phase sequence (NAV), leveraging rich radiological signs in all possible phases. We also introduce an asymmetric contrastive learning method to improve discrimination of rare liver lesion types from common ones in real-world scenarios. We curated an extensive dataset of CECT scans, including 1,921 patients, where two-thirds are NAVD scans and one-third are NAV ones . We comprehensively annotated 8,138 lesions, classified into eight categories. In addition to seven prevalent lesion types (HCC, ICC, metastases, hemangioma, FNH, calcification, and cyst), we integrated an "others" category to cover more than 20 types of less common tumors.

### RESULTS

LIDIA achieved an average patient-wise classification AUC of 93.6% within an eight-class framework and 94.6% in the binary classification of benign versus malignant lesions. For lesion-wise analysis, LIDIA reached a detection precision of 0.886, recall of 0.866, an 8-class classification accuracy of 0.881, and an overall segmentation Dice of 0.869. Evaluated on an external cohort of 828 patients from another institution, LIDIA maintained generalizability, with a mean patient-wise classification AUC of 89.3%. Notably, the iterative fusion module contributed to an AUC improvement of 0.105 in the eight-class tumor classification. A comparative reader study with 150 independent cases showed our model's accuracy paralleling that of a senior radiologist with 15 years of experience, both achieving 75.6%.

### CONCLUSION

We introduce LIDIA, a system designed to assist radiologists in the diagnosis of liver tumors through CECT imaging. Extensive evaluation on both internal and external patient groups, along with a reader study, has confirmed the effectiveness and clinical applicability of our approach.

### CLINICAL RELEVANCE/APPLICATION

LIDIA enhances liver tumor diagnosis with its quick and accurate analysis of CECT scans, enabling precise identification of various tumor types, including rare ones. This facilitates early treatment of malignancies and promotes a collaborative healthcare approach.

## S3A-SPPH-12 ONE-STOP WHOLE-BRAIN CTP RECOMBINATION IMAGE EVALUATION ON COLLATERAL CIRCULATION

Lu Song Tang (*Abstract Co-Author*) Nothing to Disclose
Fang Wang, PhD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of multiphase CT vascular imaging based on deep learning reconstruction (DLIR) one-stop whole brain CT perfusion data reorganization in collateral circulation in patients with unilateral middle cerebral artery (MCA) stenosis.

### METHODS AND MATERIALS

13 patients with unilateral MCA and whole-brain CTP and CTA were collected. CTP, scanning protocol: tube voltage 80 kV and tube current 150 mA. All data were obtained using the DLIR-H reconstruction algorithm. Using CTP raw data, arterial peak period (m-CTA), early vein (m-CTV 1) and late vein (m-CTV 2) images (2 arterial stage, 2 early vein, 2 late veins) were compared to the enhanced CT value, image noise, signal-noise-to-noise ratio (SNR),

contrast noise ratio (CNR), subjective image quality (score system: 0-2 points). Multistage CTA images were fused with workstation and collateral cycle scoring (5, below 2 cannot be assessed). CTA vessel enhancement CT values, image noise, SNR, and CNR were compared by paired t-test, and W ilcoxon signed rank sum test was used against normal distribution. Subjective ratings of m-CTA image quality, multistage collateral circulation scores were assessed by W ilcoxon signed rank sum test. Statistical significance was considered as p <0.05.

**RESULTS**

Comparison with the conventional CTA image quality, CT value of vascular enhancement in m-CTA fusion images (550.04±145.74VS 539.08 ± 115.33, P = 0.656) and SNR (22.16 ± 10 VS 19.87 ± 9.52, P = 0.531) was slightly higher than that in the conventional CTA group, CNR(20.59±10.76VS 23.34±10.05, P = 0.533) was slightly lower than that in the conventional CTA group, The image noise was higher than the conventional CTA group (28.43±9.93VS 25.92 ± 10.40, p=0.129), There was no statistical difference in the two groups. The subjective image quality was good (7.15±0.8VS 7.23 ± 0.6), and the collateral score in the m-CTA fusion images was higher than that in the CTA group (4.77±0.44vs 3.46 ± 0.66, p=0.003).

**CONCLUSION**

The image quality of recombinant m-CTA based on CTP raw data based on DLIR-H technique can be comparable to conventional CTA, while providing a comprehensive assessment of collateral circulation status in patients with middle cerebral artery stenosis.

**CLINICAL RELEVANCE/APPLICATION**

Based on DLIR-H technology, CTP raw data is reorganized into multiphase CTA, and brain tissue blood perfusion information and collateral circulation can be obtained simultaneously without increasing the radiation dose and contrast dose.

## S3A-SPPH-3 ENHANCING PERSONALIZED CONTRAST INJECTION IN COMPUTED TOMOGRAPHY: CLINICAL VALIDATION OF A MACHINE LEARNING ALGORITHM FOR ACCURATE FAT-FREE MASS ESTIMATION

Cyril Thouly (*Abstract Co-Author*) Nothing to Disclose
Natalie Heracleous, PhD (*Abstract Co-Author*) Nothing to Disclose
Federica Zanca, PhD (*Abstract Co-Author*) Nothing to Disclose
Hugues G. Brat, MD (*Abstract Co-Author*) Research Grant, General Electric Company;Speaker, General Electric Company;Shareholder, Groupe 3R
Benoit Dufour (*Abstract Co-Author*) Nothing to Disclose
Benoit Rizk, MD (*Presenter*) Shareholder, GLEAMER

**PURPOSE**

Contrast-enhanced CT is vital for liver lesion detection, with enhancement influenced by scan parameters, contrast type, and patient characteristics [1-5]. Personalized contrast injection is critical for precise diagnosis and kidney failure prevention. Research indicates Fat-Free Mass (FFM) effectively predicts enhancement but measuring it in practice is time-consuming. We developed and clinically validated an algorithm for theoretical FFM estimation for use in clinical practice.

**METHODS AND MATERIALS**

A multivariate linear regression model was developed for estimating Fat-Free Mass (FFM). The model utilized a dataset consisting of 689 abdominal CT scans from adult patients referred for liver lesion characterization or cancer follow-up. Data were collected between 2017 and 2022 from nine centers, using 15 CT scanners. The measured FFM served as the ground truth for model training.In a second phase, the model underwent validation in clinical settings, through integration into an algorithm that uses FFM to predict personalized contrast volume for liver CT. An earlier version of such algorithm included measured FFM and was validated in clinical settings for harmonized image quality (50 HU) across patients. To evaluate whether the theoretical estimation of FFM could replace the measured FFM, image quality was assessed by measuring a single Region of Interest (ROI) for both the portal and native phases of the CT scans. The resulting measurements were then plotted for analysis and compared to the data of the previous validation using measured FFM.

**RESULTS**

The results demonstrated excellent predictive performance for estimating Fat-Free Mass (FFM) within our patient dataset, characterized by high coefficient of determination (R2) of 0.91 +/- o.o2. In our clinical validation, we examined 109 cases across six distinct 3R diagnostic sites. Liver image quality was centered around 52 Hounsfield Units (HU), with 85% of images falling within an acceptable 30-70 HU range. This percentage is lower compared to earlier studies conducted by our team, where Fat-Free Mass (FFM) was measured (92% of images within 30-70 HU) [8]. Further analysis of additional cases, totaling 250 exams, will contribute to a more comprehensive understanding of the final results.

**CONCLUSION**

The validation of our model in clinical settings demonstrated very good enhancement, although further data will be crucial in solidifying its performance in practice.

**CLINICAL RELEVANCE/APPLICATION**

Accurate estimation of FFM allows saving time for effortless personalization of contrast volume injection, ensuring consistent enhancement of the liver in clinical practice.

## S3A-SPPH-4 EVALUATION OF A DEEP LEARNING CT RECONSTRUCTION ALGORITHM ON SMALL LOW-CONTRAST LUNG LESIONS USING 3D-PRINTED PHANTOMS

Jessica Im, BEng (*Presenter*) Nothing to Disclose

**PURPOSE**

Deep learning reconstruction (DLR) has been shown to improve image quality of low dose computed tomography (CT) scans, which is promising for lung cancer screening. While most malignant pulmonary nodules (PN) have high contrast on CT, ~20% of these lesions exhibit low contrast attenuations of = -600 Hounsfield Units (HU). Furthermore, for PNs which are thin in the z-axis direction, thinner reconstruction slice thicknesses are necessary for

resolving the lesion, at the cost of increased noise. This study uses a custom 3D-printed phantom to investigate the performance of a DLR algorithm on low contrast PNs of varying HU and sizes, and across various slice thicknesses and doses.

**METHODS AND MATERIALS**

The phantom in this study had a background lung-like attenuation of -800 HU, and inclusions of -750, -700, -650 and -600 HU, varying sizes between 1 - 10 mm, and thicknesses of 0.4 - 1 mm. The phantom was 3D-printed as a 10 cm cylinder out of polylactic acid, using PixelPrint technology. The phantom was placed in a 20 cm 3D-printed water equivalent ring inserted into a CT ACR 464 phantom body ring (33 x 26.4 cm) to mimic an average sized patient. CT scans were acquired on a conventional CT (Incisive CT, Philips Healthcare) at exposures between 0.5 - 20 mGy, with three scans acquired at each exposure. Images were reconstructed at slice thicknesses of 2, 1, and 0.8 mm using filtered back projection (FBP), iterative reconstruction (IR), and five denoising levels of a DLR algorithm (Precise Image, Philips Healthcare). The reconstructions were compared by measuring noise in each image, as well as line profiles, mean HU, and contrast-to-noise ratio (CNR) for each inclusion.

**RESULTS**

No significant difference in HU quantification was observed between the different reconstruction algorithms. HU quantification was primarily influenced by slice thickness, with slices of 2, 1, and 0.8 mm resulting in average HU errors of -87, -60, and -40 respectively for the 10 x 10 x 1 mm inclusion. Meanwhile, noise increased significantly as slice thickness decreased, with 1 and 0.8 mm slice thicknesses resulting in 59% and 89% mean increase in noise respectively compared to 2 mm slice thicknesses. CNR was primarily influenced by the reconstruction algorithm, with average percent improvements in CNR of 15% for IR and between 36-360% for DLR compared to FBP.

**CONCLUSION**

This study showed that using DLR with thinner slices enhances HU quantification and significantly improves CNR compared to both FBP and IR. These findings indicate that DLR is effective in improving the image quality of low-contrast PNs.

**CLINICAL RELEVANCE/APPLICATION**

The enhanced image quality and quantitative accuracy of thin-slice DLR images may enhance the sensitivity and specificity of lung cancer screening protocols.

## S3A-SPPH-5 OPTIMAL TRANSPORT FRAMEWORK TO INDICATE SOURCES OF AI PERFORMANCE BIAS THROUGH SUBGROUP FEATURE ALIGNMENT

Nicholas Petrick, PhD (*Abstract Co-Author*) Nothing to Disclose
Alexis Burgon, BS (*Abstract Co-Author*) Nothing to Disclose
Yelena Yesha, PhD (*Abstract Co-Author*) Nothing to Disclose
Mohammad Abu Baker Siddique Akhonda (*Abstract Co-Author*) Nothing to Disclose
Kenny H. Cha, PhD (*Abstract Co-Author*) Nothing to Disclose
Ravi K. Samala, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The determination of appropriate inclusion of subgroups in performance assessment studies is needed to estimate the effectiveness of artificial intelligence (AI)-enabled medical devices. However, factors such as AI's ability to learn shortcut patterns can complicate the process, leading to a mismatch between human-intended and model-learned solutions. We propose a novel method to measure the difference in AI subgroup representation in the training data sets. This is used to indicate subgroups that may be sources of AI performance bias on the test data set.

**METHODS AND MATERIALS**

We hypothesize that sources of AI performance bias can be determined by assessing the similarity of the feature representations across subgroups. Optimal transport (OT) measurements are used to measure this similarity, which estimate the "cost" of transforming features between subgroups by framing the problem as an alignment issue between two distributions. An AI model trained to classify COVID-19 status on chest X-ray images was used to quantitatively analyze the differences in feature representations for case I: sex (male, female) and case II: race (white, black) subgroups. Different amounts of bias were simulated by varying the disease prevalence of a pair of subgroups (e.g., male vs female) in the training set. The measured OT values, after adjusting based on the inter-class cost, indicate the degree of dissimilarity between subgroup feature representations. The approach was validated by evaluating the model performance on equally stratified test sets.

**RESULTS**

A relationship between the OT values (from the training set) and the AI performance bias (from the test set) was observed for both cases. In case I, lower OT values were observed at equal prevalence (0.91±0.40) than at higher prevalence differences (1.30±0.55 and 1.29±0.50). A similar trend was observed in the model test performance, with lower subgroup sensitivity differences for models trained on equal prevalence (0.03±0.02) than for those trained on higher prevalence differences (0.47±0.06 and 0.45±0.05). A similar trend was observed for race subgroups in case II.

**CONCLUSION**

Our results show that the AI performance bias in the test set can be indicated via analyzing the difference in subgroup feature representations in the training data set.

**CLINICAL RELEVANCE/APPLICATION**

Misalignment between human-intended and model-learned solutions complicates the process of determining important subgroups for performance assessment studies involving AI-enabled medical devices. Our proposed method can indicate potential sources of bias, thus aiding in the determination of subgroups.

## S3A-SPPH-6 DUAL-VIEW, MULTI-MODAL SEQUENTIAL AI FOR DETECTION OF PROGRESSION TO CLINICALLY SIGNIFICANT PROSTATE CANCER IN BPMRI

Derya Yakar, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Maarten de Rooij, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Henkjan Huisman, PhD (*Abstract Co-Author*) Shareholder, QView Medical, Inc;Grant Support, Siemens AG;Grant Support, Canon Medical Systems Corporation
Christian Roest, MSc (*Abstract Co-Author*) Grant, Siemens AG
Anindo Saha, MSc (*Abstract Co-Author*) Nothing to Disclose
Vilma Bozgo, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore a novel hybrid deep learning (DL) and machine learning approach to compare two sequential MRI scans in detecting progression to clinically significant prostate cancer (csPCa).

**METHODS AND MATERIALS**

This retrospective study included a multi-center cohort of 7134 consecutive single scan patients and 896 patients between 2012-2021 with at least a prior and current biparametric MRI scan of the prostate. Clinical information (PSA density, age, volume) was also collected. csPCa in the current scan was defined as a histopathological grade of ISUP=2. We compared three dual-view AI systems to assess the effect of adding clinical variables and uncertainty. All three use a nnU-Net-based DL ensemble trained on the 7134 single MRI cases integrating 5 models. The DL model was applied to each scan to generate sensitive heatmaps. The heatmaps were summarized into three parameters. 1) The patient level suspicion score computed as the maximum voxel-level prediction in each heatmap; 2) csPCa volume estimated by integrating the thresholded heatmap at 50% suspicion; 3) uncertainty as the variance in DL predictions from the five component detection models. Differential scores were additionally computed as the difference in the parameters between the current and prior. The final stage in the three AI systems was a linear regression model of the DL and clinical parameters, and the differential scores to predict csPCa in the current scan. This resulted in three systems. 1) using only the current and differential suspicion and volumetric parameters. 2) system 1 extended with clinical parameters and 3) system 2 extended with uncertainty. We used the area under the receiver-operating characteristic curve (AUROC) to compare the three classification systems at patient level. Differences in AUROC were evaluated using DeLong's tests. Bootstrapping was performed to generate the 95% confidence intervals (CI).

**RESULTS**

136 of 931 sequential studies showed histopathological progression to csPCa. System 1 AUROC was 0.81 [CI: 0.71-0.88]. System 2 AUROC significantly improved to 0.85 (CI: 0.76-0.93, p=0.02) by incorporating clinical parameters (PSA, PSA density, age). System 3 including uncertainty improved AUROC to 0.86 (CI: 0.77--0.93), but without reaching statistical significance.

**CONCLUSION**

This study provides evidence that a hybrid AI combining deep learning and machine learning can potentially detect progression to csPCa in sequential MRI with promising diagnostic accuracy that becomes even better by adding clinical parameters.

**CLINICAL RELEVANCE/APPLICATION**

Artificial intelligence may help achieve a robust and sensitive non-invasive way for the detection of progression to clinically significant disease, helping reduce unnecessary biopsies and treatment.

## S3A-SPPH-7 A FRAMEWORK FOR ROC ANALYSIS OF RULE-OUT AND RULE-IN DIAGNOSTICS AND AN APPLICATION TO MAMMOGRAPHY DATA

Weijie Chen, PhD (*Abstract Co-Author*) Nothing to Disclose
Kwok Lung Fan (*Abstract Co-Author*) Nothing to Disclose
Elim Thompson, PhD (*Abstract Co-Author*) Nothing to Disclose
Frank W. Samuelson, PhD (*Abstract Co-Author*) Nothing to Disclose
Michelle Mastrianni, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

In recent years, there has been growing interest in leveraging AI imaging devices to reduce radiologist workload, particularly in screening scenarios. In a rule-out ("believe the negative" or BN) setting, patients deemed negative with high confidence by an AI imaging device could bypass radiologist review, while in a rule-in ("believe the positive" or BP) setting, those identified as highly suspicious would be autonomously recalled. This work proposes a theoretical approach to analyze rule-out, rule-in, and combination ROC curves given the marginals and correlations of the AI and radiologist interpretations.

**METHODS AND MATERIALS**

We use bivariate copulas to approximate rule-out and rule-in ROC curves and to examine the effect of radiologist-AI correlations on the AUC and other metrics. We validate our theoretical method on clinical mammography datasets using one of the winning AI algorithms in a 2023 RNSA challenge for breast cancer detection. For each test set, we fit two ROC curves (one for radiologist-alone and one for AI-alone) and calculate the non-diseased and diseased correlations between the radiologist and the AI. We then plot the theoretical rule-out ROC curves and compare them with the empirical radiologist performance under rule-out at various AI threshold levels.

**RESULTS**

A test set with mammography images (119 diseased and 272 non-diseased) and radiologist (Se, Sp) = (0.765, 0.768) saw Pearson's correlations between radiologist assessment and AI scores of 0.09 and 0.40 respectively for non-diseased and diseased images. At AI operating FPFs of 0.5 and 0.9 respectively, empirical rule-out (Se, Sp) was (0.697, 0.882) and (0.765, 0.782). These performance values fall within the range of three of our proposed models. At AI FPF 0.9, the PPV of the rule-out diagnostic is superior to that for the radiologist-alone.

**CONCLUSION**

Empirical results show that projected radiologist performance under a rule-out or rule-in scenario are consistent with the theory. Higher correlation among diseased cases leads to improved performance of the rule-out ROC curve, while higher non-diseased correlation leads to worsened performance. The converse holds true for rule-in curves.

**CLINICAL RELEVANCE/APPLICATION**

While we assume the radiologist operates at a fixed threshold in our calculations of the empirical radiologist performance under rule-out, the proposed ROC curves are particularly useful given that a radiologist may change his or her decision threshold with the presence of an AI imaging device, an intuition that remains underexplored in current research given the complexities of conducting rule-out studies.

## S3A-SPPH-8 DOUBLING AND QUADRUPLING FRAME RATES IN DIGITAL SUBTRACTION ANGIOGRAPHY THROUGH DEEP LEARNING FRAME INTERPOLATION

Kentaro Yamada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jun'ichi Kotoku (*Abstract Co-Author*) Nothing to Disclose
Hiroshi Kondo, MD (*Abstract Co-Author*) Nothing to Disclose
Takeshi Takata, PhD (*Presenter*) Joint research, Shimadzu Corporation Patent license, MS Seisakusho

## PURPOSE

In interventional radiology, a high frame rate enhances the clarity of observed blood vessels and catheters. However, increasing the frame rate can proportionately elevate radiation exposure to patients and medical staff. This study aims to utilize deep learning-based frame interpolation on digital subtraction angiography (DSA) images, allowing the estimation of high frame rate equivalent DSA from low frame rate sources.

## METHODS AND MATERIALS

Conventional optical flow-based methods often fall short in accurately tracking the movement of fluids such as contrast agents. Consequently, we adopted the Flow-Agnostic Video Representations network for frame interpolation, which is a deep learning model designed to reason about non-linear motion trajectories, aiming to double and quadruple the frame numbers. We used models trained on the Vimeo90K and GOPRO_Large Dataset which are datasets of video frames of natural images. Test dataset included 1,194 and 1,023 DSA sequences with reduced frame counts to half and one-quarters, respectively. Then, frame interpolation was performed to achieve double and quadruple frame rates. The output interpolated frames were assessed against the omitted original frames using peak signal-to-noise ratio (PSNR) and structural similarity index measure (SSIM).

## RESULTS

The double and quadruple interpolation processes estimated 10,917 and 8,880 frames, respectively. The PSNR values recorded were 38.0 (interquartile range: 36.0-40.2) for the double interpolation and 36.2 (34.1-38.5) for the quadruple interpolation. SSIM scores were 0.935 (0.902-0.957) for the double interpolation and 0.915 (0.875-0.943) for the quadruple interpolation. The interpolated frames comfortably appeared as if the fluid was truly flowing.

## CONCLUSION

The deep learning models successfully interpolated DSA frames to an equivalent high frame rate with reasonable accuracy. Quadruple frame interpolation, which entailed higher frame reduction, resulted in poorer PSNR and SSIM values compared to double frame interpolation. This model would achieve clearer observation of DSA while mitigating radiation exposure risks to patients and medical staff.

## CLINICAL RELEVANCE/APPLICATION

High-precision frame interpolation could allow for lower frame rates in angiography, reducing radiation exposure while enabling detailed observations in DSA.

## S3A-SPVA-2 REDUCING BOTH RADIATION AND CONTRAST DOSES IN RENAL COMPUTED TOMOGRAPHY ANGIOGRAPHY IN SLIM PATIENTS USING 80KVP AND ASIR-V ALGORITHM IN COMPARISON WITH THE CONVENTIONAL 100-KVP PROTOCOL

Junjun Li (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the use of 80 kVp and high-strength adaptive statistical iterative reconstruction (ASIR-V) algorithm in renal computed tomographyangiography (CTA) for lean patients for reducing both radiation and contrast medium (CM) doses in comparison with the conventional 100-kVp protocol.

### METHODS AND MATERIALS

Twenty-eight slim patients (group A) with body mass index (BMI) 25kg/m2 =BMI=30kg/m2 were prospectively enrolled to undergo 80 kVp renal CTA with noise index (NI) of 17 HU and at weight-dependent CM dose rate of 19 mgI/kg/s for 10-s injection. Images were reconstructed with 70% ASIR-V. Radiation dose, contrast dose, and image quality were statistically compared with another 28 patients (group B) with matching BMI who underwent conventional renal CTA with 100-kVp and NI of 11 HU, 50ml of 350 mgI/ml CM at the flow rate of 4.5 ml/s and reconstructed with 50% ASIR-V. The CT values and SD values of the right and left renal arteries were measured to calculate the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). The image quality was subjectively scored by two experienced radiologists blindly using a five-point criterion. The CM dose and effective radiation dose in both groups were calculated and compared. Image quality between the two groups was also compared.

### RESULTS

There was no significant difference in patient characteristics between the two groups (P>0.05). Compared to group B, group A significantly reduced effectiveradiation dose by 15.4% (2.69±0.74mSv vs. 3.18±0.66mSv), CM dose by 19.4% (14.09g±1.49gI vs. 17.5gI), and injection rate by 14.4% (3.85±0.47ml/s vs.4.5ml/s) (all p<0.05). Group A had significantly lower SD values, higher CT values, SNR and CNR values of the renal arteries than group B (all P<0.05). There wasno difference in the subjective score of renal CTA images between the two groups (4.64±0.10 vs. 4.53±0.10) (P>0.05) and the two radiologists had excellentagreement in scoring (Kappa value >0.8, P<0.05).

### CONCLUSION

Renal CTA using 80 kVp and high-level ASiR-V provides diagnostic images with substantial reduction in both radiation and contrast doses for slim patients with 25kg/m2 =BMI=30kg/m2 compared to the conventional 100-kVp protocol.

### CLINICAL RELEVANCE/APPLICATION

BMI-based individualized kVp selection protocol in renal CTA imaging significantly reduces radiation dose and total iodine intake while maintaining diagnostic image quality and reduce the risk of contrast-induced nephropathy

## S3A-SPVA-3 PREDICTING OBSTRUCTIVE CORONARY ARTERY DISEASE IN PATIENTS WITH ACUTE ISCHEMIC STROKE OR TRANSIENT ISCHEMIC ATTACK: AN INTERPRETABLE MACHINE LEARNING APPROACH USING CT-BASED RADIOMICS

Yang Hou, MD (*Abstract Co-Author*) Nothing to Disclose
Yu Lan (*Presenter*) Nothing to Disclose

### PURPOSE

In acute ischemic stroke (AIS) and transient ischemic attack (TIA) patients, the threat of cardiovascular complications, especially CAD, is substantial. The appropriateness and selection criteria for coronary CTA (CCTA) screening in this cohort remain ambiguous. An interpretable machine learning (ML) model can provide critical insights into the significance of various risk markers for CAD prediction, thus refining patient selection for CCTA. The investigation leverages CT-based radiomics in an interpretable machine learning (ML) framework to assess obstructive coronary artery disease (CAD) risk in AIS and TIA patients. It focuses on correlating imaging biomarkers from head and neck CT angiography (CTA) with obstructive CAD incidence.

### METHODS AND MATERIALS

Utilizing the random forest algorithm, we developed an ML model that integrates a radiomic score (Rad_score) derived from CTA features, namely pericarotid adipose tissue, with established risk factors and the Framingham Risk Score (FRS). Our study retrospectively encompassed 175 patients, split into training and validation sets (7:3 ratio). Shapley additive explanations (SHAP) was used to assess how each feature contributed to risk evaluation.

## RESULTS

Of the 175 patients, 83 (47.43%) were diagnosed with obstructive CAD. A meticulous selection process whittled down 1,692 features to 10 pivotal variables for Rad_score. The composite model, integrating Rad_score, carotid artery stenosis degree, pericarotid fat density (PFD) and FRS, exhibited robust predictive capability (AUC: 0.877 in the training set, 0.801 in the validation set). SHAP analysis pinpointed the threshold values for each individual risk factor.

## CONCLUSION

Our interpretable ML model, underpinned by CT-based radiomics, effectively identifies patients at risk for obstructive CAD in AIS and TIA patients. The SHAP analysis demonstrated that the Rad_score, derived from pericarotid adipose tissue, along with the carotid stenosis degree, emerged as pivotal factors. This methodology could significantly enhance the precision of CCTA screening, offering a more nuanced approach to CAD risk stratification in this high-risk group.

## CLINICAL RELEVANCE/APPLICATION

Within the training set, an interpretable machine learning model facilitates precise risk forecasting for obstructive coronary artery disease in the patients with AIS or TIA (AUC = 0.877). An increased Rad_score emerges as a significant influence on the adverse outcome examined. Additionally, this model enables tailored recognition of key clinical and imaging factors that play a role in each patient's projected risk level.

### PURPOSE

To develop a radiomic-based machine learning model to predict triple negative breast cancer (TNBC) based on the contralateral unaffected breast's fibroglandular tissue (FGT) in breast cancer patients

### METHODS AND MATERIALS

This retrospective study included 541 patients (mean age, 51 years; range, 26-82) who underwent screening breast MRI between November 2016 and September 2018 and who were subsequently diagnosed with biopsy-confirmed, treatment-naĮve breast cancer. Patients were divided into a training set (n=250) and a validation set (n=291). Semi-automated 2D segmentation of FGT in the contralateral unaffected breast was performed using the T1-weighted fat-saturated first post-contrast sequence images. In the training set, 132 radiomic features were extracted from each segmentation using the open-source CERR platform. Following feature selection, the final prediction model was created, based on a support vector machine with a polynomial kernel of order 2. Model performance was evaluated in the validation set

### RESULTS

The training set included 250 patients (mean age, 50 years; range, 26-82), 156 with TNBC and 94 with non-TNBC; the validation set included 291 patients (mean age, 51 years; range, 26-82), 209 with TNBC and 82 with non-TNBC. The final prediction model, which included 4 radiomic features, achieved an AUC of 0.71, a sensitivity of 54% [47%-60%], a specificity of 74% [65%-84%], PPV of 84% [78%-90%] and NPV of 39% [31%-47%] in the validation set

### CONCLUSION

TNBC can be predicted based on radiomic features extracted from the FGT of the contralateral unaffected breast of patients, suggesting the potential for risk prediction specific to TNBC

### CLINICAL RELEVANCE/APPLICATION

This is a first necessary step towards the long-term goal of defining a subtype-specific risk score incorporating not only imaging features but also clinical and genetic data to identify women, including those who may not be categorized as high-risk by traditional risk models, who are at risk for TNBC

**PURPOSE**

To evaluate a deep-learning breast risk prediction algorithm (Mirai) to determine sensitivity and specificity for detection of interval cancers (ICs) from yearly risk scores on screening mammograms.

**METHODS AND MATERIALS**

Consecutive screening mammograms from 2 cohorts of women (119,669 women mean age 58.96 ± 7.80 years) from 2014-2016 at 2 NHS Breast Screening Program sites were processed by Mirai. Receiver-operator curves (ROCs) were generated and the area under the curve (AUCs) calculated from output scores for 1, 2 and 3-year timepoints. Ground truth was histopathology for all cancers; screen detected cancers were excluded from analysis; there were 469 ICs, defined as those diagnosed before the subsequent three yearly screening examination. DeLong's test was used to compare AUCs; Harrell's C-index for overall performance. IC detection rates were found for if the top 10% of risk scores were recalled, and Mann-Whitney U tests used to compare score distributions between individuals developing no cancer (normals) and ICs.

**RESULTS**

Overall AUCs were 0.72 (CI: 0.66-0.78), 0.65 (CI: 0.62-0.69) and 0.67 (CI: 0.63-0.70), for years 1, 2 and 3 respectively; c-index = 0.68 (CI: 0.66-0.71), with statistically significant differences comparing year 1 to year 2 (p=0.0435), but no differences between years 1 and 3 (p=0.111), and 2 and 3 (p=0.563). When set at thresholds to recall the top 10% of scores, sensitivities were 37.0% (26.0-49.1%), 20.5 (15.0-27.0%) and 25.7% (19.9-32.4%) with specificities all 90.0% (89.9-90.2%), successfully predicting 27/77, 39/190 and 52/202 ICs for years 1, 2 and 3, respectively, totaling 118/469 in the three-year period. Distributions of assigned risk scores were statistically different when comparing normal cases and all ICs (plt;0.05), as well as comparing normal cases to ICs for each year (plt;0.05). IC scores consistently increased each year following screening, to a statistically significant extent (plt;0.05).

**CONCLUSION**

Compared to normal cases, Mirai assigned higher risk scores to individuals that developed ICs within a triennial screening program and predicted 25.2% of ICs when set at 90% specificity. Evaluation of this model in different populations and configurations would support generalization to prospective studies.

**CLINICAL RELEVANCE/APPLICATION**

20-30% of all breast cancers are ICs, carrying a poorer prognosis. Risk scores could be used to identify women who may benefit from supplemental imaging or shorter screening intervals to detect cancer earlier and reduce underdiagnosis. Large-scale prospective population-based evaluation of such models with appropriate threshold selection and health economic modelling would determine if models are better than density measures for offering enhanced screening.

**PURPOSE**

To determine whether pre-treatment MRI as part of standard-of-care staging can be enhanced with AI to predict pathologic complete response (pCR) to neoadjuvant pembrolizumab and chemotherapy in patients with early-stage triple-negative breast cancer (TNBC)

**METHODS AND MATERIALS**

Patients with high-risk, early-stage TNBC treated with neoadjuvant pembrolizumab and chemotherapy followed by surgical resection between July 2021 and July 2022 were retrospectively included. Classical machine learning models were trained based on clinical-only, image-only, or both image and clinical features. A deep learning 3D UNet segmentation network coupled with a convolutional classifier head attached to the bottleneck was used to train a hybrid network based on image-only or both image and clinical features

**RESULTS**

Of 110 patients, 59% (n=65) had pCR while 41% (n=45) had residual disease. On multivariable analysis, younger age (OR=0·96, 95% CI: 0·93-0·99, p=0·013) and smaller size on pre-treatment MRI (OR=0·98, 95% CI: 0·96-1·0, p=0·009) significantly predicted pCR. Classical machine learning models attained AUCs of 0·57±0·10 (sensitivity 73%, specificity 34%), 0·63±0·10 (sensitivity 77%, specificity 43%), and 0·64±0·12 (sensitivity 78%, specificity 44%) based on clinical-only data, image-only data, or both image and clinical data. Deep learning models attained AUCs of 0·53±0·12 (sensitivity 52%, specificity 52%) and 0·58±0·11 (sensitivity 61%, specificity 52%), based on image-only data or both image and clinical data

### CONCLUSION

Classical machine learning models including both clinical and radiomics-based MRI features from pre-treatment MRI scans are promising to inform on the probability of a patient with TNBC responding to combined neoadjuvant pembrolizumab and chemotherapy

### CLINICAL RELEVANCE/APPLICATION

This study provides novel evidence that machine learning models can be trained to predict pCR in TNBC patients after neoadjuvant ICI therapy and chemotherapy, suggesting that AI-enhanced standard-of-care pre-treatment MRI may be used to better select patients who could benefit from immunotherapy after validation in larger multi-institutional studies

## S3B-SPBR-3 RESIDUAL CONVOLUTIONAL NEURAL NETWORK BASED ON ENHANCED BREAST MRI INTRA- AND PERITUMORAL INFORMATION: A MULTIMODAL NEURAL NETWORK FOR PREDICTINGLYMPHOVASCULAR INVASION IN BREAST CANCER

Yun Liang (*Abstract Co-Author*) Nothing to Disclose
Yuhan Wei (*Abstract Co-Author*) Nothing to Disclose
Yaqin Zhang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Zichang Ma, MD (*Abstract Co-Author*) Nothing to Disclose
Huajin Liu (*Abstract Co-Author*) Nothing to Disclose
Junyu Lin (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to develop a multimodal model based on residual neural networks, which enhances the robustness of preoperative prediction of breast cancer lymphovascular invasion (LVI) by integrating intratumoral and peritumoral information from different modalities of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI).

### METHODS AND MATERIALS

A preoperative DCE-MRI dataset was gathered, comprising 236 patients from 2016 to 2023, whose postoperative pathological examination verified their LVI status. 70% of the data (165 cases) were used for training, and the remaining 30% (71 cases) were used for testing. DCE-MRI, fat-suppressed T2-weighted images, and diffusion-weighted imaging were used to describe morphological feature data. Radiomics features were extracted from both intratumoral and peritumoral regions of interest. After statistical testing and feature selection, these features were combined with region-of-interest tensors as inputs into a multi-channel residual convolutional neural network. Multimodal fusion was performed at the fully connected layer to achieve LVI prediction.

### RESULTS

The deep learning model (Mdl) that integrated both intratumoral and peritumoral information showed the best performance, achieving an AUC of 0.85 (95% CI: 0.76, 0.93) for predicting LVI. This was superior to the radiomics machine learning model (Mml) that also combined intratumoral and peritumoral information (AUC = 0.80, 95% CI: 0.70, 0.89), the Mml that only included intratumoral information (AUC = 0.76, 95% CI: 0.67, 0.85), and the Mdl that only included intratumoral information (AUC = 0.75, 95% CI: 0.65, 0.85). All four models were pairwise compared using the DeLong test, resulting in all six p-values being less than 0.05.

### CONCLUSION

The Mdl, which combines both intratumoral and peritumoral information, can more effectively predict lymphovascular invasion in breast cancer.

### CLINICAL RELEVANCE/APPLICATION

Breast cancer patients with positive LVI have a significantly higher risk of local recurrence after breast-conserving therapy compared to those with negative LVI. Preoperative prediction of LVI status can aid in the selection of treatment plans.

## S3B-SPBR-7 CAN AN ARTIFICIAL INTELLIGENCE SYSTEM HELP ENTRY-LEVEL RADIOLOGISTS REDUCE UNNECESSARY BIOPSY OF BENIGN LESIONS IN MAMMOGRAMS?

Jie Ma (*Abstract Co-Author*) Nothing to Disclose
Lin Li (*Abstract Co-Author*) Nothing to Disclose
Xiaohui Lin (*Abstract Co-Author*) Nothing to Disclose
Rushan Ouyang (*Abstract Co-Author*) Nothing to Disclose
Tingting Liao (*Abstract Co-Author*) Nothing to Disclose
Yuting Yang (*Abstract Co-Author*) Nothing to Disclose
Chunyan Yi (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate whether a deep learning-based artificial intelligence (AI) system can assist entry-level radiologists to reduce unnecessary biopsy of benign lesions and improve the assessment accuracy of initial BI-RADS (Breast imaging reporting and data system) 3 and 4 cases in mammograms.

### METHODS AND MATERIALS

To investigate whether a deep learning-based artificial intelligence (AI) system can assist entry-level radiologists to reduce unnecessary biopsy of benign lesions and improve the assessment accuracy of initial BI-RADS (Breast imaging reporting and data system) 3 and 4 cases in mammograms.

### RESULTS

Of the 313 cases, 143 were benign and 170 were malignant. The attending radiologists (who composed the initial mammography reports) falsely recalled 81 unnecessary cases for biopsy and misclassified 15 malignant cases as BI-RADS 3 (probably benign). These numbers for the four entry-level radiologists were 71 and 24, respectively. Assisted by the AI, the numbers were reduced to 51 and 16, respectively. Assuming that BI-RADS 3 is benign and 4needs to be biopsied, the sensitivity of the attending radiologists was 0.91 (95% CI: 0.86 to 0.95), the specificity was 0.43 (0.35 to 0.52) and the accuracy was69.3% (63.9% to 74.4%). The AI system achieved a sensitivity of 0.79 (0.72 to 0.85), a specificity of 0.69 (0.60 to 0.76) and an accuracy of 74.1% (68.9% to 78.9%). The entry-level radiologists achieved a sensitivity of 0.86 (0.80 to 0.91), a specificity of 0.50 (0.42 to 0.59) and an accuracy of 69.7% (64.2% to 74.7%). These results of the entry-level radiologists were boosted to 0.91 (0.85 to 0.95), 0.64 (0.56 to 0.72) and 78.6% (73.6% to 83.0%) with the assistance of the AI system. The combination of the AI system and entry-level radiologists significantly increased the performance of diagnosis versus radiologists alone ($p<0.01$).

### CONCLUSION

The deep learning-based AI system surpassed entry-level radiologists and significantly improved the performance of entry-level radiologists in the assessment of BI-RADS 3 and 4 lesions by reducing unnecessary biopsy.

### CLINICAL RELEVANCE/APPLICATION

The deep learning-based AI system surpassed entry-level radiologists and significantly improved the performance of entry-level radiologists in the assessment of BI-RADS 3 and 4 lesions by reducing unnecessary biopsy.

## S3B-SPBR-8 PREDICTION OF TUMORSHRINKAGE PATTERN OF HR-POSITIVE, HER2-NEGATIVE BREAST CANCER AFTER NEOADJUVANT CHEMOTHERAPY BASED ON BASELINE ENHANCED MRI RADIOMICS

Tao Zhou (*Abstract Co-Author*) Nothing to Disclose
Lijia Wang (*Abstract Co-Author*) Nothing to Disclose

Yongchen Wang (*Abstract Co-Author*) Nothing to Disclose
LI YANG (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a predictive model incorporating pathologic features, MRI image features, and radiomic features to predict the tumor shrinkage pattern (TSP) of hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer (BC) after neoadjuvant chemotherapy (NAC).

### METHODS AND MATERIALS

A retrospective analysis of 227 patients with HR+/HER2-BC who underwent surgical treatment after NAC was conducted. TSP was categorized into two groups based on baseline and preoperative MRI characteristics: Category I (complete response or simple concentric regression) and Category II (others). Clinical, pathologic and imaging features were recorded. Patients were randomly divided into a training cohort (N = 160) and a validation cohort (N = 67) at a 7:3 ratio. Feature selection was performed on the training cohort using univariable analysis and multivariable analysis to establish a clinical model. Tumor segmentation was performed on the baseline enhanced MRI sequences and radiomic features were extracted. Univariable analysis, correlation analysis, and the Boruta algorithm were used to select radiomic features to establish a radiomic model. A combined model was established by integrating the above features. The receiver operating characteristic (ROC) curves were used to assess the predictive performance of the three models. The areas under the curve (AUCs) of the three models were compared using DeLong's test. The calibration performance of the models was assessed using calibration curves. The net benefit of the models was assessed using decision curve analysis (DCA).

### RESULTS

Ki67 quantity was identified as an independent predictor of TSP. The AUCs of the three models in the training cohort and the validation cohort were 0.624 (95% CI: 0.539-0.709) and 0.551 (95% CI: 0.412-0.689), 0.826(95% CI: 0.764-0.888) and 0.808 (95% CI: 0.706-0.910), and 0.831 (95% CI: 0.770-0.891) and 0.810 (95% CI: 0.709-0.911) respectively. A nomogram was generated based on the combined model, with a prediction cut-point of 0.38. In both cohort, the combined model and the radiomic model exhibited higher AUCs than the clinical model ($P < 0.05$). The combined model had good calibration performance (the training cohort: $P = 0.011$, the validation cohort: $P = 0.13$). The combined model and radiomic model both demonstrated higher net benefit rates in the training and validation cohort than the clinical model.

### CONCLUSION

Baseline MRI radiomic features can accurately predict TSP in patients with HR+/HER2- BC after NAC.

### CLINICAL RELEVANCE/APPLICATION

Radiomic models of HR+/HER2- BC MRI images have predictive value for TSP after NAC, may guiding clinical decision making.

## S3B-SPBR-9 BREAST CANCER CARE: PREDICTING PATHOLOGIC RESPONSE TO NEOADJUVANT THERAPY USING A MACHINE LEARNING MODEL BASED ON RADIOMIC FEATURES EXTRACTED FROM MRI

### PURPOSE

To develop and validate a machine learning model (ML) based on radiomic features extracted from Breast Magnetic Resonance (MRI) to predict response to Neoadjuvant Therapy (NAT) in patients with breast cancer.

### METHODS AND MATERIALS

Breast MRIs of women candidates for NAT performed between January 2019-March 2023 were retrospectively analysed. The inclusion criteria were: completion of all NAT cycles, availability of high-quality pre and post-NAT MRI, final surgical pathological report. MRIs were performed using 1.5 T scanners of 3 different vendors with a multiparametric protocol (T2w, DWI/ADC, 1 pre-contrast T1w+six post-contrast dynamic series). We manually segmented 30 lesions from the 3rd dynamic series using open-source software (3D Slicer) to train a deep learning 3D UNet model for automatic tumor segmentation. The remaining dataset was automatically segmented after the neural network training (nnUNet). Afterward, all MRI sequences were rigidly registered to the 3rd dynamic sequence and Radiomics features were extracted using the same tumor Region of Interest for each sequence. The ML model was developed with a Radiomics feature selection (based on Recursive Feature Elimination strategy), Random-forest classification algorithm and 5 folds-cross validation training strategy. The outcome was defined to predict the response as complete (CR), partial (PR) or non-response (NR). Statistical analysis was performed through univariate (T-Test or Mann-Whitney U test) and multiclass (One-Way ANOVA or Kruskal Wallis) analysis to distinguish among CR, PR and NR ($p<0.05$ significant). The ML model performances were assessed on test set (25% stratified by outcome) by means of accuracy, sensitivity and AUROC.

### RESULTS

Of the 200 candidates for NAT, 176 women were included in the analysis. Histologically, 97/176 (56%) resulted in CR, 68/176 (39%) in PR and 11/176 (6%) in NR. Over 759 radiomic features extracted and analyzed, 49 resulted statistically significant different among the 3 classes: notably, Slope wavelet

Gray Level Co-occurrence (p=0.001) and Kurtosis (p=0.0017) showed significant correlations with intra-tumoral heterogeneity and the NR category. The ML model exhibited an accuracy of 71% and a sensitivity of 76% in predicting response, with AUROC values of 0.94, 0.83, and 0.82 for PR, NR, and CR respectively.

**CONCLUSION**

Our ML model, based on radiomic features extracted from breast MRI, demonstrates promising capabilities in predicting response to NAT, especially in patients showing Partial Response.

**CLINICAL RELEVANCE/APPLICATION**

This study provides practical assistance to breast team members by facilitating the establishment of tailored therapeutic strategies through the pre-treatment stratification of NAT patient population.

## S3B-SPCA-10 OPPORTUNISTIC AUTOMATED CORONARY ARTERY CALCIUM SCREENING ON ROUTINE CHEST CT SCANS TO COORDINATE PREVENTIVE CARDIOLOGIC CARE IN ASYMPTOMATIC ADULTS

Ross W. Filice, MD (*Abstract Co-Author*) Advisor, BunkerHill Health, Inc;Shareholder, BunkerHill Health, Inc;Speaker, General Electric Company;Speaker, Koios Medical;Researcher, Koios Medical
Angela Zhou (*Abstract Co-Author*) Nothing to Disclose
Devyani Shinde, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

Millions of patients undergo routine CT exams who have Coronary Artery Calcium (CAC) but are not informed because quantitation has not been feasible. Unlike traditional ECG-gated CAC scans, quantifying incidental CAC on routine chest CTs using a machine learning model can circumvent the need for separate dedicated exams, specialized imaging, and reduce healthcare disparities. We aim to study the applicability of noninvasive CAC screening using a reliable and accurate machine learning model on routine ungated chest CTs and integration of outpatient cardiac care in patients with subclinical atherosclerosis.

### METHODS AND MATERIALS

The study includes patients <75 years old, with no known atherosclerotic cardiovascular disease (ASCVD), not on dialysis, and not actively on a statin, with an AI CAC score of >= 100. Scores are reported from ungated unenhanced chest CTs using a deep learning algorithm supervised by a radiologist. Inclusion criteria are determined automatically from the electronic health record and confirmed by manual chart review. Eligible patients are notified by phone and offered a referral for an outpatient cardiology visit for personalized risk assessment and discussion of preventive therapies.

### RESULTS

We refined our care pathway through a pilot study of 3087 scans from 2217 unique patients between Jan-Feb ‘23. Model deployment began from Sept ‘23 and by March ‘24, we examined 1834 additional scans and contacted 77 eligible candidates (including from pilot) by April. Our preliminary findings include 27 referrals for cardiology intake, about 35% of those contacted. We excluded 7 patients with false positive elevated CAC scores.

### CONCLUSION

AI-enabled CAC screening of patients undergoing routine CTs provides an untapped avenue for identifying patients at risk for ASCVD. Coordinating a cardiology referral can close the loop by discussing preventive strategies and increasing awareness about cardiovascular health resulting in actual interventions to improve patient outcomes. Limitations include occasional challenges in identifying patients on statins due to inconsistent chart documentation, notifying some eligible patients by phone, inability to refer patients without requisite insurance, and patient discretion regarding referrals. Future steps include expanding model usage to more sites and systematic analysis of the clinical outcomes as a result of this program.

### CLINICAL RELEVANCE/APPLICATION

Deep learning-based quantification and screening of incidental CAC on routine CT exams may be of potential use to identify otherwise missed asymptomatic patients at-risk for ASCVD and provides a unique opportunity to close the care pathway loop through multidisciplinary care with cardiologists.

## S3B-SPCA-2 DEEP LEARNING SUPER-RESOLUTION RECONSTRUCTION FOR FAST AND HIGH-QUALITY CINE CARDIOVASCULAR MAGNETIC RESONANCE

Dmitrij Kravchenko, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare standard resolution balanced steady-state free precession (bSSFP) cine images with cine images acquired at low resolution but reconstructed with a deep learning (DL) super-resolution algorithm.

**METHODS AND MATERIALS**

In this prospective study, cine cardiovascular magnetic resonance (CMR) datasets (short-axis and 4-chamber views) were acquired in healthy volunteers and patients at normal resolution (cineNR; 1.89×1.96 mm2, reconstructed at 1.04×1.04 mm2) and at a low-resolution (2.98×3.00 mm2, reconstructed at 1.04×1.04 mm2). Low-resolution images were reconstructed using compressed sensing DL denoising and resolution upscaling (cineDL). Left ventricular ejection fraction (LVEF) and end-diastolic volume index (LVEDVi) were assessed. Apparent signal-to-noise (aSNR) and contrast-to-noise ratios (aCNR) were calculated. Subjective image quality (blood-pool to myocardium contrast, endocardial edge definition, and artefacts) was assessed on a 5-point Likert scale (1: non-diagnostic to 5: excellent). Student's paired t test, intraclass correlation coefficient (ICC), Blant-Altman plots, Pearson's r, and Wilcoxon matched pairs test were used for statistical analysis.

**RESULTS**

Thirty participants were analyzed (37±16 years; 20 healthy volunteers and 10 patients). For short-axis views, whole-stack acquisition duration of cineDL was 42% shorter compared to cineNR (57.5±8.7 vs 98.7±12.4 s, p<.0001). No statistical significant differences and excellent agreement were found for volumetric measurements: LVEF (59±7 vs 59±7 % p=.17, r = 0.96, ICC: 0.95) and LVEDVi (85.0±13.5 vs 84.4±13.7 ml/m2, p=.12, r= 0.99, ICC: 0.99) (Figure 1). Objective (aSNR (81±49 vs 69±38, p=.32), aCNR (53±31 vs 45±27, p=.33) and subjective image quality (5.0 [IQR 4.9-5.0] vs 5.0 [IQR 4.7-5.0], p=.99) was similar between both techniques.

**CONCLUSION**

Super-resolution DL reconstruction of cine images acquired at a lower spatial resolution led to decrease in acquisition times of up to 42% with shorter breath holds and did not affect volumetric results or image quality.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning super-resolution reconstructions of balanced steady-state free precession (bSSFP) cine images acquired at a lower spatial resolution reduce acquisition times while preserving diagnostic accuracy, improving clinical feasibility of cine imaging especially in vulnerable populations such as pediatric patients or patients with symptoms of heart failure by decreasing breath hold duration.

## S3B-SPCA-3 DIAGNOSTIC PERFORMANCE OF AI-ASSISTED CCTA IN DETECTING CORONARY ARTERY STENOSIS IN PATIENTS WITH SUSPECTED CORONARY ARTERY DISEASE

Weihua Yin (*Abstract Co-Author*) Nothing to Disclose
Bin Lu, MD (*Abstract Co-Author*) Nothing to Disclose
Yang Chen (*Presenter*) Nothing to Disclose

**PURPOSE**

Noninvasive coronary computed tomography angiography (CCTA) plays an important role in the screening of coronary artery disease (CAD). The interpretation of CCTA results is time-consuming and relies on the reader's expertise. we conducted a study to investigate the accuracy of deep learning in detecting CAD patients with =50% coronary artery stenosis.

**METHODS AND MATERIALS**

This retrospective, multicenter, and blinded evaluation study included 1765 patients undergoing CCTA from 5 centers. CCTA data from suspected CAD patients (mean age: 59.90 ±11.51 years, 47.3% female) were retrospectively analyzed using artificial intelligence (AI) based software for comprehensive assessment, including coronary segmentation, lumen, and vessel wall evaluation, plaque quantification and characterization, and stenosis determination with comparison to the reference standard of consensus by three experts.

**RESULTS**

The artificial intelligence(AI) performance at a patient level was excellent for accuracy, sensitivity, specificity, positive predictive value(PPV), and negative predictive value(NPV) for =50% stenosis as follows: 92.8%, 95.3%, 91.4%, 85.6%, and 97.3%, respectively. Excellent agreement is seen between expert readers and AI determined maximal diameter stenosis for per-patient (kappa coefficients: 0.84 (95% CI: 0.81-0.88)). Regarding diagnostic efficiency, comparing the AI versus human reader, the average reading time decreased from 5.94 min to 2.01 min (p < 0.0001).

**CONCLUSION**

A novel AI-based assessment of CCTA can accurately and rapidly identify patients with coronary artery stenosis =50% and effectively aid in triage, reducing unnecessary downstream procedures and optimizing the utilization of healthcare resources.

**CLINICAL RELEVANCE/APPLICATION**

Given CAD is the most important socioeconomic healthcare problem in the world, the application of AI-assisted CCTA to triage firstly this disease in suspected CAD patients is surprisingly helpful. Our study demonstrates that AI can swiftly screen patients with coronary artery stenosis =50%, potentially reducing unnecessary downstream procedures and optimizing the utilization of healthcare resources in real clinical practice. In addition, the divergent interpretations of CCTA findings among different radiologists. The implementation of AI can aid in the professional development of less experienced radiologists.

## S3B-SPCA-5 DEEP LEARNING MAY PREDICT EARLY CORONARY ARTERY DISEASE FROM PERICORONARY ADIPOSE TISSUE ATTENUATION AND FAT FRACTION IN CHEST CT ANGIOGRAPHY

Andrew Nguyen (*Abstract Co-Author*) Nothing to Disclose
Ronald M. Summers, MD, PhD (*Abstract Co-Author*) Royalties,iCAD, Inc;Royalties, Koninklijke Philips NV;Royalties, ScanMed, LLC;Royalties, Ping An Insurance (Group) Company of China, Ltd;Royalties, Translation Holdings;Research support, Ping An Insurance (Group) Company of China, Ltd
Tejas Sudharshan Mathai, PhD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Coronary artery disease (CAD) is the leading cause of mortality worldwide. Pericoronary adipose tissue (PCAT) is an early biomarker of CAD. Prior semi-automated approaches measure PCAT at the right coronary artery (RCA) but not the left coronary artery (LCA) and its branches. The purpose of this project is to develop a fully automated approach to measure PCAT mean attenuation and fat fraction at both arteries.

### METHODS AND MATERIALS

A 3D full resolution nnUNet was trained (n = 745 studies) and tested (n = 183 studies) on the ImageCAS dataset to segment the RCA and LCA. PCAT was defined as the adipose tissue at twice the 3D radial distance from the artery centerline to the outer artery wall within [-190, -30] Hounsfield units (HU). For the RCA, PCAT was measured 10 mm from the ostium for a radius of 40 mm. For the LCA, PCAT was measured from the aorta to the first coronary branchpoint and from that branchpoint to a radius of 40 mm. The branchpoint was used to split the LCA into the left main (LM), left anterior descending (LAD), and left circumflex (LCX) arteries (Fig. 1a-c). The ASOCA dataset was used to externally validate our model to detect differences in studies with (n = 20) and without CAD (n = 20).

### RESULTS

For the ImageCAS test set, Dice scores for PCAT at the RCA and LCA were 0.70 ± 0.19 and 0.78 ± 0.12. For the ASOCA validation set, Dice scores for PCAT in CAD and non-CAD studies were 0.54 ± 0.08 vs. 0.49 ± 0.14 at the RCA, and 0.52 ± 0.07 vs. 0.47 ± 0.06 (p = 0.02) at the LCA (Fig. 1d). Of the four coronary arteries, mean PCAT attenuation (-75.08 ± 7.93 HU vs. -68.98 ± 8.04 HU; p = 0.02) and fat fraction (0.38 ± 0.11 vs. 0.30 ± 0.14; p = 0.04) at the left main artery were significantly different between CAD and non-CAD studies (Fig. 1e-g). Concordant with the literature, mean PCAT attenuation at the RCA was higher in CAD studies (-80.58 ± 6.43 HU vs. -83.40 ± 5.74 HU), though no significant difference was found. Furthermore, no significant difference in PCAT volume was found.

### CONCLUSION

We developed a fully automated method to measure PCAT attenuation and fat fraction at both the RCA and LCA. We found significant differences in mean PCAT attenuation and fat fraction at the left main artery between CAD and non-CAD studies.

### CLINICAL RELEVANCE/APPLICATION

Automated opportunistic screening of PCAT in chest CT angiography using deep learning promises to be an early predictor of CAD.

## S3B-SPCA-6 AI-BASED CHEST RADIOGRAPHIC CARDIOVASCULAR BORDER ANALYSIS FOR DIAGNOSING PULMONARY THROMBOEMBOLISM

Ki Seok Choo, MD (*Abstract Co-Author*) Nothing to Disclose
Jong Eun Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Dong Hyun Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Jiyun Ok (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the feasibility of AI-based cardiovascular border analysis on chest radiographs for the suspicion of pulmonary thromboembolism.

### METHODS AND MATERIALS

We collected posteroanterior chest radiographs from patients diagnosed with pulmonary thromboembolism before and after treatment, from January 2019 to December 2023. For comparison with a normal reference, we also gathered posteroanterior chest radiographs of healthy subjects aged 20 to 40. Our AI-based model for the automated diagnosis of cardiovascular abnormalities evaluated the radiographs based on the CT ratio, the distance from the midline to the borders of the superior vena cava (SVC)/aorta, right atrium (RA), aortic knob, pulmonary trunk, left atrium (LA) appendage, left ventricle (LV), descending aorta, and carina angle, as well as age-sex corrected Z-scores. To compare pre-treatment with post-treatment and the normal reference group, we used Student's t-test.

### RESULTS

Sixty-five patients with pulmonary thromboembolism, who had undergone both pre-treatment and post-treatment posteroanterior chest radiographs, were included along with 459 normal control subjects with posteroanterior chest radiographs. After treatment, the pulmonary thromboembolism group showed a significant reduction in the measured variables compared to pre-treatment values, aligning them closer to those of the normal reference. Age-sex corrected Z-scores also showed significant differences; pre-treatment values of the CT ratio, SVC/Aorta, RA border, aortic knob, pulmonary trunk, LA appendage, descending aorta, and Carina angle were significantly higher than the post-treatment values.

### CONCLUSION

The AI-based model for cardiovascular border analysis demonstrates potential in the suspicion of pulmonary thromboembolism in patients based on chest radiographs.

### CLINICAL RELEVANCE/APPLICATION

AI-based radiographic cardiovascular analysis represents a new clinical approach to diagnosing pulmonary thromboembolism, offering a more quantitative and comparable method for managing this serious condition.

## S3B-SPCA-7 PAIRED COMPARISON OF CARDIAC MRI AND CT FOR THE COMPREHENSIVE EVALUATION OF CARDIAC FUNCTION

James W. Goldfarb, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study compares global cardiac functional values from clinical cine cardiac CT (CCT) and cardiac MRI (CMR) patients to evaluate intermodality variability. It aims to determine the level of agreement and identify any systematic biases that might affect their interchangeability. Understanding agreement and bias between these modalities is essential for their effective use in clinical settings.

### METHODS AND MATERIALS

The retrospective study included 24 consecutive clinical patients (54% male; average age 74.6 ± 10.8 years), undergoing both CMR and 20-phase CCT within a 14-day period (average 5.3 ± 4.3 days). Measurements included left ventricular (mass, end-diastolic volume, end-systolic volume, ejection fraction, and stroke volume for all ventricles and atria. We compared fully automated deep learning-based 3D segmentation of CCT with conventional CMR segmentation using correlation coefficients, Bland-Altman plots, and ICC analysis.

### RESULTS

Despite the small sample size, the distribution of cardiac function values was normal, with a wide range observed: LV mass had a mean of 129g and range: 62-257g; LVEF had a mean of 54% and range: 30-80%. There was excellent correlation and agreement for LV mass between CMR and CCT ($r = 0.98$, $p < 0.001$, ICC = 0.99), although a significant bias was noted (-84 g, 95%CI: -132, -35 g), likely due to the inclusion of papillary muscles within

the LV cavity in CCT, but not in CMR tracings. Strong correlations (r = 0.82-0.91) were observed for LV measurements, alongside notable biases (LVEDV = +19 ml [95%CI: -31, 69]; LVESV = +23 ml [95%CI: -15, 62]; LVEF = -10% [95%CI: -25, 4]). RV measurements showed lower correlations (r = 0.52-0.80) and significant biases (RVEDV = -60 ml [95%CI: -110, -10]; RVESV = -60 ml [95%CI: -118, -1]). Left atrial measurements also demonstrated strong correlations (r = 0.70-0.90) but with substantial biases (LAEDV = -31 ml [95%CI: -68, 7]; LAESV = -31 ml [95%CI : -61, -1]; LAEF = -12% [95%CI: -1, 26%]). Right atrial values exhibited the weakest correlations (r = 0.42-0.67), with large biases and broad ranges of agreement.

**CONCLUSION**

The study reports strong correlation for LV mass between CCT and CMR, supporting the reliability of CCT with necessary adjustments for bias. However, variability in ventricular and atrial measurements suggests the need for caution when using these modalities interchangeably. Future research should focus on refining automated segmentation techniques to improve modality agreement and reliability.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning provides a powerful tool for the comprehensive functional evaluation of 3D cardiac CT cine acquisitions. However, clinically significant biases currently limit the interchangeability of values between CCT and CMR.

## S3B-SPCA-8 AUTOMATED AORTIC CALCIUM SEGMENTATION AND SCORING TOOL IN NON-CONTRAST CT IN CORE320

Bharath Ambale-Venkatesh, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation;Co-founder, Third Eye Health Inc;Research Grant, Myocardial Solutions, Inc
Armin A. Zadeh, MD, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Joao A. Lima, MD (*Abstract Co-Author*) Nothing to Disclose
Sangmita Singh (*Abstract Co-Author*) Nothing to Disclose
Devina Chatterjee (*Presenter*) Nothing to Disclose

**PURPOSE**

Aortic calcification is associated with cardiovascular risk, but manual quantification is time-consuming for routine assessment. We investigated automated aortic calcium scoring as an incidental finding in CORE320 patients with a non-contrast CT

**METHODS AND MATERIALS**

381 participants referred for cardiac angiography were enrolled in CORE320, a prospective multicenter diagnostic study. MACE was defined myocardial infarction, cardiac death, hospitalization for chest pain over 5 years. Aortic calcification was manually quantified from non-contrast DICOMs using 3D Slicer, resulting in Agatston scores for 379 patients in the aortic root, ascending and descending aorta. For automated methods, segmentation of the aorta was achieved through 3D Slicer, using the TotalSegmentator algorithm. Aortic calcifications were segmented using Hounsfield Unit voxel thresholding (>130 HU). Noise was reduced through serial erosion and dilation. Agatston scores were calculated as previously described. Multivariable Cox regression associated aortic calcium with the 5-year clinical outcomes with adjustments for age, gender, race, statin use, and coronary calcium. Correlation coefficients evaluated the agreement between automated and manual scores

**RESULTS**

Mean age was 62 years, 34% were women. MACE occurred in 99/379 patients over 5-year follow-up. 45.1% had any aortic calcium scores (19.0% aortic root, 44.3% ascending aorta, 36.7% descending). Aortic root and total aortic calcium were not correlated with coronary artery calcium. The automated aortic root calcium score (r=0.98), ascending aorta (r=0.99), and descending aorta (r=0.99) demonstrated good agreement with manual scoring. Automated and manual aortic root, ascending aorta, descending aorta, and total aortic calcification scores were significantly associated with increased risk of MACE in both univariable and multivariable Cox regression analyses. Hazard ratios were comparable between automated and manual scoring methods, with aorta root (manual: 1.128; automated: HR 1.145), ascending (manual: 1.122; automated: HR 1.139), descending (manual: 1.086; automated: HR 1.096). The C-statistic for aortic root calcium scores (0.584), ascending (0.577), descending (0.579), and total (0.570) compared well to automated methods. All differences in C-statistics statistically insignificant

**CONCLUSION**

The study demonstrated the accuracy and predicability of automated aortic calcium scoring with no statistically significant differences in predictive performance

**CLINICAL RELEVANCE/APPLICATION**

Using the CORE320 study, automated aortic calcification is predictive of 5-year MACE, independent of coronary artery calcification, supporting its use as an incidental finding in routine scans

## S3B-SPCA-9 APPLICATION AND ACCURACY ANALYSIS OF CT-FFR IN PREDICTING MYOCARDIAL ISCHEMIC EVENTS CAUSED BY TYPE A AORTIC DISSECTION

Feifei Zhou, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to evaluate the accuracy of CT-FFR technology in predicting myocardial ischemic events caused by Type A aortic dissection and to explore its potential clinical applications.

**METHODS AND MATERIALS**

This retrospective study included patients diagnosed with Type A aortic dissection who had complete coronary computed tomography angiography (CCTA) imaging data. CT-derived fractional flow reserve (CT-FFR) measurements were performed using proprietary software developed by Siemens to analyze the CCTA images. The study examined the concordance between CT-FFR and myocardial ischemic events during hospitalization. Additionally, the predictive value of CT-FFR for coronary revascularization and major adverse cardiac events (MACE) was evaluated over a one-year follow-up period. The impact of CT-FFR on clinical decision-making processes was analyzed, along with its potential to improve patient outcomes.

**RESULTS**

This study analyzed data from 84 patients with Type A aortic dissection (mean age 43 ± 11 years; 78.6% male), among whom 45 experienced myocardial infarction during hospitalization and 7 encountered major adverse cardiac and cerebrovascular events (MACE) within one year. CT-derived fractional flow reserve (CT-FFR) demonstrated a sensitivity of 62.1% and a specificity of 49.1% in predicting myocardial infarction, with a positive predictive value (PPV) of 39.1% and a negative predictive value (NPV) of 71.1%. Receiver operating characteristic (ROC) curve analysis revealed that CT-FFR had moderate diagnostic accuracy for predicting myocardial ischemic events, with an area under the curve (AUC) of 0.556. In terms of predicting MACE, patients with positive FFR results were more likely to experience MACE, with the ROC analysis showing a CT-FFR AUC of 0.67 for MACE events.

These findings suggest that CT-FFR has moderate accuracy and potential clinical application in predicting myocardial ischemic events and MACE, particularly among high-risk patient groups.

## CONCLUSION

CT-FFR identifies high-risk patient groups through a non-invasive approach. FFR-CT may become an important tool for assessing cardiac risk and guiding clinical decisions in such patients.

## CLINICAL RELEVANCE/APPLICATION

AI-based CT-FFR can provide clinicians with crucial information about the risk of myocardial ischemia in patients with Type A aortic dissection. Accurately identifying patients at risk of major adverse cardiac events (MACE) can enhance the efficiency and cost-effectiveness of treatment.

## S3B-SPCH-1 A CT-BASED QUANTITATIVE NOMOGRAM FOR DIFFERENTIATING COPD AND ASTHMA

Li Fan, MD (*Abstract Co-Author*) Nothing to Disclose
Yueze Li (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the application value of a model established by combining quantitative features from chest CT with clinical information in distinguishing between patients with chronic obstructive pulmonary disease (COPD) and asthma.

### METHODS AND MATERIALS

A retrospective analysis was performed on the chest CT quantitative features and clinical data of 798 patients who were confirmed to have COPD or asthma through pulmonary function tests, including 516 COPD patients and 282 asthma patients. These patients were randomly divided into training and internal validation sets at a ratio of 7:3. Commercial software was used to perform whole-lung vessel segmentation on chest CT images and extract quantitative features of the lung vasculature. Pearson correlation analysis, the minimum Redundancy Maximum Relevance (mRMR) algorithm, and the Least Absolute Shrinkage and Selection Operator (LASSO) were applied for feature reduction and selection. A predictive model was established using multivariate logistic regression analysis, and a nomogram was plotted. The calibration, diagnostic efficacy, and clinical value of the nomogram were evaluated.

### RESULTS

Nineteen radiomics features were selected to calculate the Quantitative score. Multivariate logistic regression showed that age, height, and Quantitative score were independent predictors of the combined model. The area under the curve (AUC) of the combined prediction model in the training set was 0.78, which was higher than the clinical model (AUC=0.68) and the radiomics model (AUC=0.76). In the validation set, the AUC of the combined model was 0.74, also higher than the clinical model (AUC=0.67) and the radiomics model (AUC=0.72). Decision curve analysis revealed that the combined prediction nomogram demonstrated good clinical utility within the threshold range of 0.1 to 0.9.

### CONCLUSION

The combination of quantitative CT features and clinical characteristics can effectively differentiate between COPD and asthma patients.

### CLINICAL RELEVANCE/APPLICATION

The study has good predictive efficacy in distinguishing between COPD and asthma by incorporating age, height, and quantitative scores into a nomogram, offering considerable clinical benefits and providing a certain reference value for clinical decision-making and treatment.

## S3B-SPCH-2 ASSESSING EMPHYSEMA ON X-RAY DOSE-EQUIVALENT PHOTON-COUNTING DETECTOR CT: EVALUATION OF A DEEP LEARNING ALGORITHM AND VISUAL SCORING IN A PROSPECTIVE STUDY

Cecilia Strappa, MD (*Abstract Co-Author*) Nothing to Disclose
Jonas Kroschke (*Abstract Co-Author*) Nothing to Disclose
Falko Ensle (*Abstract Co-Author*) Nothing to Disclose
Thomas Frauenfelder, MD (*Abstract Co-Author*) Advisory Board, Agfa-Gevaert Group;Advisory Board, Boehringer Ingelheim GmbH
Lisa Jungblut, MD (*Abstract Co-Author*) Nothing to Disclose
Bjarne Kerber, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the feasibility and efficacy of visual scoring, low-attenuation volume (LAV) and deep learning methods for emphysema severity estimation in ultralow-dose Photon-counting detector CT, aiming to explore future dose reduction potentials.

### METHODS AND MATERIALS

In this IRB-approved, prospective study 101 patients underwent non-contrast low- and chest x-ray equivalent dose CT scans at the same day using a first-generation clinical dual-source photon-counting detector CT. Visual emphysema pattern (no, trace, mild, moderate, confluent and advanced destructive emphysema; as defined by the Fleischner Society) was assessed by two experienced radiologists for low- and ultralow-dose images independently. In a second step, automated emphysema quantification was performed using an established low attenuation volume (LAV) algorithm with a threshold of -950 HU and a commercially available deep learning model for automated emphysema quantification. The LAV algorithm applied to low-dose images served as the reference standard for emphysema quantification.

**RESULTS**

X-ray dose equivalent scans exhibited a significantly lower Computed Tomography dose index (CTDIvol) compared to low-dose scans (low-dose: 0.66 ± 0.16 mGy, X-ray dose equiv.: 0.11 ± 0.03 mGy, p<0.0001). Inter-reader agreement for visual scoring was excellent (? = 0.83). Visual emphysema scoring showed good agreement between low-dose and X-ray dose equivalent scans (? = 0.70), with significant and strong correlation (Spearman's ? = 0.79). While trace emphysema was underestimated in X-ray dose equivalent scans, there was no significant difference in the distinction of higher grade (mild to advanced destructive) emphysema (p=0.125) between the two scan doses. Deep learning and LAV algorithm demonstrated no significant difference in predicted emphysema volume (p=0.57) on low-dose and X-ray dose equivalent scans. Both models significantly overestimated emphysema volume compared to the reference standard (both p<0.0001) in X-ray dose equivalent scans.

**CONCLUSION**

Emphysema severity estimation is feasible with X-ray dose equivalent scans using visual scoring. A deep learning algorithm delivered promising results and performed comparable to an established LAV method on low-dose scans. Still, both quantification methods overestimated emphysema on X-ray dose equivalent scans. Therefore, more robust automated emphysema quantification methods are needed.

**CLINICAL RELEVANCE/APPLICATION**

Photon-counting detector CT enables diagnostic scans with significantly reduced radiation dose, facilitating optimized emphysema surveillance protocols for COPD patients.

## S3B-SPCH-5 CT FEATURES OF PATHOLOGICALLY PROVEN SMOKING-RELATED INTERSTITIAL FIBROSIS: COMPARED WITH EMPHYSEMA AND UIP

Chanu Jeong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To differentiate smoking-related interstitial fibrosis(SRIF) from emphysema and usual interstitial pneumonia(UIP) on CT.

**METHODS AND MATERIALS**

From January 2016 to October 2023, total 123 patients who underwent lung surgery and pathologically proven SRIF (n=23), emphysema (n=50), and UIP (n=50) were included. Three radiologists retrospectively reviewed preoperative chest CTs for the presence of centrilobular/paraseptal emphysema, multiple thin-walled cysts(MTWC), honeycomb, traction bronchiectasis, subpleural GGO/reticulation, and centrilobular GGO and compared CT features by subgroups.

**RESULTS**

Centrilobular emphysema, paraseptal emphysema, MTWC, honeycomb, traction bronchiectasis, subpleural GGO/reticulation, and centrilobular GGO were identified in SRIF (100%, 100%, 73.9%, 8.7%, 100%, 100%, 34.8%), emphysema (94%, 60%, 2%, 2%, 4%, 8%, 12%), and UIP (48%, 40%, 0%, 42%, 100%, 100%, 8%) respectively. In univariate analysis of SRIF and emphysema, MTWC traction bronchiectasis, subpleural GGO/reticulation were predictive features of SRIF (p<0.05). In multivariate analysis of SRIF and emphysema, MTWC and subpleural GGO/reticulation were predictive features of SRIF (p<0.05). In both univariate and multivariate analysis of SRIF and UIP, MTWC was predictive features of SRIF (p<0.05).

**CONCLUSION**

MTWC, traction bronchiectasis, and subpleural GGO/reticulation on CT might be differentiating image feature of SRIF from emphysema and UIP.

**CLINICAL RELEVANCE/APPLICATION**

SRIF, emphysema and UIP have overlapping imaging/clinical features but different treatments and prognoses. This study may help differentiate these three diseases through CT imaging findings.

## S3B-SPCH-8 AUTOMATIC SEGMENTATION AND RADIOMIC ANALYSIS FOR DISCRIMINATING PRISM AND COPD PATIENTS

Taohu Zhou (*Presenter*) Nothing to Disclose

**PURPOSE**

It is vital to develop noninvasive approaches with high accuracy to discriminate the preserved ratio impaired spirometry (PRISm) group from the chronic obstructive pulmonary disease (COPD) groups. Radiomics has emerged as an image analysis technique. This study aims to develop and confirm the new radiomics-based noninvasive approach to discriminate these two groups.

**METHODS AND MATERIALS**

Totally 1066 subjects from 4 centers were included in this retrospective research, and classified into training, internal validation or external validation sets. The chest computed tomography (CT) images were segmented by the fully automated segmentation algorithm for radiomics feature extraction. We established the radiomics signature (Rad-score) using the least absolute shrinkage and selection operator algorithm, then conducted tenfold cross-validation using the training set. Last, we constructed a radiomics signature by incorporating independent risk factors using the multivariate logistic regression model.

**RESULTS**

The Rad-score, including 15 radiomic features in whole lung region, which was segmented by the fully automated segmentation algorithm, was demonstrated to be effective for discriminating between PRISm and COPD. Its diagnostic accuracy was improved through integrating Rad-score with a clinical model, and the AUCs were 0.82(95%CI 0.79-0.86), 0.77(95%CI 0.72-0.83) and 0.841(95%CI 0.78-0.91) for training, internal validation and external validation sets, respectively. As revealed by decision curve analysis, our constructed radiomics nomogram showed superior clinical utility.

**CONCLUSION**

The present work constructed the new radiomics-based nomogram and verified its reliability for discriminating between PRISm and COPD.

**CLINICAL RELEVANCE/APPLICATION**

The radiomics nomogram is developed in this study for differentiating PRISm from COPD groups, which may be used as the virtual approach for clinical radiologists.

## S3B-SPER-1 DIAGNOSTIC PERFORMANCE OF ARTIFICIAL INTELLIGENCE IN CHEST RADIOGRAPHS REFERRED FROM THE EMERGENCY DEPARTMENT

Raquel Cano Alonso, MD (*Abstract Co-Author*) Nothing to Disclose
Ana Fernandez Alfonso (*Abstract Co-Author*) Nothing to Disclose
Randall Rojas, MD (*Abstract Co-Author*) Nothing to Disclose
David Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Vicente Martinez de Vega, PhD (*Abstract Co-Author*) Nothing to Disclose
Ana Alvarez Vazquez (*Abstract Co-Author*) Nothing to Disclose
Bianca Umana (*Abstract Co-Author*) Nothing to Disclose
Alejandro Diaz Moreno, MD (*Abstract Co-Author*) Nothing to Disclose
Lucia Sanabria, MD (*Abstract Co-Author*) Nothing to Disclose
Julia Lopez Alcolea, MD (*Presenter*) Nothing to Disclose

### PURPOSE

• Evaluate sensitivity (Se) and specificity (Sp) of an AI software and a radiology resident in interpreting Chest X-ray examinations referred from the Emergency Department (ED) against a senior radiologist (considered the Gold Standard, GS). • Assess the concordance rate between AI and the resident. • Describe the frequency of doubtful cases in each category and determine how many were considered positive by the GS. • Evaluate other variables AI is not trained to detect to analyze its weaknesses and potential diagnoses.

### METHODS AND MATERIALS

We conducted an observational, transversal, double-blind descriptive, and retrospective study, analyzing thoracic radiographs from a sample of 784 patients referred from the ED at our hospital between October and November 2022. The AI is trained to detect five categorical variables: pulmonary nodule, pulmonary opacity, pleural effusion, pneumothorax, and fracture. Each finding is outlined with a bounding box and associated with a confidence label ("positive," "doubtful," or "negative"). We compared the diagnostic performance of AI and a resident against the GS and described the frequency of doubtful results and other variables not evaluated by AI (mediastinal abnormalities, surgical material, and other pulmonary findings).

### RESULTS

Se for fracture and pneumothorax was high (100%), moderate for pulmonary opacity (AI= 76%, resident= 71%), and reasonable for pleural effusion (AI= 60%, resident=67%), with NPV>95% and AUC>0.8. For pulmonary nodule, the resident's Se was moderate (75%), while AI's was low (33%). When AI doubted, only a few of these doubtful diagnoses were considered positive by the GS. The resident doubted less. The Kappa Coefficient between resident and AI was fair (0.3) for all variables, except for pleural effusion, which was moderate (0.5). The prevalence of other variables was: 16% mediastinal abnormalities, 20% surgical material, and 20% other pulmonary findings. Cardiomegaly was the most frequent finding (80%).

### CONCLUSION

Our study evaluates the impact of AI in a real work environment by comparing its diagnostic performance against radiologists. AI achieved high AUC and VPN for all variables, except for pulmonary nodule. Se was high for fracture and pneumothorax and moderate for pulmonary opacity. There was fair concordance between AI and resident.

### CLINICAL RELEVANCE/APPLICATION

Chest radiography is the most common diagnostic imaging examination performed in EDs. The integration of AI software in the evaluation of Chest X-ray examinations could assist clinicians (not only radiologists but also emergency physicians) and enhance accuracy and workflows. This could prioritize the reporting of patients with urgent findings and reduce reading times, benefiting patient care.

## S3B-SPER-2 ASSESSMENT OF THE EFFICACY OF USING A DEEP LEARNING-BASED MODEL TO SCREEN FOR HEART FAILURE ON CHEST RADIOGRAPHS IN EARLY DIAGNOSIS: PRELIMINARY STUDY

Yunkyoung Jun (*Abstract Co-Author*) Nothing to Disclose
DONGSEOP KIM (*Abstract Co-Author*) Nothing to Disclose
Dongbin Na (*Abstract Co-Author*) Nothing to Disclose
Yoona Hwang (*Abstract Co-Author*) Nothing to Disclose
Hyunwoo Kim (*Abstract Co-Author*) Nothing to Disclose
Hyungjoon Jang (*Presenter*) Nothing to Disclose

## PURPOSE

This preliminary study assesses the efficacy of a deep learning-based model to screen for heart failure (HF) using chest radiographs (CXR) for early diagnosis in emergency department settings.

## METHODS AND MATERIALS

This study evaluates a model for the early screening of heart failure (HF) using the publicly available MIMIC-CXR and MIMIC-IV datasets, which comprise data from emergency admissions. The proposed algorithm predicts HF likelihood by detecting pleural effusion in chest X-rays (CXRs) and calculating the cardiothoracic ratio (CTR) to assess cardiac enlargement. The reference standard was HF confirmed by ICD diagnosis codes (4280, 4281, 40291, I502, or I508 from the MIMIC-IV dataset). By applying natural language processing (NLP) to the MIMIC-CXR reports, we identified 7,866 studies mentioning heart failure. Only CXR images from the admission and discharge dates with corresponding ICD codes for HF (1,324 patients) were included as positive cases. Patients without a prior HF diagnosis (2,517 patients) were categorized as negative cases. We evaluated the model's efficacy by measuring sensitivity, specificity, positive likelihood ratio (LR+), and negative likelihood ratio (LR-).

## RESULTS

The model demonstrated a sensitivity of 71% and a specificity of 93%. The LR- of 0.31 indicated that the use of deep learning for early screening of HF on CXRs could moderately reduce the likelihood of disease occurrence when AI model results are negative. The LR+ of 10.14 implied that the use of deep learning for early screening of HF on CXRs could often generate conclusive shifts in probability and increase the likelihood of disease occurrence when AI model results are positive. These results are like a previous prospective, blinded study in the emergency physicians demonstrated a high specificity of 96% and a relatively moderate sensitivity of 59%, along with a positive likelihood ratio (LR+) of 14.6 and a negative likelihood ratio (LR-) of 0.43.

## CONCLUSION

While the AI model shows high specificity (93%) and relatively low sensitivity (71%), it effectively aids in identifying HF in emergency settings when present, though it could under-detect HF. Given the real-life clinical correlation, actual sensitivity might be higher, suggesting that AI could efficiently enhance early HF detection and potentially reduce hospital admissions due to late-stage HF identification.

## CLINICAL RELEVANCE/APPLICATION

Early HF screening and flagging potential HF cases by using the AI model could be useful tools in clinical applications for physicians to decide on diagnosis by combining medical records, ECG findings, or brain-type natural peptide criteria.

## S3B-SPGI-1 AUTOMATED ANALYSIS OF ABDOMINAL BODY COMPOSITION USING MRI: ALGORITHM DEVELOPMENT AND VALIDATION VIA CT COMPARISON

Sun Kyung Jeon, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Jong-Min Kim, PhD (*Abstract Co-Author*) Employee, Medical IP Co, Ltd
Sangjoon Park (*Abstract Co-Author*) Nothing to Disclose
Jeong Min Lee, MD, PhD (*Abstract Co-Author*) Grant, Bayer AG Grant, Canon Medical Systems Corporation Grant, Koninklijke Philips NV Grant, General Electric Healthcare Grant, Guerbet SA Grant, Samsung Electronics Co, Ltd Grant, Bracco Group Grant, Dongkuk Pharma Grant, Starmed Ltd Grant, RF medical Grant, Siemens AG Speakers, Bayer AG Speakers, Philips Healthcare Speakers, Samsung Medison Speakers, GE Healthcare
Han-Jae Chung (*Abstract Co-Author*) Employee, MEDICAL IP, Co
Ijin Joo, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a deep learning-based algorithm for analyzing abdominal body composition through fully-automated volumetric segmentation of MRI and validate its effectiveness via comparison with CT analysis.

### METHODS AND MATERIALS

A 3D nnU-Net-based deep learning algorithm for MRI was developed to perform fully-automated segmentation of three body components: abdominal visceral fat [AVF], abdominal subcutaneous fat [ASF], and skeletal muscle [SM]. This algorithm utilized 105 whole-body MRI dual-echo imaging scans acquired at 3T as input. Its segmentation performance was evaluated on dual-echo in-phase imaging in an external dataset consisting of 67 3T abdominal MRI scans, using the dice similarity coefficient (DSC). Inter-modality correlation and reliability between MRI-based and CT-based measurements of each body composition was assessed using the Pearson's correlation analysis and intraclass correlation coefficient (ICC) for both 2D (area [cm2] at L3 level) and 3D (volumetric [cm3]) approaches in 59 patients with both MRI and CT examinations.

### RESULTS

The developed algorithm achieved mean (± standard deviation) DSCs of 0.862 (± 0.077), 0.923 (± 0.045), and 0.920 (± 0.036), for the 3D segmentation of AVF, ASF, and SM on MRI, respectively, in the external test dataset. Additionally, for all AVF, ASF, and SM, MRI-based measurements demonstrated robust correlation (Pearson r = 0.971, 0.960, and 0.981 for 2D; and 0.993, 0.959, and 0.946 for 3D, respectively; Ps<0.001) and excellent agreement (ICC = 0.979, 0.990, and 0.980 for 2D; and 0.996, 0.978, and 0.967 for 3D, respectively) with CT-based measurements.

### CONCLUSION

Our deep learning-based algorithm provides accurate 3D segmentation of abdominal fat and muscle components on MRI, exhibiting strong correlation and agreement with CT-based measurements, thus showcasing its potential for efficient body composition analysis.

### CLINICAL RELEVANCE/APPLICATION

Automated MRI body composition analysis algorithm enables precise and efficient quantification of abdominal fat and muscle components, facilitating early detection and monitoring of conditions like visceral obesity and sarcopenia.

## S3B-SPGI-10 CHOLANGIO-NET: A DEEP LEARNING APPROACH FOR THE EARLY DETECTION OF CHOLANGIOCARCINOMA USING MRI

Yashbir Singh, PhD, MEng (*Presenter*) Nothing to Disclose

### PURPOSE

The primary aim of this study is to evaluate the efficacy of a deep learning model, specifically the 3D-DenseNet121, in detecting perihilar cholangiocarcinoma (CCA) in patients with primary sclerosing cholangitis (PSC) through MRI scans. This research aims to establish a more reliable early CCA identification method, potentially increasing the number of patients eligible for curative interventions.

### METHODS AND MATERIALS

We reviewed 310 adult patients diagnosed with large-duct PSC across multiple centers. Excluding 13 patients due to inadequate image quality, 297 were included, split into derivation (150 patients, 64 CCA cases) and validation (147 patients, 65 CCA cases) cohorts. The derivation cohort was used to train the 3D-DenseNet121 model using five-fold cross-validation. The model's best fold performance was then applied to the validation cohort to predict CCA presence.

### RESULTS

The model displayed robust diagnostic accuracy in the derivation cohort, with AUC scores of 91%, 96%, 94%, 93%, and 94% across the folds. The separate validation cohort effectively differentiated between PSC patients with and without CCA, achieving an overall sensitivity of 88%, specificity of 75%, and AUROC of 81%. These metrics surpassed the performance of traditional radiological assessments, particularly in identifying CCA cases.

### CONCLUSION

The findings underscore the potential of the 3D-DenseNet121 deep learning model to enhance early CCA detection in PSC patients via MRI. The model outperformed standard radiological methods and demonstrated high sensitivity and specificity, particularly in complex cases.

### CLINICAL RELEVANCE/APPLICATION

This study highlights a promising advancement in the diagnostic processes for PSC-associated CCA, suggesting that deep learning could play a crucial role in early detection and decision-making for potentially curative treatments. Further research and validation are necessary to confirm these results and facilitate the integration of such models into routine clinical practice, potentially improving outcomes for this high-risk patient population.

## S3B-SPGI-11 DWI OF THE RECTUM WITH DEEP LEARNING RECONSTRUCTION: COMPARISON OF PROPLLER, REDUCED FOV, AND CONVENTIONAL DWI

### PURPOSE

The purpose of this study was to compare the image quality and diagnostic ability of periodically rotated overlapping parallel lines with enhanced reconstruction (PROPELLER), reduced field of view (rFOV), and conventional diffusion-weighted imaging (cDWI) combined with deep learning reconstruction in the evaluation of rectal tumors.

### METHODS AND MATERIALS

This prospective study included 42 patients with rectal tumors who underwent initial staging or restaging MRI. Written informed consent was obtained. Three sequences of coronal DWI parallel to the tumor were obtained using deep learning reconstruction: PROPELLER-DWI, rFOV-DWI, and cDWI. The signal-to-noise ratios (SNRs) were measured on the 3 sequences. Two radiologists independently evaluated the image quality of DWI and assessed the extramural tumor spread, extramural venous invasion (EMVI), and response to chemoradiotherapy using T2-weighted imaging and DWI. The 5-point image quality scores were compared with Friedman's test. The diagnostic performance was compared with Cochran's Q test in 26 patients who underwent surgery after MRI without additional therapy.

### RESULTS

The SNR was significantly highest with PROPELLER ($P < 0.05$). In the image quality assessment, PROPELLER-DWI had significantly the least artifacts and distortion, but the worst noise for both readers ($P < 0.05$). rFOV-DWI showed significantly the best sharpness for both readers ($P < 0.05$). For overall image quality and rectal/tumor conspicuity, PROPELLER-DWI and rFOV-DWI were significantly superior to cDWI in both readers ($P < 0.05$), and PROPELLER-DWI was significantly the best in 1 reader ($P < 0.05$). Of the 42 patients, poor image quality (score 1 and 2) was found in 5 and 1 patient with PROPELLER-DWI, 14 and 6 with rFOV-DWI, and 29 and 25 with cDWI by the 2 readers. The accuracies were the highest with PROPELLER-DWI for both readers regarding EMVI and complete response, though not significant.

### CONCLUSION

PROPELLER-DWI of the rectum with deep learning reconstruction can provide high image quality by reducing artifacts and distortion, and may increase the diagnostic performance for the assessment of rectal cancer.

### CLINICAL RELEVANCE/APPLICATION

PROPELLER-DWI with deep learning reconstruction may have the potential to improve the assessment of local tumor extent and treatment response in rectal cancer.

## S3B-SPGI-12 APPLICATION OF A COMBINED CLINICAL PREDICTION MODEL BASED ON ENHANCED T1WI FULL VOLUME HISTOGRAM IN PERINEURAL INVASION AND LYMPHOVASCULAR INVASION IN RECTAL CANCER

Bin Huang (*Abstract Co-Author*) Nothing to Disclose
Yumeng Zhang (*Abstract Co-Author*) Nothing to Disclose
Yuntai Cao, MS,MS (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to use a combined clinical prediction model based on enhanced T1WI full-volume histogram to predict preoperative perineural invasion (PNI) and lymphovascular invasion (LVI) in rectal cancer.

### METHODS AND MATERIALS

We included a total of 68 PNI patients and 80 LVI patients who underwent surgical resection and pathological confirmation of rectal cancer from two medical institutions. According to the PNI/LVI status, patients were divided into PNI positive group (n=39), the PNI negative group (n=29), LVI positive group (n=48), and the LVI negative group (n=32). All patients underwent 3.0T magnetic resonance T1WI enhanced scanning. We use Firevoxel software to delineate the region of interest (ROI), extract histogram parameters, and perform univariate analysis, LASSO regression, and multivariate logistic regression analysis in sequence to screen for the best predictive factors. Then, we constructed a clinical prediction model and plotted it into a column chart for personalized prediction. Finally, we evaluate the performance and clinical practicality of the model based on the area under the curve (AUC), calibration curve, and decision curve.

### RESULTS

Multivariate logistic regression analysis found that variance and the 75th percentile were independent risk factors for PNI, while maximum and variance were independent risk factors for LVI. The clinical prediction model constructed based on the above factors has an AUC of 0.734 (95% CI: 0.591-0.878) for PNI in the training set and 0.731 (95% CI: 0.509-0.952) in the validation set; The training set AUC of LVI is 0.701 (95% CI: 0.561-0.841), and the validation set AUC is 0.685 (95% CI: 0.439-0.932).

### CONCLUSION

This study indicates that the combination of enhanced T1 WI full-volume histogram and clinical prediction model can be used to predict the perineural and lymphovascular invasion status of rectal cancer before surgery, providing valuable reference information for clinical diagnosis.

### CLINICAL RELEVANCE/APPLICATION

This study is based on the parameters of T1WI enhanced full volume histogram analysis, combined with the advantages of clinical prediction models, and proposes a new method to predict the neural and vascular invasion of rectal cancer. It provides useful reference information for patients to develop personalized diagnosis and treatment plans and evaluate the prognosis of rectal cancer.

## S3B-SPGI-13 DEEP LEARNING-BASED CT IMAGE RECONSTRUCTION: IMAGE QUALITY EVALUATION IN AMPULLARY AND PERIAMPULLARY LESIONS

Min Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Shi Tian Wang (*Abstract Co-Author*) Nothing to Disclose
Xuan Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Jia Xu (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the effect of a deep learning reconstruction (DLR) method on the conspicuity of ampullary and periampullary lesions on abdominal CT image, in comparison with iterative reconstruction (IR) algorithms (hybrid IR [AIDR3D]) and conventional filtered back projection (FBP).

### METHODS AND MATERIALS

This retrospective study included 30 patients who underwent contrast-enhanced abdominal imaging at our hospital between December 2021 and November 2023 with ampullary and periampullary lesions (include ampullary cancer, ampullary adenoma, distal common bile duct cholangiocarcinoma, duodenal adenocarcinoma, pancreatic adenocarcinoma). The arterial and portal venous phase scan data were reconstructed to obtain DLR (body and body sharp), HIR (AIDR3D, FC08) and FBP (FC08). Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of the lesions, bile duct, pancreas, duodenum wall, liver, as well as image noise (which was calculated as the SD of the CT values for anterior subcutaneous fat) were compared among the four datasets (DLR body, DLR body sharp, AIDR3D, FBP). CNR of the lesions were calculated as follow: CNR lesion to pancreas = (HU[lesion] - HU[pancreas])/SD[fat],CNR lesion to bile duct = (HU[lesion] - HU[bile duct])/SD[fat], CNR lesion to duodenum wall = (HU[lesion] - HU[duodenum wall])/SD[fat]. In qualitative image analyses, two radiologists independently ordered images (best: 4, worst: 1) based on the visual image quality. The Friedman and the Dunn-Bonferroni post-hoc tests were used for comparison.

### RESULTS

DLR body and DLR body sharp images yielded significant higher SNR and CNR than FBP and AIDR3D images in all regions of interest in both arterial and portal venous phases (all $P<0.05$). DLR body (arterial: 11.86±3.45, portal venous: 11.84±2.60) and DLR body sharp (12.82±3.04, 12.54±2.16) images showed significant lower image noise than FBP (28.1±6.70, 29.09±5.46) and AIDR3D (17.74±4.54, 18.31±4.03) in both arterial and portal venous phases (all $P<0.05$). AIDR3D showed significant higher SNR and CNR, and lower image noise than FBP images (all $P<0.05$). DLR body (arterial: 3.83[3;4], portal venous: 3.87[3;4]) and DLR body sharp (3.17[3;4], 3.13 [3;4]) images obtained higher scores than FPB (1,1) and AIDR3D (2,2) (all $P<0.05$). There were no significant differences in CNR, image noise, as well as qualitative scores between DLR body and DLR body sharp images (all $P>0.05$).

### CONCLUSION

DLR images yield significant lower the image noise, higher SNR and CNR compared to FBP and AIDR3D images. DLR images showed the best visual image quality of the ampullary and periampullary lesions.

### CLINICAL RELEVANCE/APPLICATION

DLR method can improve the image quality, resulted in a better observation of the ampullary and periampullary lesions.

## S3B-SPGI-3 DEEP LEARNING FOR AUTOMATED SEGMENTATION AND PREDICTION OF RECTAL CANCER ON T2-WEIGHTED MAGNETIC RESONANCE IMAGES

Sung Kyoung Moon (*Abstract Co-Author*) Nothing to Disclose
Myung-Won You, MD (*Abstract Co-Author*) Nothing to Disclose
Seong Jin Park, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Choongwui Cho, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop deep learning-based automated segmentation model for rectal cancer on T2-weighted(T2W) magnetic resonance(MR) images

### METHODS AND MATERIALS

A total of 212 patients who underwent baseline MR for rectal cancer were retrospectively enrolled from July 2007 to November 2018. Either the axial or coronal plane of the T2W images that best represented the tumor mass was selected for each patient, and an experienced radiologist labeled the mass on each slice of the entire tumor mass. After excluding 2 patients with erroneous images, 170 patients were grouped into training datasets and 40 patients were grouped into test datasets in an 8:2 ratio. Attention U-Net was trained on the T2W images of the training datasets to classify each voxel as tumor or non-tumor.

### RESULTS

At the stage of testing, the accuracy, intersection over union (IoU), and Dice similarity coefficient (DSC) were used to quantitatively evaluate the performance of tumor segmentation. Internal validation datasets selected from training datasets before training (1% of 1533 images) showed 99.40 % accuracy, 68.06% IoU, and 80.72% DSC. The accuracy, IoU, and DSC of the test datasets (437 images) were 98.88 %, 46.05 %, and 61.99 %.

### CONCLUSION

Deep learning-based automated segmentation model can predict rectal cancer with fair diagnostic ability.

### CLINICAL RELEVANCE/APPLICATION

Automated segmentation of rectal cancer using deep learning can aid both radiologists and clinicians in patient care.

## S3B-SPGI-4 HEPATIC STEATOSIS PREDICTION IN ABDOMINAL CT SCANS OF LIVING DONORS FOR LIVER TRANSPLANTATION USING DEEP LEARNING

Hyunjung Park, MSc (*Abstract Co-Author*) Nothing to Disclose
Namkug Kim, PhD (*Abstract Co-Author*) Stockholder, Anymedi, Inc
Jongjun Won, BS (*Abstract Co-Author*) Nothing to Disclose
Hyunseok Lim, MS (*Presenter*) Nothing to Disclose

### PURPOSE

To predict a fatty liver (FL) severity on abdominal CT images of living donors for liver transplantation using deep learning.

### METHODS AND MATERIALS

A total of 5,468 cases of abdominal CT scans from living donors and their liver needle biopsy data prior to liver transplant surgery at a tertiary hospital from 2004 to 2023 were obtained. The dataset was initially split into internal (N = 574) and external (N = 106) datasets based on CT scans hospitals. The internal dataset was subdivided into training, validation, and test sets (4,193:573:574) for model training. From CT scans, three consecutive axial slices showing the largest areas of liver and spleen were selected as 3-channel inputs. The ImageNet pretrained Resnet50 was fine-tuned to classify three classes of fatty liver severity including normal, mild, and moderate to severe using cross-entropy loss and to predict the steatosis severity value using mean-squared-error loss . Each case was categorized into three steatosis severity classes: normal (<5%) (N = 3,405), mild (5-33%) (N = 1,784), moderate to severe (>33%) (N = 279). The ground truth of severity class and steatosis severity value was determined based on the biopsy results. The sampling rate for the moderate to severe groups doubled in a training set to address the class imbalance issue. We compared the performance of the classification and regression models with their classification accuracy by converting the predictions of the regression model into the previously mentioned three classes.

### RESULTS

The classification model had an accuracy of 0.683, sensitivity of 0.489, and F1 score of 0.505 across three fatty liver severity classes. The regression model achieved a concordance correlation coefficient (CCC) of 0.644, root mean squared error (RMSE) of 0.067, and mean squared error (MAE) of 0.039. When the regression results were classified into 3 classes, the model had an accuracy of 0.751, sensitivity of 0.503, and F1 score of 0.515. Both models tended to predict moderate/severe cases as mild due to data imbalance.

### CONCLUSION

Our regression models could better predict 3-classes of fatty liver severity to classification model using only abdominal CT images. To overcome the performance limitations caused by imbalances, better sampling strategies and better generative models such as different model would be required.

### CLINICAL RELEVANCE/APPLICATION

Based on biopsy results of liver donors for evaluating steatosis, functional prediction with deep learning using abdominal CT could be used as screening tool for finding suspected steatosis patients without the need for biopsy. This non-invasive approach has the potential to improve patient welfare.

## S3B-SPGI-5 THE IMPACT OF DEEP LEARNING RECONSTRUCTION ALGORITHM ON THE QUALITY OF ABDOMINAL IMAGES IN GASTRIC DISEASE PATIENTS BASED ON NEW DUAL INSTANTANEOUS CUT ENERGY SPECTRUM MODE

Jing Wang (*Abstract Co-Author*) Nothing to Disclose
Ya Wang (*Presenter*) Nothing to Disclose

### PURPOSE

The Impact of Deep Learning Reconstruction Algorithm on the Quality of Abdominal Images in Gastric Disease Patients Based on New Dual Instantaneous Cut Energy Spectrum Mode

### METHODS AND MATERIALS

Prospective collection of 47 patients for energy spectrum imaging (GSI) mode scanning, four sets of original images with different weights of ASiR-V40%, DLIR-L, DLIR-M, and DLIR-H were reconstructed, with a layer thickness of 1.25 mm. Record the dose length product ED (mSv) for each patient scan=DLP (mGy * cm) x ?, among ? Group as conversion factor, abdomen ?= 0.015mSv/(mGy * cm). Select abdominal venous phase images, use spectral analysis software GSI Viewer to delineate the area of interest (ROI, area approximately 50-150mm2) at the same level, measure abdominal aorta, gastric lesions, and left vertical muscle, further post-process to obtain CT values and noise (SD) of 70 keV, water iodine, and iodine water single energy images in each ROI, and calculate signal-to-noise ratio (SNR).

### RESULTS

The DLP of abdominal energy spectrum venous phase images in 47 patients was (504.07 ± 57.63) mGy * cm. In the same single energy image, there was no statistically significant difference in CT values among different reconstruction algorithms and DLIR levels (P>0.05). Among them, the CT values of 40% of the abdominal aorta in the ASiR-V40% of the 70keV, water iodine, and iodine water single energy images were (167.59 ± 20.04; 1017.91 ± 6.06; 57.54 ± 7.68) Hu, respectively; In the same single energy image, with different reconstruction algorithms and different DLIR levels, the SD value of the single energy image gradually decreases and the SNR gradually increases, resulting in a significant improvement in image quality. Among them, the SD values of the abdominal aorta for 70 keV, water iodine, iodine water single energy images ASiR-V40%, DLIR-L, DLIR-M, DLIR-H are (24.20 ± 1.95; 21.86 ± 3.14; 19.09 ± 3.26; 14.54 ± 3.23) Hu, (10.08 ± 1.17; 9.46 ± 1.18; 8.10 ± 0.90; 5.95 ± 0.79) Hu, (6.03 ± 0.82; 5.16 ± 1.02; 4.75 ± 1.23) Hu, and (6.03 ± 0.82; 5.16 ± 1.02; 4.75 ± 1.23) Hu, respectively. 2; 3.87 ± 1.28) Hu; And the SD value and SNR showed statistically significant differences between groups (P<0.05). The subjective scores of reconstructed images using different algorithms showed statistically significant differences (P<0.001).

### CONCLUSION

Deep learning reconstruction technology based on new dual instantaneous cut energy spectrum mode can optimize the quality of abdominal energy spectrum images

**CLINICAL RELEVANCE/APPLICATION**

Further improving the quality of abdominal energy spectrum images using depth reconstruction technology based on new dual instantaneous cut energy spectrum scanning mode without increasing radiation dose

## S3B-SPGI-9 A FORGOTTEN CORNER: IMAGING SIGNS OF ILEOCECAL VALVE IN CROHN'S DISEASE AND THEIR RELATIONSHIP TO DISEASE ACTIVITY

Li Shi, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The imaging features of the ileocecal valve (ICV) in Crohn’s disease (CD) patients have been poorly studied; therefore, little is known about their role in the course of CD. We aimed to summarize the imaging signs of the ICV in CD patients, explore their relationship with disease activity, and evaluate the correlation between ICV radiological and endoscopic findings.

**METHODS AND MATERIALS**

This retrospective study included 93 patients who simultaneously underwent endoscopic and radiological examinations; these patients were divided into Group 1 (G1, Simple Endoscopic Score for Crohn’s Disease [SES-CD] =3, n=57) and Group 2 (G2, SES-CD <3, n=36). The ICV where the terminal ileum projects into the caecum was located. The shape of the ICV was categorized as the labial, papillary, fatty infiltration, or deformed/indiscernible types. The height and hyperenhancement pattern of the ICV also were recorded. Disease remission was defined as a CRP concentration <5 mg/dl and an SES-CD <3. The follow-up endpoint was the time occurring penetrating lesion/surgery at the ileocecal area or September 30, 2023 if absent of adverse clinical outcome.

**RESULTS**

The shape of the ICV was significantly different between the two groups (P =0.007) and changed dynamically according to disease activity. The papillary and deformed/indiscernible types were the main ICV shapes on CTE at baseline (both 47.4% in G1; 52.8% and 22.2% in G2, respectively), and the deformed/indiscernible type not only accompanied a higher SES-CD than the other three types but was also a risk factor affecting CD remission (hazard ratio, 1.342). The fatty infiltration type may be related to remission. A moderate positive correlation in ICV shape was found between the CTE and endoscopy results (Cramer's V =0.325, P <0.0001). In addition, persistent hyperenhancement of the ICV during follow-up might suggest active CD.

**CONCLUSION**

The shapes and enhancement patterns of the ICV on CT may help evaluate CD activity and offer essential messages for clinical treatment, especially when patients with Crohn’s disease cannot accomplish endoscopic examination or endoscopy cannot reach the ileocecal valve area when intestinal stenosis or severe anal lesions are present.

**CLINICAL RELEVANCE/APPLICATION**

This study provided effective auxiliary information for clinicians to evaluate CD activity.

Vishnu Murthy, BA (*Presenter*) Nothing to Disclose

### PURPOSE

Prior studies in the pre-multiparametric MRI (mpMRI) era have shown that more than 25% of clinically significant prostate cancer (csPCa) at biopsy is downgraded to indolent prostate cancer after robotic-assisted laparoscopic prostatectomy (RALP). This project aims to assess associations between mpMRI and upgrading of prostate cancer from biopsy-confirmed histopathology (BCHP) to whole-mount histopathology (WMHP).

### METHODS AND MATERIALS

In this retrospective study, we identified patients who underwent both mpMRI-ultrasound fusion biopsies and RALP from 2009 to 2022. Clinicodemographic, mpMRI, and histopathologic data were extracted from our prospectively maintained Integrated Diagnostics database with IRB and HIPAA approval. 399 true positive mpMRI lesions from 333 patients were mapped into a sector map, described in Prostate Imaging Reporting and Data System (PI-RADS) v2.1, for the standardized prostate segmentation model. Lesions were identified as being upgraded, downgraded, or isograded based on changes in their Gleason Grade from BCHP to WMHP. The number of lesions in each sector of the prostate that was upgraded, downgraded, or isograded was recorded, and adjusted weights were calculated based on the relative prevalence of lesions in each sector. The sum of adjusted weights was calculated for each region of the prostate (transition vs. peripheral zone, anterior vs. posterior, base vs. midgland vs. apex, and left vs. right). A modified $?^2$ test was used to assess associations between mpMRI lesion location, lesion PI-RADS score (<4 vs. >4), lesion size (<1cm vs. 1-2cm vs. >2cm), race (Black vs. Non-Hispanic White), and upgrading.

### RESULTS

Lesions in the peripheral zone and posterior region of the prostate had a higher likelihood of being upgraded than lesions in the transition zone and anterior region respectively ($p < 0.001$). Lesions in the base vs. midgland vs. apex and the left vs. right side of the prostate did not have a statistically significant difference in rates of upgrading vs. non-upgrading ($p = 0.93$ and 0.76 respectively). Lesion PI-RADS score, size, and race did not predict upgrading ($p = 0.93$; $p = 0.36$; $p = 0.28$ respectively). Table 1 summarizes the results of our analysis.

### CONCLUSION

mpMRI lesions in the peripheral zone and posterior region were more likely to be upgraded than those in the transition zone and anterior region respectively. Multicenter, prospective trials are necessary to further generalize the role of mpMRI in predicting discrepancies between BCHP and WMHP.

### CLINICAL RELEVANCE/APPLICATION

Linking prostate mpMRI with BCHP and WMHP within the same cohort allows us to directly assess the role of mpMRI in predicting upgrading patterns, which can improve the diagnosis and local treatment planning of csPCa.

## S3B-SPGU-3 AUTOMATIC BLADDERAND TUMORSEGMENTATION FROM CTUROGRAPHYIMAGES USING U-NET

### PURPOSE

Bladder cancer is the most prevalent malignancy within the urinary system. Bladder and tumor segmentation from CT images is an essential preorder procedure for planning pelvic radiotherapy treatment and evaluating the treatment response in bladder cancer patients. Thus, this study aimed to develop

a deep learning model for the segmentation of the bladder and tumors from CT Urography (CTU) images, which will serve as an integral part of a comprehensive system designed to assist in the management of bladder cancer patients.

**METHODS AND MATERIALS**

A dataset of 381 cases from two centers was used with Institutional Review Board approval. Including 280 training cases (275 with masses, 5 normal bladders), 56 internal validation cases(54 with masses, 2 normal bladders), and 45 external validation cases (44 with masses, 1 normal bladder). The dataset included nephrographic phase CTU scans with 0.625mm and 1mm slice thicknesses, where patients with lesions had definitive pathological confirmation. A reference standard, consisting of manual bladder and tumor contours for all cases, was initially provided by an experienced radiologist and was subsequently reviewed by a senior radiologist. The U-Net-based segmentation model was trained by the self-configuring nnU-Net framework, in which the model was trained in a five-fold manner and the ensemble prediction was used. Besides, the test-time augmentation was employed to further improve the model performance. The segmentation performance was quantified in the testing set by dice similarity coefficient (DSC), 95th-percentile Hausdorff distance (95% HD), and mean surface distance (MSD).

**RESULTS**

Results show that our approach achieves superb segmentation accuracy. Specifically, in the internal validation set, the U-Net-based model demonstrates excellent performance in segmenting the bladder, with a DSC of 97.9±5.6%, a 95% HD of 0.48±1.72mm, and an MSD of 3.43±10.75mm. The model's performance was even more precise in the external validation set, achieving a DSC of 98.4±1.9%, a 95% HD of 0.34±0.56mm, and an MSD of 2.52±4.21mm. When segmenting tumors, the model achieved a DSC of 76.6±27.3%, a 95% HD of 3.70±5.81mm, and an MSD of 19.15±23.83mm in the internal validation set, while the model's performance was slightly lower in external validation set but still robust, with a DSC of 74.4±30.6%, a 95% HD of 3.73±4.63mm, and an MSD of 22.08±24.01mm.

**CONCLUSION**

While the tumor segmentation performance was inferior to the segmentation of bladder, the U-Net-based model showed satisfied accuracy in segmenting bladder and tumors, with particularly high precision in delineating the bladder.

**CLINICAL RELEVANCE/APPLICATION**

The model has shown to be a valuable tool for detecting bladder cancer and assessing treatment responses.

## S3B-SPGU-4 ASSOCIATION BETWEEN DEEP LEARNING ESTIMATED SARCOPENIA ON ABDOMINAL CT AND 24-HOUR URINE MEASUREMENTS INFORM RISK OF KIDNEY STONE FORMATION

Anant Madabhushi, PhD (*Abstract Co-Author*) Stockholder, Elucid Bioimaging Inc;License agreement, Elucid Bioimaging Inc;Stockholder, Inspirata, Inc;Grant, Inspirata, Inc;Scientific Advisory Board, Inspirata, Inc;Researcher, AstraZeneca PLC;Scientific Advisory Board, AstraZeneca PLC
Viraj Master, MD (*Abstract Co-Author*) Nothing to Disclose
Dattatraya Patil, MBBS,MPH (*Abstract Co-Author*) Nothing to Disclose
Edouard Nicaise (*Abstract Co-Author*) Nothing to Disclose
Benjamin Schmeusser (*Abstract Co-Author*) Nothing to Disclose
Nisarg Negi (*Abstract Co-Author*) Nothing to Disclose
Rakesh Shiradkar, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Sarcopenia or progressive loss of skeletal muscle has been linked to increased risk of stone formation. Deep learning (DL) allows for automated segmentation of regions of interest on CT. We sought to identify association between DL estimated sarcopenia and kidney stone risk factors derived from 24-hour urine analysis.

**METHODS AND MATERIALS**

We identified CT scans of N=493 patients with kidney disease. Skeletal and intra-fat muscle, sub-cutaneous and visceral fat regions of interest (ROI) were manually segmented at the 3rd lumbar vertebra (L3) using a commercial software (sliceOmatic; Tomovision). N=133 CT scans were used to train a UNet based deep learning (DL) model to segment the above 4 ROIs and evaluated in terms of dice similarity coefficient (DSC). DL model was used to segment skeletal muscle on N=360 studies with kidney stones who underwent a 24-hour urine analysis. Skeletal muscle area was used to compute the skeletal muscle index (SMI) and identify presence of sarcopenia using previously identified gender and age specific thresholds from Framingham study. 22 metabolic measurements associated with risk of kidney stone formation were obtained from 24-hour urine analysis and differences between patients with and without sarcopenia were evaluated using the ranksum test ($p<0.05$).

**RESULTS**

DL accurately segmented the skeletal muscle regions on L3 slice of CT with a mean DSC of 0.90 ± 0.11 and mean absolute error of 3.3 for SMI. An average of 7.5 minutes is needed for manual segmentation of ROIs while the DL can obtain them under a second. SMI obtained from DL showed significant differences in 12 of 22 urine measurements (salt, acid concentrations) between patients with and without sarcopenia. Given that all patients considered in this study were diagnosed with nephrolithiasis, patients with sarcopenia had relatively lower concentrations of urine metabolites associated with higher risk of kidney stone formation. This indicates a need to identify alternate factors accounting for body composition to standardize risk thresholds.

**CONCLUSION**

Deep learning based segmentation can be used to automate body composition measurements from CT which can be used to identify a variety of risk factors associated with kidney stone formation. Further studies are warranted to standardize thresholds of various biomarkers for kidney stone formation and evaluate the role of body composition.

**CLINICAL RELEVANCE/APPLICATION**

Automated segmentation using deep learning methods on CT allows for accurate, rapid estimation of skeletal muscle and sarcopenia. Utilization of established reference ranges on 24-hour urine analysis to guide dietary and pharmacological management in prevention of recurrent nephrolithiasis may not be appropriate for patients with anatomic sarcopenia.

## S3B-SPGU-5 AUTOMATED PROSTATE SEGMENTATION MODEL TO ASSESS THE PROSTATE ZONAL GROWTH PATTERN IN BENIGN PROSTATIC HYPERPLASIA

Gu Mu Yang Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Jiahui Zhang (*Abstract Co-Author*) Nothing to Disclose
Hao Sun, MD (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose

Xiaoxiao Zhang (*Abstract Co-Author*) Nothing to Disclose
Li Chen (*Abstract Co-Author*) Nothing to Disclose
Xin Bai III, MD (*Abstract Co-Author*) Nothing to Disclose
Lili Xu (*Presenter*) Nothing to Disclose

**PURPOSE**

To analyze the growth patterns of different zones of the prostate with the assistance of a previously developed automatic segmentation model.

**METHODS AND MATERIALS**

Consecutive benign prostatic hyperplasia (BPH) patients who had undergone at least two prostate MRI scans at our institution between December 2014 and December 2022 were identified. The deep learning model used in this study was previously developed to segment the prostate transition zone (TZ) and peripheral zone (PZ). The prostate zonal volumes and morphological features were computed from the segmentation results, and the annual absolute growth rate (AGR) and relative growth rate (RGR) of the volumes and morphological features were calculated.

**RESULTS**

A total of 398 patients with 902 MRI scans were included in the study (median age 62.0 [57.0-68.0] years). The whole-gland volume and TZ volume (TZv) increased with age, while the PZ volume (PZv) decreased with age (all $p < 0.05$). The median AGR was 2.22 mL/year for TZv and -0.15 mL/year for PZv. The RGR was 7.05%/year for TZv, and the value for the TZ base was significantly higher than that for midgland ($p = 0.003$). Patients aged 51-60 years had a significantly higher RGR than those aged = 50 years ($p < 0.05$). The RGR of PZv was -0.94%/year. While there was no significant difference among the prostate apex, midgland, and base. The RGR of PZv in patients aged 51-60 years was significantly lower than that in patients aged = 50 years ($p < 0.05$).

**CONCLUSION**

The prostate gland undergoes differential growth patterns between the TZ and PZ, which also varying with age. Additionally, the growth pattern of the TZv differed between the base and midgland. The 51-60 age group appears to be a turning point for TZv growth rate increases and PZv growth rate decreases.

**CLINICAL RELEVANCE/APPLICATION**

Our study revealed the development of the prostate zonal volumes and morphological features in the progression process of benign prostatic hyperplasia with the assistance of the deep learning-based segmentation model.

## S3B-SPGU-6 ASSOCIATION RENAL SURFACE NODULARITY WITH THE RENAL INJURY PROGRESSION IN PATIENTS WITH ARTERIAL HYPERTENSION

Qiong Wu (*Abstract Co-Author*) Nothing to Disclose
Wei Xing, MD (*Abstract Co-Author*) Nothing to Disclose
Jie Chen (*Abstract Co-Author*) Nothing to Disclose
Liang Pan, MD (*Abstract Co-Author*) Nothing to Disclose
Jiule Ding (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the association of Renal Surface Nodularity (RSN) with the renal injury progression in patients with arterial hypertension.

**METHODS AND MATERIALS**

This retrospective cohort study included patients with arterial hypertension, who underwent renal artery CT angiography or abdominal enhanced CT scans. Clinical and radiological data were collected. Patients with bilateral renal surface irregularities observed on CT imaging were defined as the RSN group, then the patients without RSN (non-RSN group) were matched to RSN group at a ratio of 1:1 based on age and gender. Baseline demographic, clinical, and radiological data were collected. They were followed up more than 0.5 year. The main endpoint was a reduction in estimated glomerular filtration rate (eGFR) = 20% from baseline or initiation of renal replacement therapy. We developed a self-developed automated method for quantifying RSN, including three surface roughness indicators (nodularity ten-point unevenness height, nodularity maximum height, and nodularity arithmetic mean deviation). Semi-quantitative scoring of RSN was based on both the distribution range of renal surface irregularities and of local indentations depth > 1/2 cortical thickness. A radiologist independently conducted the quantitative and semi-quantitative RSN analysis.

**RESULTS**

This study included 242 patients (median age of 64 years, male 70.25%). Strong positive linear correlations were identified between the quantitative indicators and semi-quantitative score (? > 0.9, all $P < 0.001$). Over a median follow-up period of 38.00 (22.00, 56.25) months, the main endpoint event was present in 44 patients in RSN group and 15 in non-RSN group, indicating a higher risk of renal dysfunction progression in patients with RSN (HR = 2.816, $P < 0.001$). In multivariate Cox regression analysis, after correcting co-existing diabetes and kidney volume, HR was 1.344 (1.117, 1.617) for nodularity ten-point unevenness height, 1.048 (1.004, 1.094) for nodularity maximum height, 1.239 (1.028, 1.494) for nodularity arithmetic mean deviation, and 1.196 (1.074, 1.332) for semi-quantitative scores. They were associated with the renal injury progression (all $P < 0.05$).

**CONCLUSION**

The developed quantitative analysis method for RSN demonstrates robust stability and high concordance with semi-quantitative Scoring. RSN was associated with renal injury progression among patients with arterial hypertension.

**CLINICAL RELEVANCE/APPLICATION**

RSN can potentially serves as an imaging biomarker for the renal injury progression.

## S3B-SPGU-7 ASSESSMENT OF CT-DERIVED PARAMETERS FOR MUSCLE INVASION IN BLADDER CANCER: EXTRACELLULAR VOLUME FRACTION AND TUMOR CONTACT LENGTH

Xuming Wan (*Abstract Co-Author*) Nothing to Disclose
Yongquan Yu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the clinical utility of the extracellular volume fraction (ECV) and tumor contact length (TCL) parameters derived from contrast-enhanced CT in assessing muscle invasion in bladder cancer.

**METHODS AND MATERIALS**

Between October 2021 and September 2023, 46 patients with pathologically confirmed of bladder cancer were enrolled for analysis. patients were devided to non-muscle invasive bladder cancer (NMIBC) and muscle invasive bladder cancer (MIBC) groups according to the pathologically assessment results. All patients were underwent unenhanced and three-phase contrast-enhanced CT preoperatively. TCL was the length which the curves drawn at the base of the tumor where it contacted the bladder wall. CT value from unenhanced and equivalent phases images were measured to calculate tumor ECV fractions. The ECV fraction and TCL were compared between NMIBC and MIBC. The diagnostic performance of ECV, TCL and the combination were assessed with the area under the receiver-operator curve (AUC). AUCs were compared with DeLong test.

**RESULTS**

The ECV and TCL values in the MIBC were both significantly higher than those in the non-MIBC group(35.73±9.01 vs 28.92±9.22, 48.14±16.68 vs 20.41±11.18, both P<0.05). The diagnostic performance of combined ECV and TCL achieved an AUC of 0.97 (95%CI: 0.87-0.99), which was singnificiantly higher than that of ECV (AUC, 0.72 (95%CI: 0.57-0.84) or TCL (0.89 (95%CI: 0.77-0.97)).

**CONCLUSION**

The conbination of CT-based ECV and TCL showed excellent preformance in distinguishing between MIBC and non-MIBC bladder cancers.

**CLINICAL RELEVANCE/APPLICATION**

This non-invasive method can serve as a valuable preoperative supplement for treatment plan for patients with bladder cancer.

## S3B-SPGU-9 AUTOMATED TOTAL KIDNEY VOLUME QUANTIFICATION USING DEEP LEARNING AS A DIAGNOSTIC TOOL FOR ADPKD ON CT SCANS

Hilde Bosmans, PhD (*Abstract Co-Author*) Stockholder, Qaelum NV;Research Grant, Siemens AG;Research Grant, General Electric Company
Frederik De Keyzer (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Koukoutegos (*Abstract Co-Author*) Nothing to Disclose
Raymond Oyen (*Abstract Co-Author*) Nothing to Disclose
Tom Oyen (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate assessment of total kidney volume (TKV) is crucial for monitoring Autosomal Dominant Polycystic Kidney Disease (ADPKD) progression and prediction of renal function decline. This study aimed to develop and validate a fast, AI-based method applied on CT scans without contrast agent injection in a patient follow up study.

**METHODS AND MATERIALS**

A dataset of 72 unenhanced abdominal CT studies and their corresponding segmentation labels were used retrospectively in a 5-fold cross-validation setting to train and validate a 3D residual UNet. The 3D UNet was trained in a patch-based approach using extensive data augmentation (including random intensity shifting, gaussian noise, and flipping in all axes). Unenhanced CT images were resampled at 1.75mm3. The network implementation and training were performed using PyTorch v1.10 and MONAI v1.0, using a single NVIDIA GeForce RTX 3090 GPU. An independent test set of 20 subjects with 2 consecutive scans each was used to test the trained network's ability to assess the functionality. The Mayo Imaging Classification (MIC) was calculated using manual segmentation (by 2 radiology experts) and then compared to AI-based classifications.

**RESULTS**

The 3D UNet achieved an average Dice coefficient of 0.92 for the initial scan and 0.93 for the second scan of the consecutive sequence. The model's reliability in measuring TVK was excellent for both scans with intraclass correlation coefficient (ICC) values of 0.96 and 0.94 (p<.001), respectively, while the average volume error was 12% (95%CI: [5%, 22%]) and 11% (95%CI: [6%, 21%]). In addition, UNet-based renal axes measurements (length, width, and thickness) were supported by high ICC values of 0.94, 0.90, 0.97 and 0.97, 0.97, 0.98 for the two scans respectively (p<.001), demonstrating the model's ability in capturing key renal anatomical descriptors. AI-based classification demonstrated high concordance with manually-derived MIC, with agreement in 85% (34/40) of scans. AI overestimated severity in 5 scans (one MIC higher than manual). The average prediction time measured for a whole abdominal CT was 14.2s.

**CONCLUSION**

From a comparison with manual delineations and MIC classification, it was concluded that the 3D U-Net based measurements of TKV and renal axes from unenhanced CT scans closely match the manual values and the MIC classification.

**CLINICAL RELEVANCE/APPLICATION**

A newly developed AI-based method applied on unenhanced CT scans can offer a robust and standardized approach to TKV measurements in patients with ADPKD. These automated measurements, easily validated by a user/radiologist, could be integrated in every (follow-up) CT scan and provide the data for a (user independent) quantitative evaluation.

Masahiko Nomura, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

It has been suggested that Ultra-high-resolution CT, using an energy integrated detector (also known as high-definition CT: HDCT), and photon counting detectors, have potential for ontological diseases. We hypothesized that newly developed deep learning reconstruction (DLR) for the inner ear can produce better image quality, diagnostic confidence level and abnormality detection on HDCT for the ear than can other reconstruction methods. The purpose of this study was to directly compare external, middle and inner ear evaluations obtained with hybrid-type iterative reconstruction (IR) and with DLR on HDCT for patients without ontological diseases.

### METHODS AND MATERIALS

Twenty inner and middle ears and temporal bones of three males (mean ± standard deviation: 64 ± 14 years) and seven females (55 ± 23 years) were examined using super high-resolution mode for HDCT. Signal-to-noise ratios (SNRs) of the temporal bone surrounding the aural vestibule of the ear and in the vestibule as well as the cerebellar hemisphere, overall image, artifact and detailed evaluation of the visibility of anatomical landmarks in middle and inner ear and temporal bone obtained with the two methods were assessed and statistically compared using the paired t-test or Wilcoxon's signed-rank test.

### RESULTS

Each SNR of DLR was significantly higher than that of hybrid-type IR ($p<0.05$). Overall image quality and artifacts of CT data reconstructed by means of DLR were significantly better than those reconstructed with hybrid-type IR (overall image quality: $p=0.009$, artifacts: $p=0.009$). On comparisons of detailed evaluation of the visibility of anatomical landmarks, CT data for middle ear, inner ear and temporal bone reconstructed by means of DLR scored significantly higher than those reconstructed by means of hybrid-type IR (middle ear: $p=0.01$; inner ear: $p=0.004$; temporal bone: $p=0.009$).

### CONCLUSION

Newly developed DLR showed superior potential to that of hybrid-type IR for better image quality and visualization of anatomical landmarks in middle and inner ears and temporal bones on HDCT used in clinical practice.

### CLINICAL RELEVANCE/APPLICATION

Newly developed DLR showed superior potential to that of hybrid-type IR for better image quality and visualization of anatomical landmarks in middle and inner ears and temporal bones on HDCT used in clinical practice.

## S3B-SPHN-2 THE STUDY OF PARANASAL SINUSES IMAGING USING GEMSTONE SPECTRAL IMAGING CT COMBINED WITH ADAPTIVE ITERATIVE RECONSTRUCTION ALGORITHM

Xiuxiu Tian (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the impact of adaptive iterative reconstruction-Veo (ASIR-V) algorithm on the quality and radiation dose of paranasal sinus CT energy spectrum imaging.

### METHODS AND MATERIALS

Eighty-six patients with suspected paranasal sinus diseases were enrolled and randomly divided into control group (n = 43) and observation group (N = 43). The control group was performed with conventional CT scan, 120 kv, FBP reconstruction, and the observation group was performed with ASIR-40% combined with energy spectrum CT scan, 100 kv,the observation group was scanned with Gemstone Spectral Imaging (GSI) mode and reconstructed with ASIR-V. The dose volume CT dose index (CTDIvol) , dose-length product (DLP) , imaging noise and contrast-to-noise ratio (CNR) on paranasal sinuses lesions, and diagnostic accuracy were compared among the two groups.

### RESULTS

There was no statistically significant difference in the sensitivity, specificity and accuracy of diagnosing paranasal sinus among the two group (P>0.05), while the observation group were higher (91.67% , 85.71% respectively vs 86.84%, 60.00% respectively). The subjective scores of the observation group were higher than those of the control group, while the CTDIvol and DLP were lower than those of the control group, and the difference was statistically significant (P<0.05). There was no significant difference in subjective evaluation noise and CNR between the two groups.

### CONCLUSION

The GSI CT combined with ASIR-V diagnoses paranasal sinus lesions with comparable efficacy and image quality to conventional CT, however, improves diagnostic confidence while reducing radiation dose.

### CLINICAL RELEVANCE/APPLICATION

The combination of Asir algorithm and energy spectrum CT can improve the imaging quality and reduce the radiation dose of patients without increasing the imaging noise, so it can be widely used in clinical practice.

## S3B-SPHN-5 RADIOMICS ANALYSIS BASED ON MRI-DWI FOR EVALUATING THE LYMPH NODE METASTASIS IN NASOPHARYNGEAL CARCINOMA

Jingjun Wu (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of radiomics analysis based on diffusion weighted imaging (DWI) MRI for evaluating the lymph node metastasis in nasopharyngeal carcinoma patients.

### METHODS AND MATERIALS

We retrospectively collected nasopharyngeal carcinoma patients newly diagnosed in our hospital. According to the histopathological examination, the lymph nodes were defined as metastatic lymph nodes (n=81) and non-metastatic lymph nodes (n=43). All patients were randomly assigned to training group and testing group according to 7:3. The DWI images were imported into 3D-Slicer software, and lymph nodes with volume more than 1 cm3 were included and segmented. The 851 radiomics features were extracted, including first-order features, shape features, texture features and wavelet transformed features. The intraclass correlation coeficient test, minimum redundancy maximum correlation (MRMR), least absolute shrinkage and selection operator (LASSO) algorithms were used to gradually select radiomics features. The clinical features were further collected and were used to constructed the clinical and combined model. Logistic regression was used to construct evaluation model. Receiver operating characteristic (ROC) analysis was used to analyze the diagnostic efficacy of the model.

### RESULTS

In present study, the 5 radiomics features were selected and included in the radiomics model, the AUCs were 0.89 in both training and testing group. The clinical feature of ki-67 protein expression level was further included into the combined model, and the AUCs in the training and testing group were 0.92 (95% CI [0.84, 0.97]) and 0.91 (95% CI [0.77, 0.98]), respectively.

### CONCLUSION

The radiomics analysis based on DWI is expected to be used for early noninvasive evaluation of lymph node metastasis in nasopharyngeal carcinoma patients.

### CLINICAL RELEVANCE/APPLICATION

The lymph node metastasis is common in patients with newly diagnosed nasopharyngeal carcinoma, and accurate diagnosis of lymph node metastasis is of great value for personalized treatment strategies. In this study, we found the radiomics features of MRI-DWI may serve as the potential imaging biomarkers for evaluation of lymph node metastasis in nasopharyngeal carcinoma patients. The radiomics analysis was a low-cost and non-invasive way to predict the lymph node metastasis, providing imaging clues for monitoring the node metastasis and assist individualized treatment.

## S3B-SPIN-1 THE VALUE OF ELECTRON CLOUD DENSITY IMAGES OF SPECTRAL CT IN THE MEASUREMENT OF PERIHEMATOMA EDEMA IN PATIENTS WITH SPONTANEOUS INTRACEREBRAL HEMORRHAGE

Qiaoying Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

Spontaneous intracerebral hemorrhage (sICH) is a subtype of stroke with high morbidity and mortality. Many previous studies have shown that perihematoma edema(PHE) is an independent predictor of prognosis, so it is crucial to accurately identify and measure the volume of PHE.At present, the measurement of PHE is based on conventional plain scan CT, but its boundary display is often fuzzy, which is easy to cause large errors, and the repeatability is low. In order to find a more accurate measurement method, this paper will study the value of electron cloud density images for measuring the volume of PHE based on spectral CT.

### METHODS AND MATERIALS

A total of 20 cases of sICH were selected. The first CT scan of patients was performed on spectral CT, and conventional CT images and reconstructed electron cloud density images were collected.The volume of PHE was measured on conventional CT images and electronic cloud density images respectively by two attending doctors, and recording whether the edema boundary is clear.The volume of PHE = total lesion volume-hematoma volume.Total lesion volume= sum of area of each layer (layer thickness is 10mm),same goes for hematoma volume.The volume of PHE measured by two doctors was statistically analyzed by paired T-test and $p<0.05$ was considered statistically significant.Intraclass correlation efficient (ICC) was used to test the consistency of the two methods.

### RESULTS

There were statistical differences in the volume of PHE measured on conventional CT images and on electronic cloud density images in the same patient by doctor1(P=0.012),and same with doctor2(P=0.001).There were statistical differences in the volume of PHE measured by different doctors on conventional CT images in the same patient (P=0.037).There was no statistical difference in the volume of PHE measured by different doctors on electron cloud density images in the same patient (P=0.269).The two doctors determined that on electronic cloud density images the PHE boundary was clear in 85% and 90% of cases, respectively, compared with 65% and 70%, respectively, on conventional CT images. The repeatability of measuring the volume of PHE by two doctors on electron cloud density images (ICC=0.998(P<0.01)) is higher than that on conventional CT images(ICC=0.987(P<0.01)).

### CONCLUSION

The electron cloud density images reconstructed in spectral CT is more clear to show the boundary of PHE than the conventional CT images.The volume of PHE of the same patient measured by different doctors on the electronic cloud density images had little difference ,and it also has better consistency and repeatability.

### CLINICAL RELEVANCE/APPLICATION

The measurement of PHE volume on electron cloud density images in spectral CT can better guide clinical risk grade and prognosis.

## S3B-SPIN-2 TOWARDS LABEL-FREE TUMOR SEGMENTATION TRAINING: SIMULATING TUMOR GROWTH AND GENERATING SYNTHETIC TUMORS IN HEALTHY COMPUTED TOMOGRAPHY IMAGES

Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuxiang Lai (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to evaluate whether data synthesis techniques can address the challenges in "AI for cancer detection" arising from (i) the low prevalence of early-stage tumor examples and (ii) the difficulty radiologists face in detecting and annotating them due to their subtle appearance, small size, and blurry boundaries.

### METHODS AND MATERIALS

We developed a data synthesis technique applicable to computed tomography (CT) that can simulate tumor development in the liver, pancreas, and kidney. This data synthesis is based on an old school algorithm called cellular automata, initially proposed for the Game of Life. Each cell (pixel) is assigned a ‘state’ between zero and ten to represent the tumor population, and a tumor can be developed based on three rules to describe the process of growth, invasion, and death, as well as the tumor-organ interaction. Finally, we integrate the tumor state into the CT scan to generate tumors in different

abdominal organs, allowing for sampling tumors at multiple stages. We collected and annotated a retrospective dataset of 972 subjects (liver: 201, pancreas: 282, kidney: 489 with tumors) and 1,217 healthy subjects as control. A reader study involving three expert radiologists evaluated the realism of synthetic tumors on 150 subjects (50% synthetic). We further used this synthetic data to train AI models and evaluated their performance, particularly for early-stage tumor detection (radius < 20mm), against models trained on real tumors.

**RESULTS**

Radiologist #1 (3-year experience) only achieved mean accuracy of 61.8% (liver: 60.9%, pancreas: 57.1%, and kidney: 67.6%). Radiologist #2 (7-year experience) achieved mean accuracy of 69.9% (69.1%, 65.7%, and 75.0%). Even senior Radiologist #3 (10-year experience) misidentified 47.1% of synthetic tumors as real, with a mean accuracy of 72.2% (68.4%, 72.4%, and 75.8%). In early tumor detection, AI models training on our synthetic tumors achieve Sensitivity of 82.6%, 62.5%, and 58.3%, Specificity of 75.5%, 77.6%, and 84.7%, and DSC of 47.2%, 36.5%, and 18.1%, for liver, pancreatic, and kidney tumors respectively.

**CONCLUSION**

We show the potential of synthetic data for AI cancer research, improving data augmentation, early (small) tumor detection, and accurate boundary segmentation. Furthermore, simulating tumor development in CT scans could substantially benefit medical education by offering detailed longitudinal examples for tumor studies.

**CLINICAL RELEVANCE/APPLICATION**

Synthetic data showed promise to improve AI models in detecting small tumors (radius < 20mm). Larger-scale external validation (N=30,000) has been launched in collaboration with City of Hope (TGen) and University of California, San Francisco to confirm the performance and robustness of these AI models.

## S3B-SPIN-3 AI-DRIVEN CASE SUPPLEMENTATION AUGMENTS AND DIVERSIFIES RESIDENT TRAINING EXPOSURE TO IMPORTANT PATHOLOGY: INITIAL EXPERIENCE IN PRECISION EDUCATION

Antonio Verdone (*Abstract Co-Author*) Nothing to Disclose
Michael P. Recht, MD (*Abstract Co-Author*) Nothing to Disclose
Malte Westerhoff (*Abstract Co-Author*) Employee, Pro Medicus Limited;Stockholder, Pro Medicus Limited
Anna Chen, MD (*Abstract Co-Author*) Nothing to Disclose
William R. Walter, MD (*Abstract Co-Author*) Nothing to Disclose
Renata La Rocca Vieira, MD (*Abstract Co-Author*) Nothing to Disclose
Ryan Cummings, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

A major component of diagnostic radiology resident education is exposure to a wide range of pathology through the daily readouts of clinical cases. However, the breadth of pathology in those cases varies, which may lead to underrepresentation of important but less common pathologies. This study assesses the effectiveness of a precision education curriculum created by supplementation of curated teaching cases based on a LLM's categorization of pathology seen by each resident.

**METHODS AND MATERIALS**

A list of 140 important pathologies (IP) was defined by members of our musculoskeletal (MSK) division in part based on the ABR Core Exam Blueprints. Each pathology was assigned high, intermediate, or low priority for each of three required MSK rotations (PGY2, 3, and 4). A teaching file with multiple examples of each pathology (2885 total cases) was curated by 3 MSK radiologists. A HIPAA compliant GPT-4 model analyzed 3 prior years of resident reports to determine exposure to these pathologies prior to implementation of a precision education curriculum. Over a four-month period, residents on 4-week MSK rotations each received 3 supplemental teaching file cases/day, selected by an algorithm to maximize novelty of pathology based on each resident's prior exposure and PGY level priority. These cases were dictated alongside clinical cases. GPT-4 tracked pathologies seen by each resident, updating exposure daily. Pathologies seen by residents were tallied before and after implementation of the algorithm and compared to a group of 56 MSK rotations (31 PGY-2, 17 PGY-3, and 8 PGY-4) without supplemented cases. Residents who read <20 supplemented cases were excluded. The Mann Whitney U-test was used to analyze differences between groups.

**RESULTS**

12 residents (3 PGY-2, 5 PGY-3, and 4 PGY-4) read >20 supplemental cases on their rotation during the study period. The algorithm increased average number of unique IPs seen by residents in each year of residency: 114% for PGY-2: (average = 32 vs 68, $p<0.01$), 65% for PGY-3: (44 vs 73, $p<0.01$); and 113% for PGY-4: (32 vs. 68, $p<0.01$). Excluding low-priority pathologies, an even greater increase of 227% (18 vs 60, $p<0.01$), 68% (66 vs 39, $p<0.01$) and 112% (64 vs 30, $p<0.01$) was seen in PGYs 2-4, respectively.

**CONCLUSION**

A precision education curriculum based on individualized case supplementation informed by a GPT-4 model significantly increases diversity of important musculoskeletal pathologies seen by residents compared to live clinical cases alone.

**CLINICAL RELEVANCE/APPLICATION**

Categorization of pathology of resident's reports by an LLM enables supplementation of pathology to ensure that residents see the required breadth of pathology.

## S3B-SPIN-4 HOW DO SUB-5-MINUTE NET MRI ACQUISITION TIMES TRANSLATE INTO CLINICAL PRACTICE? A TIME COMPONENT ANALYSIS

Jan Fritz, MD (*Abstract Co-Author*) Institutional research support, Siemens AG;Scientific Advisor, Siemens AG;Patent agreement, Siemens AG;Institutional research support, Johnson & Johnson;Institutional research support, Zimmer Biomet Holdings, Inc;Institutional research support, BTG International Ltd
Kai Tobias Block, PhD (*Abstract Co-Author*) Nothing to Disclose
Roy J. Wiggins, BA (*Abstract Co-Author*) Nothing to Disclose
Jan Vosshenrich, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The scientific literature typically cites the gradient time of MRI protocols, defined as the sum of the net acquisition times of each pulse sequence. However, clinical scan times are longer due to added sequence adjustments, shimming, idle time between sequences, technologist and patient interactions, and repeated pulse sequences. This study explores the transition of accelerated pulse sequence protocols into clinical settings by quantifying the differences between protocol gradient time and actual clinical scan time.

### METHODS AND MATERIALS

A retrospective analysis was conducted on 3,635 knee MRI examinations acquired across 10 outpatient sites on identically configured 3T scanners (MAGNETOM Vida, Siemens Healthineers) between January 2023 and December 2023. The imaging protocol encompassed five accelerated pulse sequences and an automated localizer for anatomic landmark identification (total acquisition time: 04:49 minutes). MRI examination log data was autonomously extracted utilizing an open-source software solution (Yarra LogServer, www.yarra-framework.org). Parameters including (1) examination duration, (2) scan time, (3) adjustment time, (4) idle time, and (5) repeat time were gauged and analyzed though descriptive statistics.

### RESULTS

The mean exam duration (from start of the localizer to completion of the last sequence) amounted to 07:42±02:19 minutes (median: 07:01 minutes). Scan time constituted 72.6% of the exam duration (mean: 05:30±01:27 minutes; median 04:57 minutes), while adjustment time and idle time represented 9.0% (mean: 00:40±00:14 minutes; median: 00:46 minutes) and 18.4% (mean: 01:32±01:15 minutes; median: 01:15 minutes), respectively. Repeat sequences accounted for 8.9% of the exam time (mean: 00:41±01:27 minutes; median: 00:08 minutes).For the five core diagnostic protocol sequences, deviations from the anticipated acquisition times due to parameter adjustments during individual MRI exams were negligible (mean: 00:03±00:13 minutes; median: 00:01 minutes).

### CONCLUSION

Modern image acceleration techniques facilitate net acquisition times below 5 minutes for joint MRI examinations. The actual clinical protocol durations are approximately 60% longer due to adjustment scans and idle time between pulse and repeat sequences. Data can be continuously measured and visualized as dashboards to monitor the efficiency within the department.

### CLINICAL RELEVANCE/APPLICATION

Even though net acquisition times of deep learning-enabled ultra-fast MRI suggest that sub-15-minute MRI booking slots can be easily established, substantial differences between gradient time and actual protocol duration need to be considered during scheduling to prevent delays in clinical routine.

## S3B-SPIN-5 RAPID HIGH-RESOLUTION COMPUTED TOMOGRAPHY WITH NEAR-MAXIMUM ENTROPY (MENT) USING UNIT-GAIN ERROR CORRECTING FEEDBACK LOOP

Wolfram R. Jarisch, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To present a novel MENT approach to computed tomography (CT) reconstruction that combines efficiency and robustness, matching the speed of Filtered Backprojection Type (FBPT) methods.

### METHODS AND MATERIALS

We introduce the MENT formulation with unique solution (Cover Thomas, 2006, Eqs. 12.1 -12.4) into an iterative, mildly non-linear estimator with a novel near unit-gain error feedback loop, derived from an extended Kalman filter with an FBPT gain. This approach rapidly adapts voxel density values via gain coefficients ?i to loop requirements. The uniqueness of the object density solution is retained and computed with minimal effort. Typically only one to a few percent of numerical effort with other ART-like methods (Biguri et al.; JPDC, 2020) or tomoCAM (Kumar et al.; JSR, 2023) are required. Gradually increasing resolution retains uniqueness and keeps the iterated numerical effort minimal. Furthermore, the MENT approach extracts information more efficiently than competing methods, permitting reduced measurement and numerical effort, and radiation. We evaluate our method through simulations and experimental studies.

### RESULTS

Our method enables enhanced voxel spatial and density resolution at greater imaging speeds, broader imaging ranges, and dynamic object changes in CT. It also allows for reduced X-ray intensity with a smaller focal spot size, resulting in sharper images and reduced patient exposure. In MRI, it offers the potential to reduce measurement time, improving patient comfort and increasing the throughput of imaging facilities.

### CONCLUSION

The novel MENT approach to CT and MRI reconstruction is highly efficient and robust, addressing the significant challenges of noise, sparse projections, high contrast, and stringent time constraints. It offers significant potential for medical diagnosis and non-destructive evaluation.

### CLINICAL RELEVANCE/APPLICATION

The practical applications of our high-speed and precise method are far-reaching. In CT, it enables enhanced voxel spatial and density resolution at greater imaging speeds, broader imaging ranges, and dynamic object changes, while reducing patient exposure to radiation. In MRI, it offers the potential to reduce measurement time, improving patient comfort and increasing the throughput of imaging facilities. These advancements hold significant potential for improved patient care and innovative industrial applications.

## S3B-SPIN-6 ACCURATE SKELETON SEGMENTATION WITHOUT MANUAL CONTOURING: A STUDY OF 9,262 SUBJECTS

Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Yucheng Tang, PhD (*Abstract Co-Author*) Nothing to Disclose
Zheyuan Zhang (*Abstract Co-Author*) Nothing to Disclose
Wenxuan Li, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To enhance automatic skeleton segmentation, this study integrates public AI models with anatomical priors, reducing the need for manual contouring by radiologists.

### METHODS AND MATERIALS

Manual contouring is an inevitable and labor-intensive task for radiologists to segment skeletal structures from computed tomography (CT) scans. We develop an automatic strategy called Bag of Priors (BoP) that leverages anatomical priors from medical knowledge with publicly available AI models to segment skeleton structures accurately without manual contouring from radiologists. The anatomical priors include the location, shape, size, intensity distributions, and other imaging characteristic features of skeletal structures. We assess the quality of skeleton segmentation, which includes 24 vertebrae, 24 ribs (L/R), clavicula (L/R), humerus (L/R), scapula (L/R), hip (L/R), sacrum, and femur (L/R). Specifically, a senior radiologist with 10 years of clinical experience conducted manual contouring, while five junior radiologists with three years of experience performed a visual inspection, rating the quality of both manual and automated segmentation by our BoP strategy on a scale from 1 to 5. No publicly available CT dataset with skeletal annotations

currently matches the precision of manual contouring. Examples of typical errors in TotalSegmentator (the latest public CT dataset; N=1,204) are presented in the figure. We have created and released an extensive dataset of 9,262 CT volumes (unique subjects), where all 59 skeletal structures were annotated per voxel. This is the largest public CT dataset to date with high-quality skeletal annotations. This dataset was used to assess the performance of public AI models and those enhanced by our BoP strategy.

**RESULTS**

Public AI models (U-Net as backbone) augmented with our BoP strategy achieved almost perfect segmentation performance across all skeleton structures, exceeding 90% DSC compared with manual contouring. Notably, the segmentation of clavicula, scapula, hip, sacrum, and femur reached > 95% DSC score. Our BoP strategy significantly improves the performance of public AI models by an average of 3.4%, where increases of 4.4% for vertebrae and 4.8% for femur segmentation specifically.

**CONCLUSION**

Our strategy significantly enhances the accuracy of skeletal segmentation across various structures, achieving near-manual quality without the need for radiologist manual contouring.

**CLINICAL RELEVANCE/APPLICATION**

Accurate skeleton segmentation is crucial for trauma diagnosis and image-guided surgery, enhancing fracture typing, pre-operative planning for fracture reduction, and screw fixation planning in clinical scenarios.

## S3B-SPIN-7 CAN PRIVACY-PRESERVING VISION-BASED LARGE LANGUAGE MODELS PRE-FILL THE FINDINGS SECTION OF RADIOLOGY REPORTS?

Qingqing Zhu (*Presenter*) Nothing to Disclose

**PURPOSE**

In this pilot experiment, the ability of vision-based large language models (VLMs) to pre-fill the "Findings" section of radiology reports was assessed. Also, GPT-4 (text-based) was assessed as a novel evaluator for the generated findings in contrast to a clinician.

**METHODS AND MATERIALS**

This retrospective study used a CT and report dataset (23436 CT slices; 8340 studies with reports, 3832 patients; mean age 51 ± 17 [s.d.] years; 2085 males, 1747 females). The report sentences containing prospective RECIST-based measurements (called "bookmarks") made by radiologists were extracted using regular expressions. An enclosed bounding box was also created from the measurement to highlight the finding in the CT slice. Next, the GPT-4 API was employed to structure the finding into six segments (Current {Description/Size}, Previous {Description/Size}, Comparison to Prior, Additional), which were validated by a clinician with two years of experience. The current description was used as the ground-truth. Three VLMs were evaluated for their ability to describe findings: GPT-4 with Vision (GPT-4V), LLaVA-Med, and RadFM. These models analyzed the CT slices (with/without bounding box), to generate descriptions. The descriptions were initially assessed using conventional metrics like BLEU, METEOR, and ROUGE to evaluate their linguistic quality. Further analysis using GPT-4 decomposed the findings into specific components (body part, location, type), enhancing the evaluation of their clinical relevance. Finally, the privacy-preserving RadFM model was fine-tuned on this dataset and its performance was also compared.

**RESULTS**

GPT-4 was highly consistent with clinicians' assessments ($0.87 \pm 0.02$, $p < 0.001$), showing its potential to aid radiologists in evaluating task. Using this method to test model performance, GPT-4V was best at correctly identifying location (17.1%), body part (46.4%), and type (44.6%) of findings without specific tuning. Despite its effectiveness, it lacks privacy features. To address this, we fine-tuned the RadFM model, enhancing its performance markedly: location accuracy increased from 3.41% to 12.8%, body part from 29.12% to 53%, and type from 9.24% to 30%. These improvements make RadFM a viable, privacy-conscious alternative to GPT-4V.

**CONCLUSION**

The use of the CT dataset and the novel evaluation framework has shown significant improvement in the automation of CT finding generation. Additionaly, the decomposed evaluation model helps identify the strengths and areas for enhancement in the model.

**CLINICAL RELEVANCE/APPLICATION**

Radiologists evaluating cancer burden and overseeing patient treatment will benefit from a "second reader" AI model that provides a structured list of suspicious lesions in the "Findings" section.

## S3B-SPIN-8 A FEASIBILITY STUDY OF PULMONARY NODULE DETECTION BY ULTRA-LOW-DOSE CT WITH DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM

Zhiming Xiang (*Abstract Co-Author*) Nothing to Disclose
Kun Ma (*Abstract Co-Author*) Nothing to Disclose
Zhijuan Zheng (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the effect of deep learning image reconstruction (DLIR) algorithm on the image quality and detection of pulmonary nodules in ultra-low-dose computed tomography (ULD-CT) in comparison with the adaptive statistical iterative reconstruction-V (ASIR-V) algorithm.

**METHODS AND MATERIALS**

152 patients underwent standard-dose CT (SDCT), followed immediately by ULD-CT. SDCT was the reference standard using ASIR-V at 50% strength (50%ASIR-V). ULD-CT was reconstructed with 50%ASIR-V, DLIR (Medium, High; TrueFidelity™). The number, type, and diameter of pulmonary nodules

were recorded in the SDCT image. Effective dose and image quality were compared between ULD-CT and SDCT. The logistic regression was used to analyze the independent predictors of pulmonary nodules detection sensitivity.

## RESULTS

The Effective Dose (ED) of SDCT is 4.30±0.32 mSv, while that of ULD-CT is 0.33±0.03 mSv. There was no difference between the ULD-CT and SDCT for the CT values of nodules and lung tissue, SD values of nodules, and SNR values of nodules (P>0.05). DLIR had significantly lower SD values of lung tissue and higher SNR values of lung tissue and CNR values of nodules compared with ASIR-V ( P>0.05). The SDCT revealed 727 nodules and the overall detection sensitivity on ULD-CT was 97.11%. In nodules with a diameter 2-6 mm, the detection sensitivity is 98.95% (565/571) for solid nodules (SN) and 85.58% (89/104) for pure ground glass nodules (pGGN). All SN, pGGN, and partial solid nodules (PSN) 6mm or larger in diameter were detected on ULD-CT (20/20, 24/24, 8/8). Based on multivariate analyses, BMI (P = 0.026), the nodule types (P<0.001), and the nodule diameter (P = 0.002) were independent predictors of nodule detection sensitivity. However, the gender and age of patients had no significant effect on the detection sensitivity of pulmonary nodules (P > 0.05).

## CONCLUSION

The DLIR algorithm is a promising reconstruction technique, which can reduce radiation dose, optimize image quality, and ensure the detection sensitivity of pulmonary nodules in ULD-CT scan.

## CLINICAL RELEVANCE/APPLICATION

The application of the DLIR algorithm in ULD-CT scan can significantly improve image quality and ensure good detection sensitivity. This technique is helpful to reduce radiation dose, improve diagnostic accuracy, and save medical resources, so it is of great significance in clinical practice.

## S3B-SPIR-1 SAFETY AND EFFICACY OF GENICULAR ARTERY EMBOLIZATION USING CALIBRATED 250-µM PARTICLES: REAL-WORLD DATA FROM EARLY STAGES OF AN ACADEMIC PRACTICE

Theresa M. Caridi, MD (*Abstract Co-Author*) Consultant, Boston Scientific Corporation;Speaker, Boston Scientific Corporation;Consultant, Cook Group Incorporated;Speaker, Cook Group Incorporated;Consultant, Terumo Corporation;Speaker, Terumo Corporation;Consultant, Siemens AG;Speaker, Siemens AG;Speaker, Penumbra, Inc;Research Grant, Siemens AG
Emily Gullette (*Abstract Co-Author*) Nothing to Disclose
Omid Shafaat, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Genicular artery embolization (GAE) is a novel interventional radiology technique for managing knee pain attributed to osteoarthritis. This study assesses the safety and efficacy of GAE using calibrated 250-µm particles in a clinical setting, focusing on its impact on pain reduction and safety.

### METHODS AND MATERIALS

This retrospective study analyzed data from 17 patients undergoing 19 GAE procedures. Demographic data, procedural details, Visual Analog Scale (VAS) scores, pre- and post-procedure, and complication rate were evaluated. Statistical analyses included descriptive statistics, paired t-tests to compare pre- and post-procedure VAS scores, and 95% confidence intervals (CI) calculation.

### RESULTS

The patient cohort had a mean age of 54.7 years (SD = 15.4) and a mean BMI of 37.1 (SD = 8.9); most patients were female (70.6%). The average VAS score pre-procedure was 8.06 (SD = 1.68), which significantly decreased to 4.33 (SD = 2.50) post-procedure (p=0.00035). The mean number of arteries embolized per procedure is approximately 1.37 (SD=0.50). Complications were minor and occurred in only two procedures and were related to pain control and hematoma of femoral access that both resolved without interventions. The average fluoroscopy time was 34.17 minutes (SD=17.27), and the average radiation dose was 653.6 mGy (SD=470.39). The average time to post-procedure VAS assessment was 52 days (range 30-129 days). The average reduction in pain score was 3.67 points, suggesting effective pain relief.

### CONCLUSION

GAE using calibrated 250-µm particles significantly reduces knee pain in patients with osteoarthritis, demonstrating substantial clinical efficacy in pain management and safety with minor complications within an academic practice setting. Early results from real-world data, which represent some of the first findings outside of clinical trials, from this academic practice offer promising evidence supporting the efficacy and safety of GAE using calibrated 250-µm particles.

### CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of GAE calibrated 250-µm particles to offer significant pain relief, enhance patient quality of life, and reduce reliance on more invasive procedures such as total knee arthroplasty. These findings warrant further study with larger cohorts and more extended follow-up periods to better understand the benefits and limitations of GAE using calibrated 250-µm particles in managing osteoarthritic knee pain.

## S3B-SPIR-5 EFFICACY OF PROSTATIC ARTERY EMBOLIZATION IN TREATING LARGE PROSTATES (≥ 80 CC) AT 12 MONTHS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Pedro L. Lino, MD (*Abstract Co-Author*) Nothing to Disclose
Joao S. Pais, MD (*Abstract Co-Author*) Nothing to Disclose

Fernanda Uchiyama Golghetto Domingos (*Abstract Co-Author*) Nothing to Disclose
Matheus Fritzen, MD (*Abstract Co-Author*) Nothing to Disclose
Marcello Giovanni Messias Da Silva, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To perform meta-analysis of available data on prostatic artery embolization (PAE) as a treatment option for patients with symptomatic benign prostatic hyperplasia (BPH) with prostate = 80 mL.

**METHODS AND MATERIALS**

PubMed, Cochrane, and Scopus were searched up to April 1, 2024. Peer-reviewed studies with > 5 patients and standard deviations and/or individual-level data on one or more of the following outcomes were included: prostate volume (PV), peak flow rate (Qmax), postvoid residual (PVR), International Prostate Symptom Score (IPSS), quality of life (QOL) score and prostate-specific antigen (PSA) level. A random-effects meta-analysis was performed on the outcomes at 12 months after PAE compared with baseline values, with a $P < .05$ decision rule as the null hypothesis rejection criterion.

**RESULTS**

Thirteen of 1243 studies were included in data collection, with six included in the meta-analysis. At 12 months, PV decreased by 60.22 cm3 ($P < .001$), PSA remained unchanged ($P = .05$), PVR decreased by 56.93 mL ($P < .001$), Qmax increased by 5.06 mL/s ($P < .02$), IPSS improved by 15.13 points ($P < .001$), QOL score improved by -2.78 points ($P < .001$). Minor complications after PAE procedure frequently occur but typically resolve within a two-week period. Major complications were rare. There were no minor or major complications at 12 months.

**CONCLUSION**

PAE in large prostates (> 80 cc) provided improvement in Qmax, PVR, IPSS, and QOL at 12 months. There were no minor or major complications at 12 months, and there was no adverse effect on erectile function.

**CLINICAL RELEVANCE/APPLICATION**

This systematic review and meta-analysis underscores the clinical significance of PAE in managing BPH among patients with larger prostatic volumes (> 80 mL). Conventional therapeutic modalities for BPH often exhibit limited efficacy and heightened risks in the context of larger prostates, necessitating consideration of invasive procedures such as subtotal prostatectomy. However, the findings of this study highlight PAE as a promising alternative with notable efficacy and safety profiles.

## S3B-SPIR-6 MR-GUIDED VAGAL CRYOABLATION FOR THE TREATMENT OF OBESITY IN A CANINE ANIMAL MODEL - PRELIMINARY RESULTS

Clifford R. Weiss, MD (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Siemens AG;Research Grant, Boston Scientific Corporation;Consultant, Boston Scientific Corporation;Research Grant, Medtronic plc;Consultant, Medtronic plc;Research Grant, Guerbet SA;Consultant, Guerbet SA
Dara L. Kraitchman, DVM, PhD (*Abstract Co-Author*) Advisory Board, Ardent Animal Health
Cheri Rice (*Abstract Co-Author*) Nothing to Disclose
Robert Anders (*Abstract Co-Author*) Nothing to Disclose
Eun Shin (*Abstract Co-Author*) Consultant, Boston Scientific Corporation;Consultant, Medtronic plc
Arun Kamireddy, MBBS, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess safety, feasibility, and efficacy of MR-guided vagal cryoablation for managing obesity in an obese canine model, based on promising results from a prior CT-guided cryovagotomy study.

**METHODS AND MATERIALS**

All studies were approved by IACUC. Pilot studies involved healthy dogs (30+2.64 kgs, n=3) with ~2 weeks follow-up, while chronic studies included obese dogs (14.12+0.63 kgs, n=4) with ongoing ~4 month follow-up. Procedure was performed using a 1.5T MRI under GA. Pre-procedural CBCT and MRI determined optimal entry point. Fat percentage (FP) maps were obtained with multi-echo DIXON sequences. Cryoprobe targeted posterior vagal trunk in lower thorax. Freeze-thaw durations varied (2-1-2-1, 4-2-4-2, and 6-3-6-3 minutes) in pilot dogs and were consistent 6-3-6-3 minutes in chronic studies. Post-procedure MRIs were repeated to assess immediate adverse events. Safety was monitored via weekly blood draws, follow-up MRI at ~2 weeks in pilot dogs, and at 1 and 4 months in ongoing chronic studies. Follow-up endoscopy (~7 days) was performed in chronic studies. Analysis involved comparing ROIs from FP maps of liver and intramuscular thigh. Subcutaneous and visceral fat areas were obtained. The Wilcoxon signed-rank test assessed changes in FP between pre- and post-procedures. Weekly weight and dietary intake were monitored, with pilot studies concluding with humane anesthesia and tissue harvest.

**RESULTS**

Cryoablation was successfully performed in all dogs. Three dogs from chronic studies showed an average weight gain of 7.1% over a two-month post-procedure follow-up. Dietary intake remained excessive at ~1000 kcal/day post-procedure in chronic studies. Statistical analysis found no significant differences ($p > 0.05$) in pre- and post-procedure FP measurements (Table). Minor cryoinjury of right lung adjacent to target area, without injury to aorta, IVC or azygos was seen in all dogs. In one sub-acute dog, over-advancement of cryoprobe led to esophageal perforation. Two dogs developed small, self-resolving pneumothorax immediately post-ablation. Endoscopy confirmed absence of esophageal or gastric inflammation in chronic studies. Pending histopathology and ghrelin assays may provide insights into metabolic and tissue-level effects.

**CONCLUSION**

Early data reveals technical challenges with MR-guided vagal cryoablation in canines, highlighting need for precise probe placement. Contrary to a prior CT-guided cryovagotomy study, observed weight gain suggests vagal cryoablation alone may not suffice for weight reduction.

**CLINICAL RELEVANCE/APPLICATION**

Although MR-guided vagal cryoablation is technically feasible, contrasting results of our study highlight the need to investigate long-term metabolic effects of vagal nerve modulation.

## S3B-SPIR-8 COMPARATIVE RANDOMIZED CLINICAL TRIAL OF A MASTER-SLAVE INTERVENTIONAL ROBOT FOR PERCUTANEOUS LUNG PUNCTURE

Xueling Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Wenge Xing (*Abstract Co-Author*) Nothing to Disclose
Zhi Guo, MD (*Abstract Co-Author*) Nothing to Disclose
Yong Li (*Abstract Co-Author*) Nothing to Disclose
Nan Wang (*Abstract Co-Author*) Nothing to Disclose

Bin Xiong (*Abstract Co-Author*) Nothing to Disclose
Haipeng Yu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

A novel CT fluoroscopy image guided master-slave robotic system was developed to improve clinical outcomes and avoid radiation to radiologists. The manipulator and end-effector of this system can be deployed in separate room. To assess the safety and feasibility of the robot in lung percutaneous puncture procedure, a multicenter randomized controlled clinical trial was conducted.

**METHODS AND MATERIALS**

136 patients (M: 80, F: 56; mean lesion size 4.75cm) were enrolled from three centers. 68/68 baseline-matched patients were randomly divided into study group and control group. The developed system was employed in study group, while the conventional CT freehand puncture approach was used in control group. The primary aim was one-time puncture success rate, the secondary aims included the entire procedure duration, puncture time, patient radiation dose of entire procedure and complication rate. The procedure time analysis of each step (including preoperative planning, sterilization and anesthesia, preparation, puncture and target confirmation) was also evaluated.

**RESULTS**

131 patients (67 control / 64 study group; M: 76, F: 55; mean lesion size 4.83cm) of Per Protocol Set were analyzed. The results of study and control group were respectively: one-time puncture success rate: 95.3% (61/64) vs 59.7% (40/67) (p<.01); Procedure duration: median 14.63min (12.96-18.65) vs 7.65min (IQR 6.01-10.27) (p<.01); Puncture time: 0.71min (0.38-1.33) vs 2.07min (1.03-2.84) (p<.01); Radiation dose: 4.60mSv (3.72-6.01) vs 10.40mSv (7.50-14.18) (p<.01); Complication rate: 15.63% (10/64) vs 22.39% (15/67) (p=.33). Specifically, the occurrence of pneumothorax, hemoptysis and bleeding were 10.94% vs 11.94% (p=.86), 1.56% vs 7.46% (p=.46) and 2.21% vs 2.99% (p=.23). The evaluation of procedure duration is shown in Figure 1.

**CONCLUSION**

The one-time puncture success rate, puncture time and radiation dose to the patients showed a significant difference with a margin of 35.6%, 1.36min and 5.80mSv better than control group. Procedure duration of study group was slightly increased due to longer preoperative planning (3.21min), anesthesia (1.93min) and preparation (4.21min) time. The complication rate had no significant difference between two groups, while the number of complications in study group decreased.

**CLINICAL RELEVANCE/APPLICATION**

In traditional approach, patient suffers from high radiation due to repeated CT scan and needle adjustments. This work suggested that the developed system benefits the patients in reducing radiation exposure and the duration of risky operations. Moreover, the system eliminates all radiation to physicians and minimizes their skill variability.

## S3B-SPIR-9 X-RAY ACOUSTIC COMPUTED TOMOGRAPHY (XACT) FOR RADIOLOGY INTERVENTION

Yuchen Yan (*Abstract Co-Author*) Nothing to Disclose
Liangzhong Xiang, PhD (*Abstract Co-Author*) Nothing to Disclose
Prabodh K. Pandey, PhD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Introduced in 2013 by Xiang et al., X-ray Acoustic Computed Tomography (XACT) overcomes traditional x-ray limitations and has enabled new clinical applications such as radiation therapy monitoring, interventional radiology, and non-destructive evaluations. This study demonstrates the use of 2D and 3D XACT imaging with arrays of 128 and 256 elements, respectively, enhancing needle monitoring and confirming its effectiveness in imaging X-ray contrast agents for potential blood clot monitoring.

**METHODS AND MATERIALS**

A portable X-ray device (Golden Engineering Inc., 10Hz repetition rate) emits X-ray pulses with a 50ns width, causing a minor thermal increase in millikelvins, which generates pressure waves known as the X-ray Acoustic (XA) signal. The setup features a linear ultrasound transducer (L12-5L40N-4, 5-12MHz, 39mm field of view, TELEMED Co.) with 128 elements that simultaneously captures 2D XA and ultrasound images. Additionally, a 1MHz ultrasound transducer (Doppler Co.) with a 16x16 element grid produces 3D XA images of the needle. A contrast agent (omnipaque 300) is injected into a silicone tube mimicking a blood vessel (2.5mm in diameter), enabling 3D visualization of the contrast agent. The image reconstruction utilizes a Model-Based XACT back-projection method with iterative regularized LSQR (Model-Based LSQR).

**RESULTS**

Using a 2D linear array, our system captures synchronized X-ray Acoustic (XA) and ultrasound images, displaying needle movements with a resolution of 0.1 mm at 5 frames per second. 3D XA images were produced with a resolution of 0.3 mm and captured using fewer than 10 X-ray pulses. This capability is crucial for real-time needle monitoring during therapeutic procedures.

**CONCLUSION**

The XA+US system integrates X-ray Acoustic (XA) imaging with ultrasound to enhance visualization of needles, contrast agents, and tissues, supporting its use in blood clot monitoring. Future enhancements might include higher energy X-rays and more sensitive ultrasound probes. Further ex vivo and in vivo studies are necessary to fully demonstrate its clinical effectiveness

**CLINICAL RELEVANCE/APPLICATION**

XACT + US technology aims to monitor the entire needle insertion process, contrast agent injection, and flow within tissues, applicable in embolism or blood clot monitoring. It provides comprehensive imaging with significantly lower radiation, aiding surgeons in precise targeting and minimizing damage to healthy tissues, thus improving medical interventions

## S3B-SPMK-2 ASSOCIATION BETWEEN DEEP LEARNING PREDICTED BODY COMPOSITION FROM CXR AND SURVIVAL IN THE ELDERLY

Namkug Kim, PhD (*Abstract Co-Author*) Stockholder, Anymedi, Inc
Sunghwan Ji (*Abstract Co-Author*) Nothing to Disclose
Hong-Kyu Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Miso Jang (*Abstract Co-Author*) Nothing to Disclose
Kyungjin Cho, MSc, BS (*Abstract Co-Author*) Nothing to Disclose
Ki Duk Kim, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The objective of this study is to investigate the association between body composition predicted by a deep learning network of chest radiographs (CXR) and all-cause mortality in elderly individuals.

### METHODS AND MATERIALS

A total of 5,932 individuals aged 65 years and older were included in the survival dataset. Deep learning model predicted skeletal muscle mass and fat mass from CXR. All-cause mortality was assessed using the National Health Insurance eligibility status. Participants were grouped according to tertiles of bioelectric impedance analysis (BIA)-measured body composition (skeletal muscle mass divided by body mass index, SMM/BMI, and fat percent). Multivariable Cox proportional hazards regression adjusted for age was used to calculate hazard ratios (HRs) with 95% confidence intervals (CIs) comparing the second tertile group with other groups.

### RESULTS

During a median follow-up of 8.7 years, 417 (7.0%) participants died. In the survival analysis, lower CXR-measured SMM/BMI was associated with higher all-cause mortality in both female (HR: 1.50, 95% CI: 1.02-2.22, P-value=0.039) and male (HR: 1.77, 95% CI: 1.36-2.20, P-value<0.001). However, after the adjustment for age, only elderly population of males (HR: 1.42, 95% CI: 1.08-1.85, P-value=0.011) showed statistically significant association. The association was not statistically significant after the adjustment in females. The association between fat percent and mortality as not statistically significant in both BIA-measured fat percent and CXR-measured fat percent.

### CONCLUSION

In this deep learning model development and validation of survival impact in elderly individuals, SMM/BMI was significantly associated with all-cause mortality in elderly males. Fat percent was not statistically associated with all-cause mortality in elderly individuals.

### CLINICAL RELEVANCE/APPLICATION

Higher SMM/BMI was protective for elderly males. These findings suggest that deep learning analysis of routine CXR may provide valuable prognostic information regarding body composition in the management of elderly participants.

## S3B-SPMK-3 FULLY AUTOMATED 29 SUBSTRUCTURES TOTAL KNEEMRI SEGMENTATION USING DEEP LEARNING: IMPLICATIONS FOR POTENTIAL FACTORS OF OSTEOARTHRITIS PROGRESSION

Huimao Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Haoyu Liu (*Abstract Co-Author*) Nothing to Disclose
Lin Mu, MD,MS (*Presenter*) Nothing to Disclose

### PURPOSE

We aimed to develop a model that enables automatic segmentation of the 29 major anatomical structures in the whole knee Magnetic Resonance Imaging(MRI)and explore the potential precursors to Knee Osteoarthritis(KOA)based on the total knee radiomics features (TKRF).

### METHODS AND MATERIALS

The prospective nested case-control study analyzed 3.0T (MRI) ,DESS sequence of the right knee of 519 participants with Kellgren-Lawrence(KL) grade 0 or 1 at baseline from the Osteoarthritis Initiative(OAI). According to the occurrence of incident radiographic KOA during the 4-year follow-up period, participants with KOA(n=173) and without KOA(n=346) were distinguished with 1:2 propensity score matching(PSM) based on gender, race, Body Mass Index (BMI) and contralateral knee status at baseline.We employed the nnU-Net for an active learning strategy to progressively optimize the iterative model, and it were used to segment 29 anatomical structures in total knee (tibia, femur, patella and corresponding subchondral bone, 19 cartilage

subdivisions, anterior cruciate ligament, posterior cruciate ligament, meniscus and joint effusion). The final annotations served as the ground truth for training and testing. Dice similarity coefficients (Dice) was calculated to evaluate the model's performance. TKRF calculated 111 radiomics features in each substructure based on pyradiomics, and to investigate features with statistical differences in KOA progression cohort.

**RESULTS**

We developed a tool for segmentation of 29 knee anatomical structures on 519 MRI datasets obtained using different KL-related changes. The tool demonstrated high accuracy (mean Dice score 0.957) and works robustly on a wide range of clinical data, superior to other free segmentation tools. We assessed the TKRFs which describe 29 knee areas feature sets that capture the full richness of the image information to investigate possible causes for KOA progression. One of the shape features, Maximum 3D Diameter from effusion, is by far the most important parameter for automatic classification.The Least Axis Length of posterior lateral tibial cartilage, which is the most important cartilage features showed significant differences in the KOA progression datasets.

**CONCLUSION**

We developed a MRI segmentation model that is (1) easy to use; (2) segments most anatomically relevant structures in the whole MRI, and contains 19 divisions of cartilage (3) works robustly in any clinical setting.We introduce TKRF and show that rich radiomics-based feature enables improved predictive KOA progression.

**CLINICAL RELEVANCE/APPLICATION**

We propose that TKRF could spark the establishment of a new generation of KOA imaging biomarkers with benefits for a range of applications.

## S3B-SPMK-4 A CLINICAL-RADIOMICS NOMOGRAM BASED ON PRE-TREATMENT MRI FORPREDICTINGPROGRESSION-FREE SURVIVALAFTER NEOADJUVANT CHEMOTHERAPY FOR OSTEOSARCOMA: A MULTICENTER STUDY

Bin Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Haimei Chen (*Abstract Co-Author*) Nothing to Disclose
Xiaoyun Liang (*Abstract Co-Author*) Nothing to Disclose
Shui Xing Zhang Sr, MD (*Abstract Co-Author*) Nothing to Disclose
Xiao Zhang (*Abstract Co-Author*) Nothing to Disclose
Yuchi Tian (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate a clinical-radiomics nomogram based on pre-treatment MRI for progression-free survival (PFS) prediction after neoadjuvant chemotherapy for osteosarcoma.

**METHODS AND MATERIALS**

A total of 109 patients with histologically confirmed osteosarcoma without evidence of recurrence or distant metastases were enrolled from four hospitals (Hospital 1/2/3/4: n = 57/34/12/6), which were strictly divided into the training (Hospital 1 and 4) and validation cohorts (Hospital 2 and 3). Baseline clinical characteristics were derived from medical records. A set of 1130 radiomics features were extracted from contrast-enhanced fat-suppressed T1-weighted images (CE-FS-T1WI), further screened by Pearson correlation analysis and Relief algorithm, which were finally combined with the classifier to construct the optimal radiomics signature for predicting PFS. A clinical-radiomics nomogram was developed based on the Cox proportional hazards regression analysis, and the patients were divided into high- and low-risk groups according to their nomogram score. Furthermore, the predictive performance and clinical usefulness were assessed.

**RESULTS**

Seven features were identified to construct the radiomics signature. The corresponding radiomics feature maps of highly predictive texture features showed large difference in patients with different prognosis (FIGURE 1). The clinical-radiomics nomogram, incorporating the radiomics signature and a significant clinical risk factor, exhibited better prediction performance for PFS compared with either the clinical model or radiomics signature, with C-indexes of 0.845 (95% CI, 0.782-0.907) and 0.759 (95% CI, 0.674-0.844) in the training and validation cohorts, respectively (TABLE 1). The nomogram-defined high-risk group had a significantly shorter PFS than those in the low-risk group (FIGURE 2, $P < 0.05$). Clinical decision curve analysis confirmed the clinical utility of the clinical-radiomics nomogram (FIGURE 3).

**CONCLUSION**

Our results have demonstrated that the proposed CE-FS-T1WI-based clinical-radiomics nomogram could serve as a powerful predictor of PFS in patients with osteosarcoma.

**CLINICAL RELEVANCE/APPLICATION**

The proposed approach has the potential to assist doctors in making informed treatment decisions, which may prolong patient survival and improve patient treatment outcomes.

## S3B-SPMK-5 RADIOPSY, QUANTITATIVE WB-MRI ADC AND FAT FRACTION SEQUENCES FOR DISCRIMINATION OF SMOLDERING MULTIPLE MYELOMA AND MULTIPLE MYELOMA: A PROSPECTIVE OBSERVATIONAL STUDY

## PURPOSE

To distinguish between Multiple Myeloma and High-Risk Smouldering Myeloma at staging using image-based biomarkers obtained from Whole Body-MRI (WB-MRI) Apparent Diffusion Coefficient (ADC) and Fat Fraction (FF) sequences.

## METHODS AND MATERIALS

From January 2021 to March 2024, we enrolled consecutive myeloma patients at staging into an observational prospective trial and divided them into two groups based on International Myeloma Working Group (IMWG) criteria: High-risk Smouldering Multiple Myeloma (SMM, group 1) and Multiple Myeloma (MM, group 2). All patients underwent WB-MRI using the Myeloma Response Assessment and Diagnosis System (MY-RADS). We use the term "Radiopsy" to indicate the quantification and modelling of image characteristics nearby the biopsy site to predict patient status. An experienced radiologist placed a cylindrical, 5 cc VOI nearby the biopsy site and 5 more identical VOIs on distant sites such the pelvis bone and on D11 and L5 vertebrae. The dataset was split into a training and test set with a 70:30 ratio. LASSO algorithm was used to select the most predictive features and build logistic regression models, which were then validated using the test set. Receiver operating curves (ROC) and area under the curve (AUC) were used as metrics for models' performance assessment. Radiopsy models were tested on distant biopsy site to predict disease invasion.

## RESULTS

The study included 102 patients (46 males, mean age 63 ± 12 [SD]) with 60 diagnosed with MM and 42 with SMM. 144 quantitative features were extracted from the VOI at the biopsy site WB-MRI ADC and FF sequences for each patient. Radiopsy model showed a median AUC of 0.85 (0.79-0.95) in the training phase and a median AUC of 0.65 (0.55-0.80) in the test phase. The best predictive model had an AUC of 0.95 and 0.75 in the training and test phase, respectively. The models used to predict patient status at biopsy site were also predictive in distant VOIs.

## CONCLUSION

Radiopsy models can distinguish between MM and SMM with good performance nearby the biopsy site. Radiopsy can be used to predict disease invasion on distant sites where biopsy is not possible or not feasable

## CLINICAL RELEVANCE/APPLICATION

This observational prospective trial showed that using quantitative features extracted from WB-MRI ADC and FF sequences can help distinguish between high-risk SMM and MM at staging, thus potentially enhancing diagnostic accuracy.

## S3B-SPMS-1 LEVOTHYROXINE USE AND BONE LOSS IN EUTHYROID OLDER ADULTS: A LONGITUDINAL ANALYSIS FROM BALTIMORE LONGITUDINAL STUDY OF AGING

Shadpour Demehri, MD (*Abstract Co-Author*) Consultant, Toshiba Corporation;Research support, General Electric Company;Research Grant, Carestream Health, Inc
Jennifer Mammen (*Abstract Co-Author*) Nothing to Disclose
QIANLI XUE (*Abstract Co-Author*) Nothing to Disclose
Hamza Ibad, MBBS (*Abstract Co-Author*) Nothing to Disclose
Elena Ghotbi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Levothyroxine (LT4) is the second most commonly prescribed medication in older adults. Frank hyperthyroidism accelerates bone turnover and even subclinical hyperthyroid has been associated with increased fracture risk. Data indicates that a significant proportion of thyroid hormone prescriptions may be given to older adults without hypothyroidism raising concerns about subsequent relative excess of thyroid hormone even when treatment is targeted to reference range goals. In this study we aimed to determine whether LT4 use and higher thyroid hormone levels within the reference range are associated with higher bone loss over time in older adults.

### METHODS AND MATERIALS

Using the Baltimore Longitudinal Study of Aging a prospective observational cohort of community-dwelling older adults, participants age 65 and older at the baseline visit with at least 2 visits with thyroid function tests within the reference ranges at all visits were included.We employed propensity score matching (1:5), to match LT4 users with non-users according to relevant baseline characteristics: age, gender, BMI, race, history of alcohol intake, smoking, multi-pharmacy, and baseline serum TSH. Dual-Energy X-ray Absorptiometry were used to measure bone density and mass at each visit. Linear mixed-effects models and an interaction term of time interval between each visit and participant's first visit were used to estimate longitudinal relationships between exposure and outcomes. Stratified analyses were performed according to tertiles of average serum free thyroxine (FT4) level.

### RESULTS

The cohort included 81 euthyroid LT4 users (32 males, 49 females) and 364 non-users (148 males, 216 females), with a median age of 73 and thyrotropin levels of 2.35 at the index visit. LT4 use was found to be associated with greater longitudinal loss of total body bone mass (beta: -6.53; 95% CI: (-10.39, -2.67); $p < 0.001$) and total body bone density (beta: -0.0014; 95% CI: (-0.002, -0.0006); $p < 0.001$) over a median follow-up of 6.3 years (IQR: 4.0, 10.4). This association was stronger with increasing tertile of average FT4.

### CONCLUSION

Longitudinal loss of bone mass and density was greater among euthyroid LT4 users. The more pronounced effects at higher levels of FT4 suggest that LT4 use may be associated with a relative excess of thyroid hormone in some older adults on therapy, even with TSH levels within the reference range.

### CLINICAL RELEVANCE/APPLICATION

Even when adjusted to current treatment targets, bone loss may be an iatrogenic effect of levothyroxine use in older adults.

## S3B-SPNMMI-1 DIAGNOSTIC IMAGING METHODS USED IN THE PLANNING AND FOLLOW-UP OF PATIENTS UNDERGOING RADIOEMBOLIZATION WITH YTTRIUM-90 AND HOLMIUM-166 - A REVIEW

Rubens dos Santos Barbosa, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Viviane Campos Vaz, MD (*Abstract Co-Author*) Nothing to Disclose
Emilia Sousa, MBBS (*Abstract Co-Author*) Nothing to Disclose
Laryssa Maia, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

Hepatic radioembolization with radiolabeled microspheres is a locoregional treatment for unresectable hepatocellular carcinoma. It is essential to perform PET-CT (Positron Emission Tomography and Computed Tomography) and/or SPECT-CT (Single Photon Emission Computed Tomography and Computed Tomography) to predict the biodistribution and dose of microspheres before treatment. The objective of this study is to compare the diagnostic imaging techniques used for therapeutic planning and follow-up of patients undergoing radioembolization with Yttrium-90 (Y-90) and Holmium-166 (166-Ho).

### METHODS AND MATERIALS

The present study is a systematic review of the literature. In February 2024, a search was carried out on the Pubmed and Scielo platforms using the following terms: holmium, yttrium, nuclear medicine and radioembolization. Articles from the last 5 years written in English were filtered.

### RESULTS

To evaluate an extrahepatic shunt, it is necessary to perform a liver perfusion scintigraphy using 99mTc-MAA or Ho-166 itself at a lower dose. Studies demonstrate that planning with Ho166 demonstrates greater agreement with therapy than planning with 99mTc-MAA, as MAA has different physical characteristics from microspheres, not exactly mimicking their biodistribution.

### CONCLUSION

Holmium, as a personalized treatment option, has generated interest due to its imaging options and more precise planning. 99mTc-MAA, despite being widely used, presented limitations in therapeutic planning. Holmium radioembolization demonstrates feasibility and safety together with intraprocedural MRI due to its paramagnetic characteristics.

### CLINICAL RELEVANCE/APPLICATION

Hepatocellular carcinoma has an aggressive profile with a high death rate. It is one of the types of tumors that benefit most from SIRT, due to its predominant arterial vascularization. Commonly diagnosed in more advanced states, conventional curative therapies such as surgical resection may be contraindicated, with radioembolization being one of the few viable options in these cases. Planning with Ho166 scout demonstrates greater agreement with therapy than planning with 99mTc-MAA, reducing the likelihood of a patient being erroneously excluded from therapy or receiving a suboptimal therapeutic dose.

## S3B-SPNMMI-2 EARLY PREDICTION OF RESPONSE TO REPEATED RADIOIMMUNOTHERAPY WITH $^{131}$I-RITUXIMAB IN LYMPHOMA USING SEQUENTIAL $^{18}$F-FDG PET/CT

Byeonghyeon Byeon (*Presenter*) Nothing to Disclose

### PURPOSE

We prospectively evaluated the usefulness of sequential 18F-FDG PET/CT scans before and after the first radioimmunotherapy with 131I-rituximab (RIT) to predict response to subsequent repeated RIT in patients with relapsed or refractory non-Hodgkin’s lymphoma.

### METHODS AND MATERIALS

A total of 26 clinical patients received RIT and patients who had no progression after the first RIT underwent subsequent repeated RIT until disease progression or up to a maximum of six cycles. Patients underwent 18F-FDG PET/CT and maximum standardized uptake values (SUVs) and the sums of the products of the greatest perpendicular diameters (SPDs) were measured before, 5 d, and 4 weeks after the first RIT. Then, the % changes of SUVs and SPDs were calculated and designated as %SUV5d, %SUV4w, %SPD5d, and %SPD4w, respectively. The response was evaluated 1 month after each cycle of RIT. We assessed the predictive values of imaging parameters for response to the first or repeated RIT. Then, a predictive model for predicting responders to repeated RIT based on imaging parameters were devised.

## RESULTS

Objective responses to RIT were observed in 12 of 26 patients (46%) after the first RIT and 19 of 26 patients (73%) after repeated RIT. ROC curve analysis revealed that %SUV4w and %SPD4w predicted response to the first RIT, while %SUV5d, %SUV4w, and %SPD4w predicted response to repeated RIT. In the first step of our prediction model, patients with %SPD4w > 40% and %SPD4w = 0% were predicted to be responders and non-responders, respectively. In the second step, patients with 0% < %SPD4w = 40% were categorized into 2 groups: %SUV5d > 2% (responders) and SCR1 = 2% (non-responders). By using this prediction model, sensitivity, specificity, PPV, NPV, and accuracy for predicting responders to repeated RIT were 95%, 86%, 95%, 86% and 92%, respectively.

## CONCLUSION

Serial 18F-FDG PET/CT scans before and after the first RIT, including day 5 PET, will be of benefit in the planning of subsequent repeated RIT considering its efficacy and toxicity.

## CLINICAL RELEVANCE/APPLICATION

18F-FDG PET/CT scans before and after the first RIT can predict non-responders to subsequent repeated RIT in relapsed or refractory NHL.

## S3B-SPNPM-1 REPRESENTATION OF INTERNATIONAL MEDICAL GRADUATES AMONG DIAGNOSTIC RADIOLOGY CHAIRS, NEURORADIOLOGY CHIEFS, AND PROGRAM DIRECTORS

David M. Yousem, MD, MBA (*Abstract Co-Author*) Royalties, RELX;Speaker, MRI Online;Board Member, MRI Online;
Mona Dabiri, MD (*Abstract Co-Author*) Nothing to Disclose
Mina Hesami, MD (*Abstract Co-Author*) Nothing to Disclose
Ali Sheikhy, MD (*Abstract Co-Author*) Nothing to Disclose
Sara Ramezanpour (*Abstract Co-Author*) Nothing to Disclose
Mahla Radmard, MD (*Abstract Co-Author*) Nothing to Disclose
Fatemeh Dehghani Firouzabadi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The number of international medical graduates (IMGs) entering radiology residencies and neuroradiology fellowships averaged 9.7% and 20.9% from 2021-2023 respectively. We aimed to determine whether IMG graduates are populating leadership roles at a proportionate rate in diagnostic radiology (DR) and neuroradiology (NR).

### METHODS AND MATERIALS

We surveyed 191 DR program directors (PDs), 94 NR PDs, 192 chairs of DR and 91 directors of NR inquiring about their original citizenship and medical school [American Medical Graduates (AMG) vs IMG]. We reviewed institutional web sites to obtain missing data and recorded H indices for each person using Scopus.

### RESULTS

We confirmed the original citizenship and medical school location in 61 75% and 93-98% of each leadership group. We found that 19/119 (16.2%) DR PDs, 31/71 (43.7%) NR PDs, 33/116 (28.5%) DR Chairs and 28/69 (40.6%) NR Chiefs were not originally US citizens. The IMG rate was 18/188 (9.6%), 20/90 (22.2%), 26/186 (14.0%), and 19/85 (22.4%) for DR PDs, NR PDs, Chairs and NR Chiefs respectively. The most common country of origin and medical school cited was India for all leadership groups. IMGs had a median H index of 14 while AMGs 10, significantly different (p=0.021)

### CONCLUSION

Compared to the rate of DR/NR trainees entering from 2021-2023, IMGs are proportionately represented at the NR PD), NR chief, DR Chairs, and DR PDs positions. The H index of the IMGs was higher than AMGs. We conclude that IMGs have made substantial and proportionate inroads in radiology and neuroradiology leadership.

### CLINICAL RELEVANCE/APPLICATION

The proportional presence of IMGs in critical leadership roles within DR and NR, alongside their notably higher academic productivity, signifies a promising trend towards a more inclusive and dynamic leadership paradigm. This advancement not only enriches the diversity of perspectives but also enhances a culture of excellence and innovation within these pivotal medical specialties.

## S3B-SPNPM-2 THE INCREASING ROLE OF SUBSPECIALIZATION IN THE INTERPRETATION AND PERFORMANCE OF BREAST IMAGING EXAMINATIONS: MORE BREAST IMAGING EXAMINATIONS ARE PERFORMED BY BREAST RADIOLOGISTS

Richard E. Sharpe JR, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Aditya Khurana, MD (*Abstract Co-Author*) Nothing to Disclose
Alan Zhu, BS (*Abstract Co-Author*) Nothing to Disclose
Tariq Rashid (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to evaluate for potential subspecialization among radiologists interpreting breast imaging (BI) examinations for the US Medicare population.

### METHODS AND MATERIALS

Outpatient imaging claims for the US Medicare population from 2013 to 2021 were extracted from the CMS POSPUF database. Examinations were classified as either BI or not, and tallied by year, and by individual radiologists. A BI case mix was calculated for each radiologist. Radiologist BI case mixes were stratified into quartiles. Radiologists submitting 75th percentile of claims as BI examinations were considered breast subspecialized, and were

compared to radiologists submitting fewer BI claims. We further analyzed urban versus rural practice settings, geographic regions, and female versus male gender. T-test, Kruskal-Wallis one-way analysis of variance test, and Multivariate Linear Regression Analysis tests were computed.

**RESULTS**

The total number of BI examinations increased from 8009216.1 in 2013 to 13783647.0 in 2021 (+72.1%). The total number of BI wRVUs increased from 5593430.7 in 2013 to 9761024.8 in 2021 (+74.5%). The total number of radiologists interpreting BI examinations decreased from 13,770 in 2013 to 11,540 in 2021 (-16.2%). The proportion of all imaging wRVUs associated with BI exams increased from 25.1% in 2013 to 41.9% in 2021 (+24%). Radiologists with a high case mix of BI examinations (above the upper 75th percentile), the percent of their case mix that were BI examinations increased from 19.2% in 2013 to 57.3% in 2021 (P<0.01). The percent of their case mix that were BI wRVUs also increased from 33.1% in 2013 to 74.4% in 2021 (P<0.01). Increased subspecialization in BI was consistently observed with stratified cohorts of urban versus rural setting, Northeast US, United States in comparison to the rest of the country, and female versus male gender radiologists (all $p < 0.00001$).

**CONCLUSION**

Breast imaging services and wRVU trends from 2013 to 2021 suggest that interpretation of breast imaging examinations have become increasingly concentrated in a smaller number of subspecialized breast radiologists, particularly in the Northeast US, in urban practice settings and in relation to female gender radiologists. Practice leaders should optimize recruitment efforts and processes to support the trend of breast subspecialized radiologists performing most of their work in their specialty.

**CLINICAL RELEVANCE/APPLICATION**

While increasing subspecialization in breast imaging may lead to better overall care, this raises concern for increased discrepancies within the radiology workforce. Further attention to ensure that patients are adequately cared for across a spectrum of clinical settings throughout the United States is necessary.

## S3B-SPNPM-3 AI-DRIVEN REPORTING TIME STANDARDIZATION

Roberto Ardon (*Abstract Co-Author*) Employee, AXA Venture Partners
Maria Elena Laino, MD (*Abstract Co-Author*) Nothing to Disclose
Chloe Adam, PhD (*Abstract Co-Author*) Employee, Incepto Medical SAS
Guillaume Herpe (*Abstract Co-Author*) Medical Officer Incepto-France Grant, Guerbet
Leo Alberge (*Abstract Co-Author*) Nothing to Disclose
Tom Vesoul (*Abstract Co-Author*) Nothing to Disclose
Gaspard d'Assignies, MD, PhD (*Presenter*) Founder, Incepto Medical SAS;Employee, Incepto Medical SAS;Stockholder, Incepto Medical SAS

**PURPOSE**

To assess the time gain using AI algorithm among radiological tasks from differents commercially available algorithms

**METHODS AND MATERIALS**

A multi-reader, multi-case methodology was used in this retrospective multicentric study. The study dataset (n= 504 ) included 56% men and a mean age of 45 years (SD = ± 15.8 years). Three subsets consisted of 106 aortic scans ( segmentation ), 202 MRI scans of the knee ( detection ) , and 196 MRI scans of the prostate ( characterization ) of each of them with a controlled prevalence for each.Ground Truth for each task was established in consensus for each subset by two experts radiologist of each domain ( MSK, Vascular and Urogenital ).An Aortic segmentation algorithm (ARVA V2.0) analyzed the included CTA, an knee MR detection algorithm ( KEROS V2.0) analyzed the knee MR and a prostate cancer characterization algorithm ( PAROS V1.0 ) analyzed the Prostate MR.The dataset also presented to six general radiologist, with and without AI assistance, which including a washout period of one month. The main comparison criteria were the reading/analysis time for the three subset using similar annotation tool to ensure consistency ( Genesis V.2.1).

**RESULTS**

From the 504 examination included, 504 were finally analyzed.For the aortic scans, 618 segments of the aorta were annotated, The average time to measure the aortic diameters during an examination for both radiologists together demonstrated a significant mean decrease of 62% in time with AI assistance (138 ± 97 sec) compared to without AI assistance (364 ± 456 sec) ($p<0.001$). A significant decrease in standard deviation was also assessed ( - 80%,$p<0.001$ ).For the knee MR detection subset : The introduction of AI assistance led to an overall decrease in the average time required per exam by 38% (from 98.2 ± 64.2 to 60.9 ± 36.5seconds, $p<0.001$) associated with a significant decrease of standard deviation ( - 60% , $p<0.001$).For the prostate subset: The introduction of AI assistance led to an overall decrease in the average time required per exam by 38% (from 141.32 ± 55.6 to 66.6 ± 23.5seconds, $p<0.001$) associated with a significant decrease of standard deviation ( - 59 % , $p<0.001$).

**CONCLUSION**

AI algorithms have demonstrated an impact on the time taken to perform various radiological tasks, but an even greater impact on standardising the time taken to read examinations, paving the way for an improvement in the reproducibility of relative value units.

**CLINICAL RELEVANCE/APPLICATION**

AI significantly reduces exam times and enhances standardization across radiological evaluations, improving diagnostic efficiency and consistency.

## S3B-SPNR-1 CAN BRAIN-TO-TUMOR OUTER INTERFACE RADIOMICS IMPROVE THE EFFICIENCY OF MRI IN PREDICTING THE BRAIN INVASION OF MENINGIOMAS

Yunjing Xue, MD (*Abstract Co-Author*) Nothing to Disclose
Kai Wang (*Abstract Co-Author*) Nothing to Disclose
Yichao Zhang (*Abstract Co-Author*) Nothing to Disclose
Dingfu Wei (*Abstract Co-Author*) Nothing to Disclose
Lin Lin (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic efficacy of predicting the brain invasion of meningiomas based on radiometric features extracted from three different regions: brain-to-tumor interface (BTI), brain-to-tumor inner interface (BTII), and brain-to-tumor outer interface (BTOI).

### METHODS AND MATERIALS

A retrospective study of 729 patients with pathologically confirmed meningiomas was conducted between 2013 and 2022. We constructed three radiomics models using features extracted from three different regions of interest (ROIs): BTII region (with an automatic 4mm shrinkage of the tumor ROI boundary, referred to as the BTII model), BTOI region (with an automatic 4mm expansion of the tumor ROI boundary, referred to as the BTOI model), and BTI region (with an automatic 4mm extension of the tumor ROI boundary, referred to as the BTI model). The features were extracted from T1-weighted, T1-weighted post-contrast, and T2-fluid attenuated inversion recovery magnetic resonance imaging. Support Vector Machine (SVM), Linear Discriminant Analysis (LDA), and Logistic Regression (LR) were employed as the classifiers. The decision curve analysis (DCA) and integrated discrimination improvement (IDI) index were used to compare the benefits of different models.

### RESULTS

The AUC values of BTOI, BTII and BTI models were 0.918, 0.883 and 0.898 in the training set and 0.894, 0.815 and 0.825 in the test set, respectively. The DCA curve shows that the BTOI model has the best net return. IDI showed that compared with BTII and BTI models, the BTOI model had a significant improvement in predicting the brain invasion of meningiomas ($P < 0.05$).

### CONCLUSION

Radiomic signatures from the BTOI region demonstrated the most robust performance in predicting meningioma brain invasion.

### CLINICAL RELEVANCE/APPLICATION

Brain invasion is an independent diagnostic criterion for the diagnosis of WHO grade 2 meningiomas, and preoperative prediction of brain invasion in meningiomas is crucial for making treatment decisions. Our findings have the potential to assist in predicting the brain invasion of meningioma before surgery.

## S3B-SPNR-10 ALTERATIONS IN CORTICAL THICKNESS AND VOLUMES OF SUBCORTICAL STRUCTURES IN PEDIATRIC PATIENTS WITH COMPLETE SPINAL CORD INJURY

Ling Wang (*Presenter*) Nothing to Disclose

### PURPOSE

To study the changes of cortical thickness and subcortical gray matter structures in children with complete spinal cord injury (CSCI), reveal the possible causes of dysfunction beyond sensory motor dysfunction after CSCI, and provide a possible neural basis for corresponding functional intervention training.

### METHODS AND MATERIALS

Thirty-seven pediatric CSCI patients and 34 age-, gender-matched healthy children as healthy controls (HCs) were recruited. The 3D high-resolution T1-weighted structural images of all subjects were obtained using a 3.0 Tesla MRI system. Statistical differences between pediatric CSCI patients and HCs in cortical thickness and volumes of subcortical gray matter structures were evaluated. Then, correlation analyses were performed to analyze the correlation between the imaging indicators and clinical characteristics.

**RESULTS**

Compared with HCs, pediatric CSCI patients showed decreased cortical thickness in the right precentral gyrus, superior temporal gyrus and posterior segment of the lateral sulcus, while increased cortical thickness in the right lingual gyrus and inferior occipital gyrus(Figure1). And the volume of the right thalamus in pediatric CSCI patients was significantly smaller than that in HCs(Figure2). No significant correlation was found between the imaging indicators and the injury duration, sensory scores, motor scores of pediatric CSCI patients.

**CONCLUSION**

These findings demonstrated that the brain structural reorganizations of pediatric CSCI occurred not only in sensory motor area, but also in cognitive and visual related brain regions, which may suggest that the visual processing, cognitive abnormalities and related early intervention therapy also deserve greater attention beyond sensory motor rehabilitation training in pediatric CSCI patients.

**CLINICAL RELEVANCE/APPLICATION**

Our study revealed the possible causes of dysfunction beyond sensory motor dysfunction after CSCI, and provide a possible neural basis for corresponding functional intervention training.

## S3B-SPNR-12 DIFFERENTIAL DIAGNOSIS BETWEEN MENINGIOMA AND SCHWANNOMA IN CEREBELLOPONTINE ANGLE REGION USING FIREFLY IMAGING

Xin Cao (*Presenter*) Nothing to Disclose

**PURPOSE**

The 3D contrast-enhanced T1-weighted Imaging Flow Sensitive Black Blood (CE-T1WI FSBB), known as "firefly imaging", suppresses the flowing blood signal by the flow phase destroying the pulse, thus providing a clear contrast compared with the enhanced brain tumor with a high signal. This study aimed to quantify image features of intratumoral vessels and intratumoral microbleeds by firefly imaging, and to investigate the biological behavior differences between meningiomas and schwannomas in the cerebellopontine angle region based on imaging features.

**METHODS AND MATERIALS**

Seventy-three cases of meningiomas and 24 cases of schwannomas confirmed by postoperative pathology were included. Two neuroradiologists independently counted intratumoral vessels and intratumoral microbleeds based on CE-T1WI FSBB images. The vessel density index (VDI) and microbleed density index (MDI) were the number of intratumoral vessels and the number of intratumoral microbleeds divided by the tumor volume, respectively. The consistency test of intratumoral vessel count and intratumoral microbleeds count between the two neuroradiologists based on the same image is summarized using 2-way random ICC (C, 1). Mann-Whitney U-test and chi-square test were used to determine significant differences between meningiomas and schwannomas and between fibrous meningiomas and epithelial meningiomas.

**RESULTS**

The ICC for intratumoral vessels count and intratumoral microbleeds count based on CE-T1WI FSBB was 0.89 (95%CI:0.85-0.93) and 0.99 (95%CI:0.99-0.99), respectively. A comparison of 73 meningiomas and 24 schwannomas based on CE-T1WI FSBB images revealed differences in the number of intratumoral microbleeds ($P<0.01$) and MDI values ($P<0.01$). Comparison between fibrous meningiomas and epithelial meningiomas based on CE-T1WI FSBB images revealed differences in the number of intratumoral microbleeds ($P<0.01$), MDI values ($P<0.01$), and sex of patients ($P<0.05$).

**CONCLUSION**

According to the CE-T1WI FSBB imaging features, schwannomas have a higher incidence of intratumoral hemorrhage, more intratumoral microbleeds, and higher MDI values than meningiomas, which aids in preoperative differential diagnosis and treatment decisions. Compared with fibrous meningiomas, epithelial meningiomas are more prone to imaging features of intratumoral microbleeds, which contributes to a better understanding of the biological behavior of different pathological types of meningiomas.

**CLINICAL RELEVANCE/APPLICATION**

This technique will help to distinguish meningiomas from schwannomas by imaging features based on biological behavioral differences.

## S3B-SPNR-13 VOLUME QUANTIFICATION OF INTRACEREBRAL HEMORRHAGE, INTRAVENTRICULAR HEMORRHAGE, AND PERIHEMATOMA EDEMA THROUGH DEEP LEARNING APPROACHES

Laurent Letourneau-Guillon, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Igor G. Padilha, MD (*Abstract Co-Author*) Nothing to Disclose

Eleyine Zarour, MD (*Abstract Co-Author*) Nothing to Disclose
Delphine Pilon (*Abstract Co-Author*) Nothing to Disclose
An Ni Wu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We aimed to curate a multiclass segmentation dataset and develop models that can accurately segment intracerebral hemorrhage (ICH), intraventricular hemorrhage (IVH), and perihematoma edema (PHE) using non-contrast CT (NCCT).

**METHODS AND MATERIALS**

We extracted NCCT volumes from the RSNA Intracranial Hemorrhage Detection 2019 Kaggle dataset - a head NCCT dataset with image-level classification consisting of five subtypes of intracranial hemorrhage. A board-certified neuroradiologist filtered the database to extract volumes containing at least one image labeled with ICH. Through an iterative process, our team manually annotated ICH, IVH, and PHE regions. Inter-annotator reliability during the refinement process was calculated. The dataset was subdivided (105/22/30 train/validation/test splits) and brain extraction was performed. A self-configuring fully convolutional neural network UNet-based model (nnUNet) and one transformer-based model (Swin UNETR) were trained to segment ICH, IVH, and PHE classes. Model performances were assessed using the Dice coefficient, and agreement statistics on extracted volumes were calculated.

**RESULTS**

One hundred fifty-seven (157) volumes were annotated. Inter-rater reliability, measured by Dice coefficients (95% confidence interval) for 146 volumes, was 0.95 (0.94-0.96) for ICH, 0.78 (0.69-0.86) for IVH, and 0.81 (0.76-0.85) for PHE. In our test set, Dice coefficients were 0.84 (0.77-0.90), 0.42

(0.25-0.59), 0.52 (0.42-0.62) for nnUNet; 0.81 (0.73-0.87), 0.26 (0.13-0.39), 0.50 (0.40-0.59) for Swin UNETR. Relative volume differences were 4.0% (7.4-22.3), 44.5% (24.7-64.2), 103.5% (35.3-218.9) for nnUNet; and 19.0% (10.3-29.8), 43.5% (17.8-77.6), 104.5% (42.1-207.1) for Swin UNETR. The intra-class correlation coefficients were 0.99 (0.99-1.00), 0.86 (0.77-0.94), and 0.74 (0.53-0.87) for nnUNet; 0.99 (0.97-0.99), 0.86 (0.74-0.93), 0.68 (0.43-0.83) for Swin UNETR. Examples of predictions are illustrated in Figure 1.

**CONCLUSION**

We curated a multiclass ICH segmentation dataset and plan to release the labels in the near future. Our best model, nnUNet, achieved good accuracy for ICH volume estimation but needs further improvements for IVH and PHE.

**CLINICAL RELEVANCE/APPLICATION**

A publicly available dataset would allow the independent comparison of existing models. Accurately segmenting ICH and its complications can support clinical management and research on this topic.

## S3B-SPNR-14 QUANTITATIVE AND QUALITATIVE PARAMETERS OF DCE-MRI PREDICT CDKN2A/B HOMOZYGOUS DELETION IN GLIOMAS

Xin Zhang (*Abstract Co-Author*) Nothing to Disclose
Bing Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Huiquan Yang, PhD (*Abstract Co-Author*) Nothing to Disclose
Jianan Zhou (*Abstract Co-Author*) Nothing to Disclose
Zhengyang Zhu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Homozygous deletion of CDKN2A/B holds important prognostic value in gliomas. This study aimed to explore the predictive potential of conventional MRI imaging parameters combined with dynamic contrast-enhanced MRI parameters in predicting CDKN2A/B homozygous deletion status in gliomas.

**METHODS AND MATERIALS**

Preoperative MRI data of 105 patients (69 without CDKN2A/B homozygous deletion, and 36 with CDKN2A/B homozygous deletion) with gliomas were retrospectively collected. Conventional MRI features and dynamic contrast-enhanced-MRI qualitative parameter time-intensity curve types, quantitative parameters Ktrans, Kep, Ve, Vp, and iAUC were obtained. Logistic regression models for prediction of CDKN2A/B homozygous deletion status were constructed in all types of gliomas and both subtypes of IDH-mutant and IDH-wild gliomas.

**RESULTS**

Multivariate analysis for all patients demonstrated that age (OR = 1.103, p = 0.002) and Ktrans (OR = 1.051, p < 0.001) independently predicted CDKN2A/B homozygous deletion. In IDH-mutant subgroup, multivariate analysis results indicated that Ktrans (OR = 1.098, p = 0.031) emerged as autonomous predictors of CDKN2A/B homozygous deletion. In IDH-wild subgroup, age (OR = 1.111, p = 0.002) and Ktrans (OR = 1.032, p = 0.001) were independent predictors of CDKN2A/B homozygous deletion according to the multivariate analysis. The areas under the receiver operating characteristic curve of the corresponding models were 0.90, 0.95 and 0.84, respectively.

**CONCLUSION**

Ktrans can serve as valuable predictive parameters for identifying CDKN2A/B homozygous deletion status in both subtypes of IDH-mutant and IDH-wild gliomas.

**CLINICAL RELEVANCE/APPLICATION**

These findings provide a foundation for precise preoperative non-invasive diagnosis and personalized treatment approaches for glioma patients.

## S3B-SPNR-15 LANGUAGE REORGANIZATION IN PATIENTS WITH BRAIN TUMORS: A MULTI-NETWORK PERSPECTIVE

Antonio Napolitano (*Abstract Co-Author*) Nothing to Disclose
Andrei I. Holodny, MD (*Abstract Co-Author*) Nothing to Disclose
Kyung K. Peck, PhD (*Abstract Co-Author*) Nothing to Disclose
Mehrnaz Jenabi, MS (*Abstract Co-Author*) Nothing to Disclose
Luca Pasquini, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Tumors cause local impairment of brain function, but also widespread effects on brain networks, which may be due to tumor damage or adaptive neuroplasticity. Here we studied the modifications of resting-state (rs) networks induced by brain tumors and their participation in language reorganization. Our hypotheses were: 1) patients with language reorganization would display differences in the cognitive networks which support interhemispheric communication; 2) these differences would be associated with better clinical performance.

**METHODS AND MATERIALS**

Patients were selected with the inclusion criteria: newly diagnosed, pathologically confirmed left hemispheric tumor; right handedness; task-based (tb) and rs fMRI; no artifacts. Age matched healthy controls (HC) were recruited from open sources databases. Language laterality was calculated on tb fMRI. We characterized 6 rs networks through cosine similarity and quantified the difference between patients and HC through earth mover's distance (EMD). The effect of tumor location and grade on networks' EMD was studied with ANOVA and t test. EMD changes related to language reorganization were studied with t test. The role of networks modifications on patients' speech was assessed with t test.

**RESULTS**

142 right handed patients (35 low grade, 88 high grade glioma; 19 metastases) and 180 HC were included. Frontal tumors were associated with modifications of the default mode (DM, p=0.021), sensorimotor (SM, p=0.039), cognitive control (CC, p=0.014) networks; insular with CC (p=0.006); occipital with DM (p=7.362e-5); parietal with DM (p=0.005), CC (p=0.021) networks; central with CC (p=0.003). T test confirmed significant effects of lateralization on networks' EMD: CC with Wernicke's laterality index (LI) (p=0.004), SM with cerebellar LI (p=0.03), DM with hemispheric LI (p=0.03), auditory network with Broca's LI (p=0.011). All tumor types demonstrated significant effects on brain networks. Modification of CC was associated with less speech deficits 1 week after surgery (p=0.005).

**CONCLUSION**

CC, DM, SM and auditory networks were the most affected functional structures. Inter-hemispheric language reorganization may rely on the participation of these networks to wire the cerebral hemispheres. Cognitive control may play a role in the development of adaptive neuroplasticity of language, as

demonstrated by improved speech performance.

**CLINICAL RELEVANCE/APPLICATION**

The identification of 'facilitative networks' for language plasticity may help the development of targeted therapies to prompt speech preservation: before surgery, by guiding cognitive training to enhance plastic changes and allow for radical resection; after surgery, by improving the recovery of language during rehabilitation.

## S3B-SPNR-16 ASSESSMENT OF BRAIN DEVELOPMENT IN CHILDREN WITH CONGENITAL DIAPHRAGMATIC HERNIA - AN AUTOMATED BRAIN SEGMENTATION APPROACH

Larissa Gotz (*Abstract Co-Author*) Nothing to Disclose
Victor Saase (*Abstract Co-Author*) Nothing to Disclose
Eva Neumaier-Probst (*Abstract Co-Author*) Nothing to Disclose
Meike Weis (*Abstract Co-Author*) Nothing to Disclose
Sherif A. Mohamed, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

to assess the brain development of 2year old children who underwent CDH repair, comparing those who required ECMO with those who did not, alongside a healthy control group utilising a MRI-based automated segmentation approach.

**METHODS AND MATERIALS**

This study evaluated brain development in 31 children aged 2 years who had undergone CDH repair as neonates, comparing the subcohort of those who had received ECMO therapy (n = 10) with those who had not (n =21), alongside 31 healthy age-matched controls. The CDH patients derived from a longitudinal study of the University Medical Center of Mannheim. The control children were from the NIH database of the MRI Study of the normal brain development. For segmentation T1 weighted 3D MRI images were used. The image postprocessing was performed in MATLAB 2015a. Using CerebroMatic toolbox a customized DARTEL template for the age group of 24 months was created. Coregistration of the acquired MRI images to the DARTEL template was performed using the software SPM12. Automated segmentation of cerebrospinal fluid (CSF), white matter (WM), and gray matter (GM) was performed using CAT 12 toolbox. This segmentation process utilised surface based and voxel based morphometry algorithms, allowing for the automated measurement of cortical thickness (CT) and total intracranial volume (TIV).

**RESULTS**

CDH patients showed a statistically significant increase in GM ($p = 0.002$), CSF ($p = 0.009$), TIV ($p = 0.01$) and CT ($p < 0.001$) in comparison to healthy controls (HC). None of the before mentioned volumes showed statistically significant differences between the subcohorts of CDH patients ($p >0.05$). Observed decrease in WM in CDH patients did not reach statistical significance within the subcohorts ($p > 0.05$). CT was statistically significantly increased in all subcohorts compared to the HC ($p< 0.001$). CSF volume was significantly increased in CDH patients who did receive ECMO therapy compared to HC ($p = 0.005$).

**CONCLUSION**

The increases CT in CDH patients may be an indicator for structural abnormality and therefore the reported delayed neurodevelopment. Moreover, the observed increase in CSF volume maybe associated with the application of ECMO therapy.

**CLINICAL RELEVANCE/APPLICATION**

This study offers a nuanced exploration of neuroanatomical differences in children with CDH, shedding light on the complex interplay of factors influencing brain development. The observed changes warrant further research to understand their long-term implications and potential connections to ECMO therapy. The study's methodological insights into automated segmentation provide a foundation for future investigations in pediatric neuroimaging, emphasizing the importance of refining techniques for accurate and clinically relevant assessments.

## S3B-SPNR-17 LONGITUDINAL ASSOCIATION OF DTI-ALPS INDEX WITH COGNITIVE PERFORMANCE

Chang-Soo Yun (*Abstract Co-Author*) Nothing to Disclose
Youngjin Lee (*Abstract Co-Author*) Nothing to Disclose
Hajin Kim, BS (*Abstract Co-Author*) Nothing to Disclose
Kyuseok Kim (*Abstract Co-Author*) Nothing to Disclose
Sewon Lim, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

The diffusion tensor image analysis along the perivascular space (DTI-ALPS) index has been found to be associated with multiple cognitive scores through existing cross-sectional studies. As AD is progressive, cross-sectional studies can't quantify longitudinal changes in cognitive status and glymphatic function, necessitating a longitudinal approach. This study aims to evaluate the DTI-ALPS index's capability for detecting AD by investigating its association with longitudinal cognitive performance changes, specifically assessing how variations in the DTI-ALPS index correspond to shifts in cognitive status—ranging from cognitively normal to incident mild cognitive impairment (MCI), persistent MCI, and incident AD—over a two-year period.

**METHODS AND MATERIALS**

The DTI-ALPS index was measured in participants who were cognitively normal (n = 119), had incident MCI (n = 13), persistent MCI (n = 74), or incident AD (n = 19) from the Alzheimer's Disease Neuroimaging Initiative. We calculated the DTI-ALPS index and correlated them with montreal cognitive assessment (MOCA), mini mental state examination (MMSE), and clinical dementia rating scale (CDR) scores using partial correlation and linear regression which the influence of age, gender, APOE4 genes and education was controlled.

**RESULTS**

Comparative analysis of the two-year changes in the DTI-ALPS index among the cognitively normal, incident MCI, persistent MCI, and incident AD group revealed average changes (%) of -0.428 (SE = 0.601), -4.572 (SE = 1.145), -1.526 (SE = 0.653), and -5.296 (SE = 1.304), respectively. Significant differences in mean values were observed between the cognitively normal and the incident MCI group (ß = -4.112, P = 0.023), as well as between the cognitively normal and the incident AD group (ß = -5.196, P = 0.001). An analysis of the correlation between changes in the DTI-ALPS index and changes in cognitive performance over a period of two years revealed significant positive correlations between the changes in the DTI-ALPS index and changes in MoCA scores (r = 0.192, P = 0.004), MMSE scores (r = 0.167, P = 0.012), and CDR scores (r = 0.269, P < 0.001).

### CONCLUSION

In conclusion, this study validates the DTI-ALPS index as a longitudinal biomarker for Alzheimer's disease progression. Significant changes in this index correlate with cognitive decline, especially in groups transitioning to incident MCI and AD over two years. These results underline the utility of the DTI-ALPS index in predicting and tracking cognitive impairment progression.

### CLINICAL RELEVANCE/APPLICATION

The findings show that the DTI-ALPS index effectively emphasizes the glymphatic system's key role in cognitive progression in Alzheimer's research.

## S3B-SPNR-19 MACHINE LEARNING TO PREDICT AMYLOID POSITIVITY IN MILD COGNITIVE IMPAIRMENT BASED ON BRAIN ATROPHY

Soohwan Choi (*Abstract Co-Author*) Nothing to Disclose
Seongbeom Park, MS (*Abstract Co-Author*) Nothing to Disclose
Kichang Kwak (*Presenter*) Nothing to Disclose

### PURPOSE

Amyloid-beta deposition, a hallmark of AD, plays an increasingly pivotal role in mild cognitive impairment (MCI) progression. Recent advancements in neuroimaging have highlighted brain atrophy as a potential hallmark of MCI, indicating disease progression. 2D MRI scans, vital for diagnosis, provide crucial structural data, yet protocol variability challenges conventional analysis tools, limiting their clinical utility. Leveraging machine learning on 2D MRI data unlocks complex patterns indicative of amyloid positivity, aiding early AD intervention. This study aims to explore machine learning's efficacy in accurately predicting amyloid positivity from brain atrophy patterns in MCI, facilitating early AD diagnosis.

### METHODS AND MATERIALS

In this study, we predicted amyloid positivity in MCI subjects using machine learning, based on patterns of brain structural atrophy, cognitive test and APOE genotyping. The amyloid PET scans were analyzed from the Beaubrain Amylo. We generated 2D MRI by uniformly selecting slices from the 3D MRI. The deep learning model was developed to segment extracerebral cerebrospinal fluid (eCSF) volumes, with a focus on analyzing eCSF near the gray matter in each lobe region, as well as the anterior and posterior lateral ventricles, and neighboring volumes near the hippocampus regions.

### RESULTS

We analyzed data from 363 subjects, obtained from the Alzheimer's Disease Convergence Research Center at Samsung Medical Center in South Korea. We utilized support vector machine, which relies on multi-modal input data. 5-fold cross-validation was employed within the training set to optimize and fine-tune the model's performance, resulting in similar performance across the different folds. The model with the best performance achieved maximal accuracy of 91.74%, with an area under the curve (AUC) of the receiver operating characteristic (ROC) of 0.83 (95% CI: 0.75- 0.91).

### CONCLUSION

In summary, the findings indicate that patterns of atrophy in individuals with MCI are reliably predictable, suggesting their potential utility in forecasting amyloid positivity. Future research in this area may further refine predictive models and contribute to the development of personalized treatment strategies for individuals with MCI at risk of developing AD.

### CLINICAL RELEVANCE/APPLICATION

The use of 2D MRI scans and machine learning algorithms to predict amyloid positivity in individuals with MCI holds significant clinical relevance. Early identification of amyloid deposition, a hallmark of AD, enables timely intervention strategies, potentially slowing disease progression and improving patient outcomes. This approach has direct implications for enhancing the clinical management of individuals at risk for developing dementia.

## S3B-SPNR-3 IMPAIRMENT OF THE GLYMPHATIC SYSTEM ON THE SHORT-TERM PROGNOSIS OF PATIENTS WITH ACUTE ISCHAEMIC STROKE: A DTI-ALPS STUDY

Xiaolan Du, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The glymphatic system is significantly damaged after acute ischemic stroke (AIS).We aimed to confirm the correlation of glymphatic damage with short-term outcome in patients with acute ischemic stroke (AIS) by tracking the changes of two imaging parameters, diffusion tensor image analysis along perivascular space (DTI-ALPS), and enlarged perivascular spaces (EPVS).

### METHODS AND MATERIALS

Fifty AIS patients and fifty healthy control (HC) were included. The AIS group underwent brain magnetic resonance imaging at 24 hours, 7 days and 3 months, and the National Institutes of Health Stroke Scale (NIHSS) was used to score. The HC group was matched according to the same time interval. We assessed DTI-ALPS indices in the bilateral hemispheres and EPVS volume fractions in bilateral centrum semiovale (CSO), basal ganglia (BG), and lateral ventricles.

### RESULTS

AIS patients showed a mildly elevated ALPS index of 1.61±0.1 on the infarcted side within 24 hours (P=0.012), and a decreasing trend in ALPS index of 1.35±0.15 and 1.45±0.13 at 7 days and 3 months, respectively, (P<0.001). BG-PVS volume scores were significantly greater in stroke patients than HC group and were negatively correlated with ALPS index (r=-0.312,P=0.041). Lower ALPS index was associated with NIHSS score (r=0.515,P=0.021).

### CONCLUSION

Decreased DTI-ALPS was associated with increased BG-PVS and worse neurological function in the short term and can serve as non-invasive assessments for glymphatic dysfunction and its interventions in clinical studies.

### CLINICAL RELEVANCE/APPLICATION

To reveal the effect of glymphatic system damage on the short-term recovery of patients with ischemic stroke

## S3B-SPNR-5 FIRST DEMONSTRATION OF THE VENOUS PLEXUS OF REKTORZIK ON ULTRA-HIGH RESOLUTION VESSEL WALL MRI

Seena Dehkharghani, MD (*Abstract Co-Author*) Nothing to Disclose
Eytan Raz, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Siddhant Dogra, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The plexus of Rektorzik (PoR) is a venous arcade that surrounds the petrous internal carotid artery (ICA). The plexus has rarely been studied with imaging, mostly with sporadic exploration using high-resolution catheter angiography, and never with MRI. Vessel wall imaging (VWI) is increasingly used for characterizing intramural disease in the cerebral circulation. We recently reported a high-performance accelerated approach featuring robust flow suppression and achieving better than 400 micron isotropic multicontrast VWI. We observed a remarkably consistent enhancing vascular plexus corresponding anatomically to the expected PoR, exceeding vasa vasorum and persisting even with full flow suppression in the ICA. Further, we have noted the PoR commonly to engorge further in subjects with high-grade anterior circulation steno-occlusive disease and felt a formalization of this intriguing use of VWI to be timely.

### METHODS AND MATERIALS

28 patients underwent 35 VWI examinations using compressed sensing and CAIPI-accelerated variable-flip SPACE with DANTE as previously reported. Studies were assessed for asymmetric extraluminal enhancement surrounding the petrous ICA, blinded to history. Presence and location of stenoses derived from CTA and/or catheter angiography was noted afterward. A Z-test was used to compare the proportion of patients with and without high-grade ICA stenosis who demonstrated asymmetric ipsilateral extraluminal enhancement.

### RESULTS

Altogether 27 studies were evaluated, with one subject excluded due to absence of post-contrast VWI. 15 of 27 (55.6%) were determined to have asymmetrically increased enhancement about the petrous ICA. Among 15 patients without ICA stenosis, 5 (33.3%) showed bilateral enhancement while among 12 patients with high-grade ICA stenosis, 10 (83.3%) had strong asymmetric enhancement ($p = 0.009$), all on ipsilateral sides. No evidence for engorged vasa vasorum was noted elsewhere in the pathologic ICA and findings were isolated to the expected location of the PoR for all cases.

### CONCLUSION

We detected asymmetrically increased extraluminal enhancement surrounding the petrous ICA in a majority of patients undergoing VWI, proposed to represent the venous PoR in a manner not previously reported by MRI. This enhancement was observed significantly more frequently in patients with ICA stenoses, always on ipsilateral sides, suggesting a potential sensitivity to the hemodynamic effect of stenoses but requiring further dedicated study.

### CLINICAL RELEVANCE/APPLICATION

The venous plexus of Rektorzik may be encountered on vessel wall MR imaging, particularly in patients with high-grade ICA stenosis, requiring recognition and discrimination from unsuppressed flow or vasa vasorum proliferation.

## S3B-SPNR-6 INTRACRANIAL ATHEROSCLEROSIS IS LINKED TO LOWER VOLUME IN THE POSTERIOR BODY AND TAIL OF THE HIPPOCAMPUS

Julie A. Schneider, MD (*Abstract Co-Author*) Nothing to Disclose
Arnold M. Evia JR, PhD (*Abstract Co-Author*) Nothing to Disclose
David A. Bennett, MD (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Arfanakis, PhD (*Abstract Co-Author*) Nothing to Disclose
Mahir Tazwar, BS (*Abstract Co-Author*) Nothing to Disclose
Gulam Mahfuz Chowdhury (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to investigate brain morphometric anomalies associated with intracranial atherosclerosis in a large number of community-based older adults.

### METHODS AND MATERIALS

This work included 891 community-based older adults participating in four cohort studies of aging: MAP, ROS, MARS, AACC. After autopsy, hemispheres from all participants were imaged approximately one month postmortem on 3T clinical MRI scanners using a multi-echo spin-echo sequence with a voxel size=0.6×0.6×1.5 mm3. All images were non-linearly registered to an ex vivo brain hemisphere template using ANTs. The logarithm of the Jacobian determinant of the deformation fields was calculated in each voxel and the resulting maps (LogJ) were smoothed using a Gaussian filter with a FWHM=4mm. Following ex-vivo MRI, all hemispheres underwent detailed neuropathologic examination. The assessed pathologies included atherosclerosis, arteriolosclerosis, cerebral amyloid angiopathy, gross and microscopic infarcts, Alzheimer's pathology, Lewy bodies, LATE-NC, and hippocampal sclerosis. Voxel wise linear regression was used to test the association of atherosclerosis with deformations shown in the smoothed LogJ maps, controlling for other age-related neuropathologies, demographics (age at death, sex, years of education), postmortem interval to fixation, postmortem interval to imaging, and scanner. The FSL PALM tool with 1000 permutations, threshold-free cluster enhancement, and tail acceleration was used for the statistical analysis. Associations were considered significant at $p<0.05$ after FWER correction for multiple comparisons.

### RESULTS

Intracranial atherosclerosis was significantly associated with lower volume in the posterior body and tail of the hippocampus ($p<0.05$), independently of the effects of other age-related neurodegenerative and vascular pathologies. No part of the brain showed significantly higher volume with atherosclerosis.

### CONCLUSION

This work combined DBM on ex-vivo MRI with detailed neuropathologic examination in a large number of community-based older adults and demonstrated that intracranial atherosclerosis is associated with lower volume of the posterior body and tail of the hippocampus.

### CLINICAL RELEVANCE/APPLICATION

This finding is of great interest due to the important role of the hippocampus in cognition. Furthermore, atherosclerosis is often mixed with Alzheimer’s pathology and/or LATE neuropathological change, which have previously shown independent associations with lower hippocampal volume. Therefore, hippocampal volume by itself cannot serve as a reliable marker of any of the three pathologies, but more localized metrics of hippocampal atrophy may potentially provide higher specificity.

## S3B-SPNR-7 EXPLORING THE BEST MONOCHROMATIC ENERGY LEVEL IN DUAL ENERGY SPECTRAL IMAGING FOR INTRACRANIAL VENOUS STENTS

Shobhit Mathur, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor Mendes Pereira (*Abstract Co-Author*) Nothing to Disclose
Timothy Reynold U. Lim, MD (*Abstract Co-Author*) Nothing to Disclose
Yingming Amy Chen, MD (*Abstract Co-Author*) Nothing to Disclose
Vinu Mathew, MD (*Abstract Co-Author*) Nothing to Disclose
Nicole Cancelliere (*Abstract Co-Author*) Nothing to Disclose
Joel Kosowan, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Dual energy spectral CT enables creation of virtual monoenergetic reconstructions, enhancing contrast-to-noise ratio (CNR) at lower monochromatic energy levels (MELs) and reducing artifacts such as beam hardening at higher MELs. Previous studies have evaluated the optimal MEL in the setting of endovascular aortic repair stent grafts, peripheral arterial and coronary stents, and intracranial aneurysm clips and coils. However, the application of dual energy CT in evaluating intracranial stents, particularly in venous stenting for idiopathic intracranial hypertension and pulsatile tinnitus, remains unexplored. Hence, we aimed to evaluate the optimal MEL in patients with intracranial venous stents.

### METHODS AND MATERIALS

A total of 13 stents were evaluated in 10 patients (3 with bilateral stents). Images were reconstructed at 10 keV intervals from 40 to 140 keV. Subjective image quality was evaluated by two neuroradiologists using a 5-point Likert scale with overall image quality, ability to evaluate the stent lumen and beam hardening artifacts as criteria. For quantitative analysis, ROIs (minimum 5 mm in diameter) were drawn within and outside the stented vessel, the internal jugular vein and masseter muscle (used as a surrogate measure of background) to measure CT values (HU). Contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) were calculated at different MELs.

### RESULTS

Images at 90 and 100 keV had the highest ratings for both radiologists. Overall Likert scale responses between the two raters showed high correlation ($R = 0.95$, $p<0.0005$). Statistically significant differences were found comparing 100 keV to other energy levels using Conover's all-pairs test for neuroradiologist 1 ($p<0.01$) but not for neuroradiologist 2 ($p = 0.096$). The mean CT value in-stent showed a decreasing trend with increasing MEL: [40-140 keV] (1180.72 ± 245.49) HU to (112.53 ± 15.65) HU. CNR and noise demonstrated a decreasing trend with increasing MEL: [40-140 keV] CNR: (50.91 ± 16.84) to (10.62 ± 4.47) and noise (444.89 ± 33.54) to (49.38 ± 3.94), while SNR stayed constant (11.15 ± 4.95) to (9.43 ± 3.15). Tukey's HSD showed no difference in CNR, SNR and noise between 90 keV and 70 keV, but CNR was significantly decreased at 100 keV compared to 70 keV ($p <0.05$).

### CONCLUSION

This study supports 90 keV as being the optimal MEL for imaging patients with intracranial venous stents, balancing CNR within the vessel being evaluated while minimizing beam hardening artifacts.

### CLINICAL RELEVANCE/APPLICATION

For CT performed for patients with intracranial venous stents on dual-energy CT scanners, 90 keV images should be preferred for review.

## S3B-SPNR-8 BEAMS: A BOUNDARY-ENHANCED APPROACH FOR MS LESION CHANGE SEGMENTATION

Prateek Mathur (*Abstract Co-Author*) Nothing to Disclose
Brendan Kelly, BMBCh, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The accurate identification of new or growing lesions in patients suffering from Multiple Sclerosis (MS) is crucial for treatment planning. We leverage longitudinal MRI imaging and boundary constraints of these lesions to build deep-learning pipelines and assess their impact on lesion segmentation.

### METHODS AND MATERIALS

A cohort of 170 patients with at-least two examinations, a baseline and a follow-up were included. Images were acquired on a 1.5 T system (SIEMENS MAGNETOM Avanto syngo MR B19, SIEMENS, Munich, Germany). Imaging included three-dimensional T2 fluid-attenuated inversion-recovery (FLAIR) sequences rigidly registered to the baseline T1 sequence. Lesion annotation involved two steps: automated lesion segmentation followed by manual cleanup and verification by two radiologists referencing original radiology reports, with final annotations verified by a third expert. The data is divided into training, validation and a hold-out test set which match the size of the external MSSEG2 validation dataset. A baseline and a follow-up image slice is fed to a deep-learning pipeline to identify and segment new or enhanced lesions. Pipelines included a 2D (1) nnUNet (2) Siamese-UNet (3) BEAMS Siamese UNet which are the lesion detection benchmark, a change detection model and a boundary enhanced change detection model respectively. The predicted area segmentation is re-stacked to form a volume. Evaluation metrics included Dice Scores (DSC), Precision (PRC), and Recall (REC) to assess pipeline efficacy in lesion identification.

### RESULTS

The trained pipelines are also evaluated on an external dataset with longitudinal MS data. Boundary-enhanced pipeline achieves best performance both on internal and external datasets(DSC=0.40,0.46;PRC=0.30,0.44;REC=0.71,0.25) followed by the Siamese UNet (DSC=0.39,0.42;PRC=0.25,0.43;REC=0.63,0.25) outperforming the nnUNet (DSC=0.21,0.28;PRC=0.014,0.022;REC=0.68,0.38).Evaluation on internal and external dataset showcases the generalization, robustness and reliability of the BEAMS pipeline.

### CONCLUSION

Our study demonstrates the BEAMS pipeline's superior performance validated on both internal and external datasets. These findings underscore the potential of boundary-enhanced methods and their utility in clinical practice.

### CLINICAL RELEVANCE/APPLICATION

Identification of new and enhancing MS lesions is a challenging and time consuming problem prone to observer bias. Automating lesion identification with a BEAMS pipeline offers swift and objective analysis, aiding clinicians in identifying probable regions of lesion growth and improving patient-care.

## S3B-SPNR-9 ASSOCIATION BETWEEN BODY MASS INDEX AND BRAIN AGINGIN ADULTS: A 16-YEAR POPULATION-BASED COHORT AND MENDELIAN RANDOMIZATION STUDY

Han Lv, MD (*Presenter*) Nothing to Disclose

## PURPOSE

High body mass index (BMI), a modifiable factor associated with poor cardiovascular health, is linked to brain health, but the causal relationship between BMI and brain health remains unclear. This study aimed to demonstrate the effect of cumulative BMI on neuroimaging features in adults of different ages and verify the causal relationship.

## METHODS AND MATERIALS

This study was based on the KaiLuan Study, a multicenter, long-term follow-up, community-based longitudinal cohort study of the adult population that began in 2006. The study included participants who visited the hospital at least 3 times and underwent brain MRI examination, with no evidence of dementia or mental disorders. Exclusion criteria were incomplete or poor-quality neuroimaging data and diagnosed cancer. We modeled the trajectories of BMI over 16 years to evaluate cumulative exposure. Multimodality neuroimaging data were collected using 3.0-T MRI, starting in 2020, for volumetric measurements of the brain structure, white matter hyperintensity (WMH), and skeletonized white matter tract at the voxel level. We performed two-sample Mendelian randomization analysis using genetic data from 681,275 individuals to analyze the causal relationship between BMI and neuroimaging features.

## RESULTS

In the population-based longitudinal study, clinical and neuroimaging data were obtained from 1,074 adults (aged 25-83 years). High BMI was associated with a wide range of negative brain health effects. For adults aged under 45 years, the differences in cerebral parenchyma volume between those with BMI > 26.2 kg/m2 and those with normal BMI corresponded to 12.0 years (95% confidence interval [CI], 3.0 to 20.0) of brain aging. The volumetric results corresponded to -17.9 ml (95% CI, -29.8 to -4.5). Differences in WMH were statistically significant for participants aged over 60 years, with a 6.0-ml (95% CI, 1.5 to 10.5) larger volume. Genetic analysis of 681,275 individuals indicated causal relationships among high BMI, smaller volume of the cerebral parenchyma and gray matter, and higher fractional anisotropy in projection fibers.

## CONCLUSION

These findings provide a basis for future brain health promotion and disease prevention strategies.

## CLINICAL RELEVANCE/APPLICATION

High BMI is causally associated with smaller brain volume and abnormal microstructural integrity in projection fibers, especially in young adults.

## S3B-SPOB-1 MRI TEXTURE FEATURES AND ADC VALUES FOR DIFFERENTIATING UTERINE SARCOMA AND CELLULAR UTERINE LEIOMYOMA

Chao Wei (*Abstract Co-Author*) Nothing to Disclose
Zhong Yang (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to evaluate the capability of MRI texture features and ADC values in the differential diagnosis of uterine sarcoma (US) from cellular uterine leiomyoma (CUL).

### METHODS AND MATERIALS

61 patients confirmed by pathology were retrospectively reviewed, including 27 cases of USs and 34 cases of CULs. All patients underwent conventional pelvic MRI and DWI (b values of 0 and 1000 s/mm2), and the ADC values (mean ADC value (ADCmean), min ADC value (ADCmin) and standardized ADC value (ADCst)) were measured and calculated. Whole tumors were segmented by manually drawing the lesion contours on each slice of T2WI and DWI images, then the texture features were selected by using the intraclass correlation efficient (ICC) analysis, Pearson correlation analysis, and the least absolute shrinkage and selection operator (LASSO). Mann-Whitney U test to compare the ADC values. The model(LRADC, LRtexture and LRcombinations) were developed using logistic regression analysis based on the optimal texture features, ADC value and their combinations respectively, and then area under receiver operating characteristic curve(AUC-ROC) was used to assess the diagnostic efficiency of each model.

### RESULTS

The ADCmean, ADCmin and ADCst of USs were significantly lower than those of CULs ($P < 0.05$). The LRcombinations model showed better performance for the tumor differentiation (AUC:0.921) than LRADC model(AUC:0.696),($z=3.358, P<0.001$). The calibration curve was basically the same as the ideal curve, and decision curve analysis confirmed better clinical usefulness than the other two models.

### CONCLUSION

MRI texture features and ADC values could be useful in the preoperative assessment of uterine masses to differentiate US with CUL. Incorporation of texture features into ADC values improves the differential diagnostic accuracy.

### CLINICAL RELEVANCE/APPLICATION

MRI texture features and ADC values give a better method to identify US and CUL, providing a more reliable basis for the choice of clinical treatment.

## S3B-SPOB-2 TIME-DEPENDENT DEPENDENT DIFFUSION MRI FOR QUANTITATIVE MICROSTRUCTURAL MAPPING OF ENDOMETRIAL CANCER

Qi Yang, MD (*Abstract Co-Author*) Nothing to Disclose

Ruxue Han (*Abstract Co-Author*) Nothing to Disclose
Wenyi Yue (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the feasibility of time-dependent diffusion MRI to delineate microstructural features for noninvasive evaluation of cellular characteristics in endometrial cancer (EC).

### METHODS AND MATERIALS

Patients with a clinical suspicion of EC were prospectively enrolled between September 2023 and April 2024. Time-dependent diffusion MRI data were prospectively acquired with pulsed and oscillating gradient diffusion MRI sequences, alongwith other routine clinical protocols, on a 3.0 T MR scanner. Microstructural parameters, such as cell diameter, intracellular volume fraction, cellularity, and diffusivities, were derived from the time-dependent diffusion MRI data, using a two-compartment model. The estimated microstructural parameters were evaluated for their efficacy in distinguishing patients with EC presenting different pathological characteristics including myometrial invasion status, lymphovascular space invasion (LVSI), status lymph node (LN) status and overall FIGO stage by an unpaired two-tailed t-test and one-way analysis of variance. Additionally, the correlations between the microstructural parameters were assessed by linear regression.

### RESULTS

A total of 21 women who underwent time-dependent diffusion MRI followed by surgical pathology were included in the study. We illustrated the comparison of microstructural parameters obtained from time-dependent diffusion MRI among different pathological characteristics of EC patients. The analysis revealed significant differences in diffusivities based on the myometrial invasion status, LVSI status, LN status and overall FIGO stage of EC ($P<0.05$). Specifically, early-stage EC and cases without LVSI showed higher diffusivities, whereas deep myometrial invasion and LN metastasis showed lower diffusivities. However, microstructural parameters did not show differences among progesterone receptor status, p53 status and aggressive histological types. Additionally, the relationship between microstructural parameters and conventionally used diffusivity at 0 Hz was examined at the participant level in EC participants with various pathological characteristics.

### CONCLUSION

The time-dependent diffusion MRI-derived microstructural properties in distinguishing the different microstructural features showed complementary strength in the clinical staging and identification of high-risk factors of EC patients.

### CLINICAL RELEVANCE/APPLICATION

The microstructural mapping based on time-dependent diffusion MRI correlates with pathological findings and holds promise for characterizing endometrial cancer.

## S3B-SPOB-3 INITIAL EVALUATION OF SENTINEL LYMPH NODES IN PATIENTS WITH CERVICAL AND VULVAR CANCER USING LYMPHOSONOGRAPHY COMPARED TO SURGICAL PATHOLOGY

Norman G. Rosenblum, MD, PhD (*Abstract Co-Author*) Research Grant, General Electric Company
Aaron Shafer (*Abstract Co-Author*) Nothing to Disclose
Flemming Forsberg, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation;Research support, Canon Medical Systems Corporation;Research support, General Electric Company;Speaker, General Electric Company;Research support, Siemens AG;Research Grant, Butterfly Network, Inc;Research support, Lantheus Medical Imaging, Inc;Research support, Bracco Group
Trang Vu (*Abstract Co-Author*) Nothing to Disclose
Priscilla Machado, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The identification of the sentinel lymph node (SLN) is an important aspect of predicting outcomes for patients with cancer. Lymphosonography is a contrast-enhanced US modality that uses subcutaneous injection of US contrast agents to localize the SLNs and it has been studied as a novel technique to lymphatic mapping. The objective of this study was to evaluate this technique in subjects diagnosed with cervical or vulvar cancer scheduled for surgery with SLN excision comparing the lymphosonography findings with pathology.

### METHODS AND MATERIALS

Subjects diagnosed with cervical or vulvar cancer scheduled for surgery with SLN excision were eligible to be enrolled in this ongoing, IRB-approved study. The US contrast agent Sonazoid (GE Healthcare, Oslo, Norway) was administrated in 4 aliquots at 12, 3, 6, and 9 o'clock positions around the primary tumor by the clinical surgical team, with 0.25 ml for each aliquot for a total dose of 1.0 ml. Real time contrast enhanced US imaging (CEUS) was performed to identify SLNs that demonstrated contrast-enhancement. Results were recorded and compared to the pathology results obtained after the surgical procedure. An Aplio i800 Prism scanner (Canon Medical Systems USA, Tustin, CA) with curvilinear (8C1) and linear (18L5) probes with CEUS capabilities were used during the study.

### RESULTS

A total of 11 SLNs in 5 subjects were surgically excised. Three subjects had cervical cancer with iliac SLNs being excised, 8 SLNS were sent to pathology. From the 8 SLNs, 6 were determined to be benign by pathology and 2 were determined to be malignant. Two subjects had vulvar cancer with inguinal SLNs being the ones excised, 3 SLNS were sent to pathology. From the 3 SLNs, 2 were determined to be benign by pathology, while 1 was determined to be malignant by pathology. Lymphosonography identified 17 SLNs in the 5 subjects. Comparing the surgically excised SLNs and the ones identified by lymphosonography showed that10 of the 11 SLNs surgically excised or 91% were identified by lymphosonography. Lymphosonography identified all the benign SLNs and 2 out of the 3 malignant SLNs.

### CONCLUSION

This initial evaluation on the use of lymphosonography to identify SLNs in subjects with cervical or vulvar cancer undergoing surgery with SLN excision demonstrate that lymphosonography identified 10 out of the 11 SLNs surgically excised, including all the benign SLNs and 2 malignant SLNs.

### CLINICAL RELEVANCE/APPLICATION

Lymphosonography is a US modality that uses US contrast agents to identify SLNs, which is an important aspect of predicting outcomes for patients with cancer.

## S3B-SPOB-4 DIAGNOSTIC ACCURACY AND INTER-OBSERVER AGREEMENT OF THE O-RADS SCORING SYSTEM

Li Tao (*Presenter*) Nothing to Disclose

### PURPOSE

The objective of this study is to evaluate the diagnostic accuracy, inter-observer agreement and inter-observer agreement of adnexal masses using the Ovarian-Adnexal Reporting and Data System (O-RADS) Magnetic Resonance Imaging (MRI) risk stratification system

### METHODS AND MATERIALS

A total of 572 adnexal lesions of 463 patients with pathological results were retrospectively collected in our hospital from June 2017 to May 2023. Two different experienced readers who were blinded to the patients' clinical data and pathological results independently evaluated the images and then assigned a score to each adnexal lesion using the O-RADS MRI risk stratification system. One of the readers reviewed the images and reassigned the scores after three months. Intra- and inter-observer agreements were evaluated with the k-coefficient value. The gold standard of O-RADS MRI score was determined by the evaluation of two senior radiologists with more than 20 years of experience. Any disagreements were resolved by re-review and discussion, and then the O-RADS MRI score of the adnexal lesions was finally determined with 1-5 points.

### RESULTS

Excellent intra-observer agreement and inter-observer agreement were observed with the k values of 0.941 (95 % CI, 0.926-0.960) and 0.854 (95 % CI, 0.821-0.881), respectively. Good sensitivity (90%-100%), positive predictive values (89%-100%) and variable specificity (78%-100%), negative

predictive values (74%-100%) were observed for each O-RADS MRI classification by two readers and one reader three months apart. The area under the curve (AUC) of readers ranged from 0.951 to 0.960 when regarded O-RADS MRI = 4 as malignancy. There was no statistical significance in the comparison of ROC curves between the two readers ($p > 0.05$).

**CONCLUSION**

intra-observer agreement and inter-observer agreement of O-RADS MRI were excellent with high diagnostic accuracy. O-RADS MRI can be used as a good diagnostic tool in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

Radiologists encounter patients with adnexal masses every day,and correct preoperative diagnosis and risk classification can reduce the rate of unnecessary surgery for benign lesions and improve the prognosis for malignant lesions.O-RADS MR is a good tool to do that.

## S3B-SPPD-1 CLINICAL AND CMR ASSESSMENT OF CORONARY ARTERY DILATION ONLY IN CHILDREN WITH KAWASAKI DISEASE: ANALYSIS OF THE CHINA-COHORT STUDY

Lingyi Wen JR, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhongqin Zhou (*Abstract Co-Author*) Nothing to Disclose
Shengkun Peng, MD (*Abstract Co-Author*) Nothing to Disclose
Lei Hu (*Presenter*) Nothing to Disclose

### PURPOSE

Kawasaki disease (KD) is an acute vasculitis of childhood with unknown etiology. The most common and severe sequelae of KD is coronary artery lesion (CAL) and the American Heart Association (AHA) proposed the risk stratification resting on the severity of it. In the risk stratification guideline, KD patients with coronary artery (CA) no involvement and CA dilation only shared the same long-term management algorithm. The clinical and CMR assessment of KD patients would be an important reference for risk stratification and long-term management but this remains unclear in patients with CA dilation only. Therefore, our study aims to investigate the clinical and CMR characteristics and compare them with KD patients with CA no involvement.

### METHODS AND MATERIALS

455 KD patients diagnosed from 2012 to 2023 were recruited in the study. They were divided into the CA no involvement group (n=313, 180 males, average age 2.2±1.3 years) and the CA dilation only group (n=142, 86 males, average age 2.2±1.3 years). 50/311 (16.1%) and 22/142 (15.5%) of them underwent cardiac magnetic resonance (CMR) examinations during convalescence. The laboratory data, echocardiography results and CMR parameters between the two groups were compared and Kaplan-Meier analysis was performed to estimate the cumulative probability of the endpoints including coronary events, cardiac death, heart failure and new-onset malignant arrhythmias of KD patients.

### RESULTS

The abnormities of laboratory analysis and echocardiography results in KD patients recovered after the standard therapy and there were no significant differences between the two groups of KD patients both at onset and during convalescence (all $p>0.05$). For CMR assessment, no differences were discovered in cardiac diameters and volumes, cardiac function (GRS: 38.3±8.7% vs. 39.9±20.5%, $p=0.563$; GCS: -18.7±6.8% vs. -18.3±7.2%, $p=0.612$; GLS: -13.2±3.7% vs. -13.4±4.1%, $p=0.219$) and myocardial tissue parameters (native T1 values: 1296.5±74.1 ms vs. 1313.3±80.5 ms, $p=0.078$; global T2 values: 38.2±4.1 ms vs. 38.1±3.5 ms, $p=0.334$; LGE proportion: 4.0% vs. 2.5%, $p=0.876$) between the two groups. The median follow-up of 4.2 years revealed a favorable prognosis in both patients with CA no involvement and dilation only, with no adverse cardiovascular events observed.

### CONCLUSION

The clinical and CMR characteristics of CA dilation only in children with KD were similar to patients with CA no involvement and they shared a favorable medium- and long-term prognosis.

### CLINICAL RELEVANCE/APPLICATION

It's the first time to illustrate that the two groups of KD patients should follow the same long-term management algorithm from the perspectives of clinical and CMR, providing important support for the elevation of guideline evidence level.

## S3B-SPPD-2 FEASIBILITY OF VIRTUAL REALITY COMPARED TO MULTIPLANAR REFORMATION WITH BALLOON-SIZING AS THE GOLD STANDARD IN ASSESSING PULMONARY VALVE DIAMETERS IN PATIENTS WITH CONGENITAL HEART DEFECTS

Matthias Gutberlet, MD, PhD (*Abstract Co-Author*) Speaker, Siemens AG;Speaker, Koninklijke Philips NV;Speaker, Bayer AG;Speaker, Bracco Group;Author, Thieme Medical Publishers, Inc
Anne Sophie Weber (*Abstract Co-Author*) Nothing to Disclose
Martin Kostelka (*Abstract Co-Author*) Nothing to Disclose
Sebastian Schaudt (*Abstract Co-Author*) Nothing to Disclose
Ingo Dahnert (*Abstract Co-Author*) Nothing to Disclose
Robin F. Gohmann, MD (*Abstract Co-Author*) Nothing to Disclose
Florian Loeffelbein (*Abstract Co-Author*) Nothing to Disclose
Christian Luecke, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

3D-visualizations including Virtual Reality (VR) have a long history in imaging; however, their benefit seems to be mainly visualization driven. Measurements in these visualizations are not sufficiently evaluated and radiologists rely on multiplanar reformations to measure the correct dimensions prior percoutanous pulmonary valve implantation (PPVI), [Ebel et al., 2019]. However, an intensive training might be needed to make residents familiar with these techniques, while VR has probably a more intuitive approach. We wanted to evaluate if one can assess essential right outflow tract (ROT) dimensions using VR on MRI data, in patients with congenital heart defects with repaired conotruncal anomalies, in regard to further interventions needed.

**METHODS AND MATERIALS**

23 patients, aged 8 to 59 years, underwent preinvasive 1.5 T MRI scans after corrective surgery. An ECG-gated diastolic 3D SSFP-whole-heart-sequence with a 300 mm FoV was acquired and reconstructed with voxel sizes down to 0.69 mm. A dedicated VR-software (Vea-Sim) and an Oculus Quest 2 VR headset was used to measure the area of the infundibulum (INF), the maximal (MAX) and minimal (MIN) diameter of the pulmonary outflow tract and the bifurcation (BIF), after calibration by the abdominal aorta. 4 patients were excluded due to stent artifacts. Reference measurements were performed using curved MPR (cMPR) by IntelliSpace Portal 12.1. Comparisons were performed using Bland-Altman plots. Balloon sizing was available as a standard of reference in 9 patients.

**RESULTS**

VR underestimated the diameter area vs. cMPR: At the height of INF the difference was -4.2 mm with an upper limit (UL) of 55.7 mm and lower limit (LL) of -64.1 mm. Mean bias at MIN was: : -8,8 mm², UL: 36,0 mm², LL: -53,7 mm², and at MAX was -15,7 mm², UL: 62,9 mm², LL: -94,3 mm² respectively. At BIF mean difference was -14,6 mm², with a LL of -89,2 mm², and an UL of 60,1 mm² (all differences not statistically significant p>0,123). Compared to the ballon sizing both methods showed excellent agreement with MIN at the possible landing zone. VR underestimated by -0.5 mm LL: 9.6 mm; UL: 8.6 mm and cMPR underestimated by -0.1 mm LL: -9.2 mm; UL: 9mm (both n.s. with p>0.8).

**CONCLUSION**

VR and cMPR based on MRI data both can assess essential diameters in non-stented ROT needed for PPVI, suggesting potential for non-invasive precise measurements in clinical routine via VR or cMPR.

**CLINICAL RELEVANCE/APPLICATION**

VR does not only offer an intuitive and potentially valuable educational tool but is able to enable imagers and interventionalists to evaluate crucial diameters from non stented ROT for PPVI. However, it requires further validation in larger cohorts against established measurement techniques to support this promising results.

## S3B-SPPD-3 DIAGNOSTIC AND PROGNOSTIC UTILITY OF CARDIAC MRI IN NEONATES AFTER CONGENITAL DIAPHRAGMATIC HERNIA REPAIR

Christopher Hart (*Abstract Co-Author*) Nothing to Disclose
Florian Kipfmueller (*Abstract Co-Author*) Nothing to Disclose
Julian A. Luetkens, MD (*Abstract Co-Author*) Speakers Bureau, Koninklijke Philips NV;Research Consultant, Bayer AG

Dmitrij Kravchenko, MD (*Abstract Co-Author*) Nothing to Disclose
Ulrike I. Attenberger, MD (*Abstract Co-Author*) Consultant, Bayer AG
Narine Mesropyan, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The triad of pulmonary hypoplasia, pulmonary hypertension, and early cardiac dysfunction has been postulated to be responsible for poor postnatal outcomes in neonates with congenital diaphragmatic hernia (CDH). The aim of this observational prospective study was to investigate whether cardiac MRI markers of cardiac dysfunction are associated with clinical outcomes in neonates after CDH repair.

**METHODS AND MATERIALS**

In this prospective study (from June 2020 to December 2022) neonates after CDH repair underwent cardiac MRI in a neonatal ICU-sited and neonatal-sized 3T scanner in deep sedation. Cardiac MRI protocol included assessment of biventricular function and volumes (left and right ventricular ejection fraction [LVEF, RVEF], end diastolic [EDV] and end systolic [ESV] volumes, shunt fraction [Qp/Qs], and lung perfusion). The study cohort was binarized based on median RVEF (cutoff value >54%) to compare clinical variables and outcome data (need for extracorporeal membrane oxygenation support (ECMO) and death) between the two groups. Measurements were performed separately and/or in consensus by two board certified radiologists. Unpaired t test, Mann-Whitney U test, Spearman correlation coefficient, and a univariable ordinal regression model were used for statistical analysis.

**RESULTS**

A total of 47 neonates (mean gestational age: 37±2 weeks, 11 female, 40 left-sided CDH, 22 "liver-up") were evaluated. Baseline anthropometric and clinical characteristics (incl. age, sex, birth weight and height [percentile], time to repair, etc.) were similar in both groups (P>0.05). Impaired RVEF correlated with the need for ECMO support after CDH repair (r=0.46, P=.042). Neonates with lower RVEF (<54%) had worse clinical outcomes (17 vs. 4% mortality, P=0.049; 52 vs. 17% ECMO, P=0.044). Univariable ordinal regression analysis revealed an association between MRI-derived RVEF and the need for ECMO support (odds ratio: 0.87, 95% confidence interval: 0.75-0.98; P=0.019). LVEF was more impaired in the group with RVEF<54% (LVEF: 55±4vs. 59±4%, P=0.023).

**CONCLUSION**

Cardiac MRI allows for accurate and objective assessment of cardiac dysfunction in neonates after CDH repair. MRI-derived parameters of right ventricular dysfunction were associated with adverse short-term clinical outcomes.

**CLINICAL RELEVANCE/APPLICATION**

Cardiac MRI might play an important role in risk stratification and clinical decision-making in neonates after CDH repair.

## S3B-SPPH-1 MULTISOURCE CBCT SCANNING GEOMETRY FOR THE REDUCTION OF METAL ARTIFACTS IN MAXILLOFACIAL APPLICATIONS

Antonio Minopoli (*Abstract Co-Author*) Nothing to Disclose
Jianping Lu (*Abstract Co-Author*) Consultant, Xintek Inc;Consultant, Surround Medical Systems, Inc;Consultant, XinRay Systems Inc
Shuang Xu (*Abstract Co-Author*) Nothing to Disclose
Otto Zhou, PhD (*Abstract Co-Author*) Board of Directors, Surround Medical Systems, Inc;Board of Directors, NuRay Technology Co, Ltd;Board of Directors, Xintek Inc
Christina R. Inscoe, PhD (*Abstract Co-Author*) License agreement, Xintek Inc
Antonio Sarno (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the use of a multi-source cone-beam CT (CBCT) scanner with unconventional scanning geometry for the reduction of metal artifacts from dental implants via experimental and in-silico studies.

### METHODS AND MATERIALS

Experimental studies were conducted on carbon-nanotube multi-source CBCT (ms-CBCT) developed at the Univ. of North Carolina on a phantom incorporating two metallic pins. The ms-CBCT scanner embodied a 99-μm pixel C-MOS flat-panel detector and the x-ray source was operated at 110 kV by using two focal spots placed on a segment parallel to the rotation axis. 300 projections were alternatively taken from the two sources - 150 projections per source - over a scanning angle of 360 deg. The distance between the two sources (H) was fixed during the scan. The image quality was investigated varying the distance H and as a function of the relative position of the segment and the metallic pins. Evaluations focused on the relation between H and both voxel fluctuations introduced by the metal artifacts and distortion on HU evaluation. Metal artifacts were evaluated as the normalized metal artefact index (nMAI) calculated as the square root of the difference between the variance in a region of interest between the pins and that evaluated within a region of interest not affected by metal artefacts; the value was normalized by the expected voxel value. Tests were also performed in-silico, via a GPU based Monte Carlo platform, that permitted to further explore the proposed scanning geometry.

### RESULTS

The nMAI presented a decrescent trend as the distance between the sources increased. It passed from 0.67 for CBCT configuration (H = 0), to 0.59 for H = 40 mm and 0.57 for H = 80 mm. A drastic reduction is obtained for H = 100 mm, down to 0.26. This may be mainly due to the fact that no portion of the two metallic pins is included in the same x-ray beam direction for H = 100 mm and the signal is spread over several planes by the reconstruction algorithm. From a visual point of view, the metal artefacts resulted drastically reduced in the axial slices containing the metallic inclusions.

### CONCLUSION

The proposed CBCT scanner configuration embodying a two-spot source allowed a reduction of metal artifacts due to the presence of small pins in a phantom. Such artefacts reduced as the distance between the focal spot increased, with the evaluated nMAI index reducing by 12% passing from CBCT to 40 mm distance focal spot configuration; nMAI reduced by 61% when used 100 mm between the two sources.

### CLINICAL RELEVANCE/APPLICATION

The proposed application showed the potential of reducing metal artifacts in CBCT maxillo-facial imaging towards an improvement of the image quality for planning and verification of implants, as well as for image guided surgery.

## S3B-SPPH-10 EFFECTS OF RADIATION DOSE LEVEL AND IODINE CONCENTRATION ON THE ACCURACY OF IODINE QUANTIFICATION USING DEEP LEARNING IMAGE RECONSTRUCTION IN DUAL-ENERGY SPECTRAL CT: AN IODINE PHANTOM STUDY

Le Cao (*Abstract Co-Author*) Nothing to Disclose
Jianxin Guo (*Abstract Co-Author*) Nothing to Disclose
Jianying Li, PhD (*Presenter*) Employee, General Electric Company

### PURPOSE

To investigate the accuracy of iodine quantification using deep learning image reconstruction (DLIR) in dual-energy CT (DECT) at different radiation dose levels and iodine concentrations.

**METHODS AND MATERIALS**

A DECT quality control phantom simulating adult abdomen (Multi-Energy CT Quality Assurance Phantom; GPH-75B, Science in Kyoto) with three iodine inserts (4.0, 8.0, 12.0mg/mL) was imaged using DECT mode. Scans were repeated 5 times at CT dose index (CTDIvol) levels of 4, 7, 10, 14mGy. Images were reconstructed using 50% adaptive statistical iterative reconstruction (ASIR-V) (ASIR-V50%) and DLIR at low (DLIR-L), medium (DLIR-M) and high (DLIR-H) settings. Iodine concentration of the three iodine inserts were measured. The coefficient of variation (CV) of iodine concentration in target inserts was calculated as CV = (SD÷M) * 100%, where SD and M refer to the standard deviation and mean of the iodine concentrations, respectively. The one way repeated-measures analysis of variance with Bonferroni correction was used to evaluate the differences in iodine concentration and CV among different reconstructions.

**RESULTS**

The iodine quantification did not differ significantly at different radiation dosages among reconstructions. The CV of the 4mg/mL iodine was significantly higher than that of the 8 and 12mg/mL iodine. With the increase of radiation dose, CV decreased significantly, and the difference was more obvious at low iodine inserts. The CV values on ASIR-V50% images at 4, 7, 10, 14mGy were 0.20, 0.15, 0.16, 0.13 for the 4mg/mL, 0.09, 0.09, 0.06, 0.06 for the 8mg/mL, and 0.07, 0.07, 0.05, 0.04 for the 12.0mg/mL iodine inserts, respectively. DLIR algorithms significantly reduced the measurement variability. At 4mGy, the CV values for the 4.0, 8.0, 12.0mg/mL iodine inserts (0.13, 0.05, 0.06) were the lowest on DLIR-H images, and highest (0.20, 0.09, 0.07) on ASIR-V50% images. Using DLIR, the CV values for iodine quantification at 4mGy were similar to ASIR-V50% images at 14mGy dose level (0.13, 0.06, 0.04), $P<0.001$.

**CONCLUSION**

DLIR significantly reduces the image variability and improves the accuracy of iodine quantification in low-dose conditions.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning image reconstruction to improve accuracy of iodine quantification.

## S3B-SPPH-12 VIRTUAL MONOENERGETIC IMAGING OF STENOSIS AT DIFFERENT KEV IN MOBILE PHOTON-COUNTING DETECTOR CT

Kwanhee Han (*Abstract Co-Author*) Employee, Samsung Electronics Co, Ltd
Su-Jin Park (*Abstract Co-Author*) Empolyee, Samsung Electronics Co, Ltd
Duhgoon Lee (*Abstract Co-Author*) Employee, NeuroLogica Corporation
Jinwook Jung (*Abstract Co-Author*) Employee, Samsung Electronics Co, Ltd
Junyoung Park (*Presenter*) Employee, Samsung Electronics Co, Ltd

**PURPOSE**

The main purpose of this study is to evaluate accurate quantification for the degree of carotid artery stenosis that causes ischemic stroke using virtual monoenergetic images (VMI) with mobile PCD-CT which can be brought closer to the bedside, the risks associated with transport can be reduced.

**METHODS AND MATERIALS**

In this study, the FDA 510(k) cleared mobile PCD-CT (OmniTom Elite PCD, Samsung-Neurologica, Danvers, MA, USA) was used. We developed our own VMI algorithm to find the inverse problem mathematically. The measured CT number in VMI for iodine inserts of Gammex phantom was compared with manufacturer reference values. In addition, VMI were generated between 33keV and 34keV to evaluate incremented signal of iodine which has k-edge as 33.2keV. Using the university of Dundee's soft embalmed perfused human cadaveric model, degree of stenosis was evaluated. The right common carotid artery was cannulated, and 10% iodine contrast was injected. VMI were obtained at 40, 60, 80, 100, 120 and 140keV. The degree of stenosis of the left internal carotid artery was assessed using the NASCET criteria.

**RESULTS**

To demonstrate the virtual monochromatic image (VMI) function, we evaluated that the CT values of the iodine rods (or other rods in the phantom) in the VMI images agree well with the CT values computed from NIST tables in the keV range available. The measured CT number in VMI for iodine inserts of Gammex phantom was compared with manufacturer reference values. The measured CT number in VMI closely matched the reference value with mean percent error of 5.615%. We also confirmed the iodine signal increased after k-edge energy of iodine (33.2keV). The degree of stenosis with the human cadaveric showed that as keV increased from 40keV to 100keV, percentage stenosis decreased from 100% to 39.59%. Between 100keV and 120keV, percentage stenosis increased from 39.59% to 40.16%, then decreased to 33.8% at 140keV. We confirmed improved the accuracy of carotid artery stenosis assessment by offering different inherent contrast images.

**CONCLUSION**

Our quantitative results of multi-energy phantom verified the accuracy of our VMI with mobile PCD-CD. In addition, the qualitative results of Gamex phantom demonstrate new possibilities for K-edge imaging which can distinguish different materials by a K-edge characteristics within single acquisition. Through VMI reconstructions at different keV and the qualitative and quantitative results, mobile PCD-CT has the potential to improve the accuracy of carotid artery stenosis assessment.

**CLINICAL RELEVANCE/APPLICATION**

The VMI with mobile PCD-CT can lead to simplified clinical imaging protocols and improved workflow for neuroimaging of critical patients with the risks associated with transportation and life-threatening illness.

## S3B-SPPH-2 EFFECTS OF SUBJECT MOTION AND ACQUISITION TIME ON CONE-BEAM CT IMAGE QUALITY FOR NOVEL FAST SCANNING PROTOCOLS

Alejandro Sisniega, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Micro-X Ltd;Research Grant, Izotropic Corporation
Michael J. Salerno, PhD,MBA (*Abstract Co-Author*) Nothing to Disclose
Taoran Li, PhD (*Abstract Co-Author*) Nothing to Disclose
Boon-Keng K. Teo, PhD (*Abstract Co-Author*) Nothing to Disclose
David Adam, PHD (*Abstract Co-Author*) Nothing to Disclose
Xun Jia, PhD (*Abstract Co-Author*) Nothing to Disclose
William Hrinivich, PHD (*Abstract Co-Author*) Nothing to Disclose
Alexander Lu (*Presenter*) Nothing to Disclose

**PURPOSE**

Patient motion during cone-beam CT acquisition produces blur, streaks, shape distortion, and position shift of soft-tissue and high-contrast targets. Such effects hamper the utility of CBCT imaging for identification and targeting of structures experiencing motion for intra-procedural planning or guidance. This work systematically assesses the effects of reduced acquisition time (16 s to 6 s) on CBCT image quality, shape distortion, and target positioning accuracy in the presence of intra-acquisition patient motion for two on-board CBCT scanners.

**METHODS AND MATERIALS**

Two phantoms were used to characterize motion: a polyethylene cylinder bearing 6 electron-density inserts (P1) and a deformable abdominal phantom containing a liver with contrast-enhanced lesions and vascular surrogates (P2). Both phantoms were coupled to a 2-DOF motion actuator and imaged using two CBCT systems with acquisition times of 16.6 s (CBCT-16.6s) and 6 s (CBCT-6s). Sinusoidal motion (4 s period) was applied during image acquisition with translational amplitudes ranging from 0.0 to 10.0 mm, paired with rotational amplitudes from 0.0 to 19.5 degrees when imaging P1. High-contrast inserts (P1, P2) and low-contrast soft tissues (P2) were used to quantify spatial resolution, using edge spread function (ESF) measurements for each type of tissue. Circularity error and centroid excursion were also computed for high-contrast inserts (P1).

**RESULTS**

CBCT-6s demonstrated reduced blur and streak artifacts compared to CBCT-16.6s, with consistently improved edge sharpness and structural integrity in both phantoms for both high- and low-contrast regions. Under moderate motion (2.5 mm), median ESF was 1.37 and 0.88 mm, circularity error was 4.30 and 2.35 mm, and centroid excursion was 1.06 and 1.26 mm for the CBCT-16.6s and CBCT-6s scanners, respectively. For all motions, CBCT-6s was more robust to ESF degradation.

**CONCLUSION**

Reduced acquisition time improved the image sharpness and reduced circularity error in on-board CBCT images, but increased centroid excursion, suggesting a tradeoff between accurate target position and accurate target shape / sharpness.

**CLINICAL RELEVANCE/APPLICATION**

In the presence of patient motion, faster CBCT acquisition increases shape reconstruction accuracy, but may result in deviation in reconstructed object position.

## S3B-SPPH-3 DETECTABILITY OF IODINE IN MEDIASTINAL LESIONS ON PHOTON COUNTING CT: A PHANTOM STUDY

Mathias Prokop, MD, PhD (*Abstract Co-Author*) Speakers Bureau, Canon Medical Systems Corporation;Research Grant, Siemens AG;Speakers Bureau, Siemens AG

David Goos (*Abstract Co-Author*) Nothing to Disclose
Marcel Greuter, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the detectability of iodine in mediastinal lesions with photon counting CT (PCCT) compared to conventional CT (CCT).

**METHODS AND MATERIALS**

A 10cm diameter solid water phantom containing 5 cylindrical inserts with diameters from 1 to 12 mm was placed in the mediastinal area of an anthropomorphic chest phantom (QRM-thorax) including fat ring (QRM L-ring) 30cm x 40cm cross-section at inserts level. Inserts were filled with iodine contrast at concentrations of 0.24 to 27 mg/ml. The phantom was scanned with clinical chest protocol at 120 kV on PCCT (Naeotom Alpha, Siemens Healthineers) and on a high-end CCT (Somatom Force, Siemens Healthineers) using identical dose. For PCCT the effect of virtual mono-energetic images (VMI) was also examined at 40, 50, 60 and reference 70 keV, and the effect of dose reduction by 66%. Two observers with similar experience independently determined the smallest insert size for which iodine enhancement could still be detected. Consensus was reached when detectability thresholds differed between observers. This allowed for constructing contrast-detail curves for the various scan settings.

**RESULTS**

CTDIvol on PCCT and CCT were 3.8±0.1 and 3.6±1mGy, respectively. PCCT was substantially more sensitive than CCT for detection of iodine in mediastinal lesions 3-5mm: to detect a 3mm lesion, 11mg/ml iodine was needed with CCT while only 4.5 mg/ml was required with PCCT. A 66% dose reduction on PCCT at 70 keV still yielded results that were equal to PCCT at 70 keV at 100% dose. VMI at 40 and 50 keV improved detectability over reference PCCT reconstruction, except for 1-mm lesions, for which it yielded equal detectability to CCT. The detection threshold for 5-mm lesions, however, could be reduced from 4.5mg/ml iodine for CCT to 1.4mg/ml for VMI at 60 keV and 0.24 mg/ml for 40 and 50 keV VMI at PCCT.

**CONCLUSION**

Iodine detectability with PCCT is superior to CCT for simulated mediastinal lesions 3-5mm. Iodine detectability further increases with virtual monoenergetic images for lesions = 3 mm, with best results seen for 40 and 50 keV. Chest CT with PCCT obtained at 1.3mGy yields better iodine detectability than CCT at 3.8mGy at 66% dose reduction.

**CLINICAL RELEVANCE/APPLICATION**

PCCT can detect small iodine-enhanced lesions at a lower iodine concentration or a substantially lower exposure dose than CCT.

## S3B-SPPH-4 PATIENT-SPECIFIC ANALYSIS OF IMAGE QUALITY OF VIRTUAL MONOCHROMATIC IMAGES AND ORGAN DOSES IN ABDOMINAL DUAL ENERGY CT EXAMINATIONS

Yutaka Chiba (*Abstract Co-Author*) Nothing to Disclose
Masafumi Shinozaki, RT (*Abstract Co-Author*) Research Grant, Amin Inc
Saeko Mochinaga, RT (*Abstract Co-Author*) Nothing to Disclose
Yoshihisa Muramatsu, PhD, RT (*Abstract Co-Author*) Nothing to Disclose
Keiichi Nomura, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuichi Nagai (*Abstract Co-Author*) Nothing to Disclose
Keisuke Fujii, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The aims of this study are to evaluate image quality of virtual monochromatic (VM) images and organ doses for individual patients in abdominal dual energy CT (DECT) examinations, and to compare the image quality and organ doses in DECT examinations with them in single energy CT (SECT)

examinations.

**METHODS AND MATERIALS**

We evaluated image quality of 50-80 keV VM images for 20 normal weight and overweight patients in abdominal DECT examinations with the administration of iodine contrast agent (Iopamidol 370, Bayel) and CT images for the 20 patients in the SECT examinations with Aquilion ONE / PRISM Edition (Canon Medical Systems). SECT and VM images were reconstructed with deep learning reconstruction algorithms of Advanced intelligent Clear-IQ Engine (AiCE) Body and Spectral Body, respectively. We set region of interests (ROIs) of 40×40 pixels on liver region of the plain SECT and VM images, applied moving average filters in the ROI, and evaluated apparent noise from standard deviation of the mean CT values for each filter size. Image contrast was also calculated as differences between CT values of aorta region on the late arterial phase images and those of liver region on the plain images, and contrast-to-noise ratio (CNR) was calculated as the ratio of the contrast and apparent noise of each image. Next, we performed Monte Carlo simulations for each voxelized phantom of the patients in abdominal SECT and DECT scans with the CT scanner by inputting the CT images, descriptions of each CT scanner, and scanning parameters including our estimated tube current modulation profiles into MC simulation software ImpactMC (Advanced Breast CT, GmbH). ROIs of liver region were set on the simulated dose distribution images, and liver doses for each patient were calculated as average doses within liver ROIs.

**RESULTS**

Apparent noise of 70 keV VM images was lower than the other keV VM images, and it was approximately 25% lower than SECT images. Image contrast of VM images exponentially decreased as the VM energy increased while contrast of 70 keV VM images was approximately 30% higher than SECT images. CNR of the 60 and 70 keV VM images was approximately 2 times higher than SECT images. Liver doses for patients in abdominal DECT scans were 16-22 mGy, the doses in abdominal SECT scans were 12-24 mGy, and there was no significant difference in liver doses between abdominal SECT and DECT scans.

**CONCLUSION**

60 and 70 keV VM images from abdominal DECT examinations provide higher CNR than SECT images while liver doses in DECT examinations are similar to those in the SECT examinations.

**CLINICAL RELEVANCE/APPLICATION**

60 and 70 keV VM images for patients in abdominal DECT examinations can be useful in the detection of low contrast lesions because CNR of the VM images are higher than SECT images.

## S3B-SPPH-5 COMPARISON OF THE SPECTRAL PERFORMANCE BETWEEN TWO DUAL-SOURCE CT SYSTEMS ON LOW-ENERGY VIRTUAL MONOENERGETIC IMAGES: A PHANTOM STUDY

Maxime PASTOR (*Abstract Co-Author*) Nothing to Disclose
Julien Erath, MSc (*Abstract Co-Author*) Employee, Siemens AG
Jean-Paul Beregi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Joel Greffier, PhD (*Abstract Co-Author*) Nothing to Disclose
Sebastian Faby, DIPLPHYS (*Abstract Co-Author*) Employee, Siemens AG
Julien FRANDON (*Abstract Co-Author*) Nothing to Disclose
Djamel Dabli (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the spectral performance of two different DSCT (DSCT-Pulse and DSCT-Force) on virtual monoenergetic images (VMIs) at low energy levels.

**METHODS AND MATERIALS**

An image quality phantom was scanned on the two DSCTs at three dose levels: 11/6/1.8mGy. Level 3 of an advanced modeled iterative reconstruction algorithm was used. Noise power spectrum and task-based transfer function were computed on VMIs from 40 to 70 keV to assess noise magnitude and noise texture (fav) and spatial resolution (f50). A detectability index (d') was computed to assess the detection of one contrast-enhanced abdominal lesion as a function of the keV level used.

**RESULTS**

For all dose levels and all energy levels, noise magnitude was higher with DSCT-Pulse than with DSCT-Force (12.2±0.9% at 1.8 mGy, 9.0±0.4% at 6 mGy and 3.9±0.5% at 11 mGy). For all energy levels, fav values were higher with DSCT-Pulse than with DSCT-Force (4.7±2.2% at 1.8 mGy, 4.5±1.4% at 6 mGy and 2.6±0.8% at 11 mGy). For all energy levels, f50 values were higher with DSCT-Pulse than with DSCT-Force (13.4±0.9% at 1.8 mGy, 17.0±0.7% at 6 mGy and 13.2±0.1% at 11 mGy). For all keV, similar d' values were found with both DSCT-Force and DSCT-Pulse at 11 mGy (-1.1±0.5%). For other dose levels, d' values were lower with DSCT-Pulse than with DSCT-Force (-8.4±0.7% at 1.8 mGy and -6.4±0.1% at 6 mGy).

**CONCLUSION**

Compared with the DSCT-Force, the DSCT-Pulse improved noise texture and spatial resolution, but noise magnitude was slightly higher and detectability slightly lower, particularly when the dose level was reduced.

**CLINICAL RELEVANCE/APPLICATION**

In this study, we assessed the quality of virtual monoenergetic images at low energy levels on a new dual-source CT for the first time.

## S3B-SPPH-6 COMPARISON OF LOW-ENERGY VIRTUAL MONOENERGETIC IMAGES BETWEEN PHOTON-COUNTING CT AND ENERGY-INTEGRATING DETECTORS CT: A PHANTOM STUDY

Julien Erath, MSc (*Abstract Co-Author*) Employee, Siemens AG
Djamel Dabli (*Abstract Co-Author*) Nothing to Disclose
Maxime PASTOR (*Abstract Co-Author*) Nothing to Disclose
Sebastian Faby, DIPLPHYS (*Abstract Co-Author*) Employee, Siemens AG
Jean-Paul Beregi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Julien FRANDON (*Abstract Co-Author*) Nothing to Disclose
Joel Greffier, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study was to assess image quality and dose level using a photon-counting CT (PCCT) scanner by comparison with a dual-source CT (DSCT) scanner on virtual monoenergetic images (VMIs) at low energy levels.

**METHODS AND MATERIALS**

A phantom was scanned on a DSCT and a PCCT with a volume CT dose index of 11 mGy, and additionally at 6 mGy and 1.8 mGy for PCCT. Noise power spectrum and task-based transfer function were evaluated from 40 to 70 keV on VMIs to assess noise magnitude and noise texture (fav) and spatial resolution on two iodine inserts (f50), respectively. A detectability index (d') was computed to assess the detection of two contrast-enhanced lesions according to the keV level used.

**RESULTS**

For all keV levels, noise magnitude values were lower with PCCT than DSCT at 11 and 6 mGy, but higher at 1.8 mGy. fav values were higher with PCCT than with DSCT at 11 mGy (8.6 ± 1.5 [standard deviation [SD]] %), similar at 6 mGy (1.6 ± 1.5 [SD] %) and lower at 1.8 mGy (17.8 ± 2.2 [SD] %). For both inserts, f50 values were higher with PCCT than DSCT at 11- and 6 mGy for all keV levels, except at 6 mGy and 40 keV. d' values were higher with PCCT than with DSCT at 11- and 6 mGy for all keV and both simulated lesions. Similar d' values to those of the DSCT at 11mGy, were obtained at 2.25 mGy for iodine insert at 2 mg/mL and at 0.96 mGy for iodine insert at 4 mg/mL at 40keV.

**CONCLUSION**

Compared to DSCT, PCCT reduces noise magnitude and improved noise texture, spatial resolution and detectability on VMIs for all low-keV levels.

**CLINICAL RELEVANCE/APPLICATION**

VMIs obtained with PCCT may offer great potential for dose reduction for patients undergoing dual-energy CT of the abdomen.

## S3B-SPPH-7 ACCURACY AND CONSISTENCY OF EFFECTIVE ATOMIC NUMBER OVER OBJECT SIZE USING DEEP SILICON PHOTON-COUNTING DETECTOR CT

Sean Rose, PhD (*Abstract Co-Author*) Research Grant, medInt Holdings, LLC;
Teva Shapiro (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon-counting (PCD) CT is the newest generation of CT detector technology. Thus, it is critical to characterize its performance in measuring important biomarkers used in quantitative CT including effective atomic number (EAN). More accurate EAN measurements could be beneficial in tissue classification and proton therapy tasks. Previous work has shown that PCD CT can measure CT number more consistently and accurately. This study measures the precision and accuracy of EAN in a prototype deep silicon PCD CT over multiple water-equivalent diameters (WED).

**METHODS AND MATERIALS**

A Gammex Mercury phantom containing clinically relevant inserts was scanned at 120 kV using a deep silicon PCD CT. EAN maps were generated. Variation of EAN of the inserts was analyzed over the different WEDs (157, 203, 251, 298, and 345 mm) for polystyrene, water, iodine, and bone inserts. The measured EANs were compared to ideal values based on the elemental composition of the inserts provided by the manufacturer and calculated using their electron fraction weighted EAN.

**RESULTS**

The maximum percent difference between the measured EANs of the center of the phantom (251 mm WED) and the other sections (157-345 mm) for the polystyrene, water, iodine, and bone inserts were 5.9%, 7.2%, 0.5%, and 1.0% respectively. The average percent difference between the measured and ideal EANs across all inserts was 3.6% and the maximum percent difference was 7.2%.

**CONCLUSION**

When compared to previous studies using energy integrating detectors, this study shows a higher accuracy in EAN measurements. The high consistency and accuracy of measured EAN using deep silicon PCD CT could make quantitative CT increasingly possible over a large range of patient sizes. The results of this study also help us understand uncertainties which should be considered when using these biomarkers in clinical decision making. Additionally, this study may help to improve the algorithms used to calculate these quantities. Limitations of this study include that it used a prototype which may not accurately reflect the final product and that the scatter and beam hardening corrections for the prototype were not fully developed at the time of this study.

**CLINICAL RELEVANCE/APPLICATION**

The use of CT as a biomarker for tissue classification has historically been impeded by inaccurate and unreliable CT numbers; this study demonstrated deep silicon based PCD CT may move CT closer to be used more effectively as a biomarker.

## S3B-SPPH-8 ASSESSING IODINE QUANTIFICATION ERRORS WITH PARTIAL IODINE VOXEL CONTENT DURING IODINE-WATER BASIS PAIR MATERIAL DECOMPOSITION

Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*) Consultant, Aidoc Medical Ltd;Consultant, Flowhow.ai;Consultant, medInt Holdings, LLC;Consultant, Alara, Inc;Consultant, AstoCT, Inc;Research Grant, General Electric Company;Research Grant, Canon Medical Systems Corporation
Aria Salyapongse, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Iodine quantification is an important CT based biomarker in quantitative CT imaging. This study quantifies sources of errors in quantitative spectral CT.

**METHODS AND MATERIALS**

This work examines the theoretical relationship between linear attenuation coefficients, material decomposition basis pairs, and material quantification. Voxels are simulated using the spektr MATLAB package with clinically appropriate volume fractions of iodine and tissue backgrounds. Voxel linear attenuation coefficients were calculated using the National Institute of Standards and Technology (NIST) XCOM database for tissue chemical compositions and clinical concentrations of iodine. Then the voxels' contents are decomposed onto an iodine-water basis pair and the iodine volume fraction was

calculated. This value was then compared with the known iodine volume fraction as a percent error. Quantification errors are also demonstrated experimentally using a clinically relevant phantom with known iodine and background density inserts.

**RESULTS**

For a voxel of some background material and iodine with the choice of a water-iodine material basis pair for material decomposition of iodine in the range of 0.2-2.0 mg/mL, the error in iodine density was 0% for a water background, 6.6% to 66% for a muscle background, 9.1% to 91% for a lung background, 6.9% to 69% for a soft tissue background, 13% to 134% for a blood background, -57% to -572% for an adipose tissue background and over 15,000% for a bone background. This translates to a difference in iodine mass of 0 mg/mL for a water background, 0.03 to 0.05 mg/mL for muscle, lung, soft tissue, and blood backgrounds, -0.23 mg/mL for an adipose tissue background, and 6.92 mg/mL for a bone background. A negative mass difference means the calculated iodine mass was underestimated, and a positive mass difference means the calculated iodine mass was overestimated.

**CONCLUSION**

We derive two new understandings: (1) iodine-water material decomposition is never accurate in vivo, and (2) for error free material decomposition a voxel must only consist of the basis decomposition vectors. Our work demonstrates material quantification is fundamentally limited when measured in vivo due to measurement conditions differing from assumed conditions and the errors are at or above detection limits for spectral iodine quantification. To define CT derived biomarkers, the errors we demonstrate should either be avoided or built into uncertainty bounds.

**CLINICAL RELEVANCE/APPLICATION**

Improving error bounds in quantitative CT, specifically in iodine quantification, could further the development of CT biomarkers.

## S3B-SPRO-1 CT AND MRI BIMODAL RADIOMICS NOMOGRAM FOR PREDICTING EGFR STATUS INNSCLC PATIENTS WITH BRAIN METASTASES:A MULTICENTER STUDY

Ouyang Zhiqiang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In advanced non-small cell lung cancer (NSCLC), brain metastasis (BM) is one of the most common types of distant metastases. These metastases are closely related to the status of epidermal Growth Factor Receptor (EGFR). The aim of this study is to fully utilize the radiomics information from both NSCLC primary tumors and BM, and develop and validate a bimodal radiomics nomogram that can accurately predict the EGFR status.

### METHODS AND MATERIALS

A total of 309 NSCLC patients with BM from three independent centres were recruited to conduct the retrospective multicentre cohort study. All chest CT and brain MRI images of each patient were obtained for image registration and sequence combination within a single modality. After image preprocessing, 1037 radiomics features were extracted from each single sequence. Six machine learning algorithms were used to construct the radiomics signature for CT and MRI respectively. The best CT and MRI radiomics signatures were fitted to establish the bimodal radiomics nomogram for predicting the EGFR status.

### RESULTS

The CT-CE_XG Boost and MRI-T2WI+T1CE_Random Forest models were chosen as the radiomics signature representing primary lesion and BM. Both models were found to be independent predictors of EGFR mutation, with OR values and 95% confidence intervals (CI) of 11.859 (3.922-35.856) and 17.064 (5.858-49.707), respectively. The bimodal radiomics nomogram, which incorporated CT radiomics signature and MRI radiomics signature, demonstrated a good calibration and discrimination in the internal test cohort (AUC, 0.866; 95% CI, 0.778-0.950) and the external test cohort (AUC, 0. 0.818; 95% CI, 0.691-0.938).

### CONCLUSION

Our CT and MRI bimodal radiomics nomogram could timely and accurately evaluate the likelihood of EGFR mutation in patients with limited access to necessary materials.

### CLINICAL RELEVANCE/APPLICATION

Making up for the shortcoming of plasma sequencing and promoting the advancement of precision medicine.

## S3B-SPVA-2 HOW QIR SHOULD IT BE? - INFLUENCE OF QUANTUM ITERATIVE RECONSTRUCTION STRENGTH IN PHOTON-COUNTING CT ANGIOGRAPHY OF THE UPPER LEG

Jan P. Grunz, MD (*Abstract Co-Author*) Research Consultant, Siemens AG
Henner Huflage, MD (*Abstract Co-Author*) Nothing to Disclose
Viktor Hartung (*Abstract Co-Author*) Nothing to Disclose
Jan-Lucca Hennes (*Abstract Co-Author*) Nothing to Disclose
Thorsten A. Bley, MD (*Abstract Co-Author*) Speakers Bureau, F. Hoffmann-La Roche Ltd;Research Consultant, F. Hoffmann-La Roche Ltd;Speakers Bureau, Novartis AG;Research Consultant, Novartis AG;Research Consultant, Baltimore RH Typing Laboratory
Theresa Sophie Patzer, MD (*Abstract Co-Author*) Nothing to Disclose
Robin Hendel (*Abstract Co-Author*) Nothing to Disclose
Kristina Krompass (*Abstract Co-Author*) Nothing to Disclose
Philipp Gruschwitz, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to evaluate the influence of different quantum iterative reconstruction (QIR) levels on the objective and subjective image quality of vascular convolution kernels in femoral photon-counting CT angiographies (PCD-CTA) using an extracorporeally perfused human in-vitro model.

### METHODS AND MATERIALS

Ultra-high resolution PCD-CTA were obtained from both extremities of 5 cadavers using constant tube voltage and max. radiation dose (71.2±11.0mGy). Images were reconstructed with 3 kernels (Bv48,60,76) and the 4 available levels of QIR. Signal attenuation in the arterial lumen, muscle, and fat were measured. Contrast-to-noise-ratios and blurring scores were calculated for objective assessment. Six radiologists evaluated the subjective image quality using a browser-based pairwise comparison tool. Significance was assumed for any p-level =.05. Objective and subjective image quality were compared using Friedman's rank test. Interrater-agreement was determined using Kendall's concordance coefficient.

### RESULTS

Higher QIR level resulted in a reduction of image noise regardless of kernel selection (e.g., Bv60: Q1 11.5±6.3HU vs. Q4 9.5±2.3HU; p<.001). Both the absolute reduction in noise and the noise difference between the individual QIR levels were larger for sharper convolution kernels (Bv76: Q1 19.3±3.2HU vs. Q4 13.9±1.1HU; p<.001) than for softer ones (Bv48: Q1 7.1±2.4HU vs. Q4 6.6±3.2HU; p=.001). CNR increased significant with higher QIR levels. The gain Q1 vs. Q4 creates a dose saving potential of ~25% without image quality loss. Blurring decreased with higher QIR levels for soft, remained constant for medium, and increased for sharp reconstructionsSharper kernels were preferred over softer ones by all raters. While there was no unanimous consensus for the subjectively preferred QIR level, interrater agreement was very high. Bv48Q1 was rated the worst and Bv76Q3 the best combination overall. Bv48Q4, Bv60Q2, and Bv76Q3 achieved the best subjective ratings per kernel.

### CONCLUSION

Quantum iterative reconstruction of PCD-CTA has a positive influence on their image quality in terms of image noise and CNR. In particular, reconstructions with sharp convolution kernels benefit quantitatively from higher QIR levels. While the subjectively preferred QIR level is dependent on kernel selection, QIR level 3 provided the best objective and subjective image quality results over all reconstruction settings.

### CLINICAL RELEVANCE/APPLICATION

This study provides a recommendation for the reconstruction of PCD-CTA of the lower extremity runoff to achieve the best possible image quality based on objective and subjective image parameters to improve the diagnostic value of PCD-CTA and/or enable for reduction of radiation dose.

## T2-SPBR-1 PERFORMANCE OF A DIGITAL BREAST TOMOSYNTHESIS AI DETECTION ALGORITHM IN COMMON US RACIAL/ETHNIC GROUPS

Scott Pohlman, MSc, BEng (*Abstract Co-Author*) Employee, Hologic, Inc
Andrew P. Smith, PhD (*Abstract Co-Author*) Employee, Hologic, Inc
Ashwini Kshirsagar (*Abstract Co-Author*) Nothing to Disclose
Sarah M. Friedewald, MD (*Presenter*) Consultant, Hologic, Inc;Research Grant, Alphabet Inc

### PURPOSE

Artificial intelligence (AI) algorithms can exhibit racial disparities, potentially due to underrepresentation of certain racial or ethnic groups in the training data. Thus, it is important to evaluate the performance of AI algorithms in racial/ethnic groups for which they will be used clinically. This study evaluated the performance of a commercially available digital breast tomosynthesis (DBT) AI system in racial/ethnic groups common in the US.

### METHODS AND MATERIALS

DBT cases with available ground truth data were consecutively selected from a pool of biopsy-proven malignant cancer cases and normal cases that were read as BI-RADS 1 or 2 at screening. These cases were not involved in the training or development of the AI algorithm. Each case was placed into one of the following self-identified racial/ethnic cohorts: White (non-Hispanic), Black (non-Hispanic), Hispanic, Asian, or Other. AI performance for each cohort was measured using several metrics: Receiver Operating Characteristics (ROC) curves, area under the ROC curve (AUROC), location specific sensitivity, and specificity. ROC curves and their areas and uncertainties were calculated using a maximum likelihood estimation of binormal ROC curves from continuously distributed test results.

### RESULTS

The cohort included 7519 examinations overall (2532 with cancer). The breakdown of examinations was 72% White (5395 cases, 1653 cancers), 13% Black (956 cases, 446 cancers), 10% Hispanic (774 cases, 274 cancers), 4% Asian (279 cases, 117 cancers), 2% Other (115 cases, 42 cancers). AUROC (2 Standard Deviation Error) by race/ethnicity was 0.91 (0.01) White, 0.92 (0.02) Black, 0.93 (0.02) Hispanic, 0.95 (0.02) Asian, and 0.94 (0.05) Other. Sensitivity (95% CI) by race/ethnicity was 90.3% (88.9-91.7%) White, 88.6 (85.6-91.6%) Black, 90.1% (86.6-93.6%) Hispanic, 91.5% (86.4-96.6%) Asian, 95.2% (84.2-98.7%) Other. Specificity (95% CI) by race/ethnicity was 60.0% (58.4-61.6%) White, 61.2% (56.9-65.3%) Black, 57.6% (53.2-61.9%) Hispanic, 71.6% Asian (64.2-78.0%), 52.6% (40.8-63.2%) Other. The only performance metrics which demonstrated a statistically significant ($p<0.05$) difference when compared to the overall cohort (AUROC = 0.92, sensitivity = 90.1%, specificity = 60.1%) were AUROC and specificity in the Asian cohort.

### CONCLUSION

Except for a small improvement in AUROC and specificity in the Asian cohort, the measured performance of the AI algorithm was similar for all the race/ethnicity cohorts which were evaluated. Future studies with larger populations are warranted.

### CLINICAL RELEVANCE/APPLICATION

To reduce the risk of disparities in clinical practice, the performance of medical AI systems should be evaluated in the racial/ethnic populations for which they will be used clinically.

## T2-SPBR-10 ARTIFICIAL INTELLIGENCE-ASSISTED SYSTEM ASSIST THE CLASSIFICATION OF BREAST ULTRASOUND GLANDULAR TISSUE COMPONENT IN DENSE BREAST TISSUE

Xiao-jing Xu (*Abstract Co-Author*) Nothing to Disclose
Lifang Yu (*Abstract Co-Author*) Nothing to Disclose
Chaochao Dai (*Abstract Co-Author*) Nothing to Disclose
Ling-yun Bao, MD (*Abstract Co-Author*) Nothing to Disclose
Yan Hongju, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to investigate the viability of implementing a novel artificial intelligence-assisted system for aiding physicians in the accurate classification of glandular tissue component (GTC) in dense breast tissue.

### METHODS AND MATERIALS

A total of 1848 breast ultrasound images, categorized as category C or D glandular tissue on mammography, the GTC were classified into four groups based on the ratio of glandular tissue to fibrous stroma: minimal (P1) <25%, mild (P2) 25-49%, moderate (P3) 50-75%, and marked (P4) >75%. Three ultrasound specialists more than 10-year-experiences in breast imaging established the gold standard. An artificial intelligence image processing segmentation-classification model, ResNet101, was established. 1325 images were used for model training, while 523 images for external validation. 3 breast specialists (Group A) and 3 non-breast specialists (Group B) were involved in the validation of the model. Each of the six physicians conducted independent image reviewes and utilized AI-assisted mage interpretation.

### RESULTS

In the validation set comprising 523 images, there were 109 cases of P1, 166 cases of P2, 131 cases of P3, and 117 cases of P4. In Group A, the AI-assisted group exhibited significantly sensitivity compared to the independent group for P1, P2 and average sensitivity (45.2% vs. 23.8%, 73.4% vs. 63.6%, and 58.6% vs. 51.6%, respectively) ($P < 0.05$). It`s also showed significantly specificity compared to the independent group for P3(74.4% vs. 68.7%)($P < 0.05$). Regarding accuracy, the AI-assisted group outperformed the independent group in P3 and average accuracy, significantly statistical disparities (73.1% vs. 56.1%, 79.8% vs. 74.7%) ($P < 0.01$). In Group B, the AI-assisted group showed superior sensitivity in P1, P2, and the average sensitivity compared to the independent group (41.2% vs. 31.1%, 69.4% vs. 43.5%, and 53.3% vs. 46.3%, respectively) ($P < 0.01$). In P3, P4, and average specificity, the AI-assisted group showed superior performance (63.9% vs. 58.7%, 95.3% vs. 79.4%, and 83.2% vs. 78.7%) ($P < 0.05$). In accuracy, the AI-assisted group outperformed the independent group, with statistically significant differences observed in the accuracy of P3 and P4, as well as average accuracy (69.8% vs. 60.4%, 86.1% vs. 71.7%, and 76.9% vs. 71.0%, respectively) ($P < 0.01$).

### CONCLUSION

The ResNet101 AI image processing segmentation-classification model has demonstrated its effectiveness in aiding medical professionals in accurately classifying breast GTC, particularly benefiting non-breast specialists. Additionally, it has shown potential to enhance the accuracy of classifying P3 and P4 glandular types.

### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence, dense breast, glandular tissue component

## T2-SPBR-11 EVALUATING NNU-NET FOR DETECTING MALIGNANT BREAST LESIONS ON MRI

### PURPOSE

This study evaluates an open-source machine-learning model for detecting malignant breast MRI lesions.

### METHODS AND MATERIALS

We reviewed breast MRIs from one institution from January 2006 to April 2021, which were approved by the research ethics board with consent waived. Inclusion criteria were patients with a BI-RADS scored lesion, biopsied or followed-up for two years if not biopsied. Two breast radiologists, each with over 20 years of experience, classified all cases using the BI-RADS lexicon, resolving discrepancies by consensus. We used nnU-Net v2 in a two-step cascade. A 5-fold cross-validation for detecting any lesions using the first and last subtracted dynamic contrast-enhanced (DCE) series followed by a second model to segment breast cancers only. True positives were cancers detected by AI and confirmed by pathology; true negatives had no cancer on pathology or follow-up and were undetected by AI. False positive regions were assessed by overlap percentage between predicted voxels and radiologist-segmented cancers.

### RESULTS

Of 19,473 MRIs, 12,243 were excluded as normal, and 314 were excluded for inadequate follow-up, leaving 6,916 MRIs (5,028 benign/normal and 1,898 malignant). After randomly selecting 1,000 for manual segmentation, 191 were excluded due to technical issues, resulting in 809 cases (524 training, 131 validation, 154 tests (85 benign, 69 malignant)). Case-level comparison of radiologists (BI-RADS threshold of >=4a) to the 3D and 2D models showed: 100% sensitivity vs. 88.4% [0.82, 0.92] and 91.3% [0.85, 0.95]; 60% specificity [0.52, 0.67] vs. 71.8% [0.64, 0.78] and 60% [0.52, 0.67]; 67% PPV [0.59, 0.74] vs. 71.8% [0.64, 0.78] and 64.9% [0.57, 0.72]; 100% NPV vs. 88.4% [0.82, 0.92] and 89.5% [0.84, 0.94]; 77.9% accuracy [0.71, 0.84] vs. 79.2% [0.72, 0.85] and 74% [0.67, 0.8]. Models were close to radiologist performance, with overlapping confidence intervals for most metrics. Mean voxel overlap was 55% for 2D and 56% for 3D models. In cancer cases with predicted lesions, only two had no overlap for both models.

### CONCLUSION

An open-source model closely matches the performance of subspecialty breast radiologists in distinguishing benign from malignant lesions on MRI, paving the way for large-scale, open-model collaborations.

### CLINICAL RELEVANCE/APPLICATION

An open-source AI model promises near-human-level performance in differentiating benign from malignant breast lesions. This can enhance transparency in machine learning methodologies and foster multicenter collaboration.

## T2-SPBR-2 AI-DRIVEN AUTONOMOUS RULE-OUT PROCESS HELPS UNDER-PERFORMING RADIOLOGISTS EXCEED ACCEPTABLE PERFORMANCE STANDARDS

Giorgia Grisot, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Bryan Haslam, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Jiye G. Kim, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Matthew McCabe, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

A major obstacle to mammography screening effectiveness is variability in radiologists' interpretive performance, with studies suggesting that close to 50% underperform in terms of recall rate (RR) or cancer detection rate (CDR). One proposal to reduce RR while increasing CDR is to use AI tools both as a reading aid, and to automatically rule-out the lowest suspicion exams (i.e. decide to not recall them without further review by a radiologist). We explore

the benefits of this combined approach and of using varying levels of Autonomous Rule-out (AR) on a dataset of >193k patients imaged with DBT, and focus on how it could standardize patient care by helping radiologists' with different degrees of baseline performance.

**METHODS AND MATERIALS**

Our study cohort included 26 radiologists at three U.S. practices, covering 40 clinical sites, who interpreted a total of 154,636 screening mammograms across two consecutive periods (a standard of care period and an intervention period; radiologists must have read at least 800 exams per period to be included), from January 2022 to January 2023, with exam counts of 66,037 and 88,599 respectively. These included 832 screen detected cancers. In the first period, radiologists read mammograms according to standard-of-care without AI assistance. In the second period, they used an AI-based CADe/x tool. AI scores indicating the level of suspicion for cancer (ranging from 0 to 1), were used to simulate different levels of AR by increasing the proportion of low suspicion exams autonomously read by the device. RR, CDR, and positive predictive value of recalls (PPV1) were computed during both study periods, as well as across different levels of AR simulation.

**RESULTS**

Before AI-CADe/x introduction, 3 radiologists had CDRs below the performance benchmark of 2.5 per 1000 exams, and 7 radiologists had RRs above the performance benchmark of 12%. In total, 38% of radiologists (10/26) were categorized as "underperforming." Reading with the AI-CADe/x tool increased CDR by 15%, RR by 8%, and PPV1 by 7%, and helped all radiologists achieve CDRs >2.5. Still, 34% of radiologists (9/26) had RRs >12%. Simulated rule-out of a large fraction of low-suspicion mammograms was very effective at reducing RR: an AR threshold of 60% brought almost all radiologists (24/26, 92%) into an acceptable range for both RR and CDR.

**CONCLUSION**

Combining AI-CADe/x with an AR tool may be effective at helping radiologists detect more cancers, reduce recalls and perform above acceptable performance standards.

**CLINICAL RELEVANCE/APPLICATION**

Combining AI-CADe/x with AI-driven autonomous rule-out may improve screening mammography outcomes by increasing cancers found and lowering the number of recalls.

## T2-SPBR-3 INFLUENCE OF PATIENT CHARACTERISTICS ON AN AI ALGORITHM'S SCREENING DIGITAL BREAST TOMOSYNTHESIS FALSE NEGATIVE PERFORMANCE

Joseph Lo, PhD (*Abstract Co-Author*) Research Grant, iCAD, Inc
Yinhao Ren (*Abstract Co-Author*) Nothing to Disclose
Jeffrey Nelson (*Abstract Co-Author*) Nothing to Disclose
Samantha Thomas (*Abstract Co-Author*) Nothing to Disclose
Lars J. Grimm, MD (*Abstract Co-Author*) Advisor, Hologic, Inc;Consultant, Hologic, Inc;Editorial Advisory Board, WebMD Health Corp (WebMD, Inc)
Tyler Jones (*Abstract Co-Author*) Nothing to Disclose
Derek L. Nguyen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To understand the impact of patient characteristics on the performance of an AI algorithm in evaluating screening detected malignancies.

**METHODS AND MATERIALS**

This retrospective cohort study identified screening DBT examinations from our academic institution from 2/1/19 to 12/31/2023 with screening detected malignancies. This final cohort was interpreted by an FDA approved AI algorithm (ProFound AI 3.0, iCAD, Inc) which generated case scores for each mammogram. Per the vendor, examinations with case scores > 49 have a high certainty for malignancy. Therefore, a false negative examination in our study was defined as having a case score = 49. Patient characteristics (age, race/ethnicity, and breast density) were compared between those with and without false negative case scores and logistic regression was used to estimate the association of characteristics with the odds of a false negative case score.

**RESULTS**

373 unique patients (median age: 64 years [range: 37-91]) were included. The cohort's race/ethnicity distribution was 62% (233/373) Non-Hispanic White, 28% (104/373) Non-Hispanic Black, and 10% (36/373) other. The cohort's breast density distribution was 5% (19/373) almost entirely fatty, 51% (191/373) scattered fibroglandular density, 39% (145/373) heterogeneously dense, and 5% (18/373) extremely dense. The AI's false negative rate was 11% (42/373). Breast density was significantly associated with a false negative case score ($p=0.03$) while patient age and race/ethnicity were not significantly associated with a false negative case score ($p=0.86$ and $p=0.22$, respectively). Heterogeneously or extremely dense patients comprised of 62% (26/42) of the examinations with a false negative case score compared to 42% (137/331) of dense patients with a positive case score. This remained significant on multivariate analysis when adjusting for age and race.

**CONCLUSION**

The AI's false negative rate was 11%. Breast density did influence the performance of an AI algorithm in evaluating screening detected malignancies. However, patient demographics (age and race/ethnicity) did not influence the AI algorithm's performance.

**CLINICAL RELEVANCE/APPLICATION**

Like radiologists, the performance of an FDA-approved AI algorithm for breast cancer detection is influenced by breast density. Therefore, it is essential to train these algorithms on diverse datasets to enhance their diagnostic accuracy regardless of breast density.

## T2-SPBR-4 EVALUATING THE BENEFIT OF USING ARTIFICIAL INTELLIGENCE SYSTEM FOR BREAST ULTRASOUND: RESULTS OF A MULTICENTER, READER STUDY

Won Hwa Kim, MD, PhD (*Abstract Co-Author*) Stockholder, BeamWorks
Jaeil Kim, PhD (*Abstract Co-Author*) Stockholder, BeamWorks, Inc.
Kyunghwa Han, PhD (*Abstract Co-Author*) Nothing to Disclose
Jung Hyun Yoon, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the diagnostic performances of breast ultrasound (US) examinations before and after using artificial intelligence (AI) system for decision support among readers of different experience levels.

**METHODS AND MATERIALS**

For this multicenter reader study, 1,000 (500 cancer, 250 benign, 250 normal) breast US images were retrospectively collected from three institutions. A deep learning-based AI system for breast US was developed to localize abnormalities as heatmaps highlighting the area of abnormality with corresponding 1) AI score (0-100%) and 2) BI-RADS (category 1-5) assessment. Fifteen readers (6 radiologists, 6 clinicians, 3 radiographers) participated in the reader study and assessed each breast US image in terms of probability of malignancy (POM, 0-100%) and BI-RADS assessment. Readings were in two sessions, without AI vs. with AI, separated by 2 weeks for wash-out. Area under the receiver operating characteristic curve (AUC), sensitivity, and specificity were evaluated for multireader, multicase studies. Subgroup analysis was performed according to the level of experience (11 readers <5years, 4 readers =5 years of experience) in breast US.

**RESULTS**

Reader performances for detecting cancers measured by mean AUC for 1) POM increased 0.053 (95% CI: 0.032, 0.073, P<0.001), from 0.892 to 0.945, and 2) BI-RADS assessment increased 0.046 (95% confidence interval [CI]: 0.029, 0.063, P<0.001), from 0.891 to 0.937. Mean sensitivity was significantly increased from 85.3% without AI to 95.0% with AI (9.7%, 95% CI: 8.5%, 10.8%, P<0.001) while mean specificity was significantly decreased from 79.3% without AI to 76.5% with AI (-2.8%, 95% CI: -4.3%, -1.3%, P<0.001), respectively. Subgroup analysis showed that mean AUC of readers <5years of experience increased 0.058 (95% CI: 0.036, 0.079, P<0.001), from 0.873 to 0.937, but did not show significant differences for readers =5 years of experience, from 0.933 to 0.956 (P=0.091).

**CONCLUSION**

Using AI for decision support for assessing breast US images was found to improve the performances in a reader study demonstrating significant increase in AUC and sensitivity, with a tradeoff for decreased specificity. Less experienced readers had significantly increased AUC after using AI reaching the level of experienced readers, but not for experienced readers.

**CLINICAL RELEVANCE/APPLICATION**

Using a deep learning-based AI system for decision support for assessing breast US was found to improve the performances of readers of various medical professions. AI benefits less experienced readers by improving performances to the level of experienced readers, reflecting the potential of improved cancer detection when AI for breast US is incorporated for supplemental screening.

## T2-SPBR-5 AUTOMATIC CLASSIFICATION OF PUBERTAL BREAST SONOGRAPHY IN CHILDREN USING ARTIFICIAL INTELLIGENCE

Chao Geng (*Abstract Co-Author*) Nothing to Disclose
Li Yuan, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate classification of the adolescent mammary gland is essential for assessing the developmental status of adolescent breasts. We propose a hybrid convolutional neural network (CNN)-Transformer model to enhance the automated classification of breast ultrasound images.

**METHODS AND MATERIALS**

A retrospective cohort of adolescent breast ultrasound images was assembled from a hospital database. The samples were randomly divided into a training(n=1676) and a testing(n=300) set. All images were categorized into five stages, the staging protocol is proposed based on a previous study, where different staging features of breast ultrasound correspond to respective Tanner stages (figure 1). The gold standard for classification was established by a highly experienced ultrasonographer. The classification performances of the proposed model StransXNet was assessed using accuracy, recall, precision, and specificity, and was compared with two alternative models; Swin-T and ResNet34. Furthermore, the model was compared with ultrasonographers of varying clinical experience and professional background: two resident physicians and two attending physicians, with accuracy as the classification performance evaluation metric.

**RESULTS**

The StransXNet model exhibited superior performance in the classification task relative to the other two models. The model achieved an accuracy of 0.880, a recall of 0.884, a precision of 0.880, and a specificity of 0.970. Furthermore, the model outperformed two resident physicians with respective accuracies of 0.727 and 0.730 and closely matched the proficiency of two attending physicians, with accuracies of 0.857 and 0.773.

**CONCLUSION**

The proposed StransXNet model demonstrated promising capabilities in classifying pubertal breast stages from ultrasound images, achieving high accuracy comparable to that of human ultrasonographers.

**CLINICAL RELEVANCE/APPLICATION**

The accurate evaluation of breast development is essential for diagnosing and monitoring various conditions that affect adolescents, especially in discerning between normal puberty and precocious puberty. Traditionally, the classification of pubertal breast stages has relied on subjective assessments by clinicians or ultrasonographers, which can vary in accuracy and consistency. The advent of our proposed model offers a standardized, efficient, and replicable method for breast tissue classification. By reducing inter- and intra-observer variability, our model contributes to reducing variability, facilitating standardized management practices, shortening the learning curve for physicians, and enhancing diagnostic accuracy.

## T2-SPBR-6 THE EFFECTIVENESS OF BREAST CANCER DIAGNOSTIC ASSISTANCE SOFTWARE (VIS-BUS) IN DETERMINING WHETHER LESIONS ON ULTRASOUND ARE BENIGN OR MALIGNANT, ADDS VALUE FOR THE BREAST RADIOLOGIST

Mijung Jang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoon Ah Do (*Abstract Co-Author*) Nothing to Disclose
Hunjong Lim, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Bo La Yun, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Soyeon Ahn (*Abstract Co-Author*) Nothing to Disclose
Sun M. Kim, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the value of computer-aided diagnosis (CAD) programs utilizing artificial intelligence (AI) for diagnosing and characterizing breast lesions on ultrasound (US), considering the radiologist's experience level.

**METHODS AND MATERIALS**

Transverse and longitudinal sets of US images of 258 breast masses from 258 women (from May 2010 to December 2016) were collected and retrospectively analyzed by AI-CAD (Vis-BUS, Barreleye, Seoul, Republic of Korea). AI-CAD provided the suspicion of the lesion (benign or suspicious), the likelihood of cancer on a scale from -100 (very low probability) to 100 (very high probability), and the region of interest (ROI). Four general radiologists and 1 experienced breast imaging radiologist reviewed images from all cases in two visits separated by a memory washout period of approximately 2 weeks. Each radiologist read the US during visit 1 without CAD results and the US plus CAD during visit 2. Radiologists also provided their assessment on the same scale, where negative values (-100 to 0) denote a lower likelihood (benign) and positive values (0 to 100) denote a higher likelihood (malignant) of cancer. The diagnostic performance and reading time of radiologists with or without CAD were evaluated.

**RESULTS**

Out of the 258 breast masses, 129 (50%) were malignant and 129 (50%) were benign. The sensitivity (91.5%-96.9% vs 94.6%-97.7%, respectively) and AUC (0.89-0.942 vs 0.937-0.974, respectively) were increased with CAD in all reviewers but statistically significant in the breast radiologist and 2 general radiologists in AUC ($p < 0.05$). The specificity (41.1%-73.6% vs 61.2%-81.4%, respectively), positive predictive value (62.2%-77.6% vs 71.6%-83.8%, respectively), and accuracy (69.0%-82.6% vs 79.5%-88.8%, respectively) were statistically significantly increased with CAD assistance in 4 general radiologists (all $P < .05$). The reading time (3.09 sec - 10.3 sec vs 2.37 sec - 6.78 sec) of all radiologists decreased with CAD but statistically significant in the breast radiologist and 2 general radiologists ($p < 0.05$).

**CONCLUSION**

The use of computer-aided diagnosis programs in breast ultrasound imaging significantly enhances diagnostic performance, especially in terms of sensitivity, specificity, and accuracy among general radiologists. Additionally, CAD reduces reading time for all radiologists, thereby improving efficiency in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

These findings underscore the potential of CAD systems, integrated with artificial intelligence, to augment the diagnostic capabilities of radiologists, especially in breast imaging where accurate and timely diagnosis is crucial for patient care.

## T2-SPBR-7 OBESITY AND SARCOPENIA IN BREAST CANCER PROGNOSIS COULD BODY COMPOSITION ANALYSIS PREDICT THERAPEUTIC RESPONSE IN BREAST CANCER?

Federica Pediconi, MD (*Abstract Co-Author*) Nothing to Disclose
Francesca Galati, MD (*Abstract Co-Author*) Nothing to Disclose
Federica Cicciarelli, MD (*Abstract Co-Author*) Nothing to Disclose
Veronica Rizzo, MD (*Abstract Co-Author*) Nothing to Disclose
Roberto Maroncelli, MD (*Abstract Co-Author*) Nothing to Disclose
Marcella Pasculli, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the relationship between each individual body composition parameter (VAT, SAT, SMA, SMI) and the outcomes of patients with ER-positive/HER2-negative metastatic breast cancer treated with CDK 4/6 inhibitors, with the goal of defining their prognostic value.

**METHODS AND MATERIALS**

The design of our research is prospective. During the first semester of our study, we enrolled all of the patients. Mammography, ultrasound, and/or breast MRI were performed to assess breast lesions. The enrolled patients underwent a total body CT scan as part of the standard diagnostic protocol in methastatic disease. CT scanner (Somatom Sensation 64; Siemens Healthineers, Erlangen, Germany): Non contrast phase acquisition, Portal venous phase acquisition, Slice thickness 1-5 mm, 120 kvp. The baseline patients' CT scans were uploaded to the "Quantib, body composition" software, which automatically extracted the axial slice passing through the third lumbar vertebra. The software calculated the area of adipose tissue and muscle tissue based on the automated assessment of the different densities using the Hounsfield scale. According to the literature, a VAT area greater than 130 cm2 suggests obesity, while a SMI value less than 40 cm2/m2 indicates sarcopenia. Recist criteria were used to identify and classify the response to therapy in Progressive disease, stable disease, partial response and complete response.

**RESULTS**

52 patients met the inclusion and exclusion criteria. Of all the patients, 33 were obese, 30 were sarcopenic. 19 patients showed obesity and sarcopenia at the same time. After 6 months of therapy: 4 patients had a progressive disease, 13 patients a stable disease, 29 a partial response and 6 a complete response to treatment. Overall, 17 patients showed a poor response and 35 a good response to treatment. Statistical analysis demonstrated a significant correlation between skeletal muscle area and response to therapy.

**CONCLUSION**

In conclusion our study confirms the role of sarcopenia as a potential early predictor of prognosis in metastatic BC patients treated with CDK 4/6 inhibitors and that the evaluation of body composition may be useful in personalizing treatment approaches.

**CLINICAL RELEVANCE/APPLICATION**

to be useful in personalizing treatment approaches in metastatic BC patients.

## T2-SPBR-8 ENHANCING AI-BASED MULTI-VIEW MEDICAL IMAGE ANALYSIS WITH RANDOM TOKEN FUSION

Fredrik Strand, MD, PhD (*Abstract Co-Author*) Speaker, Lunit Inc
Kevin Smith, MSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Christos Matsoukas (*Abstract Co-Author*) Nothing to Disclose
Jingyu Guo (*Presenter*) Nothing to Disclose

**PURPOSE**

Artificial intelligence systems (AI CAD) must be able to effectively leverage complementary information from different views to minimize ambiguity. However, current AI-based methods for multi-view analysis often overfit to view-specific features, leading to suboptimal diagnostic performance. To address this issue, we propose a novel approach named Random Token Fusion (RTF), which encourages AI models to emulate the way physicians interpret scans, thereby improving diagnostic performance.

### METHODS AND MATERIALS

This retrospective study was performed on two public benchmark datasets: CBIS-DDSM for mammography and CheXpert for chest X-rays. We developed RTF as a model-agnostic training technique that can be integrated with existing multi-view fusion strategies in AI models. RTF randomly drops tokens (intermediate features) from different views during the fusion phase of training, encouraging the model to learn more generalized and robust representations across all views. We examined how area under the receiving operating characteristic curve (AUC) and region of interest (ROI) assessments by AI CAD were affected by training using RTF.

### RESULTS

In a study involving 708 mammography exams from 636 patients (46% malignant, 54% benign), AI CAD with RTF achieved an AUC of 0.811 (± 0.004), compared to 0.807 (± 0.003) without RTF. Additionally, in an analysis of 31,413 chest X-rays from 22,414 patients, annotated for 14 diagnostic observations, AI CAD with RTF demonstrated an average AUC of 0.848 (± 0.004), versus 0.841 (± 0.001) without RTF. In both cases, saliency maps revealed that RTF directly influences the ROIs of AI models, promoting a more comprehensive focus between views. Moreover, RTF generally improves the quality of intermediate representations, with increased attention on relevant areas.

### CONCLUSION

RTF can enhance the performance and improve diagnostic accuracy of AI models for multi-view medical image analysis. By encouraging models to integrate insights from multiple views, RTF contributes to more robust and informative representations, thereby increasing the trustworthiness of the models.

### CLINICAL RELEVANCE/APPLICATION

RTF enables AI CAD to effectively utilize information from multiple views. Our findings highlight the potential of RTF to advance AI-based medical diagnosis and support healthcare professionals in the clinical decision-making process.

## T2-SPBR-9 IMPROVEMENT OF MAMMOGRAPHY BREAST POSITIONING QUALITY SCORES WITH TECHNICAL REPEAT VIEWS

Julia Kay Harms (*Abstract Co-Author*) Nothing to Disclose
Robyn Letts (*Abstract Co-Author*) Nothing to Disclose
Melissa L. Hill, BEng, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the likelihood of improved mammography breast positioning quality score by technical repeat (TP).

### METHODS AND MATERIALS

We retrospectively identified two cohorts with negative 4-view screening mammograms for clients aged 47-73 from the OPTIMAM database (2 UK sites). No Repeat (NR) studies are controls relative to Same Day Repeat (SDR) cases with one paired original-repeated view, coded as a TP for technologist or client reasons. Volpara Imaging Software was used to evaluate breast volume (BV), Volpara Density Grades (VDG), compression pressure (CP), and breast positioning quality scores, according to Perfect, Good, Moderate, Inadequate (PGMI) classification. Univariate statistical analyses were performed to identify confounding variables between the NR and SDR groups; Coarsened exact matching yielded 827 NR and 1532 SDR studies. Study-level comparisons between NR and original SDR (before retake), and between NR and final SDR (includes repeated image) were performed. Paired analysis was carried out on Study PGMI between SDR original and final studies. Transition matrices compared paired unaccepted original (UO) and accepted final (AF) image-level PGMI scores. Conditional logistic regression was used to model the effect of image PGMI on an image being AF rather than UO using a simple and expanded model.

### RESULTS

Study-level comparison of SDR original and SDR final showed that the PGMI distribution changed significantly ($p<0.001$) with TP; 250 (19%) M-ranked studies improved to G, while only 1/1532 SDR studies reduced PGMI score ($p<0.001$). Final SDR studies displayed greater frequencies of M rankings compared to NR studies (OR=9.77, $p<0.05$). P and I frequencies were low across all groups. Image-level comparison between paired UO-AF images indicated significant changes in PGMI rankings ($p<2.2e-16$). Following repeat, at least half of P, G, and M did not change score, while 87% of I improved, (44% to M and 38% to G) only 4% of M and 6% of G reduced to I ($p<0.001$). Logistic regression confirmed this trend. As image PGMI reduces from P, the odds of an image being a repeat vs original drastically decrease (OR: G=0.47; M=0.098, I=0.015; $p<0.01$), indicating that repeat of lower score views is likely to result in quality improvement.

### CONCLUSION

Study-level mammogram PGMI was shown to be relatively stable in response to single-view TP, with a trend for quality improvement. In contrast, image-level PGMI is greatly sensitive to TP, with substantial net movement to a better quality score.

### CLINICAL RELEVANCE/APPLICATION

Automated PGMI scores show strong potential to inform technical repeat decisions. Low image-level PGMI scores, especially I, suggest a high probability that the positioning quality could be improved by technical repeat.

Brett Carroll, MD (*Abstract Co-Author*) Research Consultant, Reliant Medical;Research Grant, Bristol Meyers Squibb
Yuval Liberman, MD, MMedSc (*Presenter*) Nothing to Disclose

### PURPOSE

Small left atrial (LA) volume was recently reported to be one of the best predictors of acute pulmonary embolism (PE)-related adverse events (AE). There is currently no data available regarding the impact that body surface area (BSA)-indexing of atrial measurements has on the association with PE-related adverse events. Our aim is to assess the impact of indexing atrial measurements to BSA on the association between computed tomography (CT) atrial measurements and AE.

### METHODS AND MATERIALS

Retrospective study (IRB: 2015P000425). A database of hospitalized patients with acute PE diagnosed on CT pulmonary angiography (CTPA) between May 2007 and December 2014 was reviewed. Right and left atrial volume, largest axial area, and axial diameters were measured. Patients undergo both echocardiographies (from which the BSA was extracted) and CTPAs within 48 hours of the procedure. The patient's body weight was measured during each admission. LA measurements were correlated to AE (defined as the need for advanced therapy or PE-related mortality at 30 days) before and after indexing for BSA. The area under the ROC curve was calculated to determine the predictive value of the atrial measurements in predicting AE.

### RESULTS

The study included 490 acute PE patients; 62 (12.7%) had AE. There was a significant association of reduced BSA-indexed and non-indexed LA volume (both <0.001), area (<0.001 and 0.001, respectively), and short-axis diameters (both <0.001), and their respective RA/LA ratios (all <0.001) with AE. The AUC values were similar for BSA-indexed and non-indexed LA volume, diameters, and area with LA volume measurements being the best predictor of adverse outcomes (BSA-indexed AUC=0.68 and non-indexed AUC=0.66), followed by non-indexed LA short-axis diameter (indexed AUC=0.65, non-indexed AUC=0.64), and LA area (indexed AUC=0.64, non-indexed AUC=0.63).

### CONCLUSION

Adjusting for BSA does not substantially affect the predictive ability of atrial measurements on 30-day PE-related adverse events, and therefore, this adjustment is not necessary in clinical practice. While LA volume is the better predictor of AE, LA short-axis diameter has a similar predictive value and is more practical to perform clinically.

### CLINICAL RELEVANCE/APPLICATION

Adjusting for BSA does not substantially affect the predictive ability of atrial measurements on 30-day PE-related adverse events, and therefore, this adjustment is not necessary in clinical practice.

## T2-SPCA-10 PRELIMINARY STUDY OF CMR COMBINED WITH MYOCARDIAL STRAIN IMAGING FOR LEFT ATRIAL FIBROSIS ASSESSMENT IN ATRIAL FIBRILLATION PATIENTS

Fuhua Yan, MS (*Abstract Co-Author*) Nothing to Disclose
Lahu Like (*Abstract Co-Author*) Nothing to Disclose
Wenjie Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Haipeng Dong (*Abstract Co-Author*) Nothing to Disclose
Peng Wu (*Abstract Co-Author*) Nothing to Disclose
Huanhuan Chong (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the effectiveness of 3D-LGE CMR and strain techniques for assessing left atrial (LA) fibrosis in paroxysmal or persistent atrial fibrillation (AF; PaAF, PeAF).

**METHODS AND MATERIALS**

80 patients with PaAF and PeAF who were scheduled for ablation from January 2022 to May 2023 at our institution were retrospectively enrolled. LA storage function, conduit function, booster pump function, total strain (es), passive strain (ee), active strain (ea), and corresponding strain rates (SRs, SRe, SRa) were analyzed. The extent and degree of LA wall enhancement were quantitatively analyzed using the ratio of signal intensity between the LA wall and blood pool (IIR) as a reference. Independent t-tests, Mann-Whitney U tests, and multivariate logistic regression were used to stratify AF categories and develop models.

**RESULTS**

Compared to PaAF, PeAF exhibited significantly increased total volume, sphericity, end-diastolic volume, and end-systolic volume ($P<0.05$). LA storage function, conduit function, booster pump function, es, ee, ea, SRs, SRe, and SRa were significantly reduced in PeAF ($P<0.001$). In the 20-minute and 30-minute 3D-LGE sequences, the PeAF group displayed a higher area and proportion of enhanced myocardium (IIR > 1.2), scar tissue (IIR > 1.32), and interstitial fibrosis (IIR 1.2~1.32) compared to the PaAF group. Multivariate logistic regression revealed that in the clinical subgroup, BMI (OR 1.195, $P=0.012$) and CHA2DS2-VASc score (OR 1.471, $P=0.008$) were independent risk factors for PeAF, yielding an AUC of 0.753 ($P<0.001$). In the myocardial strain subgroup, es (OR 0.749, $P<0.001$) and LA conduit function (OR 1.079, $P=0.038$) were independent predictors of AF classification (AUC=0.927, $P<0.001$). In the 3D-LGE subgroup, the 20-minute LA enhancement total area (OR 1.080, $P<0.001$) and interstitial fibrosis percentage (OR 1.377, $P<0.001$) were independent risk factors for stratifying PeAF and PaAF (AUC=0.933, $P<0.001$). After integrating the aforementioned parameters, the comprehensive model achieved an AUC of 0.957 ($P<0.001$), with ea (OR 0.709, $P=0.024$) and 30-minute LA enhancement total area (OR 1.060, $P=0.005$) as independent predictors.

**CONCLUSION**

Preoperative 3D-LGE CMR with strain techniques can provide a quantitative and visual assessment of LAF, offering crucial imaging evidence for surgical planning and intraoperative electrophysiological navigation fusion.

**CLINICAL RELEVANCE/APPLICATION**

Our research provides a promising imaging tool for the management of AF patients, with potential translational applications focused on quantitatively and visually assessing LA function and structural remodeling, personalizing treatment, and enabling long-term monitoring.

## T2-SPCA-5 RIGHT VENTRICULAR FUNCTION PREDICTS OUTCOME IN HEART FAILURE WITH PRESERVED EJECTION FRACTION: STRAIN ANALYSIS DERIVED FROM MR FEATURE-TRACKING

Jian He, MD (*Abstract Co-Author*) Nothing to Disclose
Shihua Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Minjie Lu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Leyi Zhu (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the association between right ventricular (RV) strain parameters derived from cardiac magnetic resonance feature tracking (CMR-FT) and adverse outcomes in patients with heart failure with preserved ejection fraction (HFpEF).

**METHODS AND MATERIALS**

Patients with HFpEF who underwent CMR examination from January 2010 to December 2018 were retrospectively enrolled. FT strain analysis was performed to measure left ventricular (LV), left atrial (LA), and RV strain parameters. The primary endpoint was all-cause death, and the secondary endpoint was cardiovascular death. The association between variables and clinical outcomes was assessed by Cox proportional regression and receiver operating characteristic analysis.

**RESULTS**

A total of 1170 consecutive patients with HFpEF (age 56.7±12.2 years; 70% male) were enrolled in this study. During a median follow-up of 7.3 years (interquartile range, 5.2-10.1 years), 128 (10.9%) patients reached the primary endpoint, and 111 (9.5%) patients reached the secondary endpoint. In multivariable Cox regression analysis, RV global longitudinal strain (RV-GLS) and RV global circumferential strain (RV-GCS) were independent predictors for the primary endpoint (hazard ratio [HR] per 1% increase, 1.08 [95% CI: 1.02, 1.14; P = .007] and 1.11 [95% CI: 1.02, 1.21; P = .017], respectively) and for the secondary endpoint (HR per 1% increase, 1.09 [95% CI: 1.03, 1.17; P = .006] and 1.12 [95% CI: 1.02, 1.23; P = .016], respectively), whereas LV-GLS was not for either endpoint. The full model (Model 3) based on clinical, conventional imaging, and RV strain (RV-GLS and RV-GCS) variables for the primary endpoint improved the discrimination ability (C-index = 0.785) compared with Model 1 based solely on clinical variables (C-index = 0.708, P < .001) and Model 2 incorporating clinical variables and left atrial volume index (C-index = 0.746, P < .001). In receiver operating characteristic analysis for the primary endpoint, the addition of left atrial volume index and RV strain (RV-GLS and RV-GCS) yielded an improved area under the curve of 0.793 for Model 1 (P < .05).

**CONCLUSION**

RV-GLS and RV-GCS derived from CMR-FT were independent predictors for adverse clinical outcomes in patients with HFpEF, providing incremental prognostic value over traditional clinical and CMR-derived risk markers.

**CLINICAL RELEVANCE/APPLICATION**

RV strain analysis derived from CMR-FT into the assessment of patients with HFpEF shows promise in improving risk stratification beyond traditional risk markers. The current study provides supplementary insights into the prognostic value of RV dysfunction evaluated by CMR-FT in patients with HFpEF.

## T2-SPCH-1 LUNG CANCER SCREENING CT TEMPLATE WITH STRUCTURED FIELDS FOR LIVER AND VERTEBRAL BODY ATTENUATION IMPROVES HEPATIC STEATOSIS, OSTEOPENIA, AND OSTEOPOROSIS REPORTING RATES

Arun Krishnaraj, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Tyler Foley, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Cross-sectional imaging often includes valuable information unrelated to the study indication. Leveraging this additional data for patient benefit is known as opportunistic screening. Three findings which can be noted on low-dose computed tomography (LDCT) of the chest are hepatic steatosis, osteopenia, and osteoporosis. It is unknown how frequently these diagnoses are reported in practice. The aim of this study was to determine if there is a gap between prevalence and reporting of the aforementioned findings on lung cancer screening CTs.

### METHODS AND MATERIALS

One year of LDCTs obtained at a large academic center were reviewed for the presence of hepatic steatosis, osteopenia, and osteoporosis. Liver attenuation was measured in four regions on an axial slice, then averaged. Hepatic steatosis was defined as an average attenuation of <40 Hounsfield units (HU). L1 vertebral body attenuation on an axial slice was measured, with osteopenia defined as 100-130 HU and osteoporosis <100 HU. Reports of each CT were analyzed for inclusion of “steatosis,” “osteopenia,” or “osteoporosis.” After acquisition of baseline data, a modified lung cancer screening CT report template including structured fields for liver and L1 vertebral body attenuation was disseminated. Data was then collected for three months after template distribution.

### RESULTS

In the pre-intervention period (August 2022-July 2023), 1,926 LDCTs were analyzed. The post-intervention group included 632 scans between February-April 2024. Patient demographics and prevalence of steatosis, osteopenia, and osteoporosis were similar between the two groups. Of all cases in which steatosis was present, 19.8% were identified using the standard reporting template. Using the modified template, 85.7% ($p<0.001$) of reports included steatosis when present. Similarly, reporting of osteopenia improved from 0.7% to 41.4% ($p<0.001$), and osteoporosis from 0% to 48.8% ($p<0.001$).

### CONCLUSION

Hepatic steatosis, osteopenia, and osteoporosis are not consistently reported when present on lung cancer screening LDCTs. Templates with structured fields to measure liver and L1 vertebral body attenuation markedly increased radiologist reporting of these findings.

### CLINICAL RELEVANCE/APPLICATION

Though time-intensive, manual measurement of liver and vertebral attenuation on LDCT can provide useful information to patients. Validated artificial intelligence tools capable of detecting steatosis, osteopenia, and osteoporosis without radiologist input could improve the consistency with which these findings are reported.

## T2-SPCH-2 PERFORMANCES OF AN END-TO-END AI/ML CADE/CADX SAMD FOR NODULE DETECTION AND CHARACTERIZATION IN LUNG CANCER SCREENING ON INDEPENDENT COHORT AND COMPARISON TO RADIOLOGISTS

Benoit HUET, PhD (*Abstract Co-Author*) Nothing to Disclose

Pierre Baudot, PhD (*Presenter*) Employee, MEDIAN Technologies

### PURPOSE

The detection and characterization of pulmonary nodules during lung cancer screening is challenging. We introduce a new AI model for computer-aided detection and characterization (CADe/CADx) to improve Lung Cancer Screening (LCS). We compare its performances against both radiologists and Lung-RADs, and evaluate it on an independent cohort.

**METHODS AND MATERIALS**

The model was trained on 10,872 patients from NLST and LIDC datasets. Diagnosis criteria included up to 6-years stability follow-up for benign nodules and histopathology proof for cancer. The model comprises 3D-CNN detection models for nodule localization and large parallel ensembles of 3D-CNNs, 2D-CNNs, radiomics-based classifiers and full-CT 3D-CNNs for malignancy risk prediction. Performances are evaluated on NLST test set (n=2,163, 136 cancers), a subset assessed by 4 groups of Chest CT radiologists, on a nodule detection and malignancy LIDC-like rating task1 (n=485, 136 cancers), and a subset with Lung-RADs1.1 assessment by 6 radiologists2 with prior time point CT information (n=404). Evaluation on an independent cohort is conducted on 264 patients (88 cancers) collected from US and European sites.

**RESULTS**

On NLST test set, patient-level AUC-ROC was 0.979 (CI 95% [0.972 0.986], 5000 bootstraps). At lesion level, FROC exhibits 0.57 FP/scan for a sensitivity of 95.9%. For the subset assessed by radiologists, mean AUC-ROC was 0.974 (CI [0.968 0.979]) compared to radiologists' mean AUC-ROC of 0.889 (CI [0.872 0.905]). Welch t-test showed significant superiority of our AI model over radiologists ($p<0.0001$). The model outperforms readers on each nodule size subgroups: in [4,10]mm range, model's mean AUC is 0.924[0.881, 0.959] vs. reader's 0.747[0.627, 0.856]; in [10,20]mm range, 0.95 vs. 0.877; in [20,30]mm range, 0.98 vs. 0.882. Lung-RADs scores had a mean AUC-ROC of 0.882 (CI [0.862 0.901]), significantly lower than our AI model ($p<0.0001$). On the independent cohort, patient-level AUC-ROC was 0.953 (CI 95% Hanley [0.922-0.985]).

**CONCLUSION**

Our AI model demonstrates high performance in detecting and predicting malignancy risk on LCS populations with a single LDCT. This result is reproductible on an independent cohort. It significantly outperforms Chest CT radiologists and Lung-RADS that use prior CT informations.

**CLINICAL RELEVANCE/APPLICATION**

The model's reliable nodule detection and malignancy risk predictions on a single timepoint could enhance LCS clinicians' clinical routines and patient management on their very first screening visit. 1. Armato, S. G. et al. Med. Phys. 38, 915-931 (2011). 2. Ardila, D. et al. Nat. Med. 25, 954-961 (2019).

## T2-SPCH-4 UTILIZING MULTI-CONDITIONAL GENERATIVE MODEL TO PREDICT LUNG NODULE APPEARANCE IN FOLLOW-UP CT SCANS FOR IMPROVEMENT OF EARLY DIAGNOSIS OF LUNG CANCER AT BASELINE SCREENING

Lubomir M. Hadjiiski, PhD (*Abstract Co-Author*) Nothing to Disclose
Chuan Zhou, PhD (*Abstract Co-Author*) Scientific Advisory Board, Perception Vision Medical Technology Co., Ltd
Lei Ying (*Abstract Co-Author*) Nothing to Disclose
Ella A. Kazerooni, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Heang-Ping Chan, PhD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Yifan Wang, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a deep learning generative model to predict lung nodule appearance in follow-up CT exam using information from baseline screening LDCT scan and study its feasibility of improving early diagnosis of lung cancer at baseline.

**METHODS AND MATERIALS**

We developed a new multi-conditional Wasserstein Generative Adversarial Network (mcWGAN) model to predict nodule progression in follow-up screening CT scans. From the National Lung Screening Trial (NLST) database, we randomly selected 776 patients containing 1121 pairs of nodules (223 malignant and 898 benign) from baseline and up to 2-year annual follow-up LDCT exams to train the mcWGAN model. The model was trained to simultaneously predict nodule size and synthesize a corresponding image of the nodule that would appear in the follow-up CT scans using the learned nodule progression path. The patient's demographics (age, sex, etc.) and radiographic risk factors provided by radiologists (nodule size, attenuation, etc.) were used as the conditional input to enhance the relevance and effectiveness for predicting the nodule size and to improve the accuracy in the synthesis of pixel-wise nodule image in the follow-up CT scan. The trained mcWGAN model was deployed to an independent test set of 450 baseline LDCT scans (53 malignant and 397 benign) from 450 patients. The predicted follow-up nodule image was input to our previously developed Lung Cancer Risk Prediction model (LCRP) to estimate the likelihood of malignancy of the nodule. The predicted follow-up nodule size was used as one of the inputs to the Brock model to simulate the clinical assessment of nodule malignancy.

**RESULTS**

For classification of mcWGAN-predicted follow-up lung nodules from the baseline CT scans, the LCRP model achieved a test AUC of 0.841±0.025, which was significantly higher than that using the baseline nodule image (AUC: 0.801±0.029, p=.03) and comparable to that using the real follow-up nodule image (AUC: 0.874±0.024, p=.13). In addition, the performance of the Brock model improved when using the mcWGAN-predicted nodule size (AUC: 0.782±0.029, p=.03) compared to using the size of the baseline nodule (AUC: 0.750±0.034, p=.14), but was lower than using the size of the real follow-up nodule (AUC: 0.844±0.028, p=.02).

**CONCLUSION**

Using the follow-up nodule image and size predicted by our mcWGAN model at baseline screening, the diagnostic accuracies of both the LCRP and Brock models were improved compared to that with the baseline nodules.

**CLINICAL RELEVANCE/APPLICATION**

Using baseline exams to predict the nodule size and its image appearance in future LDCT exams has the potential to improve early diagnosis of lung cancer and also provide radiologists with a "virtual" visualization of nodules at follow-up exams.

## T2-SPCH-5 CANARY IN THE COAL MINE: LESSONS FROM THE ANCILLARY FINDINGS OF LUNG SCREENERS

Elizabeth K. Proffitt, MD (*Abstract Co-Author*) Nothing to Disclose
Susan K. Hobbs, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Vivek Batra, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of the study is to investigate the utilization of new significant cardiovascular findings on lung cancer screening CT for initiation or adjustment of cardiovascular medications.

### METHODS AND MATERIALS

Using retrospective design and two independent databases, TriNetX and Nuance Empower, patients who underwent a lung cancer screening study between March 1, 2020, to June 30, 2023, with ages between 50-89 years old were identified in a large health network. Patients with pre-existing versus new chronic ischemic heart disease based on the lung screening report were tabulated in conjunction with Lung-RADS modifier S. Data on initiation of antiplatelets, anti-hypertensive or cholesterol lowering medications in the six months after the lung screening study was collected in the patients who had new cardiac findings.

### RESULTS

Using TriNetX database, 15,060 patients had lung screening performed in the health network during the study period. 3170 had pre-existing ischemic heart disease, and 550 had new coronary artery calcification (CAC) identified within six months of completion of the lung screening CT. 320 out of the 550 patients who had been diagnosed with new CAC were on a cardiac mediation, and 70 out of the 550 patients were started on a new cardiac medication within six months after completion of the lung screening CT. The Nuance Empower database generated 19,423 patients. Patients with moderate and severe coronary disease was 2334 and 1077 respectively (total 3411). Modifier S was used in 1669, and modifier S along with moderate or severe coronary artery disease was used in approximately 668 patients. The burden of pre-existing ischemic heart disease is 21% using TriNetX and 17.6% using Nuance Empower in the patients undergoing lung screening CT. About 3.6% and 3.4% patients had new (or significant) moderate or severe coronary artery disease in the TriNetX and Nuance Empower respectively. Only 58% of the patients who were diagnosed with new (or significant) moderate or severe coronary artery disease were on a cardiac medication within six months after completion of the study. Only 12.7 % of the patients who were diagnosed with new (or significant) moderate or severe coronary artery disease were started on a new cardiac medication within six months after completion of the study.

### CONCLUSION

Cardiovascular disease has significant morbidity and mortality and is undertreated. Using CT lung screening report CAC documentation, radiologists play a role in management of patients who may not have been treated otherwise.

### CLINICAL RELEVANCE/APPLICATION

CT lung cancer screening CAC results could have far-reaching effects on decreasing morbidity and mortality from cardiovascular events.

## T2-SPCH-6 PREDICTING INVASIVENESS OF GROUND-GLASS NODULES IN PULMONARY ADENOCARCINOMA USING DEEP LEARNING AND RADIOMICS-BASED MULTI-INSTANCE LEARNING

Jing Shen, MD (*Abstract Co-Author*) Nothing to Disclose
Jianlin Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Hai Du (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the diagnostic efficacy of preoperative CT prediction of invasive lesions in appearing as GGN lung adenocarcinomas using a combined model by both radiomics and deep learning features through multi-instance learning (MIL).

### METHODS AND MATERIALS

A retrospective analysis was conducted on preoperative chest CT images of appearing as GGN lung adenocarcinomas surgically resected and a total 1182 cases with 1247 GGNs were recruited. Two different models were established based on postoperative pathological results, distinguishing the invasive group (IAC) from the non-invasive group (AAH, AIS, MIA): (1) Standalone Radiomics Model Radiomics features were extracted using the Pyradiomics tool. (2) Radiomics and Deep Learning Joint Model (MIL-DL-Rad).These features were fused using multi-instance learning after dimensionality reduction and input into machine learning models (RF, ExtraTrees, XGBoost, LightGBM) to construct the optimal MIL-DL-Rad model.The predictive performance of the standalone radiomics model and the MIL-DL-Rad model which best suited the machine learning model were compared. ROC curves were used to evaluate these models, with AUC values compared for diagnostic efficacy. Calibration curves were used to assess discriminative ability and calibration.

### RESULTS

A total of 1247 GGNs the invasive group consisted of 841 cases (67.44%), the non-invasive group comprised 406 cases (32.56%). Results showed statistically significant differences ($P<0.001$) between the invasive and non-invasive groups in terms of age, volume, maximum diameter, minimum diameter, mean diameter, and CT value, while gender differences were also observed ($P<0.005$). The radiomics model based on ExtraTrees showed balanced performance in the test_qd, test_dl, and test_zjg test sets, with AUC values of 0.828, 0.936, and 0.914, respectively. In the MIL-DL-Rad model, the ExtraTrees model performed the best, with AUC values of 0.868, 0.926, and 0.918 in the three test sets.

### CONCLUSION

The combined model developed by both radiomics and deep learning features using multiple instance learning shows superior overall performance and discriminative capability compared to traditional radiomics models in predicting the invasiveness of pulmonary adenocarcinoma which appearing as GGN, offering a new perspective on feature fusion.

### CLINICAL RELEVANCE/APPLICATION

Radiomics and deep learning features using multiple instance learning shows superior overall performance and discriminative capability compared to traditional radiomics models in predicting the invasiveness of pulmonary adenocarcinoma which appearing as GGN.

## T2-SPCH-7 THE VALUE OF CT-BASED RADIOMICS FOR PREDICTING VISCERAL PLEURAL INVASION IN EARLY-STAGE NON-SMALL CELL LUNG CANCER

Heshui Shi, MD (*Abstract Co-Author*) Nothing to Disclose
Shen Gui (*Abstract Co-Author*) Nothing to Disclose
Qinyue Luo (*Presenter*) Nothing to Disclose

### PURPOSE

The presence of visceral pleural invasion (VPI) upstages tumors =3 cm from T1 to T2a in the eighth edition of the tumor-node-metastasis (TNM) staging system. This study aimed to develop and validate a CT-based radiomics model for preoperative prediction of VPI in early-stage non-small cell lung cancer (NSCLC).

## METHODS AND MATERIALS

We retrospectively enrolled 461 patients with histologically proven stage IA (T1N0M0) and stage IIA (T1N1M0) NSCLC from December 2019 to June 2022. Patients were divided into a training set (n=295), a validation set (n=127) and a testing set (n=39) at a ratio of 6:3:1. On all CT images, densities of nodules (pure ground-glass opacity [pGGO], mixed GGO [mGGO] and solid), five types of tumor pleura relationships (type I-V) were recorded. Region of interest (ROI) segmentation was performed semi-automatically. Radiomics features were extracted from CT images. The least absolute shrinkage and selection operator (LASSO) was applied to select radiomics features and construct a radscore. We built three predictive models (clinical model, radiomics model and combined model) based on CT features, selected radiomics features and the combination of CT features and radiomics features, respectively. The predictive performances of these three models were assessed by the area under the receiver operating characteristic curve (AUC).

## RESULTS

A total of 1291 radiomics features were extracted, and 14 optimal features were selected to construct the radiomics model. The AUC of the radiomics model was 0.843, 0.705 and 0.813 in the training, validation and testing sets. Furthermore, seven CT features were selected by multivariable logistic regression (LR) to construct the clinical model. The clinical model achieved good performance with an AUC of 0.855, 0.717 and 0.841 in the three sets. Compared with the clinical model and radiomics model, the combined model showed higher AUC (0.938 in the training set, 95% CI: 0.907-0.969; 0.924 in the validation set, 95% CI: 0.8228-1.00; 0.935 in the testing set, 95% CI: 0.889-0.980) and greater net benefit to patients.

## CONCLUSION

The CT-based radiomics model demonstrated satisfactory diagnostic performance in early-stage NSCLC for preoperatively predicting VPI, with superiority to the clinical model.

## CLINICAL RELEVANCE/APPLICATION

VPI is a known indicator of poor prognosis in NSCLC, and preoperative detection of VPI could assist in choosing an appropriate surgery type. Combining CT features with radiomics is a valuable approach for preoperative prediction of VPI, it could provide more imaging support for clinical diagnosis and treatment strategy formulation of VPI.

## T2-SPER-1 CT IMAGING IN THE EMERGENCY DEPARTMENT TO EVALUATE ABDOMINAL PAIN IN PATIENTS REPORTING INTIMATE PARTNER VIOLENCE

Bharti Khurana, MD, MBA (*Abstract Co-Author*) Consultant, General Electric Company;Editor, Wolters Kluwer nv;Author, Cambridge University Press;Consultant, ROKIT Healthcare, Inc
Patrick Lenehan, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Intimate partner violence (IPV) is associated with physical health consequences including abdominal and pelvic pain, but the radiologic manifestations of these pain syndromes have not been studied. Here we investigate the use of and reported findings on CT imaging in patients reporting IPV who presented to the emergency department (ED) with abdominal pain.

### METHODS AND MATERIALS

Cases (N = 254) were defined as females who reported physical IPV to our institution's violence prevention support program and underwent at least one imaging study in the ED. Controls (N = 377) were age- and race-matched females who have never reported IPV but also underwent at least one imaging study in the ED. From a total of 8,746 ED imaging studies, we identified 102 abdominal CT studies that were performed to evaluate pain. A retrospective review of the corresponding reports was performed to determine whether a radiologic explanation for the pain was identified. The proportions of patients undergoing abdominal CT to evaluate pain were compared with a crude odds ratio and Fisher exact test. Logistic regression was used to compare the proportions of studies with findings that could explain the reported pain, with adjustment for age at the time of the study.

### RESULTS

Abdominal CT to evaluate pain was performed at least once for 32 of 254 (12.6%) cases versus 25 of 377 (6.6%) controls (OR: 2.0; 95CI 1.1, 3.7, p=0.02). It comprised 4.4% (60/1377) and 6.7% (42/626) of all ED imaging studies for cases and controls, respectively (OR: 0.64; 95CI 0.41, 0.98; p=0.03). Radiologists indicated the absence of acute pathology or findings that explain the patient's pain in 37 of 60 (62%) studies for cases versus 16 of 42 (38%) studies for controls (aOR: 2.5; 95CI 1.1, 5.8; p=0.026). Explicit documentation that CT findings could not explain the abdominal pain was observed for 52% of case studies versus 17% of control studies (aOR: 5.1; 95CI 2.0, 14.3; p<0.001).

### CONCLUSION

This study reveals a higher incidence of unexplained abdominal pain on ED CT scans among patients reporting IPV compared to controls, highlighting potential dysregulation of the gut-brain axis.

### CLINICAL RELEVANCE/APPLICATION

Awareness by ED radiologists and providers that negative CT results do not negate the presence of pain is critical to ensure a compassionate and equitable approach to diagnosing and treating patients who have experienced IPV.

## T2-SPER-2 EXAMINATION OF EARLY PROGNOSIS OF TYPE A AORTIC DISSECTION: CORRELATION WITH PULMONARY ARTERY ADVENTITIAL HEMATOMA DUE TO RUPTURED TYPE A AORTIC DISSECTION AND EARLY DEATH

Eijun Sueyoshi, MD (*Abstract Co-Author*) Nothing to Disclose
Ryo Toya, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hirofumi Koike (*Presenter*) Nothing to Disclose

### PURPOSE

Pulmonary artery adventitial hematoma (PAAH) due to ruptured type A aortic dissection (AD) can occur and has been reported to correlate with prognosis. However, PAAH due to ruptured type A AD with early death has not yet been fully elucidated.This study aimed to evaluate the relationship between PAAH and early prognosis in type A AD patients.

### METHODS AND MATERIALS

We retrospectively studied 344 type A AD patients in our institution from April 2008 to November 2023. Patients were divided into those who died within 1 week of onset (early death group; n = 33, 9.6%) and those who survived (alive group; n = 311, 90.4%). We analyzed the relationship between CT findings including PAAH and early death. PAAH was classified into three stages on the basis of CT findings: Stage 1, PAAH only in the mediastinum; Stage 2, PAAH that extended into the lung field (changes in only lung segments with PAAH); and Stage 3, blood in the alveoli beyond the tissue surrounding the pulmonary artery (changes beyond lung segments with PAAH).

## RESULTS

Compared with the alive group, the early death group had higher rates of PAAH ($P = 0.002$), Stage 3 PAAH ($P < 0.001$), pericardial hemorrhage ($P = 0.001$), mediastinal hemorrhage ($P < 0.001$), hemothorax ($P < 0.001$), renal ischemia ($P = 0.002$), limb ischemia ($P = 0.001$), and myocardial ischemia ($P = 0.004$). In the multivariable analysis, stage 3 PAAH, limb ischemia, and myocardial ischemia were significant risk factors for early death ($P < 0.001$, $P = 0.022$, and $P = 0.001$, respectively).

## CONCLUSION

Stage 3 PAAH was one of significant risk factors for early death in patients with type A AD.

## CLINICAL RELEVANCE/APPLICATION

The results of this study are clinically important for clinicians and radiologists who encounter patients with Stanford type A AD. We can detect Stage 3 PAAH as a risk factor for early death. However, we may misdiagnose Stage 3 PAAH as pneumonia or pulmonary edema if we do not understand PAAH because pulmonary hemorrhage with stage 3 PAAH sometimes mimic those in CT.

## T2-SPGI-1 SPECTRAL CT-BASED NOMOGRAM FOR PREOPERATIVE PREDICTION OF LAUREN CLASSIFICATION IN LOCALLY ADVANCED GASTRIC CANCER: A PROSPECTIVE STUDY

Zhao Xiang Ye, PhD (*Abstract Co-Author*) Nothing to Disclose
Rongji Gao (*Abstract Co-Author*) Nothing to Disclose
Xiao Mei Lu, MMed (*Abstract Co-Author*) Nothing to Disclose
Juan Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a nomogram based on clinical features and spectral quantitative parameters to preoperatively predict the Lauren classification for locally advanced gastric cancer (LAGC).

### METHODS AND MATERIALS

Patients diagnosed with LAGC by postoperative pathology who underwent abdominal triple-phase enhanced spectral computed tomography (CT) were prospectively enrolled in this study between June 2023 and December 2023. All the patients were categorized into intestinal- and diffuse-type group according to the Lauren classification. Traditional characteristics, including demographic information, serum tumor markers, gastroscopic pathology, and image semantic features, were collected. Spectral quantitative parameters, including iodine concentration (IC), normalized iodine concentration (nIC), effective atomic number (Zeff), normalized effective atomic number (nZeff), and slope of the energy spectrum curve from 40 keV to 70 keV (?), were measured three times for each patient by two blinded radiologists in arterial/venous/delayed phases (AP/VP/DP). Differences in traditional features and spectral quantitative parameters between the two groups were compared using univariable analysis. Independent predictors of the Lauren classification of LAGC were screened using multivariable logistic regression analysis. Receiver operating characteristic (ROC) curve analysis was used to assess the discriminating capability. Ultimately, the nomogram including clinical features and spectral CT quantitative parameters was developed.

### RESULTS

Gender, nIC in AP (APnIC), and ? in DP (?d) were independent predictors for Lauren classification. The nomogram based on these indicators produced the best performance with an area under the curve of 0.841 (95% confidence interval: 0.749~0.932), specificity of 85.3%, accuracy of 76.4%, and sensitivity of 68.4%.

### CONCLUSION

The nomogram based on clinical features and spectral CT quantitative parameters exhibits great potential in the preoperative and non-invasive assessment of Lauren classification for LAGC.

### CLINICAL RELEVANCE/APPLICATION

Through the spectral CT-based nomogram, the preoperative prediction of the Lauren classification in LAGC can not only help physicians guide the appalication of chemotherapy before or after surgery, but also help surgeons detremine the range of surgical resection.

## T2-SPGI-10 COMPARISONS OF FLUOROSCOPY PULSE RATES (15 PULSES/SECOND V.S. 7.5 PULSES/SECOND) IN PANCREATICOBILIARY INTERVENTIONS: CLINICAL RETROSPECTIVE ANALYSIS

Tatsuya Sato (*Abstract Co-Author*) Nothing to Disclose
Osamu Abe, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Katsuyuki Tabei (*Abstract Co-Author*) Nothing to Disclose
Toshikazu Imae (*Abstract Co-Author*) Nothing to Disclose
Saori Koshino, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Naminatsu Takahara (*Abstract Co-Author*) Nothing to Disclose
Noriyuki Sakai, MSc, RT (*Presenter*) Nothing to Disclose

### PURPOSE

Radiation exposure is a significant concern for both patients and operators during endoscopic and percutaneous interventions such as endoscopic retrograde cholangiopancreatography (ERCP) and percutaneous transhepatic biliary drainage (PTBD) for pancreaticobiliary diseases. However, there is limited evidence regarding the radiation dose necessary to achieve sufficient imaging quality for ensuring appropriate diagnosis and therapeutic intervention. Optimization of fluoroscopy pulse rate is an effective technique for radiation dose reduction. Our purpose was to retrospectively compare fluoroscopy dose and fluoroscopy time using 15 pulses/second (p/s) with those using 7.5 p/s and to pursue the feasibility of pancreaticobiliary interventions in low-dose radiation.

**METHODS AND MATERIALS**

The institutional review board approved the clinical retrospective analysis. We extracted pancreaticobiliary interventions including ERCP, PTBD, balloon-assisted endoscope-guided ERCP (BAE-ERCP), interventional endoscopic ultrasonography (EUS), and endoscopic gastrointestinal stentings using 15 p/s fluoroscopy (from March 26, 2018 to March 31, 2021) and 7.5 p/s fluoroscopy (from April 1, 2021 to October 21, 2022). We compared the dose area product (DAP) and the fluoroscopy time between the 15 p/s fluoroscopy group (n = 3254) and the 7.5 p/s fluoroscopy group (n = 1704). We used the Mann-Whitney U test to identify any significant differences between the groups in the DAP and fluoroscopy time. A P-value less than .05 was considered statistically significant.

**RESULTS**

The extracted 4958 pancreaticobiliary interventions (3160 males and 1798 females) were consisted of 3909 ERCP, 164 PTBD, 317 BAE-ERCP, 510 interventional EUS, and 58 endoscopic gastrointestinal stentings. The median (range) of ages and body mass index were 67.0 (17.0 to 100.0) years and 21.4 (11.7 to 47.8) kg/m2, respectively. The X-ray pulse rate of 7.5 p/s reduced the DAP of fluoroscopy by 49.5% (15 p/s, median, 11899.5 mGy•cm2, range, 25.0 to 258130.0 mGy•cm2; 7.5 p/s, median, 6007.0 mGy•cm2, range, 16.0 to 78410.0 mGy•cm2; P < .001) without extending the fluoroscopy time (15 p/s, median, 690.5 seconds, range, 2.0 to 9059.0 seconds; 7.5 p/s, median, 699.5 seconds, range, 2.0 to 6897.0 seconds; P = .85) compared with the X-ray pulse rate of 15 p/s.

**CONCLUSION**

Fluoroscopy dose was reduced by 49.5% without extending fluoroscopy time in pancreaticobiliary interventions by decreasing X-ray pulse rate from 15 p/s to 7.5 p/s.

**CLINICAL RELEVANCE/APPLICATION**

Radiation dose reduction of patients and operators could be achievable in pancreaticobiliary interventions without prolonging fluoroscopy time using 7.5 p/s fluoroscopy.

## T2-SPGI-11 PROGNOSTIC VALUE OF EXTRACELLULAR VOLUME FROM EQUILIBRIUM CONTRAST-ENHANCED CT IN STAGE II-III GASTRIC CANCER

Yusuke Nishimuta, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Gastric cancer (GC) remains a significant cause of mortality worldwide, particularly in patients with stage II-III disease, who experience high recurrence rates despite curative surgery and adjuvant chemotherapy. Identifying reliable prognostic markers is critical for optimizing treatment strategies and improving outcomes. This study aimed to evaluate the prognostic significance of the extracellular volume (ECV) derived from equilibrium contrast-enhanced CT (CT-ECV) in predicting postoperative recurrence for patients with pStage II-III GC.

**METHODS AND MATERIALS**

We conducted a retrospective analysis of 74 patients with pathologically confirmed pStage II-III gastric adenocarcinoma who underwent preoperative triphasic contrast-enhanced CT and gastrectomy without prior treatment. We analyzed the correlation between preoperative CT-ECV and recurrence risk, utilizing comprehensive imaging and clinicopathological data. Disease-free survival (DFS) was assessed using Cox proportional hazards models, with CT-ECV values compared between recurrence and recurrence-free groups. The optimal cut-off value of CT-ECV for predicting postoperative recurrence was determined using receiver operating characteristic (ROC) curve analysis with the Youden index.

**RESULTS**

The mean CT-ECV value was 56.1 ± 16.8%. Patients who experienced postoperative recurrence exhibited significantly higher CT-ECV values (P < 0.001) with an optimal cutoff value identified at = 62.9% for predicting recurrence. High CT-ECV was independently associated with poor DFS (HR, 4.47; 95% CI: 1.39-14.44; P = 0.012), confirming its potential as a predictive marker of adverse outcomes.

**CONCLUSION**

CT-ECV is a non-invasive, preoperative prognostic indicator in patients with stage II-III GC, with higher values associated with increased recurrence risk and reduced DFS.

**CLINICAL RELEVANCE/APPLICATION**

CT-ECV could guide more tailored therapeutic approaches, potentially improving patient management and outcomes.

## T2-SPGI-13 RADIOMICS MODEL ASSESSMENT FOR GASTRIC SCHWANNOMAS AND GASTROINTESTINAL STROMAL TUMORS ACROSS RISK GRADES

Zimei Yang (*Abstract Co-Author*) Nothing to Disclose
LI YANG (*Abstract Co-Author*) Nothing to Disclose
Jia-Liang Ren, MD (*Abstract Co-Author*) Nothing to Disclose
Fei C. Ma (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to develop and validate an enhanced computed tomography (CT) imaging radiomics model, assessing its potential in distinguishing gastric schwannomas (GS) from gastrointestinal stromal tumors (GIST) across various risk categories.

**METHODS AND MATERIALS**

We conducted a retrospective analysis of 26 GS and 82 GIST cases, confirmed by postoperative pathology, and divided into training and validation cohorts at a 7:3 ratio. We documented patient demographics, clinical presentations, and detailed CT imaging characteristics. Univariable and multivariable logistic regression analyses were used to identify independent predictors for distinguishing GS from GIST and to construct a conventional model. Manual 3D segmentation was performed on venous phase thin-slice CT images (1mm or 1.25mm) using ITK-SNAP software (version 3.8.0), and radiomic features were extracted using pyradiomics (version 3.0.0). Univariable and correlation analyses were used to identify significant features,which were then selected using the Least Absolute Shrinkage and Selection Operator (LASSO) regression and stepwise multivariable logistic regression to construct a radiomics model. A combined model was established by integrating the independent predictors from the conventional model with the radiomic score through multivariable analysis. The diagnostic performances of all models in differentiating GS from GIST and stratifying GISTs according to malignancy risk were evaluated using the Receiver Operating Characteristic (ROC) curve analysis, the Decision Curve Analysis (DCA), the Integrated Discrimination Improvement (IDI) index.

**RESULTS**

Tumor location, cystic changes, degree of enhancement in arterial phase, and enhancement uniformity, were independent predictors for discriminating between GS and GIST. The conventional model exhibited AUCs of 0.939 and 0.869 in the training and validation cohort, respectively. The radiomics model, based on eight pivotal radiomics features, demonstrated AUCs of 0.949 and 0.839. The combined model achieved AUCs of 0.989 and 0.964 in the respective cohorts. Notably, the combined model's diagnostic precision in distinguishing GS from GIST, as well as in stratifying GISTs by high or low malignancy potential, was statistically significant, evidenced by IDI values of 0.2538, 0.2418, and 0.2749 ($P<0.05$ for all).

**CONCLUSION**

The combined model, incorporating CT imaging features and radiomics features, emerges as a promising non-invasive method for the preoperative differentiation between GS and GISTs.

**CLINICAL RELEVANCE/APPLICATION**

Both entities manifest as submucosal masses complicate differentiation. This model provides new ideas for distinguishing GS and GIST and guiding clinical treatment plan.

## T2-SPGI-4 HISTOGRAM ANALYSIS OF WHOLE-TUMOR APPARENT DIFFUSION COEFFICIENT VALUE TO SELECT OPTIMAL NEOADJUVANT THERAPY FOR ADVANCED ESOPHAGEAL SQUAMOUS CELL CARCINOMA

Hisahiro Matsubara, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Toru Tochigi, MD (*Abstract Co-Author*) Nothing to Disclose
Gaku Ohira (*Abstract Co-Author*) Nothing to Disclose
Yoshihiro Kurata (*Abstract Co-Author*) Nothing to Disclose
Atsushi Hirata (*Abstract Co-Author*) Nothing to Disclose
Koichi Hayano, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study is to evaluate whether histogram analysis of apparent diffusion coefficient (ADC) of the tumor can be a useful tool to select optimal neoadjuvant treatment for advanced esophageal squamous cell carcinoma (ESCC).

**METHODS AND MATERIALS**

We retrospectively identified 128 patients with ESCC who received chemoradiation therapy (CRT) or chemotherapy (CT) followed by curative surgery between 2009 and 2016. Histogram analysis of ADC value in whole-tumor lesion was performed before neoadjuvant treatment, and ADC value, Kurtosis, and Skewness of the tumor were measured. These DWI derived pretreatment parameters were compared with recurrence free survival (RFS) in CRT cases (n=58) as well as in CT cases (n=70).

**RESULTS**

In CRT cases, tumors achieved pathological complete response (pCR, 10 patient; 17.2%) showed significant lower ADC, higher kurtosis, and higher skewness than those of non-pCR ($p=0.005$, 0.007, <0.001, respectively). Receiver operating characteristics analysis demonstrated skewness was the best predictor for pCR (AUC=0.87), with a cut off value of 0.50 (accuracy, 86.2%). In Kaplan-Meier analysis, patients with high skewness tumors (>0.50) showed a significantly better RFS ($p=0.03$, log-rank). Whereas, in CT cases, Kaplan-Meier analyses demonstrated that high skewness and high kurtosis of the tumor significantly associated with worse survival ($P=0.04$, 0.02, respectively). Therefore, it was demonstrated that high skewness of tumor ADC value leaded to better RFS in CRT, whereas it leaded to worse RFS in CT.

**CONCLUSION**

Histogram analysis of tumor ADC may enable selection of optimal neoadjuvant treatment in advanced ESCC patients

**CLINICAL RELEVANCE/APPLICATION**

Our results revealed that the value of histogram parameters of tumor ADC in patients with favorable outcome showed opposite values between CRT and CT; and therefore, we may be able to invent new personalized neoadjuvant therapy for advanced ESCC patients according to histogram parameters of tumor ADC. For example, patients in CT cases of this study included 17 patients who had tumors with more than 0.5 of kurtosis in tumor ADC. Such patients might have achieved pCR with accuracy of 86.2%, if they received CRT rather than CT. We believe that our new findings can change current clinical practice of ESCC, leading to better outcome of advanced ESCC.

## T2-SPGI-5 FDG UPTAKE OF METASTATIC LYMPH NODE ENABLES PROGNOSTIC STRATIFICATION OF LYMPH NODE-POSITIVE ESOPHAGEAL CANCER PATIENTS

Hisahiro Matsubara, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoshihiro Kurata (*Abstract Co-Author*) Nothing to Disclose
Toru Tochigi, MD (*Abstract Co-Author*) Nothing to Disclose
Gaku Ohira (*Abstract Co-Author*) Nothing to Disclose
Koichi Hayano, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Hirata (*Presenter*) Nothing to Disclose

**PURPOSE**

Esophageal cancer (EC) with metastatic lymph nodes is considered as advanced EC with poor prognosis. Therefore, prognostic stratification of EC patients with metastatic lymph node (MLN) would be of value. On the other hands, FDG-PET has been served as a tool for detecting MLNs in the diagnosis of EC. However, it is not clear whether FDG uptake of MLN have prognostic impact in EC patients with MLN. The purpose of this study is to evaluate whether FDG uptake of pathologically confirmed MLN station can stratify prognosis of EC patients with MLN.

**METHODS AND MATERIALS**

Surgically treated 134 EC patients with MLNs who received preoperative PET-CT (113 M / 21 W; median age: 70.0 years) were retrospectively investigated. Surgical specimens were pathologically evaluated, and MLN stations were identified. SUVmax > 3.0 of pathologically confirmed MLN is defined as PET positive MLN (PP-MLN), whereas SUVmax = 3.0 of pathologically confirmed MLN station is as PET negative MLN (PN-MLN). Disease specific survival (DSS) was compared between patients with PP-MLN and those with PN-MLN.

### RESULTS

In Kaplan-Meier analysis, patients with PP-MLN showed a significantly worse DSS than those with PN-MLN (P=0.0008, log-rank test). On the other hands, patients with PN-MLN. Multivariate cox regression analysis demonstrated that PP-MLN was an independent prognostic factor for DSS (P=0.01) among T stage, lymphatic invasion, and venous invasion.

### CONCLUSION

FDG uptake of MLN can successfully stratify prognosis of EC patients with MLN. EC patients with PP-MLN might need more effective multidisciplinary adjuvant treatments to improve their outcome.

### CLINICAL RELEVANCE/APPLICATION

There is no established biomarker for prognostic stratification of EC patients with MLN. Our results suggested that FDG uptake of MLN can stratify survival of EC patients with MLN. Considering extremely worse survival of EC patients with PP-MLN, they might need more effective adjuvant multidisciplinary treatments to improve their outcome.

## T2-SPGI-6 ADDED VALUE OF REINTERPRETATION OF OUTSIDE IMAGING AND REVIEW AT HEPATOBILIARY MULTIDISCIPLINARY TUMOR BOARD (MDTB) ON THE DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH HEPATOBILIARY NEOPLASMS

Jeff L. Fidler, MD (*Abstract Co-Author*) Nothing to Disclose
Sudhakar K. Venkatesh, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Jay P. Heiken, MD (*Abstract Co-Author*) Patent agreement, Guerbet SA;
Christopher L. Welle, MD (*Abstract Co-Author*) Nothing to Disclose
Zachary S. Kelm, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Michelle Nguyen (*Presenter*) Nothing to Disclose

### PURPOSE

Radiologist participation in MDTB can be onerous and requires a significant amount of preparation time. Anecdotally radiologist participation is felt to be helpful identifying discrepancies in previous interpretations however there is limited data assessing the added value or impact on patient management. The purpose of this prospective study is to assess the value of reinterpretation of outside imaging and review at MDTB on the diagnosis and management of patients with hepatobiliary neoplasms.

### METHODS AND MATERIALS

Prospective analysis of all patients presented at weekly hepatobiliary MDTB between 6/13/23-2/6/24. One radiologist reviewed available reports of outside imaging, reinterpretation of outside imaging, updated local imaging, and discussion of the case at MDTB. MDTB included 3 abdominal radiologists who had reviewed the case. The number of discrepancies and reason for disagreement was recorded. If there was a disagreement, impact on patient management (5-point Likert scale) was determined by the radiologists present at MDTB, and clinician if needed.

### RESULTS

135 cases (81 males, 68 cirrhotic patients) were presented at MDTB between 6/13/23-2/6/24. 75 cases had imaging from outside institutions, 31 cases had imaging formally overread by our institution's radiologists, and 105 cases had updated imaging done at our institution (local). There was a significant disagreement found in either detection or interpretation of lesions in 42/135 (31.1%) cases. A discrepancy rate of 6/31 (19.4%) was found between outside imaging reports and our institution's formal overreads, with a change in management seen in 4/6 (66.7%) cases. Discrepancies between interpretations of imaging done locally and either the outside imaging report or the overread of outside imaging were seen in 8 instances, with a change in management found in 7/8 (87.5%) cases. Discrepancies between MDTB interpretations and either outside imaging reports, local overreads of outside imaging, or interpretation of imaging done locally were found in 31 instances with a change in management seen in 18/31 (58.1%) cases. Overall, a change in management was seen in 16/25 (64%) and 13/17 (76.5%) of discrepancies found in cirrhotic and non-cirrhotic patients, respectively.

### CONCLUSION

Our study found a discrepant interpretation in 42/135 (31.1%) of cases reviewed at a weekly MDTB. A change in clinical management was found in 29/42 (69%) of these discrepant interpretations. This data emphasizes the importance of reinterpretation of prior imaging and the presence of radiology at MDTB to guide appropriate management.

### CLINICAL RELEVANCE/APPLICATION

Patient care is significantly impacted by reinterpretation of prior imaging and participation of radiologists at hepatobiliary tumor board.

## T2-SPGI-7 FOUR-SECTION FORMULA BASED ON AXIAL&CORONAL CT IN THE DISCRIMINATION OF SIEWERT TYPES OF ADENOCARCINOMA OF ESOPHAGOGASTRIC JUNCTION

Lei Tang, MD (*Abstract Co-Author*) Nothing to Disclose
Yiting Liu (*Presenter*) Nothing to Disclose

### PURPOSE

To build an easy-handled formula to judge the Siewert type of AEG on CT images, through the comparison with the pathological findings.

### METHODS AND MATERIALS

A total of 56 type II and type III AEG cases that were misclassified by conventional preoperative CT March 2019 to March 2023 enrolled. All patients underwent preoperative enhancement CT and had postoperative Siewert type. Siewert type on CT was performed by two radiologists on venous phase. The following steps are taken to determine the Siewert type: On the coronal CT image, find the angular notch (A in the figure) and the counterpart point on the lesser curvature (B in the figure). Connect the two points with a smooth arc to get the EGJ line. The midpoint of the line on axial image equals to EGJ layer. Then we judge Siewert type using the layer numbers on axial images with two-section formula (TSF): formula 1. Positive values signified as Siewert III, and negative ones will use formula 2 to further discriminate between Siewerts I and II, the positive values will be determined as Siewert II, and negative values as Siewert I. (The formula will be shown in PDF attachment.)When scanned in the supine position, the distal end of the stomach is relatively anteriorly inclined and closer to the horizontal direction, while the long axis of the gastric lumen in the esophagogastric conjunction is closer to the vertical direction, so the calculated value of the infiltration range of the stomach is shorter than the actual situation (Fig. 1), which resulted in the misclassification of the Siewert type III as type II. Therefore, we roughly classified the gastric lumen alignment in the coronal position into leftward and rightward, and retrospectively included 51 patients with pathological diagnosis of Siewert type II and III AEG from June 2020 to December 2022 in our hospital, and measured the angle of leftward or rightward deviation of the main portion of the tumor with the gastric lumen alignment. The median left

deviation angle of the gastric lumen was calculated to be 35° , and the median right deviation angle was 45° .Corrections were made using the calculated values of the above angles.

**RESULTS**

The interobserver agreement was good (kappa value = 0.83). Our formula method and pathological findings reached consensus in 28 patients. The accuracy of patients with traditional imaging misdiagnosis of AEG by our formula method was 80%, and the accuracy of type III was 94.12%

**CONCLUSION**

Four-section formula using axial combing with coronal CT information provided a potential method in the preoperative judgement of the Siewert type of AEG.

**CLINICAL RELEVANCE/APPLICATION**

It might be applied to gastric cancer structured report for more convenient calculation in daily report writing.

## T2-SPGI-8 THE UTILITY OF CHEST CT IN DIAGNOSING POST-ENDOSCOPY ESOPHAGEAL PERFORATION

Peter Young, MD (*Abstract Co-Author*) Nothing to Disclose
Brittany L. Miles, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Diagnostic and operative endoscopy have been a mainstay in the evaluation and treatment of intraluminal upper gastrointestinal pathologies. Perforation is a rare and unfortunate complication of upper endoscopy, and patients suspected of esophageal perforation will require prompt evaluation. The fluoroscopy upper GI series examination has traditionally been the study of choice, though chest CT protocols have been developed to provide wider evaluation of the other mediastinal structures and thorax. We evaluated patients who presented with pain following upper endoscopy and received either fluoroscopic evaluation of the esophagus or chest CT to assess for the diagnosis of esophageal perforation within 48 hours of imaging.

**METHODS AND MATERIALS**

The TriNetX Diamond network was used for this study. TriNetX provides access to anonymized medical record information on more than 213 million patients in 92 large healthcare organizations. Two cohorts were created using the International Classification of Disease-10 (ICD-10) codes. All patients were required to have undergone endoscopy of the esophagus (CPT 74245) 48 hours prior to developing nausea and vomiting (R11) or pain in the chest and throat (R07). One cohort received fluoroscopic evaluation of the esophagus and stomach (CPT 74220 or 74240 or 74245) and patients were excluded if they had received a chest CT (CPT 71250 or 71260). The other cohort received a chest CT (CPT 71250/71260) and patients were excluded if they had received any fluoroscopic evaluation. The cohorts were balanced for age, race, gender, and ethnicity, resulting in 2562patients in each arm. They were then evaluated for the diagnosis of esophageal perforation (K22.3) within 48 hours of imaging.

**RESULTS**

The diagnosis of esophageal perforation was significantly more common in the Chest CT cohort, with a risk ratio of 1.449 (95% CI (1.011, 2.077) p-value 0.0421) and risk difference of 0.859% (95% CI (0.031%, 1.687%) p-value 0.0421).

**CONCLUSION**

Patients who received a chest CT for the workup of chest and throat pain, nausea, and vomiting within 48 hours of having received an upper endoscopy had statistically significant increased incidences of esophageal perforation discovered compared to patients who received fluoroscopic evaluation without chest CT. We hope to further discussion among specialists to determine whether a chest CT may provide benefit in the diagnosis of esophageal perforation.

**CLINICAL RELEVANCE/APPLICATION**

The utility of chest CT and specific Esophagraphy protocols for the diagnosis of esophageal perforation is growing and will hopefully be more widespread and accepted across the nation. Currently there is no specific CPT code for CT Esophagraphy, which would add research benefit.

## T2-SPGI-9 PREDICTION OF MICROVASCULAR INVASION OF HEPATOCELLULAR CARCINOMA USING RADIOMICS OF MULTI-PARAMETRIC MRI FEATURES INCLUDING INTRATUMOR AND PERITUMORAL REGIONS

Kumi Ozaki, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate if the multi parametric gadoxetic acid-enhanced MRI-based radiomics machine learning predicts the microvascular invasion (MVI) of hepatocellular carcinoma (HCC).

**METHODS AND MATERIALS**

Patients with pathologically proven 113 HCC from April 2010 to December 2022 were retrospectively included. Radiomics features were extracted from intratumor and peritumoral regions on preoperative gadoxetic acid-enhanced MRI including T2- weighted, diffusion weighted, arterial phase, and hepatobiliary phase images. Data sets were randomly split (7:3) into training and validation cohort. Univariate analysis and least absolute shrinkage and selection operator (LASSO) was performed to select the optimal radiomics features for analysis. Random forest was used for model prediction.The performance was evaluated by area under the receiver operating characteristic curve (AUC) and was compared among radiomics algorithm. The stability of each model was verified by 5-fold cross-validation.

**RESULTS**

The radiomics signatures based on the random forest algorithm achieved the optimal predictive performance. Radiomics of intratumor with peritumoral regions improved the AUC, and AUCs reached 0.854, 0.879, 0.775, and 0.764 for intratumor and peritumoral, intratumor, and peritumoral regions respectively.

**CONCLUSION**

Radiomics using multi-parametric MRI features including intratumor and peritumoral regions can improve the prediction of MVI of HCC.

**CLINICAL RELEVANCE/APPLICATION**

Radiomics using multi-parametric MRI features including intratumor and peritumoral regions can predict MVI of HCC. Information of peritumoral region can improve the predeciton of MVI of HCC.

### PURPOSE

To assess the incidence of biopsy-confirmed recurrences and adverse events in native prostate cancer patients treated with MRI-guided trans-perineal focal cryoablation.

### METHODS AND MATERIALS

In this prospective study, approved by the Institutional Review Board (IRB), 84 patients diagnosed with primary prostate cancer underwent 1.5T MRI-guided trans-perineal cryoablation from December 2020 to April 2024. The procedure on average involved the use of four cryoneedles with typically three freeze/thaw cycles. A urethral warmer was used to protect the urethra. T2-weighted MRI sequences (~20 sec) were used to monitor iceball expansion and target coverage. Post-ablation follow-up consisted of serum PSA every three months, prostate multi-parametric MRI every 6 months, and a follow-up biopsy at 1-2 years post-ablation. Addtionally, the impact on patients' urinary symptoms and sexual health was measured using the American Urological Association Symptom Score (AUASS) and the Expanded Prostate Cancer Index Composite (EPIC) with assessments at 6 and 12 months post-ablation.

### RESULTS

Trans-perineal MRI-guided cryoablation was performed on 84 male patients, mean age of 68 years (52-83), mean Body Mass Index of 29.2 (21-44) with biopsy proven primary prostate cancer. Target lesion size was 1.3 cm (0.2-5.3). 33 of 84 patients have not sought their one-year post-ablation imaging or biopsy. At 1 year follow-up, 51 of 84 patients had a significant reduction in post-ablation PSA compared to pre-ablation PSA levels at 3 months (60.71% ± 33.68; $p<0.0001$), 6 months (59.13% ± 27.02; $p<0.0001$), and 12 months (57.90% ± 26.90; $p<0.0001$). AUASS suggested that symptoms of stream strength, urgency, incomplete emptying, and hesitancy remained in the mild category in all follow-ups. (mild is considered as 1-7). One-year follow-up biopsies demonstrated 6 of 51 (12%) patients with cancer on post-ablation biopsy with five of six demonstrating in-field recurrence in the ablation zone (10%) and one of six demonstrating a out-of-field new cancer (2%) in another region of the prostate. For erectile function, 12 of 84 patients (14%) had worsening erectile dysfunction treated with Viagra/Cialis. One patient also complained of perineal pain at 6 months post-procedure and was prescribed steroids and antibiotics with resolution of the pain.

### CONCLUSION

MRI-guided trans-perineal focal cryoablation is an effective treatment combining the treatment efficacy of cryoablation with the superior soft tissue resolution and ablation monitoring capability of MRI.

### CLINICAL RELEVANCE/APPLICATION

Prostate cancer is the #1 occurrence of cancer in men and #3 cancer cause of death. Developing less morbid and more accurate methods of treatment for prostate cancer is essential.

## T2-SPGU-2 EFFECT OF DEEP LEARNING-BASED PRE-OPERATIVE AUXILIARY PLANNING SYSTEM ON KIDNEY RESECTION: A RANDOMIZED CONTROLLED NON-INFERIORITY TRIAL

Fule Wu (*Abstract Co-Author*) Employee, Infervision
Shaokang Wang (*Abstract Co-Author*) Nothing to Disclose
Ji Qi (*Abstract Co-Author*) Nothing to Disclose
Bing Zhong (*Abstract Co-Author*) Nothing to Disclose
Chen Xia (*Abstract Co-Author*) Nothing to Disclose
Gongcheng Wang (*Abstract Co-Author*) Nothing to Disclose
Dawei Wang, PhD (*Presenter*) Employee, Infervision

### PURPOSE

To evaluate whether the performance of a deep learning (DL)-based pre-operative auxiliary planning system is non-inferior to that of the conventional semi-automated systems in aiding surgery planning.

### METHODS AND MATERIALS

A total of 40 patients who underwent nephrectomy were retrospectively enrolled. Preoperative CT scans (thickness =2mm), surgery videos, and records were collected. An experienced chief surgeon established gold standards for important targeted vessel variations with collected peri-operative information. Two associate chief surgeons and 2 attending surgeons participated in the pre-operative planning simulation reader study and were randomly divided into two groups, with one assisted with conventional semi-automated system while the other aided by DL-based auxiliary planning system (InferOperate Urology Planning, Infervision). Anatomical structure identification accuracy was set as the primary endpoint, with the residual volume ratio consistency, surgery methods selection accuracy, planning time consumption, and software user satisfaction as the secondary endpoints.

### RESULTS

For the primary endpoints, higher identification accuracy for surgery related renal arteries, renal artery anatomical variations, and targeted blocking renal arteries reached 66.25%, 67.50%, and 80.00% in experimental group. The identification accuracy differences were 0.45 (95%CI: 0.24, 0.61), 0.06 (95%CI: -0.14, 0.26), and 0.09 (95%CI: -0.10, 0.27), respectively, whose lower bound of 95% CI were all above non-inferiority margin d of -0.15. Besides, the surgical method selection accuracy was also non-inferior as evidenced by a 0.06 (95%CI: -0.07, 0.2) accuracy difference. Residual volume ratios estimation between two groups was super consistent as evidenced by ICC of 0.925. Average time consumption of 3’40’’ was much shorter than that of control group (30’40’’), lower bound of 95%CI was lower than superior margin of 0. Software user satisfaction rate of 97.5% was higher than that in control group (76.25%).

### CONCLUSION

Validated DL system exhibited non-inferior performance in aiding surgeons in identifying surgery-related renal arteries and selecting surgery methods to the conventional semi-automated system. Additionally, the DL-empowered system is much more efficient and user-friendly.

### CLINICAL RELEVANCE/APPLICATION

Semi-automated three-dimensional reconstruction and auxiliary planning tools have been utilized in clinical settings. Efficiency and convenience constrained its applicability. DL-based pre-operative auxiliary planning system realized the automatic 3D reconstruction of urological structures and surgery simulation, making accurate surgery planning for each patient possible.

## T2-SPGU-3 EARLY GLEASON 3+4 PROSTATE CANCER DEMONSTRATES HETEROGENEITY OF HYPERPOLARISED MRI IN-VIVO MEASURED GLUCOSE METABOLISM

Clement Orczyk, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Richard L. Hesketh (*Abstract Co-Author*) Nothing to Disclose

Adam Retter, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
David Atkinson (*Abstract Co-Author*) Nothing to Disclose
Rafat Chowdhury (*Presenter*) Nothing to Disclose

### PURPOSE

Hyperpolarised 13C-MR (HP-MR) allows real time metabolic imaging in-vivo. Here we investigate the glucose metabolic characteristics of prostate cancer (PCa) in patients undergoing active surveillance.

### METHODS AND MATERIALS

A cohort of 28 men (mean age 67, range 58-74) with biopsy confirmed Gleason 3+4 disease on active surveillance using multi-parametric MRI (mpMRI) and visible lesions were recruited (using mpMRI). All men underwent HP-MR using an injection of [1-13C] pyruvate and imaging at 3T (as previously described). Metabolic maps visualising pyruvate to lactate conversion (kP) within the prostate were produced. Higher kP values indicate higher glucose metabolism and Warburg effect. Tumour and healthy tissue ROIs were drawn on the kP maps (using mpMRI and biopsy results as guidance) and compared using a paired t-test. Tumour metabolic activity (reflected by kP) was correlated against PSA, lesion diameter and radiologist Likert scores. The distribution of kP values across all Gleason 3+4 cancers was histographically assessed.

### RESULTS

kP was significantly higher (0.0183±0.010 vs 0.00245±0.0041, $p<0.05$) in cancer compared with non-cancer regions. The mean PSA across patients was 5.49 ng/ml (range 3-19ng/ml). The mean lesion diameter was 11mm (range 5-17 mm). The mpMRI Likert lesion scores for biopsy confirmed cancer sites were: 3/5=10, 4/5=15 and 5/5=3. There was no correlation between metabolism kP (at the cancer site) and PSA ($p=0.05$). No correlation was found between kP and lesion diameter ($p=0.02$). There was a trend towards increasing kP with lesion Likert score (mean kP±SD for 3, 4 and 5/5 scored cancer was 0.0171±0.0081 s-1, 4/5 = 0.0222±0.011 s-1, 5/5 = 0.0248±0.0107 s-1). A skewed distribution of kP was found across cancers of the same Gleason grade (with a 6-fold difference in metabolism between the least and most metabolically active).

### CONCLUSION

There was marked heterogeneity in tumour metabolism across our relatively uniform active surveillance cohort. Cancer metabolism did not reflect differences in lesion size or patient PSA. Correlations with ADC and DCE metrics will be determined and may explain the relationship with Likert score.

### CLINICAL RELEVANCE/APPLICATION

Presently, there is no reliable method for prognostication in early PCa. Quantifying metabolism in early stage PCa using in-vivo HP-MR offers the opportunity to explore glucose metabolism as a prognostic indicator in men on active surveillance.

## T2-SPGU-5 EFFECT OF RECTAL SIZE ON PROSTATE MRI PI-RADS AND CNN DIAGNOSTIC ASSESSMENT QUALITY

Markus Hohenfellner, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Heinz-Peter W. Schlemmer, MD (*Abstract Co-Author*) Speaker, Siemens AG;Speaker, Bayer AG
David Bonekamp, MD (*Abstract Co-Author*) Speaker, Bayer AG

Thomas Hielscher (*Abstract Co-Author*) Nothing to Disclose
Kevin S. Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Nils Netzer (*Abstract Co-Author*) Nothing to Disclose
Regula Gnirs (*Abstract Co-Author*) Nothing to Disclose
Magdalena Goertz (*Abstract Co-Author*) Nothing to Disclose
Carolin Eith (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate stratify diagnostic performance of clinical PI-RADS (clinPIRADS) assessment and fully automatic convolutional neural network (CNN)- based PI-RADS prediction (cnnPIRADS) by rectal volume determined using fully automatic CNN segmentation.

**METHODS AND MATERIALS**

Rectum segmentations were performed on T2-weighted images of 285 prostate MRI examinations, followed by two-stage CNN training for rectal segmentation to obtain a fully automated rectal volume segmentation model which was applied to the entire cohort. In addition, manual axial measurements of the rectum were performed. The volume of the rectal segment posterior (VolumeR) to the prostate was calculatedfrom the 3D-segmentation and the planimetric maximum ellipsiod area of the rectum determined from the manual measurements (AreaA). A previously established semantic lesion segmentation CNN based on nnUnet was applied to bi-parametric MRI images. The two rectum size parameters were used to investigate the effects of rectal volume on clinPIRADS and cnnPIRADS. ROC AUC was compared using the DeLong test. ROC regression was used to assess how rectum volume affects diagnostic performance.

**RESULTS**

VolR and AreaR were highly correlated (R=0.87; p<0.001). ROC-AUC of clinPIRADS and cnnPIRADS were nearly identical at 0.78 (p=1). ROC AUC of clinPIRADS was 0.87 (p<0.04 vs. the other 2 values)/0.73/0.75 for small/medium/large retum volume, while it was 0.88 (p<0.02)/0.73/0.73 for cnnPIRADS. ROC regression yielded regression coefficient of -0.27 (p=0.18) for clinPIRADS and -0.48 (p=0.04) for cnnPIRADS.

**CONCLUSION**

Medium and large rectal volume is associated with reduced diagnostic performance of prostate MRI compared to small rectal volume, with clinical and CNN-based PI-RADS assessment being affected similarly.

**CLINICAL RELEVANCE/APPLICATION**

Large rectum volume should be noted on prostate MRI examinations as a factor limiting assessment quality, and measures to reduce rectal filling during exam preparation discussed in this context.

## T2-SPGU-6 EVALUATING THE DIAGNOSTIC ACCURACY AND INTER-READER AGREEMENT OF THE TARGET SCORING SYSTEM FOR POST-FOCAL THERAPY RECURRENT PROSTATE CANCER DETECTION ON MULTIPARAMETRIC MRI

Bradford J. Baris Turkbey, MD (*Abstract Co-Author*) Nothing to Disclose
Stephanie A. Harmon, PhD (*Abstract Co-Author*) Nothing to Disclose
Omer Esengur, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the effectiveness of the Transatlantic Recommendations for Prostate Gland Evaluation with MRI after Focal Therapy (TARGET) scoring system in detecting clinically significant prostate cancer (csPCa) recurrence on multiparametric MRI (mpMRI) following various focal therapies (FT).

**METHODS AND MATERIALS**

A retrospective study was performed on a cohort of 38 patients (median age=69, median PSA=6 ng/mL) treated with primary FTs, including focal laser ablation (FLA) (n=28), high-intensity focused ultrasound (HIFU) (n=6), and cryoablation (n=4) for csPCa between 2013 and 2023. Post-treatment mpMRI scans were scored retrospectively using the TARGET system by two expert genitourinary radiologists. The effectiveness of the TARGET scoring system in predicting in-field recurrence of csPCa was evaluated by applying a TARGET score threshold of 4. Statistical analysis included sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy, and inter-reader agreement using quadratic weighted Cohen's kappa (?).

**RESULTS**

In total, 37% (14/38) of the patients had in-field recurrent csPCa. The scoring distribution of radiologist 1 was 37% (14/38) for TARGET-1, 3% (1/38) for TARGET-2, 18% (7/38) for TARGET-3, 0% for TARGET-4, and 42% (16/38) for TARGET-5, while for radiologist 2, 29% (11/38) for TARGET-1, 0% for TARGET-2, 5% (2/38) for TARGET-3, 8% (3/38) for TARGET-4, and 58% (22/38) for TARGET-5. Radiologist 1 scored 11 of the recurrent cases as TARGET=4 (sensitivity: 78.6%) while radiologist 2 scored all of them as TARGET=4 (sensitivity: 100%). Out of the 22 cases that radiologist 1 scored as negative for recurrence (TARGET<4), 19 of them were negative diagnoses (NPV: 86.4%), while all 13 cases that were scored as negative by radiologist 2 were negative diagnoses (NPV: 100%). For radiologist 1, specificity was found 79.2%, PPV 68.8%, and accuracy 78.9%. For radiologist 2, these were 54.2%, 56%, and 71.1%, respectively. Inter-reader agreement was moderate (? = 0.57).

**CONCLUSION**

The TARGET scoring system may be used to effectively identify recurrent csPCa following FT, demonstrating a particularly high ability to detect recurrences and to confirm absence of csPCa. Despite this, the moderate agreement between the two radiologists suggests the need for its validation with larger studies.

### CLINICAL RELEVANCE/APPLICATION

The TARGET scoring system has the potential to identify recurrent csPCa, enhancing post-FT patient monitoring and care optimization.

## T2-SPGU-8 ERECTILE DYSFUNCTION EVALUATION USING SMI AND SWE US TECHNIQUES

Ji-Bin Liu, MD (*Abstract Co-Author*) Research Grant, General Electric Company
Paul H. Chung, MD (*Abstract Co-Author*) Nothing to Disclose
Aaron Hochberg (*Abstract Co-Author*) Nothing to Disclose
Flemming Forsberg, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation;Research support, Canon Medical Systems Corporation;Research support, General Electric Company;Speaker, General Electric Company;Research support, Siemens AG;Research Grant, Butterfly Network, Inc;Research support, Lantheus Medical Imaging, Inc;Research support, Bracco Group
Priscilla Machado, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Erectile dysfunction (ED) is a highly prevalent condition that affects approximately 30 million men in the United States. While penile duplex ultrasound (DUS) has long been considered standard of care, recent advances in ultrasound (US) technology warrant investigation. Superb microvascular imaging (SMI) is a new microvascular flow imaging mode, which uses adaptative clutter suppression to extract flow signals from large and small vessels represented as a color overlay image or as a grayscale map of flow, named cSMI and mSMI, respectively. Shear wave elastography (SWE) is a technique to measure tissue stiffness. This study investigated the use of SMI and SWE to evaluate ED in subjects undergoing penile US pre and post injection of vasoactive agent.

### METHODS AND MATERIALS

To date 20 adult male subjects (=18 years old) with clinical ED defined by International Index of Erectile Function (IIEF) scores were enrolled in this ongoing, IRB-approved study. Subjects underwent spectral Doppler, CDI, PDI, cSMI, mSMI and SWE examination of the penis before and after intracavernosal injection of vasoactive agent using Aplio i800 Prism US system (Canon America Medical Systems, Tustin, CA) with an i18LX5 linear probe. Data was analyzed comparing pre (flaccid penis) and post injection (erect penis) for all images modalities using t-tests.

### RESULTS

The mean age of subjects was 51 years (range: 31 -70). The mean IIEF score was 10 (range: 3-19; lower values indicate more severe ED). The mean spectral Doppler PSV ± SD were 23.64 ± 10.98 cm/s pre injection and 40.47 ± 17.94 cm/s post injection ($p < 0.0001$), mean RI ± SD were 0.90 ± 0.07 pre injection and 0.88 ± 0.08 post injection ($p = 0.28$). The mean cSMI pixel counts ± SD were 99.64 ± 6.64 pre injection and 101.10 ± 6.14 post injection ($p = 0.69$). The mean mSMI pixel counts ± SD were 124.10 ± 3.72 pre injection and 124.0 ± 3.67 post injection ($p = 0.89$). The mean SWE ± SD were 38.44 ± 20.14 kPa pre injection and 39.63 ± 22.58 kPa post injection ($p = 0.82$).

### CONCLUSION

The values of SMI pixel counts showed no significant statistical difference between pre and post injections for cSMI or mSMI ($p > 0.65$). The evaluation of tissue stiffness using SWE also showed no significant statistical difference pre and post injections ($p = 0.20$) The results are encouraging with the findings indicating that the use of SMI and SWE without injection of vasoactive agent (flaccid penis) may be a way to diagnose ED.

### CLINICAL RELEVANCE/APPLICATION

Understandably, the sensitive nature of ED, intimate process of penile US and the need to inject medication into the penis to induce erection makes for a less than ideal patient experience. SMI and SWE may be able to identify characteristics consistent with ED in flaccid penis facilitating clinical practice and improving patient experience.

## T2-SPGU-9 EVALUATION OF CONSISTENCY BETWEEN PRIMARY CHYLURIA CTL GRADING AND CLINICAL GRADING

Qi Hao (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the application value of CT lymphangiography in grading in patients with primary chyluria.

### METHODS AND MATERIALS

Clinical and CTL imaging data of 79 patients diagnosed with primary chyluria were collected retrospectively. For CTL, the indexs were?Involved kidney and distribution of abnormal lymphatic vessels in the kidney:unilateral or bilateral kidney,renal sinus ,renal parenchymal,suprahilar area and subhilar area; ? Distribution of perirenal and retroperitoneal abnormal lymphatic vessels: retroperitoneal area,lumbar trunk area, renal perivascular area, fatty capsule area, adrenal area, etc; ?Imaging grading: the imaging grading was carried out according to the range of retroperitoneal involvement, and the retroperitoneal area was divided into 10 areas,including left and right suprahilar area, subhilar area, perirenal area, perivascular area and lumbar trunk area,involvement of five or fewer areas were defined as mild, and involvement of six or more were defined as severe. In addition, clinical classification was performed according to the clinical symptoms of patients with primary chyluria: mild symptoms showed intermittent milky discharge or milky white urine without any other clinical symptoms; Severe symptoms are characterized by intermittent or persistent discharge of milky or milky urine, with chylous clots and/or hematuria, with or without urinary retention and weight loss.The CTL signs of patients with primary chyluria were statistically described by the composition ratio of classification variables, and the consistency of imaging grade and clinical grade of patients with primary chyluria was evaluated by Kappa test.

### RESULTS

Among the 79 patients with primary chyluria, according to clinical classification, 27 cases were mild and 52 cases were severe; according to imaging classification, 40 cases were mild and 39 cases were severe. Among them, 5 cases with severe CTL image grading had mild clinical grading, and 18 cases with mild CTL image grading had severe clinical grading.The consistency of the two grades was moderate ($Kappa=0.420$, $P < 0.05$).

### CONCLUSION

CTL can accurately evaluate the distribution and range of intrarenal and retroperitoneal dilated lymphatic vessels in patients with primary chyluria, providing imaging basis for the classification of primary chyluria.

### CLINICAL RELEVANCE/APPLICATION

CTL is helpful for the classification of primary chyluria and has guiding significance for the formulation of surgical plan of primary chyluria.

Milad Ahmadian, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Human papillomavirus (HPV) is a critical biomarker in oropharyngeal squamous cell carcinoma (OPSCC). As an emerging field, radio(geno)mics offers a significant potential for non-invasively predicting the HPV status using imaging morphological information. This study aimed to externally validate the predictive performance of an MRI-based radiogenomic model for determining HPV status in OPSCC and to evaluate the impact of post-processing on the model's generalisability.

### METHODS AND MATERIALS

Post-contrast and contrast-enhanced T1-weighted MR images with histologically confirmed HPV status in OPSCC patients from two different centre cohorts were manually segmented. After radiomic feature extraction, the predictive model, trained on an internal training set (60%, n=91), was subsequently validated on both an internal validation set (40%, n=62) and an external cohort (n=157). We examined post-processing options, including data harmonisation, dropping radiomic features unstable across different segmentation and scan protocols, and removing highly correlated features to assess their impact on the model's generalisability.

### RESULTS

The predictive model, trained without post-processing, showed high performance on the internal test set, with an AUC of 0.79 (95% CI: 0.66-0.90, $p<0.001$). However, when tested on the external validation set, the model failed to generalise, resulting in an AUC of 0.55 (95% CI: 0.48-0.61, $p=0.095$). The model's generalisability substantially improved after harmonising data, identifying the stable radiomic features, and removing the correlated variables. The AUC for the internal validation reached 0.76 (95% CI: 0.63-0.87, $p<0.001$), while for the external cohort, the predictive model achieved an AUC of 0.76 (95% CI: 0.68-0.84, $p<0.001$).

### CONCLUSION

We validated a radiogenomic HPV prediction algorithm on an external patient cohort. When applied before model development, post-processing steps significantly enhanced the generalisability of the predictive radiomic models.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrates that post-processing techniques in radiogenomi models enhance the non-invasive prediction of HPV status in oropharyngeal cancer, aiding in more tailored treatment approaches.

## T2-SPHN-2 DEEP LEARNING FOR INCIDENTAL SCREENING OF PAROTID TUMORS ON CT IMAGING

Chanon Chantaduly (*Abstract Co-Author*) Nothing to Disclose
Cynthia Crystal Tang (*Abstract Co-Author*) Nothing to Disclose
Eleanor Chu, MD (*Abstract Co-Author*) Nothing to Disclose
Shirin Salehi (*Abstract Co-Author*) Nothing to Disclose

Peter Chang, MD (*Presenter*) Co-founder, Avicenna.ai;Stockholder, Avicenna.ai;Research Grant, Canon Medical Systems Corporation;Speakers Bureau, Canon Medical Systems Corporation;Research Grant, General Electric Company

### PURPOSE

Parotid gland tumors (PGT) are the most common salivary gland tumors. With increasing imaging utilization, most PGTs are detected incidentally on cross-sectional CT or MR imaging. Of these incidental PGTs, approximately 8% exhibit malignant pathology. Despite this, PGTs are often overlooked in routine exams as radiologists tend to prioritize evaluation of acute pathology. This study proposes a deep learning (DL) method to enhance incidental PGT screening and characterization on routine head CT.

### METHODS AND MATERIALS

A retrospective cohort of 11,449 consecutive non-contrast head CT exams were aggregated from two academic centers. PGTs, defined in this study as a parotid mass >10 mm, were identified from radiology and/or histopathology reports and subsequently visually confirmed. All masses were annotated with a 3D tumor mask by one of two CAQ-certified neuroradiologists. A two-stage DL pipeline was developed for PGT detection. In the first stage, the bounds of each parotid gland is identified. In the second stage, PGTs are detected with a segmentation model implemented as a 3D fully convolutional U-Net based architecture with deep supervision. Based on segmentation outputs, global thresholds for number of positive voxel predictions were calibrated to determine optimal screening sensitivity and specificity. Both voxel-level segmentation and population-level screening characteristics were assessed using a five-fold cross-validation technique.

### RESULTS

A total of 225 parotid masses were identified from a combined 11,449 exams from two academic centers (N=118 hospital A, N=107 hospital B). The median tumor volume was 4.62 cm3 (IQR 2.40-12.50 cm3). Parotid mass segmentation yielded a Dice score of 0.743 (IQR 0.567-0.819). For the screening task, 186/225 parotid tumors were identified yielding a sensitivity of 0.83. Of the algorithm positive predictions, six tumors were missed by the original interpreting physician. Out of 11,449 exams, only 52 false positives were identified yielding a PPV of 0.78. Overall, the model yielded screening AUC, accuracy, sensitivity, specificity, PPV, NPV of 0.92, 0.99, 0.83, 0.99, 0.78, and 0.99. No significant differences in performance were noted between different academic centers or imaging protocols (p>0.05).

### CONCLUSION

In a consecutive cohort of over 11k CT exams, the proposed algorithm identifies over 80% of PGTs including six tumors missed during routine interpretation. For positive cases, segmentation of identified tumors allows for volume quantification and facilitates downstream machine learning workflows.

### CLINICAL RELEVANCE/APPLICATION

A deep learning algorithm can identify incidental PGTs on routine CT imaging with high accuracy including tumors missed in a realistic clinical workflow.

## T2-SPHN-3 DETECTION OF OROPHARYNX CARCINOMA IN CT IMAGES WITH ARTIFICIAL INTELLIGENCE TECHNIQUES

Inmaculada Gonzalez Almendros (*Abstract Co-Author*) Nothing to Disclose
Javier Ignacio Perez Lara (*Abstract Co-Author*) Nothing to Disclose
Gretsy R. Quintana Sanchez, MMed (*Abstract Co-Author*) Nothing to Disclose

Carmen Morales (*Abstract Co-Author*) Nothing to Disclose
Sofia Bretos Azcona, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Oropharyngeal cancer accounts for 15-20% of squamous cell carcinomas of the head and neck. Its incidence has increased in the last 20 years, and is linked to infection by papillomavirus. Sometimes it can be complex to detect small lesions located at the base of the tongue or in the tonsil, and they may not be adequately differentiated from normal healthy tissue.The objective of this study is to assess whether the use of artificial intelligence (AI) techniques based on radiomics is useful for distinguishing between squamous cell tumors of the oropharynx and healthy tonsillar tissue.

### METHODS AND MATERIALS

Forty patients with oropharyngeal cancer (squamous cell carcinoma with available histology; oncologic group) and 40 patients with no abnormalities in the oropharynx (healthy controls) are selected. All patients have undergone a pre-treatment CT study in the oncology group.A segmentation of the entire tumor is performed in the oncological group, and of a palatine tonsil in the control group, using the 3D Slicer software. Subsequently, first-order statistics are extracted with the same software. Multiple Machine Learning algorithms are generated with the extracted radiomics data, including logistic regression, K Means, Random Forest and Support Vector Machine.

### RESULTS

Mean age exceeded 60 years in both groups. The proportion of men was higher in the cancer group. Alcohol and tobacco use increased the risk of cancer, with a combined effect resulting in a 39-fold increase in risk. Forty-two percent of cancer patients had the p16 mutation. The most common stage was T2, and the most frequent tumor location was the tonsil.The weighted voting system demonstrated 'Support vector machine,' 'Random forest,' and 'Ada Boost' as the best predictors, with 'Ada Boost' standing out for its accuracy rate of 86% and high sensitivity of 90%. Most predictors exhibited similar results, enhancing the robustness of the data obtained.

### CONCLUSION

Radiomics data analysis enables detection of oropharyngeal carcinoma with an accuracy of 86% and a sensitivity of 90% thus AI techniques may be useful in differentiating between healthy and tumor tissue in the oropharynx.

### CLINICAL RELEVANCE/APPLICATION

These findings suggest potential applications as a screening method for oropharyngeal carcinomas or for determining suspicious enhancements and could serve as a foundation for automated detection of oropharyngeal tumor lesions, which are often challenging to detect using CT alone. Expanding this study with larger databases could enhance precision, sensitivity, and specificity, thus improving the model.

## T2-SPHN-4 ARTIFICIAL INTELLIGENCE-BASED MODEL TO ASSIST NECK LYMPH NODES ULTRASOUND DIAGNOSIS: A DUAL-CENTER, RETROSPECTIVE, DIAGNOSTIC STUDY

Chunyan Li (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a dual-modality multi-feature fusion lymph node network (DMFLNN) for neck lymph nodes (LNs) assessment, and explore its utility to radiologists with varying experience levels.

**METHODS AND MATERIALS**

In this retrospective, dual-center, diagnostic study, we collected 21,298 B-mode and color Doppler flowing imaging (CDFI) images of 10,649 neck LNs (2,675 benign and 7,974 malignant) in hospital 1 for model development. We also collected 2,366 images of 1,183 neck LNs (297 benign and 886 malignant) in Hospital 1 and 776 images of 388 neck LNs (124 benign and 264 malignant) in Hospital 2 for internal and external validation, respectively. We compared DMFLNN's diagnostic performance with junior radiologists (2-5 years' experience) and senior radiologists (10-20 years' experience) and investigated whether DMFLNN could enhance their diagnostic accuracy in test sets. All neck LNs were pathologically confirmed by biopsy.

**RESULTS**

DMFLNN outperformed radiologists average, achieving an AUC of 0.937 (95%CI, 0.921-0.951) vs 0.796 (0.785-0.806) in the internal set and 0.875 (0.836-0.912) vs 0.752 (0.732-0.771) in the external set, all $P < 0.001$. Subgroup analysis in the internal set also showed DMFLNN' superior performance in smaller neck LNs (AUC, 0.885 [0.824-0.941]) compared with radiologists average (AUC, 0.726 [0.698-0.757], $P < 0.001$). Moreover, with DMFLNN's assistance in diagnosing neck LNs, the AUC of senior radiologists was improved from 0.814 (0.798-0.830) to 0.836 (0.821-0.851), and of junior radiologists from 0.778 (0.761-0.794) to 0.847 (0.832-0.861), all $P < 0.001$. Similar trends were observed in the external set. The average false-positive rate of radiologists decreased by 3.8% and 9.8% in internal and external sets, respectively. Additionally, DMFLNN enhanced inter-reader agreement of senior radiologists (kappa value: from 0.590 to 0.696 in the internal set; from 0.589 to 0.714 in the external set) and junior radiologists (from 0.571 to 0.750 in the internal set; from 0.453 to 0.713 in the internal set).

**CONCLUSION**

DMFLNN demonstrated superior diagnostic accuracy for neck LNs compared with radiologists and could help improve the performance of radiologists, potentially reducing unnecessary biopsies of neck LNs.

**CLINICAL RELEVANCE/APPLICATION**

The status of neck LNs is crucial for the subsequent decision-making management and nodal stage. Ultrasound, the most accessible method, relies on the radiologists' experience, leading to inconsistent diagnosis. Our proposed model DMFLNN, developed on B-mode and CDFI images spanning over ten years from diverse ultrasound machines, ensures robustness and generalizability for accurate diagnoses.

Rou-Yi Chen, MSc (*Abstract Co-Author*) Nothing to Disclose
Hsin-Han Tsai (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study was to develop a machine learning model utilizing radiomics features from MRI imaging to predict local recurrence following definitive concurrent chemoradiotherapy (CCRT) in patients with hypopharyngeal cancer.

**METHODS AND MATERIALS**

In this retrospective analysis, MRI and clinical outcome data from 334 patients treated for hypopharyngeal cancer were assessed. Patients were categorized based on the occurrence of local recurrence post-CCRT. The dataset was partitioned into a training set (n=268) and an internal testing set (n=66). From T2-weighted MRI scans, 1,781 radiomics features were extracted. Feature selection processes, including adjustments for skewness, reproducibility assessments, and screening for high Pearson correlation, were implemented to optimize model performance. A Light Gradient Boosting Machine (LightGBM) based model, employing nested 5-fold cross-validation, was devised to evaluate the likelihood of local recurrence.

**RESULTS**

.The machine learning model, dubbed ML_radiomics, selected 208 pertinent features and exhibited robust predictive capability. It achieved a corrected C-index of 0.802 and 0.778 in the training and internal testing cohorts, respectively. Using an ML_radiomics cut-off value of 0.181, the model predicted local recurrence with accuracies of 79.3% and 72.1% in the training and internal testing set. Patients classified into the low-risk category demonstrated significantly enhanced outcomes in terms of progression-free, laryngectomy-free, and overall survival in all analyzed groups. SHAP analysis highlighted five key features—ZoneEntropy, MaximumProbability, Kurtosis, MinorAxisLength, and Skewness—as critical in influencing the predictive accuracy of ML_radiomics.

**CONCLUSION**

The ML_radiomics prove to be effective predictors of local recurrence in hypopharyngeal cancer patients post-CCRT. This model offers a valuable tool for clinicians to identify patients at higher risk, potentially guiding more aggressive or alternative treatment strategies.

**CLINICAL RELEVANCE/APPLICATION**

Our ML_radiomics enhances the ability to predict local recurrence in hypopharyngeal cancer following definitive concurrent chemoradiotherapy, allowing for personalized treatment plans. By identifying high-risk patients early, clinicians can tailor interventions more effectively, potentially improving survival outcomes and optimizing healthcare resources.

## T2-SPHN-6 DUAL-ENERGY CT-BASED RADIOMICS NOMOGRAM FOR DISTINGUISHING PAROTID WARTHIN TUMOR FROM PLEOMORPHIC ADENOMA

Yilin Han (*Abstract Co-Author*) Nothing to Disclose
Jianying Li, PhD (*Abstract Co-Author*) Employee, General Electric Company
Lijun Wang (*Abstract Co-Author*) Nothing to Disclose
Zhiwei Gong (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the diagnostic performance of a radiomics nomogram based on Dual-energy CT (DECT) in differentiating the most common benign parotid gland tumors of pleomorphic adenomas (PA) from Warthin tumors (WT).

## METHODS AND MATERIALS

Imaging and clinical information on 43 patients with PAs and 30 patients with WTs of the parotid gland, which were pathologically confirmed, were retrospectively analyzed. In the enhanced images and material-decomposition (MD) images (iodine(water)),tumor CT enhancement degree, iodine concentration (IC), normalized IC (NIC), lymph node enlargement, cystic degeneration, and other radiological features were measured. Tumor radiomics features were extracted using u-AI software by outlining the tumor region of interest (ROI) layer by layer to obtain volume of interest (VOI). Clinical-radiological models were constructed by screening independent clinical and radiological predictors with analysis of variance and multifactorial logistic regression analysis. K-Best and LASSO were used to filter radiomics features. Support vector machine (SVM), random forest, and XGBOOST models were constructed from the selected radiomics features, and their diagnostic efficiency evaluated. The optimal radiomics model was combined with the clinical-radiologic model to create a joint model. The combined model was finally plotted on a nomogram, and its utility was assessed using calibration curves and decision curve analysis (DCA).

## RESULTS

Cystic degeneration and NIC(AP) were independent predictors, with AUC of the overall ROC of 0.837, sensitivity of 70%, and specificity of 73.9%. The radiomics model with the most consistent diagnostic efficacy was the SVM from arterial iodine (water) images, with a AUC of 0.778, sensitivity of 63.3%, and specificity of 74.2%. Ultimately, the joint model AUC amounted to 0.926, sensitivity was 66.7%, and specificity was 88.9%. The DCA showed that its nomogram had a high net clinical benefit over a wide range of thresholds.

## CONCLUSION

Clinical-radiological model based on MD images in DECT has good performance in identifying PA and WT, and its combination with radiomics further improves the diagnostic efficiency.

## CLINICAL RELEVANCE/APPLICATION

PAs is relatively aggressive compare to WTs and has a malignant tendency and a chance of recurrence after resection. WTs cause peripheral inflammation and are usually treated conservatively. The prognoses and treatment methods are also different for PAs and WTs. Therefore, it is very important to accurately diagnose PA and WT prior to operation. The aim of this study is to construct a combined model of MD technology and radiomics with spectral CT to help differentiate PAs and WTs in clinical diagnosis.

## T2-SPIN-1 REPEATABILITY OF AI-BASED CORONARY ARTERY CALCIUM SCORING (CACS) IN NON-GATED ROUTINE CHEST CT: PRECISION ANALYSIS AND RISK STRATIFICATION

Changmin Park (*Abstract Co-Author*) Nothing to Disclose
Jong H. Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoonseong Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Sihwan Kim, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

To check the repeatability of AI-based computer aided diagnosis (CAD) for coronary artery calcification (CAC) scoring and cardiovascular (CV) risk stratification in chest CT scan.

### METHODS AND MATERIALS

For a repeatability check, the public-access dataset (RIDER Lung CT, The Cancer Imaging Archive) was used. It consists of data from two CT scans on the same day for the same patient. A total number of CT scanned patients were thirty-two, but after excluding patients with metal artifacts or stents, data (46 CT scans) from 23 patients was used. The CT data was scanned with a tube-voltage of 120 kV and reconstructed with slice thickness of 1.25 mm. In this study, AI-based automatic CAC scoring software (ClariCardio, Seoul, Rep. of Korea) was used. As the one qualitive approach for checking a quality of AI-CAD performance, especially for CAC segmentation, seven-years experienced radiologist evaluated the similarity of the segmentation masks resulted from the prior and subsequent CT scan using 5-point Likert scale. To check for performance variability of AI-CAD on CAC scoring, Bland-Altman (BA) analysis and interclass correlation coefficient (ICC) were performed. The analysis targets in the BA analysis were the agatston scores at left-main (LM) coronary artery, left-anterior descending (LAD) artery, left-circumflex (LCX), right-coronary artery (RCA), and total coronary arteries (Total). The Cohen's kappa was used to evaluate the agreement of CV risk stratification between the pair-wised chest CT data. The severity of CV risk was stratified into four stages based on a total agatston score (TAS); normal for TAS = 0, mild for 0 < TAS = 99, moderate for 100 = TAS < 300, and severe for TAS = 300.

### RESULTS

For the 5-point Likert scoring on CAC segmentation, the score was turned out to be about 4.4 out of 5. The ICC value between the total agatston score of the prior and the subsequent CT data was 0.99 [95%CI, 0.978-0.996] and it was statistically significant ($p < 0.001$). The mean difference of agatston score derived from the BA analysis were 7.95, -44.04, 8.58, 2.54, and 24.79 for LM, LAD, RCA, LCX and Total, respectively. The Cohen's kappa for the CV risk stratification was 0.73 [95%CI, 0.50-0.97, $p<0.001$]. Both qualitative and quantitative results represented good reliability of AI-CAD for diagnosis assist.

### CONCLUSION

The AI-CAD for CAC scoring and CV risk stratification is found to be reliable for repetitively acquired CT scan data. We expect that it could be further applicated to a monitoring of CAC progression in low-dose chest screening CT for reliable quantification.

### CLINICAL RELEVANCE/APPLICATION

Fully automated AI-CAD to both CAC scoring and cardiovascular risk stratification would improve the prediction of future CV events in patients with suspected coronary artery disease.

## T2-SPIN-2 STATE OF NATIONAL INSTITUTES OF HEALTH GRANT FUNDING OF AI IN RADIOLOGY

Kirti Magudia, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
David F. Kallmes, MD (*Abstract Co-Author*) Research support, Terumo Corporation;Research support, Medtronic plc;Consultant, Medtronic plc;Research support, General Electric Company;Consultant, General Electric Company;Stockholder, Superior Medical Solutions, Inc;Stockholder, Marblehead Medical, LLC;Research support, NeuroSigma, Inc;Research support, Neurogami Medical, Inc;Research support, Insera Therapeutics, LLC

**PURPOSE**

This study aims to delineate the current state of National Institutes of Health (NIH) funding for artificial intelligence (AI) applications in radiology, highlighting trends by funding institute, grant mechanism, investigator demographics, and ranking of funded institutions.

**METHODS AND MATERIALS**

Data on active NIH-funded AI projects in radiology were collected from the NIH-RePORTER database using a combination of MeSH and free-text terms with boolean logic. Descriptive statistics were derived for grant types, administering institutes/centers, and principal investigator (PI) details. Correlations between PI gender, number of PIs involved, and previous grant experience were analyzed. Text mining techniques were employed to identify prevalent terms and topics in project titles and descriptions.

**RESULTS**

A total of 1,064 active AI grants in radiology, amounting to $697 million in funding, were identified. The National Institute on Aging (NIA) provided the most funding (17.6%), followed by the NIMH, NCI, NHLBI, NINDS, and NIBIB. R01 grants accounted for the largest share of funds at 40.2%. While no correlation was found between PI gender and funding amount, however the majority of PIs (68.8%) were males. Machine learning, magnetic resonance imaging (MRI), and clinical applications emerged as the most prevalent topics. Massachusetts General Hospital, University of Pennsylvania, and Stanford University secured the highest funding. The top funded states were Massachusetts, Pennsylvania, and California. The most awarded departments were radiation-diagnostic/oncology, followed by engineering, internal medicine/medicine, psychiatry, psychology, and neurology.

**CONCLUSION**

The study provides a comprehensive snapshot overview of the current landscape of NIH funding for AI research in radiology. The findings offer insights into funding patterns across institutes, mechanisms, investigators, and research topics, and key areas of focus of the awarding institutions and contributing scientists in the field.

**CLINICAL RELEVANCE/APPLICATION**

Understanding the characteristics, focus areas, and trends in AI research grants in radiology is crucial for investigators seeking funding opportunities and policymakers aiming to support impactful research. The insights gained from this study can help guide resource allocation, collaboration, and strategic decision-making to advance AI innovation in radiology.

## T2-SPIN-3 IMPROVED SEGMENTATION OF LUNG TUMORS WITH VARIED SIZES AND ATTACHMENTS USING DUAL-WINDOW FULL-SCALE SEGMENTATION NETWORK

Helen Hong, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoonseon OH (*Abstract Co-Author*) Nothing to Disclose
Min Jin Lee, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to achieve consistent segmentation of lung tumors in chest CT images, regardless of variations in size and location, including isolated tumors or those attached to chest wall, mediastinal, or vascular structures. We propose a Dual-Window Full-Scale Segmentation Network(DWFS-Net) that integrates feature map fusion obtained from dual-window images considering both lung and mediastinal windows, and incorporates full-scale concatenation paths.

**METHODS AND MATERIALS**

We evaluated 152 tumors from the NSCLC-Radiomics public dataset provided by the Cancer Imaging Archive, comprising 39 lung adenocarcinomas and 113 lung squamous cell carcinomas. To address the varied locations of lung tumors, we generated dual-window images using the lung window setting for better visualization of isolated tumors and the mediastinal window setting for tumors attached to surrounding structures. Each dual-window image underwent processing by separate encoders, and feature map fusion was achieved by concatenating the output feature maps from each layer. To effectively handle the diverse sizes of lung tumors, we employed the UNet3+ backbone with full-scale concatenation paths and deep supervision. We compared both single-lung and single-mediastinal window methods with a single encoder. Additionally, we analyzed segmentation results based on tumor size and attachment, as well as overall lung tumor segmentation.

**RESULTS**

Our DWFS-Net demonstrated the highest performance with a DSC of 79.44% in overall tumors segmentation. Compared to the single lung window method, our DWFS-Net showed slightly lower recall but higher precision, effectively reducing the number of false positives. Segmentation results across all size groups demonstrated a consistent trend with those for the overall tumors. In the heavily attached group, our DWFS-Net achieved a precision of 75.39%, indicating an improvement of 3.86% compared to the single-lung window method and 3.59% compared to the single-mediastinal window method. This result demonstrated effective mitigation of over-segmentation caused by leakage into adjacent attached structures.

**CONCLUSION**

Our DWFS-Net significantly reduced false positives (FP) in adjacent structures by utilizing dual window images that include both lung and mediastinal windows. It also achieved consistent segmentation results across tumors of various sizes by leveraging full-scale concatenation paths. This research was supported by the National Research Foundation of Korea(NRF) grant funded by the Korea government(MSIT)(No. RS-2023-00207947)

**CLINICAL RELEVANCE/APPLICATION**

Our study can assist in accurately measuring tumor volume and size, which are essential for assessing treatment response and monitoring disease progression.

## T2-SPIN-4 RACOON: ESTABLISHING A SUSTAINABLE NATIONWIDE RADIOLOGICAL INFRASTRUCTURE FOR COLLABORATIVE IMAGING RESEARCH

Andreas Bucher, MD (*Presenter*) Travel support, Bayer AG Travel support, Guebert SA Travel support, Pharmacept

**PURPOSE**

To provide a sustainable nationwide infrastructure as an end-to-end solution for a broad scope of radiological research projects, with a focus on AI training and imaging biomarker development.

**METHODS AND MATERIALS**

Initially launched in response to the pandemic emergency, RACOON (RAdiological COOperative Network) has built a unique network infrastructure connecting all of the country's university hospitals. Its capabilities have since been expanded to address a wide range of research topics, and it has evolved into a long-term infrastructure solution for the management, annotation and aggregation of imaging data of the country. This development has been carried out in strict compliance with privacy regulations and legal requirements. The infrastructure includes its own cloud solution, which enhances data accessibility and security. In addition, RACOON supports federated learning capabilities, facilitating AI training across distributed environments without compromising privacy.

**RESULTS**

Within the RACOON infrastructure, more than 17,300 thoracoabdominal CT datasets - enriched with more than 2.2 million complementary clinical parameters - have been annotated using standardized radiologist reports (containing more than 7.5 million report items) and manual annotations. This has resulted in the creation of the largest collaborative dataset of its kind. Applications now include neuroradiology MRI and CT datasets, musculoskeletal analysis of CT scans, and pediatric X-ray and CT studies. Recent use cases include a prospective gynecologic MRI cohort for adenomyosis characterization and advanced image analysis for pediatric non-Hodgkin's lymphoma, pulmonary embolism, and pancreatic adenocarcinoma, which also facilitate training and evaluation of specific AI applications. To date, the infrastructure supports more than 76 image-based research applications and has expanded its collaborative scope to include a variety of other clinical disciplines.

**CONCLUSION**

RACOON has successfully implemented a transformative and unique network that significantly reduces the organizational overhead associated with federated and centralized AI training and a broad range multicentric studies. It provides robust and scalable infrastructure, ensuring high-quality data acquisition and fostering advanced image analysis research and AI development across diverse medical fields.

**CLINICAL RELEVANCE/APPLICATION**

This initiative can provide pandemic preparedness but also sets a precedent for future collaborative research endeavors, making it a pivotal element in Germany's healthcare research infrastructure.

## T2-SPIN-5 COMPARATIVE ANALYSIS OF LUNG TUMOR SEGMENTATION WITH CNN-BASED APPROACHES USING DUAL-WINDOW IMAGES IN VARIOUS FUSION METHODS

Helen Hong, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoonseon OH (*Abstract Co-Author*) Nothing to Disclose
Min Jin Lee, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to improve the segmentation performance of lung tumors by overcoming the difficulties in segmentation caused by various tumor sizes and attachment degrees to surrounding structures. To achieve this, meaningful context extracted from dual-window images in chest CT scans is fused through various fusion methods to compare and analyze segmentation effects.

**METHODS AND MATERIALS**

We evaluated 152 tumors from NSCLC-Radiomics public dataset provided by the Cancer Imaging Archive, consisting of 39 lung adenocarcinomas and 113 lung squamous cell carcinomas. Utilizing the UNet3+ backbone with full-scale skip connections, deep supervision, and hybrid loss functions, we effectively addressed the size diversity of lung tumors and improved their segmentation performance. While the lung window image offers better visualization of isolated tumors, distinguishing lung tumors from surrounding structures with similar intensities is challenging. Conversely, the mediastinal window image offers optimal contrast, aiding in differentiation from adjacent structures, although tumors may appear smaller compared to the lung window image. To leverage the advantages of dual-window images, we employed various fusion methods, including early-fusion, intermediate-fusion, and late-fusion. Segmentation performance was evaluated for each fusion method, analyzing the results based on tumor size groups, degrees of attachment, and overall lung tumor segmentation.

**RESULTS**

Intermediate-fusion of dual-window images outperformed the other methods, achieving the highest DSC across all size groups and for heavily attached lung tumors, with 79.44% for the overall tumors and 77.57% for heavily attached lung tumors. This indicates that this method effectively incorporates the distinctive features of individual images. Conversely, early-fusion exhibited the lowest performance across all metrics, suggesting difficulty in effectively handling the characteristics of individual images. Late-fusion demonstrated performance similar to that of the single-window methods.

**CONCLUSION**

This study demonstrated that the intermediate-fusion method, utilizing dual-window images, outperformed other fusion methods across tumor size groups and degrees of attachment, while also effectively leveraging the benefits of dual-window images. (This research was supported by the National Research Foundation of Korea(NRF) grant funded by the Korea government(MSIT) (No. RS-2023-00207947))

### CLINICAL RELEVANCE/APPLICATION

Improving the accuracy of lung tumor segmentation is essential for accurately measuring tumor volume and size, which are necessary for assessing treatment response and monitoring disease progression.

## T2-SPIN-6 DEFINING CT-BASED NORMATIVE VALUES FOR BODY COMPOSITION INDICES IN AN INDIAN COHORT

Saugata Sen, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Karteek Popuri (*Abstract Co-Author*) Nothing to Disclose
Manali Mukherjee (*Abstract Co-Author*) Nothing to Disclose
Mirza Faisal Beg (*Abstract Co-Author*) Nothing to Disclose
Priya Ghosh, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Subhasis Goswami (*Abstract Co-Author*) Nothing to Disclose
Anurima Patra, MD, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

To determine sex-specific cut-off values for fat and skeletal muscle indices among healthy Indian adults at the L3 vertebral level using CT scans

### METHODS AND MATERIALS

This was a single-center study of patients who underwent Contrast CT abdomen or KUB between 2020-2023 for acute abdomen, renal calculi or blunt accidental trauma. Patients with any prior history of malignancy, or any neoplastic masses detected on the CT were excluded. Body composition analysis was performed using automated segmentation via Data Analysis Facilitation Suite by Voronoi Health Analytics, Inc. Skeletal muscle area (SMA), skeletal muscle index [SMI; SMA/height] and visceral-to-subcutaneous adipose tissue area ratio (VSR) were measured at 5mm axial CT sections at L3 vertebrae level using Hounsfield unit (HU) threshold of -30 to +150 HU for muscle, -150 to -50 HU for visceral adipose tissue and -190 to -30 HU for subcutaneous adipose tissue. Mean minus 2 standard deviation (SD) values were used to define sex-specific cut-offs for SMA, SMI and VSR. The values were compared with those in existing literature.

### RESULTS

There were 556 adults [270 males, 286 females) included in the study. The overall mean (range) age was 48.9 (18-96) yrs]. The mean +/- SD SMA ($cm^2$) and SMI ($cm^2/m^2$) for males and females was 103.3+25.4 and 75.9 + 14.2, and 39.1 + 9.1 and 33.3 + 5.8 respectively. Cutoff values for SMA ($cm^2$) for males and females were 52.5 and 47.5 respectively, and for SMI ($cm^2/m^2$) was 20.9 and 21.7 respectively. The VSR cut-offs for males and females were found to be 42.7 and 45.5 respectively (Tables 1 and 2).

### CONCLUSION

We used data from healthy Indian adults to establish sex-specific cutoffs for body composition indices. These values can aid in defining sarcopenia in the Indian population.

### CLINICAL RELEVANCE/APPLICATION

Body composition indices vary globally due to differences in body size, lifestyles and ethnicities. Applying a set of universally recommended threshold values derived from predominantly Western data to define sarcopenia in regional populations can lead to erroneous results. Currently, normative CT-based data specific to the Indian population are lacking. We found that our cut-offs were lower than the reference standards laid by the European Working Group on Sarcopenia. Large-scale prospective studies are required to validate whether our cut-offs are successful in predicting outcomes in Indian population.

## T2-SPIN-7 PUBLISHING OPEN ACCESS OR SUBSCRIPTION-BASED ACCESS? A COMPARATIVE ANALYSIS OF CITATIONS AND ALTMETRIC ATTENTION SCORES IN THE FIELD OF RADIOLOGY

Onur Simsek, MD (*Abstract Co-Author*) Nothing to Disclose
Arastoo Vossough, PhD, MD (*Abstract Co-Author*) Research Consultant, Syneos Health;Stockholder, DeepSight Technology, Inc
Dana Alkhulaifat, MD (*Abstract Co-Author*) Nothing to Disclose
Amirreza Manteghinejad, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Research teams seek to increase the impact of their work by sharing it with a wider audience, thereby enhancing its potential impact. To publish their works, researchers currently have two options: publishing as open-access (OA) or subscription-based access (SA). OA publishing is thought to have the potential to increase citation rates and attention in social media through greater accessibility. However, previous studies have produced inconsistent results and a systematic review regarding the citation counts has identified biases in many of these studies. This study aimed to focus on clinical radiology journals and use a matched methodology to compare citation counts and Altmetric attention scores between OA and SA articles in radiology journals.

### METHODS AND MATERIALS

This study is a cross-sectional study conducted on original and review articles published from 2000 to 2023 in clinical radiology journals indexed in Web of Science (WoS) and MEDLINE having a hybrid publishing model. Conference papers were excluded from this study. After obtaining the data, we performed a 1:1 matching of OA and SA papers by multiple article characteristics to minimize confounding and bias. These characteristics included the journal itself, type of study (original vs. review), publication date, number of authors, corresponding author country category based on gross national income per capita and number of references. Papers without a corresponding match were excluded. Matching of the number of authors and references was done with a tolerance of 2 and 10, respectively, to prevent excessive data loss. We also extracted citation counts and Altmetric attention scores using WoS and Altmetric Explorer platforms. We used the Mann-Whitney test to compare the citation counts and Altmetric attention scores.

### RESULTS

This study evaluated 274185 papers from 105 journals.183636 (67%) were SA papers and 90822 (33%) were open access. After article matching, 57586 were included in this study (28793 OA papers vs. 28793 SA papers). Comparing the citation counts showed a significant difference between the OA and SA papers (median=16 [IQR: 6-39] vs. 13 [IQR: 5-32], $p<0.001$). Comparing Altmetric attention scores also showed a significant difference between the OA and SA papers (median = 2 [IQR: 0-5] vs. 1 [IQR: 1-4], $p<0.001$).

### CONCLUSION

A feature-matched comparison analysis between OA and SA papers published in clinical radiology journals supports the idea of citation and attention advantage of OA radiology papers.

### CLINICAL RELEVANCE/APPLICATION

While there is no direct clinical application for this study, it is important that institutions, labs, and research teams know that publishing their projects as OA can lead to higher visibility and citations of their work, including in the same journal.

## T2-SPIN-8 TEXTURAL HETEROGENEITY OF LIVER LESIONS IN CT IMAGING - COMPARISON OF COLORECTAL AND PANCREATIC METASTASES

Stefan O. Schoenberg, MD, PhD (*Abstract Co-Author*) Research agreement, Siemens AG
Hishan Tharmaseelan (*Abstract Co-Author*) Nothing to Disclose
Florian Haag (*Abstract Co-Author*) Nothing to Disclose
Matthias F. Froelich, MD (*Abstract Co-Author*) Consultant, Smart Reporting GmbH;Consultant, Guerbet SA
Friedrich Pietsch (*Presenter*) Nothing to Disclose

### PURPOSE

Tumoral heterogeneity poses a challenge for personalized cancer treatments. Especially prevalent in metastasized cancer, it remains a major limitation for successful targeted therapy, often leading to drug resistance due to tumoral escape mechanisms. This work explores a non-invasive radiomics-based approach to capture textural heterogeneity in liver lesions and compare it between colorectal cancer (CRC) and pancreatic cancer (PNC).

### METHODS AND MATERIALS

In this retrospective single-center study, 1291 liver metastases of 42 colorectal cancer (430 metastases) and 31 pancreatic cancer (861 metastases) patients were segmented fully automated on contrast-enhanced CT images by a UNet for medical images. Radiomics features were extracted using the Python package Pyradiomics. To quantify the heterogeneity the mean absolute coefficient of variation (ACV) was calculated patient-wise for each feature. An unpaired t-test identified features with significant differences in feature variation between CRC and PNC metastases.

### RESULTS

In both colorectal and pancreatic liver metastases, interlesional heterogeneity can be observed. 75 second-order features were extracted to compare the varying textural characteristics. In total, 18 radiomics features showed a significant difference ($p<0.05$) in their expression between the two malignancies. Out of these, 16 features showed higher levels of variability in the cohort of pancreatic metastases. Visual analysis of a created radar plot suggests greater textural heterogeneity for this entity.

### CONCLUSION

Radiomics has the potential to identify the interlesional heterogeneity of CT texture among individual liver metastases originating from the same primary entity. The analysis of quantitative image data can detect differing textural expressions and a variation in the extent of heterogeneity levels in CRC and PNC liver metastases.

### CLINICAL RELEVANCE/APPLICATION

This study serves as a proof of concept for comparing the heterogeneity between liver metastases in CT imaging across two gastrointestinal tumor entities, while also illustrating the interlesional heterogeneity among individual liver metastases originating from the same primary entity. Quantifying and improving the comparability of tumoral heterogeneity holds great potential to foster the tailoring of diagnostics and subsequent therapy.

## T2-SPIR-1 USING MACHINE LEARNING TO DETECT ATHEROSCLEROTIC RENAL ARTERY STENOSIS FROM SPECTRAL DOPPLER WAVEFORMS - A PILOT STUDY

Shahriar Faghani, MD (*Abstract Co-Author*) Nothing to Disclose
Sanjay Misra, MD (*Abstract Co-Author*) Support, Cardinal Health, Inc
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*) Board of Directors, VoiceIt Technologies, LLC;Stockholder, VoiceIt Technologies, LLC;Board of Directors, FLOWSIGMA Inc;Officer, FLOWSIGMA Inc;Stockholder, FLOWSIGMA Inc;Officer, Yunu Inc;Stockholder, Yunu Inc
Seyed M. Rassoulinejad Mousavi, MD (*Abstract Co-Author*) Nothing to Disclose
Haseeb Mukhtar, MBBS, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate whether machine learning (ML) can be used to determine atherosclerotic renal artery stenosis (ARAS) from spectral doppler waveforms in renal duplex ultrasound (DUS).

### METHODS AND MATERIALS

Patients with unilateral ARAS (contralateral normal kidney) confirmed on renal angiogram and requiring renal artery stent placement were retrospectively identified from January 2000 to January 2022. Patients were excluded if they had a transplanted kidney, more than 1 renal artery on either side, a previously placed renal artery stent with in-stent restenosis, RAS due to nonatherosclerotic causes, or if pre-operative duplex scan images were unavailable. 200 patients were selected; the affected kidney was used as the positive cases, and the contralateral kidney as the control. The spectral waveforms were reconstructed by tracing the outer envelope manually using WebPlotDigitizer. The graphical coordinates obtained were then converted to one-dimensional velocity signals. Signals were labeled as ARAS and normal and then randomly divided into training (80%) and testing (20%) datasets. A one-dimensional convolutional neural network was trained to classify the signals and detect ARAS. The Adam optimizer with a learning rate of 0.001 and cross-entropy loss function were utilized. The model was trained for 500 epochs.

### RESULTS

396 signals from 198 patients were used (2 signals from each patient, 1 ARAS, and 1 control) after excluding 2 patients due to inadequate signal extraction (median age=72 years, females=51.0%). The overall accuracy of our trained model was 95%, with 94% specificity, and 94% precision. The area under the receiver operator characteristic curve was 0.97.

### CONCLUSION

Machine learning was successfully employed to detect ARAS using arterial spectral doppler waveforms in DUS.

### CLINICAL RELEVANCE/APPLICATION

This work demonstrates that artificial intelligence can be effectively used to detect ARAS using doppler waveforms. This could potentially open the door to automating the diagnosis and management of clinically significant ARAS. Future directions of this study include developing a model that can accurately determine the degree of stenosis and utilizing AI techniques to predict the risk of in-stent restenosis or progression to renal replacement therapy post renal artery stenting.

## T2-SPIR-3 AI-BASED IMAGE QUALITY ENHANCEMENT IN LOW DOSE C-ARM CT: A POTENTIAL SOLUTION FOR RADIATION REDUCTION IN TRANSARTERIAL CHEMOEMBOLIZATION (TACE)

Jong H. Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Yong-Su Bae, RT (*Abstract Co-Author*) Nothing to Disclose
Saebeom Hur, MD (*Abstract Co-Author*) Nothing to Disclose
Chul kyun Ahnn (*Abstract Co-Author*) Nothing to Disclose
AHYEONG LEE, BEng (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the potential of deep learning based denoising technique for radiation dose reduction and image quality (IQ) enhancement in C-arm based computed tomography angiography (CTA).

### METHODS AND MATERIALS

This study collected low-dose (LD) C-arm CBCT data from the Seoul National University Hospital, where each scan was conducted at a quarter level of the routine dose (RD) from 2020 to 2021. The data comprised of images from 139 patients undergoing transarterial chemoembolization (TACE) using Axiom Artis C-arm system (Siemens Healthcare, Forchheim, Germany). LD C-arm CBCT images were reconstructed via filtered back projection (FBP) and additionally denoised using commercial AI-denoising software (ClariCT.AI, ClariPi Inc., Seoul, Republic of Korea). Image quality superiority was evaluated between LD and denoised LD (DLD) images. The qualitative IQ evaluation was performed based on subjective noise, blood vessel visibility, and vessel smoothness using pairwise comparison method by three radiologists. Each qualitative evaluation categories were analyzed in Axial, maximum intensity projection (MIP), and volume rendering, respectively. The quantitative evaluation was performed based on image noise, signal-to-noise ratio (SNR) and the image sharpness. The sharpness was measured using edge rise distance (ERD) acquired by measuring 90 % and 10 % of maximum HU at the edge structure.

### RESULTS

The qualitative IQ score were 1.67 for the quantum noise, 0.47 for horizontal blood vessel visibility, and 0.36 for vessel smoothness. The visual assessment results exhibited significant superiority of AI-based DLD over LD approach. It demonstrated DLD showed significantly lower noise level than that of LD (Mean noise of DLD vs LD for liver parenchyma, erector muscles, and aorta: 36 vs 86 HU, 37 vs 174 HU, and 53 vs 117 HU, respectively). The SNR was increased by mean 2.4 times in DLD images compared to LD images. ERD in common hepatic artery was 1.18 ±0.11 mm for LD and 1.05 ±0.14 mm for DLD, indicating superior sharpness in DLD images compared to LD images.

### CONCLUSION

The utilization of DL-based denoising technique in low-dose C-arm CBCT significantly improves image quality. Implementing the DL-based denoising technique in C-arm CT has the potential to decrease patient radiation exposure during TACE procedures, a critical intervention for liver cancer treatment.

### CLINICAL RELEVANCE/APPLICATION

Application of DL-based denoising technique can be applied to C-arm based CBCT to reduce patient radiation dose for TACE which is widely used in liver cancer procedures.

## T2-SPIR-4 PRESCREENING RADIOLOGY REPORTS FOR PROSTATE CANCER RECURRENCES USING A LARGE LANGUAGE MODEL (LLM)

Bradley J. Erickson, MD, PhD (*Abstract Co-Author*) Board of Directors, VoiceIt Technologies, LLC;Stockholder, VoiceIt Technologies, LLC;Board of Directors, FLOWSIGMA Inc;Officer, FLOWSIGMA Inc;Stockholder, FLOWSIGMA Inc;Officer, Yunu Inc;Stockholder, Yunu Inc
David A. Woodrum, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shahriar Faghani, MD (*Abstract Co-Author*) Nothing to Disclose
Ali Ganjizadeh, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to evaluate the efficiency and accuracy of using the Mixtral 8x7b v0.1 Instruct LLM to prescreen radiology reports for prostate cancer recurrences post-MR-guided seminal vesicle cryoablation.

### METHODS AND MATERIALS

This retrospective study included 164 patients who underwent seminal vesicle cryoablation and were followed up with either PET or MRI scans every three months until 2 years. A total of 582 radiology reports were assessed using the Mixtral 8x7b v0.1 LLM, which was not fine-tuned but provided specific details about prostate cancer and radiological report analysis. The LLM analyzed the reports for recurrence indications at the ablation site without anatomical guidance. The performance of the model was evaluated by comparing its predictions with manual assessments of the radiology reports.

### RESULTS

The model identified 21 true positive and 498 true negative reports, alongside 63 false positive and no false negative results. The performance metrics were: PPV = 25.00%, NPV = 100.00%, sensitivity = 100.00%, and specificity = 88.77%. The use of a language model for the prescreening of radiology reports substantially enhances efficiency, processing 582 reports in approximately 4 hours.

### CONCLUSION

This study demonstrates the potential of using an LLM for prescreening radiology reports to facilitate the detection of prostate cancer recurrences. Despite a high rate of false positives, which were largely attributed to anatomical proximity errors in token embedding, the model effectively ensured that no recurrence was missed. This emphasizes its utility as a clinical tool for enhancing radiologist awareness. Further refinement of the model's performance is necessary to reduce false positives.

### CLINICAL RELEVANCE/APPLICATION

The application of LLMs in prescreening radiological reports for cancer recurrence offers a significant time-saving advantage and ensures high sensitivity in clinical settings. This technology can serve as a supplementary tool to assist radiologists in managing large volumes of data, focusing on high-priority cases, improving patient care, and improving the early detection and management of cancer recurrences. This leads to timely interventions and improved patient outcomes.

## T2-SPIR-6 RISK FACTORS PRECEDING UTERINE ARTERY EMBOLIZATION IN THE SETTING OF POSTPARTUM HEMORRHAGE

Arsalan Saleem, MD (*Abstract Co-Author*) Nothing to Disclose
Gautam Edhayan, MD (*Abstract Co-Author*) Nothing to Disclose
Rylie Ju, MD (*Abstract Co-Author*) Nothing to Disclose
Yash Ramgopal (*Abstract Co-Author*) Nothing to Disclose
Devin Reddy (*Presenter*) Nothing to Disclose

### PURPOSE

Uterine artery embolization (UAE) is a minimally invasive, uterine-sparing intervention that can help control postpartum hemorrhage (PPH) when more conservative management has failed. While the risk factors for PPH are well established, those leading to the use of embolization remain unclear. This study was designed to determine how maternal history, pregnancy characteristics, and peripartum events impact the utilization of UAE for PPH in the peripartum period.

### METHODS AND MATERIALS

This retrospective cohort study queried electronic health records from 78 healthcare organizations in the United States for patients with PPH from April 2014 to April 2024. Patients who did and did not undergo UAE were then analyzed for risk factors in the preceding year from their initial event.

### RESULTS

Among 158,741 patients identified with postpartum hemorrhage, 796 underwent UAE (mean age 32.1±6.4 years), and 157,945 did not undergo UAE (mean age 29.7±6.6 years). Patients with a history of uterine scar (attributable risk (AR) 57.20%, p<0.0001), uterine fibroids (AR 57.86%, p<0.0001), and endometriosis (AR 45.79%, p=0.01) had a significantly increased risk PPH treated with UAE. Pregnancy characteristic at significantly increased risk for PPH treated with UAE included advanced maternal age (AR 43.74%, p<0.0001), conception via assisted reproductive technology (AR 59.52%, p<0.0001), uterine over-distension (AR 29.17%, p=0.0001), placental abnormalities (AR 59.66, p<0.0001), and pre-eclampsia (AR 37.56%, p<0.0001). Peripartum events of cesarean delivery (AR 55.81%, p<0.0001), acute anemia (AR 76.62%, p<0.0001), disseminated intravascular coagulation (AR 93.21%, p<0.0001), thrombocytopenia (AR 57.39%, p<0.0001), and shock (AR 94.46%, p<0.0001) had a significantly increased risk of PPH treated with UAE. Other risk factors for PPH were not associated with a significant increase in the utilization of UAE.

### CONCLUSION

In this large retrospective cohort of patients with PPH, significant risk factors for treatment with UAE included a history of uterine scars and fibroids, and pregnancy characteristics of conception through assisted reproductive technology, and placental abnormalities. Identifying these critical risk factors can help preemptively identify patients at higher risk of needing UAE, potentially reducing maternal and neonatal morbidity and mortality.

### CLINICAL RELEVANCE/APPLICATION

Patients with PPH are at increased risk for maternal and neonatal harm. The risk factors identified in this study enable early identification of patients who may require UAE. The findings in this study can be used to improve multidisciplinary coordination of care and response times, ultimately reducing maternal and neonatal morbidity and mortality.

## T2-SPIR-7 NON-CONTRAST CT BASED AI-ENABLED EMERGENT LARGE VESSEL OCCLUSION SCREENING: IMPROVEMENT OF WORKFLOW THROUGH TIME REDUCTION FROM HOSPITAL DOOR TO REPERFUSION

Dohyun Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Soohwa Song, PhD (*Abstract Co-Author*) Nothing to Disclose
Dong Hoon Shin, MD (*Abstract Co-Author*) Nothing to Disclose
Aleum Lee, PhD, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to evaluate the time reduction from hospital door to endovascular treatment (EVT) when using a non-contrast CT (NCCT) basis artificial intelligence (AI) solution to classify and notify patients with emergent large vessel occlusion (ELVO). In real-clinical practice, the NCCT is mainly used to identify whether cerebral hemorrhage has occurred. However, if patients of suspected ELVO can be quickly screened and notified to clinicians in step of the NCCT test, it has the advantage of improving the prognosis by reducing the time required for treatment. Therefore, it was compared the time from the door of emergency room (ER) to reperfusion before and after to use of AI solution for evaluating clinical effectiveness aspects.

### METHODS AND MATERIALS

Patients over 19 years of age who visited a thrombectomy capable stroke center with acute stroke symptoms and underwent EVT were compared before and after application of AI solution basis triage and notification. For the Post-AI group, cases were collected prospectively after applying the AI solution [2022.05.01~2023.12.31], and cases with similar age, gender, and NIHSS with Post-AI group were retrospectively collected as the Pre-AI group [2020.05.01~2022.04.31]. The primary endpoint of study was the statistical difference of time from ER door to endovascular treatment between Pre-AI and Post-AI groups. Additionally, time from ER door to CT scan, CT scan to Stroke team treatment (STT), and STT to EVT were compared between groups as a secondary endpoint. Differences in time between groups were statistically compared using an unpaired t-test with Welch's correction.

### RESULTS

A total of 25 cases were enrolled as the Pre-AI group, and total 70 cases were selected after 1:3 propensity score matching with age, gender and NIHSS in retrospective ELVO cases. As a result of primary endpoint, time from ER door to EVT was significantly different between Pre-AI (174.7±75.0 min.) and Post-AI (147.7±31.6 min) [p=0.0155]. In detail results of time comparison, only time from CT scan to Stroke team treatment was significantly reduced in Post-AI group (20.2±7.9 min. vs. 35.4±41.3 min., p=0.0043).

### CONCLUSION

It has been confirmed that quickly screening ELVO patients and notifying clinicians by an AI solution at the very front of the clinical process can significantly reduce the time from ER admission to EVT, and it will influence to prognosis outcome. Therefore, it is highly recommended to use for effective workflow in clinical environment.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrated how AI improved the hyperacute endovascular treatment workflow, by showing the impact on reducing door-to-reperfusion time. It will be particularly valuable in remote regions where clinical experts may be limited.

## T2-SPIR-8 TRANSFORMATIVE APPROACH TO PREVENTING CATHETER-ASSOCIATED URINARY TRACT INFECTIONS WITH ZN/AGNP-COATED URINARY CATHETERS

Yubeen Park (*Abstract Co-Author*) Nothing to Disclose
Jung-Hoon Park, PhD (*Abstract Co-Author*) Nothing to Disclose
Dong-Sung Won, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Catheter-associated urinary tract infections (CAUTIs) are caused by prolonged catheterization, which lead to bacterial colonization and biofilm formation. Commercial catheters coated with silver nanoparticles (AgNP) inhibit bacterial growth, but their long-term efficacy is limited due to reduced silver ion release. Dual-coating strategies, targeting both antimicrobial and antiseptic actions, have emerged. This study aims to investigate the safety and efficacy of Zn/AgNP both in vitro and in vivo.

## METHODS AND MATERIALS

A commercially available silicone catheter (8 Fr, 20 cm) was coated with polydopamine, followed by silver nanoparticles (AgNP) and zinc (Zn) via RF sputtering, creating uncoated, AgNP-coated, and Zn/AgNP-coated catheter samples. Surface analysis included FESEM-EDS and FIB-EDS. Contact angle, tensile properties, ion release, and antimicrobial effects were assessed. In vivo, rabbits were divided into groups receiving each catheter type, followed by sacrifice after 4 weeks for analysis of urine, cystoscopy, and surface characteristics. HE, MT, and TUNEL analysis evaluated inflammation, epithelial layer, collagen deposition, and apoptosis.

## RESULTS

AgNP-coated and Zn/AgNP-coated catheters were successfully synthesized and showed rough and smooth surface characteristics, respectively, in FESEM images. The dual-layered strategy successfully attained a bactericidal effect while mitigating cytotoxicity through the sustained and controlled release of AgNPs and Zn ions. Catheter placement was successful without complications and all rabbits survived until the end of the study. Urethroscopic examination showed significant differences in sludge formation area among the groups ($p < 0.001$). Microscopic analysis showed significant differences in biofilm area between groups ($p < 0.001$). Moreover, histopathologic analysis showed significant differences in inflammatory cell infiltration, epithelial layer thickness, and TUNEL-positive deposition ($p < 0.001$).

## CONCLUSION

The dual-layer Zn/AgNP coating not only aims to improve the clinical management of urinary catheterizations by reducing CAUTIs, but also substantially decreases the risk of complications associated with prolonged catheter usage.

## CLINICAL RELEVANCE/APPLICATION

The introduction of Zn/AgNP-coated urinary catheters offers a transformative approach to CAUTIs by combining the antimicrobial properties of AgNPs and Zn ions with sustained release kinetics. This advanced strategy has the potential to manage patient care and minimize the incidence of healthcare-associated infections.

## T2-SPMK-2 COMPARATIVE ANALYSIS OF PATELLOFEMORAL AND TIBIOFEMORAL MOTION PATTERNS IN HEALTHY AND PATELLOFEMORAL PAIN SYNDROME KNEES: INSIGHTS FROM DYNAMIC CT-IMAGING

Gert van Gompel, PhD (*Abstract Co-Author*) Nothing to Disclose
Thierry Scheerlinck (*Abstract Co-Author*) Research Consultant, Mathys Ltd Bettlach;Research Grant, Mathys Ltd Bettlach;Speaker, Mathys Ltd Bettlach
Savanah Hereus (*Abstract Co-Author*) Nothing to Disclose

Erik Cattrysse, PhD,MSc (*Abstract Co-Author*) Nothing to Disclose
Nicolas Van Vlasselaer (*Abstract Co-Author*) Nothing to Disclose
Nico Buls, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the impact of patellofemoral pain syndrome (PFPS) on the dynamic weight-bearing kinematics of patellofemoral (PF) and tibiofemoral (TF) joints by conducting a comprehensive 3D analysis of intra-articular joint motion in both healthy individuals and PFPS patients via dynamic CT (4DCT) acquisition.

### METHODS AND MATERIALS

Five healthy and five PFPS patients were recruited to undergo dynamic four-dimensional CT imaging of a knee flexion-extension motion. Multiple subsequent 3D images of the knee joint in motion were acquired in cine mode at 80 kVp,140 mAs, 160 mm detector coverage and 0.28 s rotation time, resulting in a CTDIvol of 6.24 mGy. Total scanning time was 6.2 seconds. While scanning, a supine squat motion was performed utilizing an in-house built weight-bearing device. The acquired images were processed using a deep-learning-based semantic segmentation. Dynamic rigid registrations were applied to isolate and align the knee bones throughout the dynamic scan sequences. To quantify TF and PF kinematics, coordinates of key anatomical landmarks on the femur, tibia and patella were extracted and transformed into local reference frames for precise calculations of tibial adduction (TA) (knee varus angle), internal tibial rotation (ITR) and patellar spin (PS) (x-y-z cardan joint angles). In addition, the bisect-offset (BO) and lateral patellar tilt (LPT) (orthopedic parameters) were assessed. A Mann-Whitney U test ($p<0.05$) was used to compare the differences between the two groups.

### RESULTS

Statistically significant differences were found in the ITR and the PS between healthy subjects and PFPS patients (all $p = 0.032$). The BO demonstrated higher values in PFPS patients, while the LPT and TA demonstrated lower values compared to healthy subjects. However, these differences were not found to be significantly different ($p > 0.05$).

### CONCLUSION

Our findings, derived from dynamic CT scans acquired in weight-bearing conditions, suggest kinematic variations in knee motion between healthy individuals and those with PFPS. Moreover, our findings suggest a potential involvement of the screw-home mechanism of the knee in contributing to these observed differences.

### CLINICAL RELEVANCE/APPLICATION

4DCT enables acquisition of a series of high temporal-resolution 3D CT datasets of moving joints. This capability facilitates in-depth analysis of intra-articular joint kinematics, offering improved diagnostic precision and valuable insights into the dynamic behaviors of joints. These thorough analyses could potentially guide both diagnostic approaches and treatment decisions.

## T2-SPMK-3 DIFFERENCES IN ANATOMICAL FEATURES AND CONCOMITANT INJURIES BETWEEN TIBIAL SPINE AVULSION FRACTURES AND ANTERIOR CRUCIATE LIGAMENT TEARS IN THE PEDIATRIC POPULATION

Matthew P. Moy, MD (*Abstract Co-Author*) Nothing to Disclose
Tony T. Wong, MD (*Abstract Co-Author*) Nothing to Disclose
Sonali Lala, MD (*Abstract Co-Author*) Nothing to Disclose
Charles A. Popkin, MD (*Abstract Co-Author*) Travel support, Arthrex, Inc;Educational support, Arthrex, Inc;Educational support, Smith & Nephew plc;
Jin Yoon, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine if there are differences in femoral intercondylar notch width index (NWI) and tibial slope in pediatric patients with tibial spine avulsion fractures (TSF) compared to those with anterior cruciate ligament tears (ACLT) and controls.

### METHODS AND MATERIALS

We performed a retrospective study evaluating patients (age lt; 18) with TSF on MR between 1/1/2010 and 10/31/2023 (n = 30). Age- and gender-matched ACLT patients (n = 30) and control patients were identified (n = 30). Anatomic measurements including femoral intercondylar notch width index, medial tibial slope angle (MTS), and lateral tibial slope angle (LTS) were measured by 2 fellowship-trained musculoskeletal radiologists in consensus. Concomitant injuries, such as meniscal tears or osteochondral injuries, in TSF and ACLT patients were documented based on MR reports and analyzed using Fisher's exact test. Differences in the NWI, MTS, and LTS were assessed with one-way ANOVA and t-tests.

### RESULTS

A total of 90 patients were analyzed for the study (22 males:8 females in each of the 3 patient cohorts). The average ages of the cohorts were 12.5, 14.0, and 13.2 years old for TSF, ACLT, and control cohorts, respectively. In the TSF cohort, the Meyers and McKeever Classification distribution was as follows: Type I/II/III/IV (n = 9/9/8/4, respectively). The one-way ANOVA with post-hoc Turkey HSD test showed that the NWI was significantly higher in the TSF cohort than the control cohort (TSF 0.301 ± 0.039 vs control 0.292 ± 0.031, p = 0.01), and the NWI was significantly lower in the ACLT cohort than the control cohort (ACLT 0.271 ± 0.033 vs control 0.292 ± 0.031, p = 0.02). There was no significant difference in LTS, MTS or concomitant injuries in all three cohorts.

### CONCLUSION

In conclusion, we found that the NWI was the highest in the TSF cohort, followed by the control cohort and then the ACLT cohort. There were no significant relationships between the tibial slope angles or concomitant injuries in any of the 3 cohorts.

### CLINICAL RELEVANCE/APPLICATION

Therefore, the NWI may play a role in predisposing pediatric patients to TSF or ACLT. Our future work includes developing a machine learning algorithm to predict the risk of injury in pediatric patients.

## T2-SPMK-4 CLINICAL 4-MINUTE SIXFOLD ACCELERATED DEEP LEARNING SUPER-RESOLUTION MRI OF THE KNEE - ARTHROSCOPY-VALIDATED DIAGNOSTIC PERFORMANCE FOR INTERNAL DERANGEMENT

Ricardo Donners, MD (*Abstract Co-Author*) Nothing to Disclose

Hanns-Christian Breit, MD (*Abstract Co-Author*) Nothing to Disclose
Jan Vosshenrich, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic performance of a 4-minute clinical combined sixfold simultaneous multislice (SMS) and parallel imaging (PI) accelerated deep learning super-resolution (DLSR) knee MRI for diagnosing internal derangement.

### METHODS AND MATERIALS

Adults with painful knee conditions who underwent sixfold SMS-PI-accelerated 2D-TSE DLSR 3T knee MRI between October 2022 and July 2023 and had arthroscopic knee surgery within eight weeks of the MRI examination were retrospectively included. Seven fellowship-trained musculoskeletal radiologists independently evaluated the knee MRI studies for ligamentous, meniscal, tendinous, and cartilaginous injuries. Cartilage defects were divided into partial and full thickness defects, and assessed for each joint compartment individually. Statistical analyses included kappa-based interreader agreements and diagnostic performance testing (significance level p <.05).

### RESULTS

124 adults (mean age: 46±17 years; 79 men) who underwent arthroscopy within a median of 28 days (range: 4-56) were evaluated. Interreader agreement for detecting arthroscopy-verified structural abnormalities was good or very good (? > 0.71 [95% CI: 0.67, 0.74]). Diagnostic performance testing confirmed good to excellent AUC values for all abnormalities (> 0.81 [95% CI: 0.77, 0.86]). For the diagnosis of ACL tears (n=34), sensitivity was 100% (range among the seven readers: 82%-100%), specificity was 99% (94%-100%), and accuracy was 99% (94%-100%). For PCL tears (n=1), sensitivity, specificity, and accuracy were 100% (100%-100%). Medial meniscus tears (n=85) were diagnosed with a sensitivity, specificity, and accuracy of 95% (86%-98%), 92% (69%-97%), and 94% (87%-98%), respectively. Lateral meniscus tears (n=38) were diagnosed with a sensitivity, specificity, and accuracy of 76% (71%-84%), 97% (83%-98%), and 90% (83%-92%), respectively. The diagnosis and grading of cartilage defects (n=178) had a sensitivity of 85% (69%-84%), a specificity of 88% (86%-97%), and an accuracy of 88% (85%-91%).

### CONCLUSION

Clinical 4-minute 6-fold PI-SMS-accelerated DLSR MRI of the knee has excellent diagnostic performance for diagnosing ligamentous, meniscal, and cartilaginous abnormalities.

### CLINICAL RELEVANCE/APPLICATION

Deep learning-augmented ultra-fast MRI of peripheral joints adds value to musculoskeletal radiology practice by maximizing scan efficiency without sacrificing diagnostic accuray.

## T2-SPMK-6 JUVENILE OSTEOCHONDRITIS DISSECANS LESION STAGING USING SHORT ECHO TIME T2* MRI IMAGES

Jutta Ellermann, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Brent Burg, BA (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the interrater reliability of a novel Juvenile Osteochondritis Dissecans (JOCD) lesion staging system based on lesion healing1.

### METHODS AND MATERIALS

This retrospective IRB and HIPAA-compliant study included 52 MRIs collected for the diagnostic workup for JOCD lesions. Three board-certified MSK radiologists and two MSK fellows staged the studies based on a protocol including short-echo time (~4 ms) T2* MRI images into one of five stages

(entirely cartilaginous = I, rim mineralization = II, ossification = III, fully ossified + bridged = IV, or failed/loose body = II/IIIF)1. A simplified stability criterion was evaluated based on T2 FS images (fluid signal at interface + articular cartilage fissure = unstable). T1/PD nFS images were included to identify healed stage IV lesions. Interrater reliability was analyzed across five raters via Fliess' Kappa according to guidelines in "Radiology"2. The studies were classified into one of three clinical outcomes: conservative therapy, surgery, or both via electronic medical records. Of the 52 studies, 14 were excluded from outcome analysis due to incomplete records.

## RESULTS

Fliess' Kappa was 0.71 ($p < 0.01$), consistent with substantial interrater reliability for the staging system. Agreement for the stability classification was 0.571 ($p < 0.01$), moderate. Of the 38 studies with sufficient timeline information, 21 (43%) healed with conservative therapy, 12 (32%) failed conservative therapy requiring subsequent surgery, and five (13%) patients required immediate surgery.

## CONCLUSION

This staging system, based on JOCD pathogenesis as a disease of epiphyseal cartilage that requires mineralization and ossification to heal, generates improved interrater agreement compared to other systems3. Adding a clinically readily acquired T2* sequence allows for analysis of lesion composition across the stages of healing1. While lesion stability informs the clinical need for immediate surgery on unstable lesions, most are stable. Of these stable lesions, up to 50% eventually require surgical intervention4, emphasizing the need for a staging system that allows for earlier identification of stable lesions that require surgery. This reliable staging system could fill this need. Further research should explore the identification of stable lesions that would benefit from earlier surgery based on this system.

## CLINICAL RELEVANCE/APPLICATION

This study proposes a reliable staging system based on JOCD lesion healing that could inform treatment decisions before instability occurs.1. Ellermann et al. Radiology. 2017;282(3):798-806.2. Ros Eeles (*Abstract Co-Author*) Nothing to Disclose
Elena Cojocaru (*Abstract Co-Author*) Nothing to Disclose
Samuel J. Withey, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

Li-Fraumeni syndrome (LFS), caused by a pathogenic germline variant of the TP53 tumour suppressor gene, is an autosomal dominant condition that predisposes affected individuals to multiple cancers and at a young age. International guidelines recommend yearly screening to identify cancers: in addition to yearly breast MRI in female patients and full dermatological skin check, patients should undergo whole body imaging. Whole body MRI (wbMRI) can image from vertex to toes in a single examination without use of ionising radiation. We aimed to assess the utility of wbMRI in detecting malignancy in patients with LFS.

### METHODS AND MATERIALS

Patient with LFS were identified and invited to undergo annual wbMRI. MRI was performed at 1.5T from vertex to toes without contrast, requiring 6 to 7 imaging stations. The imaging comprised: axial T2-weighted imaging; axial T1-weighted DIXON imaging; axial diffusion-weighted imaging (free-breathing single-shot echo planar imaging; b values 50, 600, 900). Images were reviewed independently by two experienced oncological radiologists, with disagreement resolved by consensus. Suspicious lesions and incidental findings were discussed in a multidisciplinary meeting, with further investigation and management performed on a case-by-case basis as per best clinical practice.

### RESULTS

We report the baseline and 12-month follow-up screening imaging results for 54 individuals (14 male, 40 female) with LFS who underwent wbMRI between June 2022 and April 2024. At the time of abstract submission, 44 patients had undergone the second scan at 12 months. Following baseline wbMRI, 9 patients underwent biopsy/excision (16.7%), identifying 4 cancers (7.4%), stage 1-3. A further 9 patients required additional dedicated imaging (n=16.7%). Five patients developed cancer (3 invasive, 2 superficial) between baseline and 12-month wbMRIs. These were either outside of the initial wbMRI field-of-view (i.e. upper limb sarcoma, breast carcinoma), or had developed since the initial scan, including on targeted re-review of baseline imaging. Following the 12-month wbMRI, 6 patients underwent biopsy/excision (13.6%), identifying 5 cancers (11.4%), stage 0-4. Only 2 further patients underwent further dedicated imaging (4.5%). The cancer locations and stages are shown in the uploaded PDF Figure.

### CONCLUSION

WbMRI can identify early cancers in the high-risk setting of LFS screening, with cancers identified at baseline and on 12-month follow-up screening. The burden of additional investigations for incidental findings decreases with repeat imaging.

### CLINICAL RELEVANCE/APPLICATION

Whole body MRI can effectively screen for cancers in high-risk individuals.

## T2-SPNMMI-1 EFFECTS OF DATA-DRIVEN RESPIRATORY GATING ON VISUALIZATION AND QUANTIFICATION OF LIVER AND PANCREATIC TUMORS IN FDG PET-CT EXAMINATIONS

Naomi Morita (*Abstract Co-Author*) Nothing to Disclose
Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsuya Okada (*Abstract Co-Author*) Nothing to Disclose
Atsushi Nakamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akira Kida (*Abstract Co-Author*) Nothing to Disclose
Risa Momoi (*Abstract Co-Author*) Nothing to Disclose
Mitsuaki Tatsumi, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Data-driven respiratory gating (DDG) has recently been introduced to improve image quality in PET portion of PET-CT examinations. The latest DDG system (OncoFreeze AI, Siemens) requires no specific devices without additional examination time. The purpose of this study was to evaluate the effects of this new DDG system on visualization and quantification of liver and pancreatic tumors in FDG PET-CT examinations, comparing the results to those obtained using the standard free-breathing PET acquisition protocol.

### METHODS AND MATERIALS

This study included 85 upper abdominal tumor (67 liver and 18 pancreatic) lesions examined with FDG PET-CT. PET images were acquired with a Biograph mCT scanner and reconstructed using standard (STD) and DDG algorithms. Lesion blurring and conspicuity were each evaluated visually with a 3-point scale (1: poor to 3: excellent). Longest diameter (LD), SUVmax, and metabolic tumor volume (MTV, 40% of SUVmax threshold) of the lesions were used for quantitative analysis. Fifty-six texture features (TFs) were also evaluated, and entropy, homogeneity, low- and high- gray-level zone emphasis (LGZE, HGZE), and short- and long- run emphasis were included as recommended for their robustness by Orlhac, et al (JNM 2014). Visual scores and quantitative metrics were compared between STD and DDG images.

### RESULTS

Visual scores for lesion blurring and conspicuity in DDG were significantly higher than those in STD ($p < 0.0001$ for both). Increase in scores for blurring and conspicuity was observed in 29 (34%) and 20 (24%) of all 85 lesions, respectively. SUVmax and MTV in DDG were significantly higher and lower, respectively, than those in STD ($p < 0.0001$ for both). Increase in SUVmax and decrease in MTV were observed in 80 (94%) and 63 (74%) of all 85 lesions, respectively. Decrease in MTV with DDG was correlated with LD, SUVmax, or MTV in STD (Spearman ?= 0.42, 0.31, or 0.45, respectively, $p < 0.005$ for all), whereas increase in SUVmax with DDG solely correlated with SUVmax in STD (?= 0.34, $p < 0.005$). Thirty-five out of 56 TFs showed statistical differences between STD and DDG. Entropy, HGZE, and LGZE were included in the 35 TFs, and their changes indicated that lesions in DDG represented more homogeneous FDG uptake than those in STD.

### CONCLUSION

This study demonstrated that deviceless DDG improved visualization and quantification of liver and pancreatic tumors in FDG PET-CT without increasing examination time. PET images less affected by respiratory motion exhibited increase in SUVmax and decrease in MTV and may contribute significantly to the accurate evaluation of tumor lesion activity.

### CLINICAL RELEVANCE/APPLICATION

Deviceless DDG improved visualization and quantification of liver and pancreatic tumors in FDG PET-CT without increasing examination time.

## T2-SPNMMI-2 TOWARDS CLINICAL APPLICATION OF MR CELL SIZE IMAGING FOR CHARACTERIZATION OF THE TUMOR MICROENVIRONMENT

Cornelius Faber (*Abstract Co-Author*) Nothing to Disclose
Bastian Maus (*Abstract Co-Author*) Nothing to Disclose
Heiner N. Raum (*Abstract Co-Author*) Nothing to Disclose
Jochen Bauer (*Abstract Co-Author*) Nothing to Disclose
Moritz Wildgruber, MD, PhD (*Abstract Co-Author*) Consultant, Sirtex Medical Ltd;Consultant, iThera Medical GmbH;Consultant, Bayer AG
Enrica Wilken (*Abstract Co-Author*) Nothing to Disclose
Emily Hoffmann (*Presenter*) Nothing to Disclose

## PURPOSE

Given the growing significance of characterizing the tumor microenvironment (TME) in personalized therapeutic strategies, preclinical studies have identified mean cell size analysis of tumor tissue as a promising imaging biomarker. MR cell size imaging can capture cellular changes within the TME, including cell swelling or shrinkage as an early marker of tumor necrosis, as well as the infiltration of different immune cell populations, such as T-cells and macrophages. This study aims to demonstrate the applicability of MR cell size imaging in a clinical setting.

## METHODS AND MATERIALS

MR cell size imaging was performed using sine-shaped oscillating-gradient diffusion-weighted MRI (OGSE-DWI) implemented on a clinical 3 T Philips MR7700 system, followed by data analysis using the Imaging Microstructural Parameters Using Limited Spectrally Edited Diffusion (IMPULSED) model for cell size quantification. The accuracy of the clinical IMPULSED-derived cell size analysis was assessed by conducting in vitro measurements on 4T1 breast cancer cell pellets. The same pellets were scanned on the 3 T clinical MRI scanner, followed by measurements on a 9.4 T Bruker BioSpec small animal MRI system to compare result for mean cell sizes between settings. Additionally, tumor cell size was evaluated by optical microscopy.

## RESULTS

The OGSE-DWI sequence was successfully implemented on the 3 T clinical scanner, achieving high spatial resolution (875 μm) and sufficient signal-to-noise ratios of 160 ± 11 (for b = 0 ms/μm2). Using the IMPULSED model, cell size quantification of tumor cell pellets was possibe, allowing region-of-interest and pixel-wise quantification. Only minor differences were found between the clinical and preclinical MRI system: clinical measurements detected mean cell radii of 8.36 ± 0.06 μm in the cell pellets, compared to mean radii of 8.25 ± 0.08 μm from the previously established preclinical setup. Microscopic examination revealed mean cell radii of 8.62 ± 0.37 μm.

## CONCLUSION

The present study demonstrates that MR cell size imaging using OGSE-DWI is feasible in vitro for breast cancer cell pellets on a clinical MR scanner. This validation, including direct comparison with established preclinical MR cell size imaging and microscopic evaluation, will set the ground for subsequent first-in-human studies, ensuring robust and reliable translation of MR cell size imaging into clinical application.

## CLINICAL RELEVANCE/APPLICATION

The ability to assess changes in cell size using MR cell size imaging presents a potential early marker of treatment response to targeted cancer therapies. The clinical translation of MR cell size imaging may enable personalized treatment decisions based on specific changes within the TME, beyond mere lesion size and anatomy.

## T2-SPNPM-1 ADVANCING ACCESS OF VARYING EDUCATIONAL BACKGROUNDS TO RADIOLOGY: THE ROLE OF AI IN PATIENT EMPOWERMENT

Zaheer Badat (*Abstract Co-Author*) Nothing to Disclose
Ubaid Tanzim (*Abstract Co-Author*) Nothing to Disclose
Sabeeh Syed, MD, BSc (*Abstract Co-Author*) Nothing to Disclose
Salil Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Rawaha Husam Al-Deen (*Abstract Co-Author*) Nothing to Disclose
Mohammed Bilal Aziz (*Abstract Co-Author*) Nothing to Disclose
Mohammed Blaaza, BSC,MBBS (*Abstract Co-Author*) Nothing to Disclose
Mohamed Rashad Ramali, MBBS, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

This study investigates the potential for artificial intelligence (AI) to improve the understanding of radiology reports across a range of educational backgrounds. By doing so, we aim to address the comprehension gap patients face with clinical imaging results and promote patient empowerment in healthcare decision-making.

### METHODS AND MATERIALS

A survey with 64 participants assessed how well they understood 10 anonymised radiology reports. 5 reports were radiologist-authored, and 5 were AI-summarised using GPT-3.5-Turbo. Participants rated their understanding of each report using a Likert scale, where a higher score indicated greater understanding. Education levels of the participants were grouped into 6 strata, increasing from pre-university to radiologist.

### RESULTS

AI-summarised reports yielded a higher average understanding score (5.68/7) than radiologist-authored reports (3.47/7). Using paired t-tests by education level, pre-university participants showed the largest mean difference, with a 3.54 point increase in understanding for AI reports compared with radiologist-authored reports ($p<0.001$). Whereas, radiologists had a -2.35 decrease in understanding AI reports compared with radiologist-authored reports ($p<0.001$). Linear regression predicted a 0.73 point increase in understanding radiology-authored reports per increase in education level ($p<0.001$), but no significant increase in understanding AI reports with increased education ($p=0.35$).

### CONCLUSION

Overall, AI-summarised reports outperformed radiologist-authored reports in comprehension. The notable benefit to pre-university level participants, coupled with the linear regression predictions, suggest that AI could play a significant role in equalising understanding of healthcare for all patients. Nevertheless, radiologists' decreased understanding of AI reports underscores a potential limitation of these summaries at the specialist level.

### CLINICAL RELEVANCE/APPLICATION

The use of large language models in medical care is in its infancy. There are many safety concerns related to large scale use of LLMs, given inherent flaws related to hallucination and variability in response, particularly with direct patient intervention. Using LLMs/AI to improve healthcare equity, however, remains a significantly lower risk use case and one with great potential. This principle can be applied to aid patient autonomy across educational backgrounds and remove selective access to and understanding of one's own health

## T2-SPNPM-2 PREVALENCE OF HEALTH-RELATED SOCIAL NEEDS AND ASSOCIATION WITH IMAGING APPOINTMENT CANCELLATIONS AMONG PATIENTS WITH CANCER

Ali Rashidi, MD (*Abstract Co-Author*) Nothing to Disclose
Gelareh Sadigh, MD (*Abstract Co-Author*) Nothing to Disclose
Angellica Gordon, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Health-related social needs (HRSNs) such as transportation, housing instability, and financial hardship may result in delayed patients' diagnosis and care. We aimed to assess the prevalence of health-related social needs and its association with imaging appointment cancellations among patients diagnosed with cancer.

## METHODS AND MATERIALS

In this retrospective observational study, we included patients =18 years with a diagnosis of cancer who completed an oncology wellness form as part of their usual care evaluation at a single comprehensive cancer center between Jan 2022 and September 2023, and had at least one imaging exam scheduled at the same health system within 3 months after completion of the form. The form inquired patients about presence of HRSNs (financial, transportation, and housing), patients' desire to receive written information or speak to someone about their HRSN, and their quality of life measured by Patient Reported Outcomes Measurement Information System (PROMIS)-10. We further assessed whether patients had any missed imaging appointment in the next 3 months after completion of the form. Multivariable regression models were used to assess the association between HRSNs and quality of life and imaging cancellations.

## RESULTS

2,511 patients with 2,890 encounters for which a wellness form was completed were included (Mean age: 61.6±15.9; 50% were female; 57% were white; 20% Asian; 3% Black). A total of 21% were Hispanic. The majority (45%) had Medicare, 36% commercial insurance and 16% Medicaid. A total of 22.9% reported at least one HRSNs with the most common being financial hardship (18.8%), transpiration (9.2%) and housing (8.5%). Mean mental and physical health PROMIS t-scores were 47.4±9.1 and 45.0±10.2. Mean pain score was 3.0±2.9 (range 0-10). A total of 70% of patients cancelled or did not show up to at least one imaging encounter in the 3 months after completion of their form. 22.5% of patients with missed appointments reported HRSNs vs. 17.3% of those without missed appointments (P=0.002). Adjusting for demographics and neighborhood deprivation index, patients reporting at least one HRSNs were more likely to miss their imaging appointment (OR, 1.5; 95%CI, 1.2-1.9). With 1 unit increase in patients' pain score, they were more likely to miss imaging appointment (OR, 1.1; 95% CI, 1.0-1.1). Patients were less likely to miss their appointments with every 1 unit increase in PROMIS score (OR, 0.97; 95% CI, 0.96-0.98).

## CONCLUSION

Cancer patients with self-reported HRSN, higher pain score and lower quality of life tend to have higher missed imaging appointments.

## CLINICAL RELEVANCE/APPLICATION

Systems should be in place to screen for HRSNs and address them to help reduce imaging and healthcare non-adherence and improve patients' outcomes.

## T2-SPNR-11 BRAIN ATROPHY IN ALZHEIMER'S AND LATE NEUROPATHOLOGY

Abdur Raquib Ridwan, PhD (*Abstract Co-Author*) Nothing to Disclose
Julie A. Schneider, MD (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Arfanakis, PhD (*Abstract Co-Author*) Nothing to Disclose
David A. Bennett, MD (*Abstract Co-Author*) Nothing to Disclose
Khalid Saifullah, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

Alzheimer's disease neuropathologic change (AD-NC) and limbic-predominant age-related TDP-43 encephalopathy neuropathologic change (LATE-NC) are common in older adults and have been associated with brain atrophy, cognitive decline, and dementia. Since AD-NC and LATE-NC are often comorbid and due to the fact that LATE-NC can only be detected at autopsy, in this work, we combined deformation-based morphometry (DBM) on ex-vivo brain MRI and detailed neuropathological evaluation in a large number of community-based older adults to investigate the difference in brain atrophy patterns associated with AD-NC and LATE-NC.

### METHODS AND MATERIALS

Cerebral hemispheres from 912 older adults participating in four longitudinal, clinical-pathologic cohort studies of aging were included in this work: MAP, ROS, MARS, and AA Core of the Rush Alzheimer's Disease Research Center (Rush ADRC). All hemispheres were imaged ex-vivo on 3T clinical MRI scanners approximately 1-month postmortem while immersed in 4% formaldehyde solution. T2-weighted images of all hemispheres were non-linearly registered and logarithm of the Jacobian determinant (LogJ) of the deformation field was calculated in each voxel. Following ex-vivo MRI, the pathologies that were assessed were AD-NC, LATE-NC, Lewy bodies, gross infarcts, microscopic infarcts, arteriolosclerosis, atherosclerosis, and cerebral amyloid angiopathy. AD-NC-pos was defined as intermediate or high AD-NC according to the NIA-AA criteria, and LATE-NC-pos was defined as LATE-NC stages 2 or 3.Voxel-wise linear regression was used to test the association of the deformations observed in the smoothed log Jacobian maps with the four different groups, controlling for all other neuropathologies, demographics, postmortem intervals, and scanner. We used 5000 permutations, and statistical significance was set at $p<0.05$ after family wise error (FWE) correction.

### RESULTS

Both the AD-NC-pos LATE-NC-neg group as well as the AD-NC-neg LATE-NC-pos group were associated with lower tissue volume mainly in medial temporal lobe structures. The AD-NC-pos LATE-NC-pos group showed substantially lower volume in the temporal, frontal, and parietal lobes. Interestingly, the AD-NC-neg LATE-NC-pos group showed lower volume in the anterior portion of the hippocampus than the AD-NC-pos LATE-NC-neg group. These results are in agreement with previous research.

### CONCLUSION

The findings suggest that in the presence of LATE-NC, the volume of the hippocampus cannot serve as a marker of AD-NC.

### CLINICAL RELEVANCE/APPLICATION

Providing crucial insights for accurate diagnosis, targeted treatment development, and improved disease monitoring in neurodegenerative disorders.

## T2-SPNR-13 FUSION BRAIN NETWORK ANALYSIS RELATED TO CANCER PAIN IN LUNG CANCER PATIENTS

Jiahui Zheng (*Abstract Co-Author*) Nothing to Disclose
Daihong Liu (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study is to explore the interaction of structural and functional alterations related to cancer pain, based on the fusion brain networks.

### METHODS AND MATERIALS

A total of 59 lung cancer patients without pain (CP-), 62 lung cancer patients with pain (CP+), and 34 healthy controls (HC) were prospectively recruited for this study. Structural network (SN) and functional network (FN) were derived from diffusion spectrum imaging (DSI) examinations and the resting-state functional magnetic resonance imaging (rs-fMRI) data, respectively. And FBN was constructed by using self-attention mechanism algorithm. Next, connectivity strength was analyzed at both regional and modular levels by utilizing nature business system (NBS) analysis and network analysis, respectively. Finally, relationships between connectivity strength and scales scores were evaluated.

### RESULTS

The NBS analysis demonstrated that increased connectivity strengths were present both in CP+ and CP- patients, compared to HC. Two increased connectivity components were found in CP+, which primarily included in the default mode network (DMN). 36 increased connectivity components were found in CP-, which mainly included among the DMN, executive control network (ECN), salience network (SN), and limbic system. Notably, compared to CP-, 4 decreased connectivity components were found in CP+, which primarily included between DMN and the limbic system, and between ECN and SN. Network analysis demonstrated that increased connectivity strengths were present in Feeder network in CP- patients, compared to HC. Moreover, positive correlations were found between the connectivity strength of the right precentral gyrus and the inferior occipital gyrus and both SAS and SDS scores.

### CONCLUSION

Our study confirmed the correlations of FBN-related differences with cancer pain and provided novel information on the nature of cancer pain in lung cancer patients.

### CLINICAL RELEVANCE/APPLICATION

Taken together, our results reveal brain region-specific structure-function interaction as neural correlate of individual differences in cancer pian and provide insights into the basis of efficient information processing as fundamentally implicated in cancer pain.

## T2-SPNR-15 SKELETAL MUSCLE LOSS IS ASSOCIATED WITH INCREASED RISK OF DEMENTIA-RELATED OUTCOMES: LONGITUDINAL OBSERVATIONAL STUDY USING ADNI BRAIN MRIS

Yuxin Zhu (*Abstract Co-Author*) Nothing to Disclose
Shadpour Demehri, MD (*Abstract Co-Author*) Consultant, Toshiba Corporation;Research support, General Electric Company;Research Grant, Carestream Health, Inc
Hanzhang Lu, PhD (*Abstract Co-Author*) Nothing to Disclose
Eleanor Simonsick (*Abstract Co-Author*) Nothing to Disclose
Soheil Mohammadi, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Sara Momtazmanesh (*Abstract Co-Author*) Nothing to Disclose
Kamyar Moradi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Age-related skeletal muscle loss (i.e., sarcopenia), which is largely undiagnosed and potentially modifiable, is often seen in older adults with Alzheimer's disease (AD) dementia. This study aimed to examine whether temporalis muscle loss (a measure of skeletal muscle loss) is associated with an increased risk of AD dementia in non-demented older adults.

### METHODS AND MATERIALS

To quantify sarcopenia, we utilized baseline T1 brain MRIs from the Alzheimer's Disease Neuroimaging Initiative (ADNI) cohort. In non-demented participants aged =70 years, we manually segmented the bilateral temporalis muscles and calculated the sum cross-sectional area (CSA) of these muscles. Based on the CSA, participants were categorized into two distinct groups using the Maximally Selected Rank Statistics method: large CSA and small CSA. Outcomes included subsequent AD dementia incidence, and change in cognitive and functional scores, and brain volumes between the groups.

### RESULTS

We included 621 non-demented participants (age mean±SD:77.3±4.9, female/male:0.7) and established a cut-off of 1076.4 $mm^2$ to define large and small CSA. At the study baseline, 131 participants had a large CSA and 488 participants had a small CSA. Median follow-up was 5.8 years. According to the Cox proportional hazard model fitting result (adjusted for age, sex, years of education, marital status, APOE-e4 status, and intracranial volume), a small temporalis CSA was associated with a higher incidence risk of AD dementia (hazard ratio, 95% confidence interval (CI): 1.59, 1.09 to 2.33, P:0.016). Furthermore, linear mixed-effect regression models showed that having a smaller temporalis CSA was associated with a greater decrease in memory composite score, functional activity questionnaire score, as well as structural brain volumes, including whole brain, hippocampus, entorhinal cortex, and fusiform gyri over the follow-up period (P values< 0.05).

### CONCLUSION

Temporalis muscles size (a measure of skeletal muscle loss i.e., sarcopenia) is an early risk factor for cognitive decline in older adults.

### CLINICAL RELEVANCE/APPLICATION

Utilizing brain MRI scans to quantify sarcopenia, specifically through the measurement of temporalis muscle biomarkers, may serve as a readily available predictive tool for assessing the likelihood of future dementia incidence in brain imaging studies.

## T2-SPNR-2 QUANTIFICATION OF PETQUANT AMYLOID TRACER PREDICTS CLINICAL AMYLOID BURDEN STATUS

Carrie P. Marder, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Cheryl E. Vanier, PhD (*Abstract Co-Author*) Nothing to Disclose
Alan Rodriguez, MD (*Abstract Co-Author*) Nothing to Disclose
Travis H. Snyder, DO (*Abstract Co-Author*) Nothing to Disclose
Thomas Knoblauch, MS (*Abstract Co-Author*) Nothing to Disclose
Robert L. Delapaz, MD (*Abstract Co-Author*) Nothing to Disclose
John P. Uglietta, MD (*Abstract Co-Author*) Nothing to Disclose
Priya Santhanam, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Amyloid burden and regional brain atrophy are considered biomarkers of Alzheimer's disease (AD). This study compares neuroradiologist classification of amyloid presence to regional distribution of amyloid-ß (Aß) plaques using PET-based quantification and associated regional volumetrics in affected patients.

### METHODS AND MATERIALS

Anatomical 3T MRI and PET CT imaging using Aß tracers were performed on 163 patients (mean age=75 yrs, range=64-88) clinically diagnosed with mild cognitive impairment (MCI) and/or AD. Patients were classified as positive (n=88) or negative (n=75) for Aß presence based on neuroradiologist interpretation of PET images. Normalized (z-scores) amyloid tracer data from PETQuant and raw volumes from NeuroQuant from 54 regions of interest were analyzed in a hierarchical cluster analysis to identify potential sub-groups relative to Aß status. Machine learning models provided insight for regional PETQuant and volumetrics most relevant to classifying patients into Aß status groups or to four sub-groups derived from the cluster analysis.

Separate random forest models were run, using regional values or principal component scores of PET or PET+volumetric data and intracranial volume and age. Sensitivity and specificity of the model are reported, and the Gini index for classification was used to indicate variable importance.

**RESULTS**

The first three principal components from PET and volumetric data led to models with higher classification accuracy than models using the raw data. Hierarchical clustering using PET data clustered 66 of the 75 of those in the Aß negative group, characterized by having low amyloid across regions; 14% in the 'negative' cluster were classified as positive by a neuroradiologist. There were three subgroups within the predominantly Aß positive group, each with specific regional patterns of amyloid deposit (Figure 1). Random forest modeling showed good classification accuracy (88%) relative to neuroradiologist rating using PET data alone; addition of volumetric data did not improve accuracy (87%). The random forest model with four PET principal components had specificity of 88% and sensitivity of 88%.

**CONCLUSION**

PETQuant-based quantification of amyloid tracer is a good marker for predicting amyloid status on radiological read in patients with MCI and/or AD. While volumetric data did not contribute to the classification model, one subgroup of Aß positive patients did have significantly smaller hippocampal volume, possibly indicating advanced disease state. Further analysis is needed to validate the patient subgroups with respective clinical associations.

**CLINICAL RELEVANCE/APPLICATION**

PETQuant software provides predictive information for clinical determination of amyloid-ß burden status.

## T2-SPNR-3 AUTOMATIC GENERATION OF RADIOLOGY REPORTS FOR DIAGNOSING NEURODEGENERATIVE DISORDERS AND COMPARISON WITH THEBOARD-CERTIFIED NEURORADIOLOGIST-WRITTEN STRUCTURED REPORT

Wooseok Jung, MSc (*Abstract Co-Author*) Nothing to Disclose
Saehyun Kim (*Abstract Co-Author*) Nothing to Disclose
Seung Hyun Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Dong-Hee Kim (*Abstract Co-Author*) Nothing to Disclose
Chong Hyun Suh, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to develop and evaluate an advanced AI platform for generating radiology reports for the diagnosis of neurodegenerative diseases using medical imaging data processed through an AI-based quantitative MRI software.

**METHODS AND MATERIALS**

VUNO-Med DeepBrain, an AI-based quantitative MRI software was utilised to analyze input brain MRI scans. The model uses 3D image segmentation model to quantify brain atrophy and MTA scores, whereas 2D segmentation models were applied to detect WMH and lacunes. Additional machine learning methods were leveraged to provide CSF analysis results. Merging these findings, the AI platform automatically produce a structured report comprising quantitative measurements and descriptive findings. Key quantitative metrics reported by DeepBrain from a 3D T1 MRI include hippocampal and diffusive brain atrophy information derived from regional normative percentiles, followed by CSF analysis such as Ventriculomegaly determined by Evans' index, high convexity tightness, Sylvian fissure enlargement, DESH, narrow callosal angle, and choroid plexus volumes. Subsequently, the software extracted periventricular and WMH volumes and their associated Fazeakas scale. Lacunes are also detected from the FLAIR scan and their number is reported. The report generation pipeline summarized key positive findings to generate a brief conclusion. We evaluated the proportion of agreement of 10 indicies, including left/right MTA scores, periventricular/deep Fazekas scales, number of lacunes, ventriculomegaly, high convexity tightness, Sylvian fissure enlargement, DESH, narrow callosal angle between board-certified neuroradiologist's radiology reports and AI-generated reports.

**RESULTS**

3D T1 and FLAIR scans of 200 randomly selected subjects in ADNI database were collected. The average full inference time including MRI analysis and report generation was 70 seconds per case. The order of components in the report is: 1. Brain hippocampal atrophy, 2. Cerebral WMH, 3. Number of lacunes, 4. CSF analysis, and Conclusion. The proportion of agreement of 10 indicies between radiologist's radiology reports and AI-generated reports were 84%.

**CONCLUSION**

This study verified the performance of the automated reports generated by the output from DeepBrain compared to reports created by radiologists. The DeepBrain program automatically produced reliable structured reports with quantitative measurements and descriptive findings.

**CLINICAL RELEVANCE/APPLICATION**

This deep learning-based model, providing automatic generation of radiology report, will reduce typing workload for radiologists, produce a prompt and accurate standardized report, and ultimately improve patient management for neurodegenerative diseases.

## T2-SPNR-4 CAN AI SUPPORT ON-THE-FLY BRAIN MRI SCAN PROTOCOL ADAPTATION?

Silvia Ingala (*Abstract Co-Author*) Nothing to Disclose
Michael Bachmann Nielsen, MD (*Abstract Co-Author*) Nothing to Disclose
Jonathan Frederik Carlsen (*Abstract Co-Author*) Nothing to Disclose
Amine M. Korchi, MD (*Abstract Co-Author*) Nothing to Disclose
Thomas Clement Truelsen (*Abstract Co-Author*) Nothing to Disclose
Akshay Pai (*Abstract Co-Author*) Stockholder, Cerebriu A/S;Employee, Cerebriu A/S
Kaining Sheng (*Presenter*) Nothing to Disclose

**PURPOSE**

Real-time brain MRI protocol adaptation requires detection of findings on an abbreviated set of scan sequences. This study evaluates the diagnostic accuracy of an AI model (Apollo™, Cerebriu A/S), MR technologists, and consultant neuroradiologists in detecting critical findings (brain infarct, intracranial hemorrhage, and intracranial tumors) on an abbreviated protocol set as prerequisite for on-the-fly protocol adaptation.

**METHODS AND MATERIALS**

We collected a retrospective consecutive cohort with patients referred to receive a routine brain MRI scan. The cohort was consecutively enriched with positive findings of brain infarcts, hemorrhages, and tumors from routine scans. Some findings were beyond Apollo™ intended use definitions, however still clinically relevant and thus included. Three neuroradiologists, three MR technologists, and Apollo™ assessed findings using a 3-sequence protocol

(DWI, SWI/T2*, T2-FLAIR), each radiologist and technologist analyzing a third of the cohort. Reference findings for each scan were determined by a fourth neuroradiologist with access to all scan sequences and corresponding reports.

**RESULTS**

A total of 414 patients were included (56 years ± 19, 238 men) with 65 confirmed brain infarcts, 65 intracranial hemorrhages, and 65 intracranial tumors. Using the abbreviated 3-sequence set, neuroradiologists detected infarct, hemorrhage, and tumors with a pooled sensitivity of 88% (95% CI: 84, 91), 85% (95% CI: 74, 91), and 72% (95% CI: 60, 82), respectively, and specificity of 99% (95% CI: 98, 100), 98% (95% CI: 96, 99), and 97% (95% CI: 94, 98), respectively. MR technologists detected infarct, hemorrhage, and tumors with a pooled sensitivity of 92% (95% CI: 83, 97), 69% (95% CI: 57, 79), and 35% (95% CI: 25, 48), respectively, and specificity of 90% (95% CI: 83, 94), 95% (95% CI: 92, 97), and 97% (95% CI: 95, 99), respectively. Apollo™ detected infarcts, hemorrhages, and tumors with a sensitivity of 94% (95% CI: 85, 98), 83% (95% CI: 72, 90), and 71% (95% CI: 59, 80), respectively, and specificity of 86% (95% CI: 82, 89), 84% (95% CI: 80, 87), 60% (95% CI: 55, 65), respectively.

**CONCLUSION**

Given an abbreviated 3-sequence protocol set, Apollo™ has on par sensitivity with neuroradiologists and better sensitivity than MR technologists in recognizing critical findings in need of specialized scan sequences, thus providing a framework for relevant and configurable on-the-fly scan adaptation. The risk of false positive findings must be mitigated by human confirmation of findings and consequent actions.

**CLINICAL RELEVANCE/APPLICATION**

This study provides early evidence of using AI as a human support to implement a real-time adaptive MR scan acquisition workflow, that can potentially reduce scan recalls.

## T2-SPNR-6 ALTERATIONS OF FUNCTIONAL CONNECTIVITY IN COVID-19 PATIENTS MEDIATE THE RELATIONSHIP BETWEEN SERUM CRP AND AUTE-PHASE FATIGUE

**PURPOSE**

The SARS-CoV-2 infection emerges as a prominent model for investigating the intricate mechanisms underlying fatigue development. This study aimed to identify objective evidence of functional connectivity alterations in individuals experiencing acute post-COVID fatigue using fMRI and further explore the biological mechanisms with circulating inflammatory biomarkers.

**METHODS AND MATERIALS**

299 patients with mild SARS-COV-2 infection underwent MRI scans and fatigue assessments using Fatigue Assessment Scale (FAS) within 1 month post-infection. Among these patients, plasma samples were collected from 138 individuals within 48 hours before/after the MRI scan. After preprocessing the imaging data using the atlas parcellation scheme in Conn, we compared the resting state whole-brain and seed-to-voxel connectivity between patients with fatigue (n = 145) and those without fatigue (n = 154). Then, the functional connectivity (FC) values of statistically significant connections were selected for the correlation analysis with FAS scores in the full sample. Furthermore, we conducted an exploratory analysis to investigate the role of FC in the association between selected plasma inflammatory biomarkers and fatigue.

**RESULTS**

Firstly, we observed widespread increased connectivity in the fatigue group in the ROI-ROI connections from the right inferior cerebellum (cerebellum_10_R) to multiple brain regions (PFWE < 0.05). Secondly, a seed-based FC analysis was carried out for the cerebellum_10_R as the seed. Compared with non-fatigue group, the fatigue group presented six clusters of increased connectivity covering the bilateral superior frontal gyrus, bilateral middle frontal gyrus, and right inferior frontal gyrus (cluster-level PFWE < 0.05). CRP levels were significantly higher in adults with acute fatigue than those without, and positively correlated with the total FAS scores. Moreover, the Mediation analysis revealed that the relationship between CRP and FAS scores was mediated by the FC strength between right inferior cerebellum and cluster 3 (bilateral middle frontal gyrus).

**CONCLUSION**

Patients with fatigue exhibited significantly increased connectivity between the right inferior cerebellum and frontoparietal network, providing neural basis for the association between CRP and post-COVID-19 fatigue. Moreover, these findings have implications for elucidating the biological mechanism of acute fatigue.

**CLINICAL RELEVANCE/APPLICATION**

By investigating the underlying mechanisms of post-COVID fatigue, we are hopeful to acquire a deeper understanding of the nature of fatigue, ultimately paving the way for more effective prevention and therapeutic strategies.

## T2-SPNR-8 INVESTIGATION ON THE APPLICATION VALUE OF DEEP LEARNING MODEL BASED ON MULTIMODAL MRI IN THE DIFFERENTIAL DIAGNOSIS OF GLIOBLASTOMA, SOLITARY BRAIN METASTASES AND PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

Peng Du, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The accurate identification of glioblastoma (GBM), solitary brain metastases (SBM) and primary central nervous system lymphoma (PCNSL) plays a decisive role in the formulation of treatment plan. Deep learning (DL) can accurately, automatically and efficiently extract the features of medical image data, and plays an important role in the field of precision medicine. This study attempts to use DL technology to extract the features from pre-treatment multimodal MRI of GBM, SBM and PCNSL, to establish a classification prediction model for the three types of tumors and achieve non-invasive and accurate diagnosis before treatment.

**METHODS AND MATERIALS**

The standardized medical imaging database of brain tumors established by Xuzhou Medical University was reviewed, and clinical data of patients with pathologically confirmed GBM, SBM and PCNSL between March 2012 and October 2018 were consecutively analyzed. The enrolled patients were randomly

divided into training set and test set according to the ratio of 3:1. Convolutional neural networks (CNN) were used to perform deep feature extraction from CE-T1WI and T2-Flair sequences on patients' pre-treatment MRI, to establish the single modality-based classification-net (SC-Net) and multimodality MRI-based classification-net (MC-Net). Feature fusion was performed by L1-norm strategy, and finally the multimodality MRI feature fusion-based classification-net (MFFC-Net) was built and compared with the diagnostic results of radiologists.

**RESULTS**

A total of 1225 patients were enrolledd in the study, including 419 GBM, 412 SBM and 394 PCNSL. In the training set, the AUCs of the SC-Net models based on CE-T1WI and T2-Flair were 0.970 and 0.940, respectively, and the AUC of the MC-Net model based on CE-T1WI combined with T2-Flair was 0.980. The AUC of the MFFC-Net model based on the fusion of CE-T1WI and T2-Flair features was 0.990. In the test set, the AUCs were 0.707, 0.832 and 0.951 for junior, intermediate and senior radiologists, respectively, and the AUC of the MFFC-Net model was 0.960. The diagnostic performance of MFFC-Net model was not significantly different from that of senior radiologist (P=0.641).

**CONCLUSION**

MFFC-Net, a triple classification network for brain tumors based on multimodal MRI feature fusion, can achieve non-invasive and accurate diagnosis of GBM, SBM and PCNSL before treatment, providing basis for the follow-up treatment of patients, which is conducive to better prognosis of patients.

**CLINICAL RELEVANCE/APPLICATION**

The deep Learning model based on multimodal MRI established in this study can achieve non-invasive and accurate diagnosis of GBM, SBM and PCNSL before treatment, providing basis for the follow-up treatment of patients, which is conducive to better prognosis of patients.

## T2-SPNR-9 ALTERED DYNAMIC AMPLITUDE OF LOW-FREQUENCY FLUCTUATION IN INDIVIDUALS AT HIGH RISK FOR ALZHEIMER'S DISEASE

Ming Qi (*Abstract Co-Author*) Nothing to Disclose
Shuxian Wu (*Abstract Co-Author*) Nothing to Disclose
Shui Tian (*Abstract Co-Author*) Nothing to Disclose
Qinqin Zhu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the dynamic amplitude of low-frequency fluctuation (dALFF) alterations in patients at high risk for Alzheimer's disease and to explore its correlation with clinical cognitive assessment scales for identifying an early imaging biomarker of these special populations.

**METHODS AND MATERIALS**

A total of 152 participants, including 72 subjective cognitive decline (SCD) patients, 44 mild cognitive impairment (MCI) patients and 36 healthy controls (HCs), underwent a resting-state functional magnetic resonance imaging and were assessed with various neuropsychological tests. The dALFF was measured by sliding-window analysis. We employed canonical correlation analysis (CCA) to examine the bi-multivariate correlations of the neuropsychological scales with altered dALFF across multiple regions in SCD and MCI patients.

**RESULTS**

Compared to those in the HC group, both the MCI and SCD groups showed higher dALFF values in the right opercular inferior frontal gyrus, as well as lower dALFF values in the left precuneus (voxel $P < 0.001$, cluster $P < 0.05$, GRF correction). CCA models revealed that the SCD and MCI behavioral items measuring inattention were correlated with the dALFF of the right middle frontal gyrus and right opercular inferior frontal gyrus, which are involved in frontoparietal networks ($R = 0.43$, $P = 0.024$).

**CONCLUSION**

SCD and MCI patients performed significantly worse than HCs on neuropsychological scales, and the neural activity of specific brain functional areas changed in the early stages of cognitive impairment. We provide insights of the brain dynamics of neural activity in frontal areas into the shared neural basis underlying SCD and MCI.

**CLINICAL RELEVANCE/APPLICATION**

The neural activity of specific brain functional areas changed in the early stage of cognitive impairment, which may act as a valuable imaging marker for early detection and intervention of patients at high risk for AD.

## T2-SPOB-1 HEMORRHAGIC OVARIAN CYSTS OVER 50 MM ("LARGE HOCS"): PREVALENCE AND VALUE OF EXPERIENCED RADIOLOGIST ASSESSMENT

Mark D. Sugi, MD (*Abstract Co-Author*) Consultant, Nextrast, Inc;Author with royalties, RELX
Tara A. Morgan, MD (*Abstract Co-Author*) Nothing to Disclose
Maitray D. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Scott W. Young, MD (*Abstract Co-Author*) Nothing to Disclose
Alan Zhu, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluate the prevalence of large HOC and utility of routine follow-up ultrasound when characterized by an experienced radiologist..

### METHODS AND MATERIALS

Consecutive pelvic US reports on 18-50 yo women between 01/2017 to 10/2022 at one organization with separate academic and community radiology departments were retrospectively reviewed to identify adnexal masses over 50 mm maximum diameter described as possibly being HOC (large HOC). EMR review established outcome based on surgical removal or follow-up imaging (US or MR). Four academic radiologists experienced with gynecologic ultrasound independently reviewed studies blinded to outcome, scoring two assessments:.1. Mass has US features most consistent with an ovarian hemorrhagic mass (HOC or endometrioma) rather than another diagnosis..2. Mass meets O-RADS definition of characteristic HOC except for size; follow-up would not be recommended if <= 50 mm in diameter..

### RESULTS

51,305 age-appropriate women had 68,859 examinations, with 457 (0.9 %) having US report indicating possible HOC over 50 mm. For 366 patients with established outcomes (192 at a community center, 174 at an academic center), 226 had a large HOC..Experienced radiologist review of the 366 patients designated hemorrhagic mass (HOC or endometrioma) as the most likely diagnosis in 320; outcomes showed 224 (70.0%) HOC, 89 (27.8%) endometrioma, 4 (1.3%) TOA, 2 (0.6%) borderline tumor, and 1 (0.3%) cystadenoma/adenofibroma..For 46 patients, experienced radiologists would not have suggested a hemorrhagic mass; 32 had been evaluated at a community center (16.7% of the 194 community patients) and 14 at an academic center (8.0% of the 174 academic patients). In the 32 community patients, outcomes showed 27 neoplasms (23 benign, 2 borderline, and 2 malignant). In the 14 academic patients, outcomes showed 11 neoplasms (10 benign, 1 borderline, and 0 malignant)..For 191 patients designated by an experienced radiologist as having a characteristic HOC such that follow-up would not be recommended if 50 mm or smaller, outcomes showed 181 (94.8%) HOC, 9 (4.7%) endometrioma, and 1 (0.5%) cystadenoma/adenofibroma..

### CONCLUSION

For experienced radiologists, routine imaging follow-up of a characteristic large HOC has limited value. For less experienced radiologists, second-opinion review of suspected large HOC can be valuable, as nearly 1 of 6 masses classified as a possible large HOC by less experienced radiologists proved to be neoplasms, some malignant..

### CLINICAL RELEVANCE/APPLICATION

An estimated 0.5% of premenopausal women undergoing pelvic US will have an HOC over 50 mm (large HOC). Experienced radiologist review of a mass classified as a possible large HOC has potential to reduce follow-up and interpretation errors.

## T2-SPOB-2 UTERINE PERISTALSIS OF ADENOMYOSIS PATIENTS ON CINE MR IMAGING

Kyo Noguchi, MD (*Abstract Co-Author*) Nothing to Disclose
Shinya Fujii, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuki Himoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuji Nakamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ikuko Ota (*Abstract Co-Author*) Nothing to Disclose
Toshihide Ogawa, MD (*Abstract Co-Author*) Nothing to Disclose
Aki Kido, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Adenomyosis is a common benign gynecologic disease, and can be an important cause of infertility and dysmenorrhea. Uterine peristalsis (UP) is wave-like movement of the endometrial-myometrial junction. Abnormal UP is considered linked to infertility and chronic pelvic pain. The aim of this study is to compare UP between uterine wall with adenomyosis and normal wall to evaluate the effect of adenomyosis on UP on MRI.

### METHODS AND MATERIALS

The study included 139 adenomyosis patients. MRI were obtained using a sagittal T2-weighted turbo spin echo images and a half-Fourier acquisition single-shot turbo spin-echo (HASTE) images for display on cine mode. The uterus was divided into walls with and without adenomyosis, and a comparative evaluation was conducted. One radiologist evaluated the presence or absence of UP depending on the menstrual cycle phases: proliferative, luteal and menstrual phases. In cases where UP was present, frequency, direction and the presence/absence of outer myometrial conduction (OMC) were evaluated. For uterine wall with adenomyosis, characteristics of UP were evaluated: irregular signal movement and mucosal movement. In proliferative phase, UP was further evaluated in cases with and without endometriotic cysts.

### RESULTS

UP was observed significantly more often in walls with adenomyosis (113/182) than in normal walls (47/96), especially in luteal phase, but the frequency was not significantly different (6.9 vs.7.4). No significant differences were observed in the presence and the frequency of peristalsis between respective menstrual cycle phases. Peristaltic direction was observed in cervix to fundus in proliferative and luteal phase, and mixed in menstrual phase. Regarding characteristics of UP in walls with adenomyosis, half of the cases showed irregular signal movement and mucosal movement. One quarter of the cases accompanied both conduction and irregular signal movement. OMC was observed more frequently in adenomyosis patients only in proliferative (29/49 vs.7/24). In cases with endometriotic cysts, significant decrease of peristalsis was observed compared with cases without them (3/6 vs.46/48).

### CONCLUSION

Even in patients with adenomyosis, UP was observed as normal myometrium, but the tendency of hyperperistalsis was observed in luteal phase. Characteristic peristaltic movement within adenomyosis lesion, low signal conduction or irregular signal movement, was observed in half of the adenomyosis patients.

### CLINICAL RELEVANCE/APPLICATION

Adenomyosis does not disturb peristaltic movement, but characteristic peristaltic movement and signal conduction were observed within adenomyosis lesion.

## T2-SPOB-4 LEVATOR ANI MUSCLE SHAPE CHANGES IN WOMEN WITH STRESS URINARY INCONTINENCE USING DUAL-ENERGY COMPUTED TOMOGRAPHY AND 3T MAGNETIC RESONANCE IMAGING

Kun Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Kun Ou (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the levator ani muscle imaging manifestations of patients with stress urinary incontinence (SUI) and healthy group on MR and dual-energy computed tomography (DECT) images.

### METHODS AND MATERIALS

This study enrolled 50 healthy volunteers and 58 patients with SUI underwent pelvic examinations including 3.0-T MR and non-enhanced CT gemstone spectral imaging. The thickness of iliococcygeus muscle (tICM) and the angle of iliococcygeus (aICM) from coronal position were collected and compared. The correlation between results of CT and MRI was also evaluated.

### RESULTS

The measured values of CT and magnetic resonance imaging MRI had strong and positive correlation (left tICM, r=0.825, P<0.001; right tICM, r=0.719, P<0.001; left aICM, r=0.737, P<0.001; right aICM, r=0.855, P<0.001). Our MRI results showed that the tICM of SUI group (left, 3.08±0.78 mm; right, 2.98±0.87 mm) was significantly lower than that of healthy group (left, 3.60±0.91 mm, P=0.018; right, 3.78±0.98 mm, P=0.001), and the aICM (left, 33.89±6.99& 4;; right, 35.69±7.89& 4;) was higher than that of the healthy group (left, 26.90±7.15& 4;, P=0.005; right, 25.69±6.88& 4;, P=0.001). And in CT, the tICM of SUI group (left, 3.15±0.64 mm; right, 3.08±0.76 mm) was also significantly lower than that of healthy group (left, 3.69±0.98 mm, P=0.007; right 3.84±0.99 mm, P<0.001), and the aICM (left, 34.30±6.38& 4;; right, 34.98±7.99& 4;) was higher than that of the healthy group (left, 26.34±7.99& 4;, P=0.002; right , 26.59±6.24& 4;, P<0.001).

### CONCLUSION

DECT and MRI measured shape-related value of anus levator anatomy has significant correlation. The thickness of iliococcygeus muscle of SUI patients is lower than that of healthy people, and the angle of iliococcygeus is higher than that of healthy people.

### CLINICAL RELEVANCE/APPLICATION

Currently the imaging of levator ani muscle damage is still confined to MRI and ultrasound, this study proves that spectral imaging of DECT is feasible to detect levator ani muscle damage, showing strong correlation with MRI. DECT has the advantages of fast scanning speed. For patients such can't tolerate MRI examination, DECT scanning is clinically valuable.

## T2-SPPD-1 ABNORMAL PANCREATICOBILIARY JUNCTION IN CHILDREN: PREVALENCE AND ASSOCIATED COMPLICATIONS AS SEEN ON MRCP

Govind B. Chavhan, MD (*Abstract Co-Author*) Nothing to Disclose
Khuld Saeedi, MD (*Abstract Co-Author*) Nothing to Disclose
Caroline Rutten, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the prevalence and clinical significance of abnormal pancreaticobiliary junction (PBJ) in the pediatric population using magnetic resonance cholangiopancreatography (MRCP).

### METHODS AND MATERIALS

Single-center, retrospective study of MRCP examinations in children 0-18 years from 2012 to 2022. The imaging studies in each patient was reviewed by two independent readers for visibility of the PBJ, abnormal PBJ and length of common channel, pancreas divisum, choledochal cyst, lithiasis and pancreatitis. Findings were correlated with clinical history of pancreatitis, cholecystitis, any lithiasis, and ERCP or surgical findings when available.

### RESULTS

A total of 635 MRCP were included (47.3% female; mean age 12.1 ± 5.1 years), with the most common indications being primary sclerosing cholangitis (25.4%) and pancreatitis (21.7%). Interobserver agreement was fair to moderate (kappa 0.34 and 0.44) for visibility of PBJ. The PBJ was visible in 88.7% of cases. An abnormal junction was observed in 106 (19.3%) of cases, with a long common channel in 54 (9.9%) of cases and an average common channel length of 10.3 ± 4.8 mm (range, 3-25 mm). Significant associations were found between an abnormal PBJ and complications, including choledochal cyst (P<0.0001), history of pancreatitis (P=0.0002) and lithiasis (P<0.0001). 19/54 (35%) common channels (median age of 3.8 years) showed stones within them. The common channel length was also significantly associated with complications (P=0.014), with complication-free cases having an average length of 6.3 mm compared to 11.0 mm in complicated cases.

### CONCLUSION

The abnormal PBJ with long common channel is frequent on MRCPs in children. Its presence is significantly associated with choledochal cyst, pancreatitis and lithiasis. The common channel can show stones within them, particularly in small children.

### CLINICAL RELEVANCE/APPLICATION

It is important to look for abnormal PBJ and common channel in children as it is often complicated by choledochal cyst, history of pancreatitis and lithiasis.

## T2-SPPD-2 SOCIAL FACTORS AFFECTING ACR APPROPRIATENESS CRITERIA COMPLIANCE AMONG CHILDREN DIAGNOSED WITH PYELONEPHRITIS IN THE UNITED STATES

Cory Pfeifer, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Kevin Vo (*Abstract Co-Author*) Nothing to Disclose
Mehrtash Hashemzadeh (*Abstract Co-Author*) Nothing to Disclose
Garrett Trang (*Presenter*) Nothing to Disclose

### PURPOSE

Pyelonephritis, a common complication of urinary tract infections, can lead to sepsis and high medical costs. Computed tomography (CT), preferred for diagnosing pyelonephritis complications such as abscesses, poses radiation risk for children, leading to ultrasound (US) preference as reflected in the ACR Appropriateness Criteria. This study examines predictors of US utilization in children according to multiple social determinants of health.

### METHODS AND MATERIALS

Using the National Emergency Department Sample (NEDS), patients aged =17 years with a diagnosis code for pyelonephritis who received CT or US in 2019-2020 were analyzed. Patients who had both CT and ultrasound were excluded. Demographic and baseline clinical characteristics were reported as means/standard deviations for continuous variables and frequencies; percentages for categorical variables. Two-sample t-tests and Chi-squared/Fisher's Exact Test were used to compare continuous and categorical variables, respectively. P-values were 2-sided with p<0.05 as statistically significant.

## RESULTS

39,528 patients met study criteria (mean age 9.00 years). In patients with CT or US (n = 6240), 74% received CT. Mean CT recipient age (n=4,624) was 14.27 years vs. 10.19 for US (p<0.001). CT was favored among white children (14.96% vs. 6.28% Hispanic), while US preference was opposite (5.02% vs 4.11% White). Income was associated with lower CT utilization rates (14.52%, <$48,000; 7.52%, =$82,000) and higher US rates (3.69%, <$48,000; 5.09%, =$82,000). Private insurance correlated with higher CT (12.84%) and US (4.15%) utilization compared to Medicaid. CT utilization was lower in metropolitan teaching hospitals (6.96% vs. 21.61% non-teaching, p <0.001) but similar for US (4.48% vs. 4.12% non-teaching). US frequency was lower in non-metropolitan hospitals (1.93%). CT utilization was greater in the Midwest (18.05 vs. 6.45% West) while US preference was reversed (3.49% Midwest vs. 4.76% West). Mean ED service charges was $5,585; $11,291 for encounters with CT and $8,531 for encounters with US (p=0.001).

## CONCLUSION

Despite the ACR Appropriateness criteria favoring US for pediatric pyelonephritis, children are nearly three times more likely to undergo CT than US. Older age, lower income, metropolitan teaching hospital, and West region are associated with decreased CT and increased US utilization. Both modalities are associated with increased ED costs, CT greater than US.

## CLINICAL RELEVANCE/APPLICATION

Pediatric patients with pyelonephritis are three times more likely to undergo CT than US. Investigation into the reasons for this disparity is imperative to reduce unnecessary radiation exposure in the pediatric population and improve adherence to evidence-based recommendations.

# T2-SPPD-3 ASSESSMENT OF INTERSTITIAL FIBROSIS IN PEDIATRIC RENAL TRANSPLANTATION USING T2* BOLD MRI: VALIDATION WITH RENAL BIOPSY

Yurie Shirai (*Abstract Co-Author*) Nothing to Disclose
Akihiro Inoue, MD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shuji Sakai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Michinobu Nagao, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

For pediatric patients with end-stage renal failure, kidney transplantation is the only treatment that can provide growth and long-term survival. Although rejection is the common cause of renal dysfunction, there are other causes of chronic transplant nephropathy, in which the transplanted kidney develops interstitial fibrosis. We used a hybrid approache of T2*-BOLD and 4D flow MRI to assess interstitial fibrosis in pediatric transplanted kidneys and compared it to the degree of interstitial fibrosis evidenced by renal biopsy.

## METHODS AND MATERIALS

Data of T2*-BOLD and 4D flow MRI for transplanted kidney in the pelvis collected from 60 patients [mean age, 15 years; 42 boys (70%); average 38 months after transplantation; eGFR, 65±21mL/min/1.73m2; 45 living donor kidneys and 15 cadaveric kidneys] using a 3-tesla scanner were prospectively analyzed. T2*-BOLD was conducted using the black blood, breath-hold, and multi-echo gradient-echo sequence. Regions of interest were drawn in the cortex and medulla of the transplanted kidney and R2* values were measured. A free-breathing 4D flow sequence with echo-planar imaging was used as 4D flow MRI. Patients with loss of arteriovenous flow in the renal cones on 4D flow MRI were excluded. A renal biopsy performed at the same time as the MRI divided the fibrosis of the renal interstitium into Banff classification. Ci0 was defined as no fibrosis, Ci1 as mild fibrosis, and Ci2 to 3 as moderate to severe fibrosis. The relationship between the degree of fibrosis in the renal biopsy and the R2* on T2*-BOLD was examined.

## RESULTS

R2* in renal cortex was 17.3±2.4ms-1 for non-fibrosis (n=31), 17.8±2.3ms-1 for mild fibrosis (n=20), 21.1±4.5 ms-1 for moderate to severe fibrosis (n=9). R2* in renal medulla was 22.0±2.7ms-1 for non-fibrosis, 24.2±4.1ms-1 for mild fibrosis, 26.8±4.4ms-1 for moderate to severe fibrosis. R2* in both renal cortex and medullar had significant correlations with the progression of fibrosis (renal cortex: Spearman r, 0.319; renal medulla: Spearman r, 0.42). ROC analysis revealed that the optimal cut-offs of R2* 17.5 ms-1 for the renal cortex and 24.3 ms-1 for the renal medulla distinguished patients with moderate to severe fibrosis, with area under the curves of 0.797 and 0.815, sensitivities of 89% and 89%, specificities of 61% and 76%.

## CONCLUSION

T2*-BOLD for pediatric transplanted kidney strongly correlates with the degree of interstitial fibrosis on renal biopsy and can be an non-invasive means of diagnosing chronic transplant nephropathy.

## CLINICAL RELEVANCE/APPLICATION

T2*-BOLD MRI does not need the use of contrast media and is a minimally invasive and safe techniqu. It may be an alternative to renal biopsy for surveillance of pediatric transplanted kidneys.

Ioannis Sechopoulos, PhD (*Presenter*) Research Grant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation;Research Grant, Sectra AB;Research Grant, ScreenPoint Medical BV;Research Grant, Volpara Health Technologies Limited

### PURPOSE

To evaluate the precision and accuracy of volume measurements of solid (SN) and ground glass opacity (GGO) lung nodules in images acquired using conventional and CdZnTe-photon counting CT (PCCT) systems and reconstructed using hybrid iterative (HIR) and deep-learning based (DLR) reconstructions.

### METHODS AND MATERIALS

A patient-based anthropomorphic 3D printed lung phantom and four printed SNs of different size and one GGO were developed and validated. Ultra-high-resolution images of the nodules were acquired using a micro-CT system with 10μm voxel size. The phantom including the nodules was imaged using conventional CT (CCT)and a prototype PCCT system, both with a CTDIvol of 1.4 mGy. Ten acquisitions were performed per scanner with phantom repositioning to mimic clinical positioning variations. The conventional images were reconstructed in normal resolution (NR) using HIR and DLR. The PCCT images were reconstructed in normal resolution (NR) and high resolution (HR) with HIR and DLR. 3D Slicer (version 5.6.2, Slicer Community) was used to calculate the volume of the nodules in the μCT, conventional, and PCCT images. Semi-automatic segmentation based on region growing was used. The nodule volume estimates resulting from the μCT images were used as ground truth (GT). The accuracy was calculated as the relative error (RE) of the nodule volumes against the GT, and the coefficient-of-variation (CV) was used to calculate precision. ANOVA was used to determine the effect of CT systems, reconstruction methods, and spatial resolution mode (significance at $p<0.05$) on volume estimates. Bland-Altman plots were used to show measurement agreement.

### RESULTS

The GT volumes of the SNs were 4, 22, 1150, and 1774 mm3 and the GT volume of the GGO was 425 mm3. The RE varied from -21.5% (PCCT/HIR) to -0.03% (PCCT/DLR), showing a tendency to underestimate the volume of smaller SNs. The CV varied from 23% (CCT/HIR) to 6% (PCCT/DRL) for the small nodule volume. ANOVA demonstrated that acquisition system, reconstruction algorithm, and resolution setting all have a statistically-significant effect on the volume estimates. Bland-Altman analysis demonstrated a small bias of -3.7 mm3 across the solid nodule volumes, but an average disagreement of 10.6 mm3 on the volume determination of the GGO.

### CONCLUSION

The best performance in terms of measurement precision and accuracy was found using PCCT/DLR, closely followed by the PCCT/HIR.

### CLINICAL RELEVANCE/APPLICATION

The accurate and precise estimation of lung nodule volumes is essential for the optimal follow-up of screening- or incidentally-detected nodules.

## T2-SPPH-10 DEVELOPMENT AND VALIDATION OF AN OPEN-SOURCE SOFTWARE PACKAGE FOR CT SYSTEM QUALITY ASSURANCE

Frank N. Ranallo, PhD (*Abstract Co-Author*) Grant, General Electric Company
Jonathan L. Troville, PhD (*Presenter*) Research support, Canon Medical Systems Corporation

### PURPOSE

The purpose of this work is to present an open-source software package which provides comprehensive computed tomography (CT) quality assurance (QA). We also address limitations of similar packages available in literature.

### METHODS AND MATERIALS

A graphic user interface (GUI) was developed in MATLAB and batch providing the following functionality: 1) objective low contrast detectability (LCD) evaluation, 2) slice thickness measurements from averaged slice sensitivity profile (SSP) full width at half maximum (FWHM) measurements, 3) water CT number accuracy, 4) CT noise performance, 5) CT number scale accuracy, 6) spatial resolution (modulation transfer function (MTF)) measurements using two methods. The code is designed to analyze images of the CATPHAN 500 modules as well as a uniform water phantom provided by the manufacturer. Prior to analyzing the images, sorting is performed on a group and series basis with the dcm4che package. Our methods were performed during annual and acceptance tests for GE Lightspeed VCT and Canon Aquilion ONE scanners. Validations of the slice thickness, MTF, and objective LCD measurements were performed using standard qualitative measurements.

### RESULTS

The average water CT number measured in the center ROI ranged from -0.51 HU up to 0.33 HU across all tube voltages (80, 100, 120, and 140 kV). The total variation of CT number over the image at 120 kV was 0.55 HU (0.5 s rotation time) and 1.35 HU (1 s rotation time), lying well within the manufacturer tolerance of 3.0 HU. All CT numbers for the CATPHAN 500 material inserts fell in agreement with ACR and manufacturer tolerances, except for air inside the phantom at the 40 mm beam width in axial mode and LDPE at the 40 mm beam width in helical mode; air measured outside the phantom was well within ACR tolerances. Objective LCD performance at an observer SNR of 3.29 fell within the manufacturer specifications of 0.32%: 1) 5 mm object diameter: 0.24% at 200 mAs, 2) 3 mm object diameter: 0.26% at 560 mAs. Slice thicknesses were accurate with the SSP FWHM absolute error ranging from 0.0 mm to 0.3 mm. Spatial resolution analysis was highly accurate with absolute error ranging from: 1) Method 1: IQR of 0.0 lp/cm to 1.0 lp/cm, 2) Method 2: -0.2 lp/cm to 0.3 lp/cm.

### CONCLUSION

A comprehensive open-source software package for CT QA can greatly improve the consistency of system testing results by removing inter-operator variability associated with qualitative methods. Furthermore, software-based CT system evaluation may assist with improved throughput for both the testing site and medical physicist given the potential for less time spent scanner-side.

### CLINICAL RELEVANCE/APPLICATION

This work better equips medical physicists in the community for consistent and objective CT system evaluations.

## T2-SPPH-11 EVALUATION OF A WHOLE HEART MOTION COMPENSATION METHOD FOR CARDIAC CT

Zhou Yu, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Jian Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Chih-Chieh Liu (*Abstract Co-Author*) Nothing to Disclose
Liang Cai (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
John Schuzer, ARRT, BS (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Qiulin Tang (*Presenter*) Nothing to Disclose

### PURPOSE

Computed tomography angiography (CTA) serves as a pivotal clinical modality for diagnosing cardiac pathologies, encompassing conditions such as coronary artery defects, valvular anomalies, and myocardial abnormalities. Despite significant advancements in CT gantry rotation speed over the past decade, the temporal resolution offered by many commercial scanners is still limited in capturing real coronary artery motion. As such, motion artifacts are often seen in cardiac CTA images at different cardiac phases, especially for patients with fast heart rates. We have developed a novel reconstruction method to compensate motion for all cardiac region at various heart rates. Here we perform preliminary evaluations for this motion-compensated reconstruction method.

### METHODS AND MATERIALS

The assessments were performed utilizing cardiac volume scans obtained via a Canon Aquilion One 320-slice CT scanner. The entire dataset covers a wide range of dose and contrast levels as well as heart rates. A target cardiac phase was empirically chosen either the systolic period (~45%) or diastolic period (~75%) for each case. The proposed method has been implemented in an in-house reconstruction tool, to produce both images with and without motion compensation for the chosen target phase. The results were evaluated using visual inspection by clinical specialists.

### RESULTS

Without motion compensation, artifacts, including blurring, appears in both the aorta region and coronary arteries (refer to figures 1a-1b, left). After motion-compensated reconstruction, these artifacts are effectively suppressed, resulting in enhanced clarity of the aortic valve (refer to figures 1a-1b, right). Furthermore, substantial enhancement in the visualization of the lateral wall of the left ventricle is noted (refer to figures 1c-1d, right). Effective motion compensation is also noticeable in other regions, such as the encircled area and the mitral valve.

### CONCLUSION

Evaluations based on clinical data have been performed for a cardiac motion-compensated reconstruction method. The result shows that the method significantly reduces cardiac motion artifacts across all region.

### CLINICAL RELEVANCE/APPLICATION

Cardiac Computed Tomography Angiography (CTA) stands as one of the foremost applications in cardiac CT imaging, pivotal for precise clinical diagnosis of cardiac ailments. Mitigation of motion artifacts holds paramount importance in ensuring the fidelity and accuracy of diagnostic outcomes.

## T2-SPPH-12 IMAGE QUALITY AND DOSE REDUCTION POTENTIAL OF DUAL-SOURCE CT EQUIPPED WITH ENERGY-INTEGRATING OR PHOTON-COUNTING DETECTORS ON ABDOMINAL CT IMAGES: A STUDY ON PHANTOMS

Jean-Paul Beregi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Julien Erath, MSc (*Abstract Co-Author*) Employee, Siemens AG
Djamel Dabli (*Abstract Co-Author*) Nothing to Disclose
Maxime PASTOR (*Abstract Co-Author*) Nothing to Disclose
Sebastian Faby, DIPLPHYS (*Abstract Co-Author*) Employee, Siemens AG
Joel Greffier, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the image-quality and dose reduction potential of a photon-counting CT (PCCT) system with two different dual-source CT systems (DSCT-Pulse and DSCT-Force, respectively) for different clinical indications in abdominal CT.

**METHODS AND MATERIALS**

Acquisitions on phantoms were performed on the two DSCTs and one PCCT at 4 dose levels (13/6/3.4/1.8mGy). Noise power spectrum (NPS) and task-based transfer function (TTF) were computed to assess noise magnitude and noise texture and spatial resolution (f50), respectively. Detectability indexes (d') were computed to model the detection of abdominal lesions: one unenhanced high-contrast task, one contrast-enhanced high-contrast task and one unenhanced low-contrast task. Image quality was subjectively assessed on an anthropomorphic phantom by two radiologists.

**RESULTS**

For all dose levels, noise magnitude values were lower with PCCT than with DSCTs. For all CT systems, similar noise texture values were found at 13 and 6mGy, but the highest noise texture values were found for DSCT-Pulse and the lowest for PCCT at 3.4 and 1.8mGy. For high-contrast inserts, similar or lower f50 values were found with PCCT than with DSCT-Force and the opposite pattern was found for the low-contrast insert. For the three simulated lesions, d' values were higher with PCCT than with DSCTs. Abdominal images were rated satisfactory for clinical use by the radiologists for all dose levels with PCCT and for 13 and 6mGy with DSCTs.

**CONCLUSION**

Compared to DSCTs, PCCT reduced the image-noise and improved the detectability of simulated abdominal lesions without altering the spatial resolution and image texture. Image-quality obtained with PCCT seem to indicate greater potential for dose optimization than those obtained with DSCTs.

**CLINICAL RELEVANCE/APPLICATION**

The images obtained with PCCT may offer great potential for dose reduction in patients undergoing abdominal CT examinations.

## T2-SPPH-2 PILOT APPLICATION OF A PROTOTYPE ULTRA-HIGH RESOLUTION CT SYSTEM IN THE THORACIC REGION

Hiroki Kawashima, PhD (*Abstract Co-Author*) Kyoto kagaku, Research collaboration
Katsuhiro Ichikawa, PhD (*Abstract Co-Author*) Nothing to Disclose
Koichiro Nakabayashi (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this study was to develop a prototype ultra-high resolution CT system (UHRCT) for the delineation of lung microstructures. The system was also tested in healthy volunteers to investigate whether micro vessels and bronchioles in the lung could be visualized at practical doses.

**METHODS AND MATERIALS**

The system uses half-scanning to achieve a detector trajectory close to the lung and collect data at a low magnification rate. This allows an effective focal spot size of approximately 0.2 mm, which is combined with a high-resolution CMOS detector with a pixel size of approximately 0.08 mm at the rotation center. The modulation transfer function (MTF), the noise power spectrum (NPS), and the slice thickness were measured with a 0.1 mm diameter wire phantom, a water phantom, and an acrylic block, respectively. The CT dose index (CTDIw) was measured using the standard method. The NPS was compared with that of a clinical CT system at the same dose. After ethics committee approval, two healthy volunteers were scanned and the CT images were reconstructed with a pixel size of 0.16 mm.

**RESULTS**

The 5%MTF was 3.0 mm-1 (0.16 mm resolution) even with an unenhanced reconstruction kernel. The slice thickness was ~0.2 mm. The NPS was approximately twice that of a clinical CT system due to the very small voxel of UHRCT. The CTDIw was 19 mGy which was practical. In the CT images of the healthy volunteers, noise was conspicuous, as was the result of the NPS, but micro vessels and bronchi were easily visible.

**CONCLUSION**

The developed UHRCT system presented high-resolution CT images with a completely different level at a practical radiation dose. The achievement of this study suggested the possibility of clinical application of ultra-high resolution CT in the thoracic region.

**CLINICAL RELEVANCE/APPLICATION**

There are high resolution clinical CT systems with detector pith of 0.2 to 0.25 mm; however, these are not sufficient to visualize bronchiole (0.3-0.5 mm) and small vessels (0.1-0.5 mm) because the actual resolutions of such systems are equal to or larger than the sizes. Therefore, it has not been shown whether these 'in vivo' microstructures can be imaged by CT. This study presents unprecedented high-resolution lung CT images and discusses their clinical potential.

## T2-SPPH-3 DEEP SCATTER ESTIMATION (DSE) FOR STATIC CT

Marc Kachelriess, PhD (*Abstract Co-Author*) Nothing to Disclose
Karl Stierstorfer, PhD (*Abstract Co-Author*) Employee, Siemens AG
Eric Fournie (*Abstract Co-Author*) Employee, Siemens AG
Christian Hofmann (*Abstract Co-Author*) Employee, Siemens AG
Martin Petersilka, PhD (*Abstract Co-Author*) Employee, Siemens AG
Joscha Maier, PhD (*Abstract Co-Author*) Nothing to Disclose
Julien Erath, MSc (*Abstract Co-Author*) Employee, Siemens AG
Andreas Heinkele (*Abstract Co-Author*) Nothing to Disclose
Lukas Hennemann, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

4th generation static CT scanners are composed of a ring-shaped detector and an X-ray source ring. The absence of rotating parts results in many advantages, such as arbitrary firing patterns, mechanical simplification, and faster data acquisition. Still, all currently built medical CT scanners are 3rd generation scanners. One reason is that 4th generation scanner do not allow using anti-scatter grids (ASGs) due to the scanner geometry. Recently, the deep scatter estimation (DSE) offers a new deep learning-based approach that outperforms conventional methods for clinical CT [Med. Phys. 46(1):238-249, January 2019]. This work investigates deep learning-based scatter correction for 4th generation static CT.

**METHODS AND MATERIALS**

DSE is based on a U-net architecture and inferences the scattered radiation from the acquired projection data. For clinical scanners, the acquired data consist of the overlay of primary radiation and scatter. However, for static CT, the detector ring facilitates the measurement of backscattered radiation outside of the primary fan beam, which may contain additional depth information about the object that can be provided to the U-net to improve performance. In this work, DSE is generalized and trained for a static CT geometry. The training dataset consists of 200 circular and elliptic water

phantoms as well as semi-anthropomorphic thorax phantoms. The phantoms vary in size, aspect ratio, and position relative to the scanner center. The ground truth (GT) for the training dataset was generated by Monte Carlo simulations. Testing was done with a semi-anthropomorphic thorax phantom that was not contained in the training dataset. The scatter correction with DSE was compared to the correction with a kernel-based model [Eur Radiol. 9(3):563-9, 1999].

**RESULTS**

Employing DSE, visible scatter artifacts can be well corrected for. The mean absolute error (MAE) in the phantom center can be reduced from 64 HU to 8 HU. In comparison, the kernel-based model reduces the MAE to 25 HU. Even though the DSE was only trained on water and thorax phantoms, it also generalizes very well to our semi-anthropomorphic head phantom.

**CONCLUSION**

Scatter artifacts for static CT can be corrected effectively by using DSE. The adapted DSE outperforms the classical kernel-based model for a static CT geometry.

**CLINICAL RELEVANCE/APPLICATION**

While currently 4th generation scanners are not in clinical use, they may have benefits in certain use cases. E.g. in interventional CT due to the compact design or in general applications where very fast acquisition is crucial. However, since ASGs cannot be deployed for static CT, scatter artifacts have been one of the major issues in the past. Our work shows that this issue can be approached with deep learning-based methods such as the DSE.

## T2-SPPH-4 SPECTRAL PERFORMANCE OF A DUAL-SOURCE, DUAL-KV PHOTON COUNTING DETECTOR (PCD) CT

Timothy Winfree, BS, MS (*Abstract Co-Author*) Nothing to Disclose
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Shuai Leng, PhD (*Presenter*) License agreement, Siemens AG

**PURPOSE**

To evaluate the performance of a novel dual-source (DS) PCD-CT scan mode and compare it to single-source (SS) PCD-CT and DS dual-energy CT with energy-integrating detectors (DS-EID-CT).

**METHODS AND MATERIALS**

A 30cm x 40cm anthropomorphic body phantom with four iodine inserts (2, 5, 10, and 15 mg/mL) was scanned with three modalities at matched radiation dose (CTDIvol: 12 mGy): SS (120 kV) PCD-CT with two energy thresholds, DS (90/Sn150 kV) PCD-CT with three energy thresholds, and DS-EID-CT (90/Sn150 kV). For each modality, images were reconstructed with FBP algorithm using a quantitative (Qr40) kernel, 1mm slice thickness, and 500mm FOV. These images were used as the input to an image-domain least squares material decomposition algorithm with two base materials (iodine and water). The linear reconstruction (FBP) and material decomposition (least squares) algorithms were selected to compare the spectral performance of the three modalities without non-linear factors such as different iterative reconstruction algorithms. Image noise in the iodine map was used as a figure of merit. To enable a fair comparison of the iodine map noise between the three modalities, spatial resolution (point spread function, PSF) needed to be matched. When scanning in a DS configuration, the dose budget is split between two detectors, reducing the detected counts per pixel and increasing the strength of the signal-dependent filter compared to a single source acquisition. To account for this effect, the PSF for each modality was measured from a 0.05 mm tungsten wire placed in the phantom. Then, a linear filter was applied to the SS images to match the SS PSF to that of DS.

**RESULTS**

The 10% MTF cutoffs were 1.12, 1.13, 1.2, and 1.14 lp per mm for DS-EID, DS-PCD, SS-PCD, and SS-PCD-MTF-matched, respectively. Without accounting for the signal-dependent filter, the noise of SS-PCD with 2 thresholds was 8.8% higher compared to that of DS-EID. However, after matching the MTFs, the noise in the SS-PCD iodine map was 22% lower than that of the DS-EID. The best performing scan mode was DS-PCD, for which the noise was 44.7% lower compared to the DS-EID.

**CONCLUSION**

SS PCD-CT with two thresholds outperforms DS-EID-CT in terms of image noise of basis material images when spatial resolution is matched. DS PCD-CT gives the best performance due to PCD technology and improved spectral separation from the different tube potentials and beam filters.

**CLINICAL RELEVANCE/APPLICATION**

Our findings of improved material decomposition performance due to improved spectral characteristics further enhance the applications of PCD-CT in clinical practice.

## T2-SPPH-6 EVALUATION OF STENT IMAGING USING SUPER-RESOLUTION DEEP LEARNING IMAGE RECONSTRUCTION IN CORONARY CT ANGIOGRAPHY : COMPARATIVE STUDY OF IMAGE RECONSTRUCTIONTECHNOLOGY BY 3 DIFFERENT CT MANUFACTURERS USING PHANTOMS AND INVITRO

Jhii-Hyun Ahn (*Abstract Co-Author*) Nothing to Disclose
Donghee Koh (*Abstract Co-Author*) Nothing to Disclose
Pil-Hyun Jeon, PhD (*Abstract Co-Author*) Nothing to Disclose
Sung-Jin Cha, BS (*Abstract Co-Author*) Nothing to Disclose
Chuluunbaatar Otgonbaatar, MD, MS (*Abstract Co-Author*) Nothing to Disclose
JEON SANG HYUN (*Abstract Co-Author*) Nothing to Disclose
Sung Min Ko, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Coronary computed tomography angiography (CCTA) is a widely used noninvasive imaging tool for diagnosing significant coronary artery diseases. Blooming artifacts, which appears larger than their actual size, can arise from coronary stents, leading to an overestimation of in-stent restenosis and artificial in-stent luminal narrowing. Super-resolution deep learning reconstruction (SR-DLR) has been developed for CT imaging, which is trained with images acquired using commercially available ultra-high resolution CT with small detector elements. We aimed to investigate the effects of image reconstruction methods on the visualization of coronary artery stent in both in vitro and vivo studies.

**METHODS AND MATERIALS**

In vivo, a stent phantom was conducted using CT imaging on three different scanners. Stents were inserted into a plastic tube filled with contrast. Stents of 2.5 mm and 3.5 mm in diameter sized stents were evaluated, and image sharpness was assessed across the three different CT scanner. In the vivo study, Sixty-three patients (mean age, 61±11 years; range, 18-81 years; 40 men) who had undergone coronary CTA between June-October 2022 were

retrospectively included. Image noise, SNR, and CNR were quantified in both proximal and distal segments of the major coronary arteries. Two independent reviewers scored overall image quality, image noise, image sharpness, and myocardial homogeneity. The image was reconstructed with filtered-back projection (FBP), hybrid iterative reconstruction (HIR), deep learning reconstruction (DLR), and SR-DLR. The image noise, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), 10-90% edge rise slope (ERS), and 10-90% edge rise distance (ERD) were performed.

**RESULTS**

In vivo, the image sharpness was resulted in higher for DLR and SR-DLR in each differet scanner compared with FBP and IR. In vitro, Image noise in HU was significantly lower ($p<0.001$) for the SR-DLR (11.2±2.0) compared to those associated with other image reconstruction methods including FBP (30.5±10.5), hybrid IR (20.0±5.4), and DLR (14.2±2.5) in both proximal and distal segments. SR-DLR significantly improved SNR and CNR in both the proximal and distal segments of the major coronary arteries. Two reviewers graded subjective image quality with SR-DLR higher than other image reconstruction techniques.

**CONCLUSION**

SR-DLR resulted in significantly lower blooming artifact with clear stent lumen and strut, decreased the image noise, increased the SNR and CNR compared with FBP, HIR, and DLR.

**CLINICAL RELEVANCE/APPLICATION**

Coronary CT angiography with DLR resulted in lower blooming artifacts, thereby improving visualization of increased in-stent stenosis and luminal changes.

## T2-SPPH-8 TO EXPLORE THE DISCREPANCY BETWEEN HEAD AND NECK DUAL-ENERGY CTA AND THE PEAK PHASE OF CT BRAIN PERFUSION IN EVALUATING CEREBRAL ARTERY STENOSIS

Zi Tian Tsang, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to evaluate the discrepancy of diagnosing cerebral artery stenosis by analyzing arterial phase images from head and neck dual-energy CT angiography (DECTA) and peak phase images(maximum iodine concentration) from CT brain perfusion(CTP) scans.

**METHODS AND MATERIALS**

Data of 22 patients who underwent brain CT perfusion and head-neck DECTA at our hospital from December 2023 to March 2024 were respectively collected. Monochromatic image at at 68keV(100kVp-like) was reconstructed from head-neck DECTA. All perfusion images and head-neck DECTA were reconstructed with adaptive statistical iterative reconstruction-Veo at 40% strength (40%ASIR-V). Stenosis was evaluated by two radiologists using 68keV image and categorized into four grades: mild (<50%), moderate (50%-70%), severe (71%-99%), and occlusive (100%). Image quality of the peak phase of brain perfusion was assessed on a 5-point Likert scale, focusing on image quality, vessel edges, and vascular opacification versus noise. The inter-rater consistency was also analyzed. Lastly, Standard Deviation(SD) value of temporal muscle was measured in two group of images to assess background image noise.

**RESULTS**

The mean standard deviation (SD) values of DECTA and CTP were 14.60 and 26.70, respectively, with a significant difference between the two groups ($P<0.05$). The study comprised 22 patients, evenly distributed by gender (11 males, 11 females), aged between 37 to 87 years old. The Kruskal-Wallis test indicated no significant differences in vascular stenosis grading among the groups ($Z=0.947$, $P>0.05$). The image quality in the M1 segment of the middle cerebral artery and A4/A5 segments of the anterior cerebral artery met diagnostic requirements for both radiologists (=3 points). The subjective assessment scores from radiologists for these segments were as follows: M1: 4.69±0.55, 4.75±0.53 A4: 3.98±0.65, 4.09±0.76 A5:3.01±1.01;2.61±0.91.(kappa: 0.67, $p<0.05$).

**CONCLUSION**

Despite the substantial difference in background noise between the peak phase of brain CTP and head-neck CTA, there was no significant variance in diagnostic efficacy between the two.

**CLINICAL RELEVANCE/APPLICATION**

This study aimed to compare the diagnostic performance of cerebral artery stenosis between head-neck CTA images and the peak phase of CT brain perfusion. The study sought to determine whether peak phase imaging from CT brain perfusion could potentially aid in diagnosing cerebral artery stenosis for patients who are unable to undergo CTA examination. The findings may have implications for clinical practice.

## T2-SPPH-9 PERFORMANCE EVALUATION OF A DEEP-LEARNING-BASED NOISED REDUCTION METHOD FOR LESION CHARACTERIZATION USING A VIRTUAL IMAGING TRIAL

Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Scott S. Hsieh, PhD (*Abstract Co-Author*) Nothing to Disclose
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Joel G. Fletcher, MD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Pfizer Inc;Research Grant, Takeda Pharmaceutical Company Limited;Consultant, Takeda Pharmaceutical Company Limited;Research Grant, Nextrast, Inc;Consultant, Medtronic plc
Lifeng Yu, PhD (*Abstract Co-Author*) Nothing to Disclose
Hao Gong, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Zhongxing Zhou, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Characterization of malignant and benign lesions is a critically important clinical task. Performance evaluation of deep learning-based image reconstruction and non-linear noise reduction methods (collectively referred to as DLIR) remains challenging for this task. The purpose of this study was to apply a patient-data-based virtual imaging trial to evaluate the performance of a DLIR method for a lesion characterization task.

**METHODS AND MATERIALS**

The patient-data-based virtual imaging trial (VIT) framework recently developed in our group consists of five steps: (1) lesion- and (2) noise-insertion in projection domain to generate images at different lesion and noise conditions; (3) application of DLIR to denoise these images; (4) creation of DLIR-processed patient image ensembles from a large number of noise and lesion realizations; and (5) evaluation of image quality and diagnostic performance using ensemble DLIR images. A DLIR model trained on patient liver images was evaluated using this VIT framework. Cylindrical lesions (5-mm height, 15-mm diameter) with and without spiculated boundaries were inserted into the patient data to mimic malignant and benign lesions, respectively.

Ensembles of projection data were generated by 600 independent noise realizations for each of three dose levels (12.5%, 25%, and 50% of routine dose) and five lesion contrasts (-5, -10, -20, -30, and -50HU) for both round and spiculated lesions. Channelized Hotelling observer (CHO)-based index of detectability (d') was calculated using 600 pairs of images (round and spiculated) at different conditions. Multiple reconstructions were evaluated, including filtered-backprojection (FBP), iterative reconstruction (IR), and the DLIR at 3 strength settings (weak, medium, and strong).

**RESULTS**

Compared to FBP and IR, DLIR improved d' for lesion characterization in all conditions studied. For example, DLIR-Strong improved d' over IR/FBP at -5, -10, -20, and -30HU contrast (at 50% dose): 0.94/0.72/0.68, 1.78/1.36/1.26, 3.19/2.68/2.49, 4.95/4.35/4.10; and for 12.5%, 25%, and 50% dose (at -30 HU): 1.71/1.35/1.26, 2.77/2.32/2.17, 4.95/4.35/4.10. With the decrease of lesion contrast, the improvement of d' by DLIR over FBP and IR decreased.

**CONCLUSION**

Using a patient-data-based virtual imaging trial, DLIR was demonstrated to have less performance improvement at lower lesion contrast, indicating a diminishing radiation dose reduction potential for low-contrast lesion characterization tasks.

**CLINICAL RELEVANCE/APPLICATION**

The reduced performance improvement by DLIR for lesion characterization at lower lesion contrast implies less dose reduction potential for challenging lesion characterization tasks.

## T2-SPRO-1 ENHANCING LUNG CANCER TUMOR DELINEATION WITH CLOUD-BASED AI-DRIVEN CT IMAGE SEGMENTATION

Yaqi Miao, MSc, BA (*Presenter*) Nothing to Disclose

### PURPOSE

This study focuses on improving lung cancer tumor delineation using advanced artificial intelligence techniques. Previous works have been experimented on public datasets with restricted diversity and scope. Integrating a comprehensive dataset from two major institutions, this study introduces an optimized 3D U-Net architecture designed to automate tumor segmentation more efficiently, overcoming challenges related to processing times and memory demands.

### METHODS AND MATERIALS

The dataset used in this research was sourced from 1042 CT scans collected at two institutions. The study trains a 3D DynUnet model leveraging AWS cloud A100 GPU instances with 5-fold cross-validation for training. Inputs to the model are lung CT scan images, and outputs are segmented tumor regions. The architecture is designed to fully take advantage of available GPU memory and the distributed computing infrastructures. The model employs data augmentation and preprocessing to manage memory consumption and optimize training efficiency. Two inference modes and various postprocessing approaches were investigated for the optimal performance in clinical settings.

### RESULTS

The optimized 3D DynUnet model achieved an averaged testing Dice Similarity Coefficient (DSC) of 0.7149 within the ROI patch and a DSC of 0.6052 for the whole image, significantly outperforming existing models. Moreover, this new model demonstrated enhanced spatial consistency and the ability to detect multiple tumors when only one is initially marked. The inference of the model requires minimal resources and can be executed on CPU with a standard lab computer within a practical amount of time. This indicates a notable improvement in the accuracy and efficiency of tumor segmentation over traditional methods.

### CONCLUSION

The results demonstrated the effectiveness of 3D modeling in achieving accurate lung tumor segmentation. The implementation of data augmentation and parallel processing effectively tackled the challenges of memory limitations and processing speed. As a result, the success of the 3D DynUnet model represents a significant advancement in lung cancer treatment planning, suggesting a promising direction for future research in medical imaging AI.

### CLINICAL RELEVANCE/APPLICATION

This study's advancements in tumor delineation have significant implications in clinical settings. The increased accuracy in tumor segmentation enables more precisely targeted radiotherapy treatments, potentially improving patient outcomes. Additionally, the model's capability to identify multiple tumors when only one is initially detected supports earlier and more comprehensive treatment interventions.

## T2-SPVA-1 A CONTROLLED STUDY OF 5.0T MR VASCULAR IMAGING AND CT ANGIOGRAPHY FOR THE EVALUATION OF MMD BYPASS VESSELS

Tingting Zhou (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze and compare 5.0T ultra-high field MR three-dimensional time leap vascular imaging (5.0T 3D TOF MRA) and CT vascular imaging (CTA) in the evaluation of Mpatency.

### METHODS AND MATERIALS

A total of 25 patients diagnosed with MMD with intracranial and external revascularization in the First Affiliated Hospital of USTC of China from May 2023 to February 2024 were collected from the data of 13 males and 12 females, aged 15 to 42 years, average (31 ± 5) years.25 patients included 21 lateral superficial temporal artery-middle cerebral artery bypass + temporal muscle application (STA-MCA + EDMS) and 4 lateral brain-meningeal-arterial-temporotemporal muscle application (EDAMS). All patients underwent cranial 5.0T 3D TOF MRA and CTA examination within 1 week after surgery, which were divided into 5.0T 3D TOF MRA and CTA groups.The bypass vessels were divided into three sections, including extracranial segment (ECS segment), perforating skull segment (TS segment), and intracranial segment (ICS segment). The image score of bypass vessel patency was performed by the 5-point scoring method, including 0 to 4 points.4 is excellent, indicating that the bypass vessels are smooth with no stenosis; 3 are good, indicating visible contrast filling and no obvious stenosis; 2 are good, indicating mild stenosis; 1 is poor, which means that although the walking area of bypass vessel is visible, there is severe stenosis; 0 is poor, indicating that the bypass vessels are unclear. Comparative analysis of the two examination methods was performed by using the t-test.

### RESULTS

5.0T 3D TOF MRA The mean score of extracranial segment (ECS segment) compared with CTA, P> 0.05. t test. 5.0T 3D TOF MRA The mean score for bypass vessel puncture segment (TS segment) and intracranial segment (ICS segment) were higher than CTA, P <0.05 by t-test. Memean score of 5.0T 3D TOF MRA for bypass vessel was higher than CTA, P <0.05 by t-test.

### CONCLUSION

5.0T ultra high field strength 3D TOF MRA showed significantly better than CTA, especially for intracranial and cranating segments.5.0T 3D TOF MRA is a non-invasive examination technology, and no radiation, no contrast allergy and other hazards, especially suitable for low-age patients and patients who need long-term follow-up.

### CLINICAL RELEVANCE/APPLICATION

3D TOF MRA is a safe and noninvasive examination technology, which does not require the application of injection contrast agents, does not exist ionizing radiation, is cheaper than CTA, and patients feel better, especially suitable for younger patients and patients who need long-term follow-up.

## T2-SPVA-2 COMPARISON OF AORTIC HEMODYNAMICS BEFORE AND AFTER ROSS PROCEDURE BY 4D FLOW MRI

### PURPOSE

To compare aortic flow patterns in patients with congenital aortic valve disease before and after Ross procedure by 4D flow MRI.

### METHODS AND MATERIALS

12 patients (median age 35.5 years; IQR 33.0-44.5; 4 female) with either severe aortic valve stenosis or severe regurgitation were enrolled in a prospective monocentric study and underwent 4D flow MRI at 3 T before and after Ross procedure. Analysis planes were placed at the level of sinotubular junction (STJ), mid-ascending aorta (midAAo) and proximal arch (proxAA). Aortic regurgitant fraction (%) was estimated. The degree of helical and

vortical flow was graded on a 3-point scale. Relative flow displacement (FD) as a measure of flow eccentricity and wall shear stress (WSS) were estimated. Pre- and postoperative results were statistically compared using Wilcoxon matched-pairs test.

**RESULTS**

All patients underwent successful Ross procedure with a significant reduction of the aortic regurgitation fraction (38 ± 24 ml vs. 24 ± 19 ml; p = 0.01). The degree of helical flow in the ascending aorta (median pre/post = 2/1; p = 0.01) as well as the descending aorta (median pre/post = 2/0; p = 0.02) decreased significantly postoperatively but showed no significant difference in the aortic arch (median pre/post = 2/0; p = 0.08). The degree of vortical flow decreased significantly in the ascending aorta (median pre/post = 2/1; p = 0.004) and the aortic arch (median pre/post = 2/1; p = 0.01) but showed no significant difference in the descending aorta (median pre/post = 1/0; p = 0.4). FD decreased significantly at all levels: STJ (0.27 ± 0.12 vs. 0.12 ± 0.10; p = 0.003), proxAA (0.36 ± 0.07 vs. 0.25 ± 0.12; p = 0.019) and midAAo (0.35 ± 0.09 vs. 0.24 ± 0.10; p = 0.009). WSS was significantly reduced at midAAo (0.84 ± 0.36 N/m² vs. 0.58 ± 0.19 N/m²; p = 0.04) and proxAA (0.98 ± 0.59 N/m² vs. 0.57 ± 0.14 N/m²; p = 0.02) but showed no significant difference at STJ (0.43 ± 0.22 N/m² vs. 0.46 ± 0.08 N/m²; p = 0.42).

**CONCLUSION**

4D flow MRI-based assessment of aortic hemodynamics after Ross procedure revealed fewer flow alterations, less regurgitation and reduced WSS in the ascending aorta as compared to preoperative aortic hemodynamics, resulting in more physiological flow patterns.

**CLINICAL RELEVANCE/APPLICATION**

In our study 4D flow MRI allows evaluation of the success of the Ross procedure in patients with congenital aortic valve disease and may help to optimize surgical procedures in the future.

## T2-SPVA-3 IDENTIFICATION OF DISTINCT MARFAN PATIENT SUBGROUPS BY CLUSTER ANALYSIS BASED ON AORTIC 4D FLOW MRI AND Z-SCORE

Yskert von Kodolitsch (*Abstract Co-Author*) Nothing to Disclose
Christoph Riedel, MD (*Abstract Co-Author*) Nothing to Disclose
Shuo Zhang, PhD (*Abstract Co-Author*) Employee, Koninklijke Philips NV

Peter Bannas, MD (*Abstract Co-Author*) Nothing to Disclose
Bjoern P. Schoennagel, MD (*Abstract Co-Author*) Co-founder, North Medical GmbH;Stockholder, North Medical GmbH
Alexander Lenz, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Identification of distinct Marfan patient subgroups using aortic 4D flow MRI and Z-scores to categorize different hemodynamic patterns and clinical characteristics through hierarchical cluster analysis.

**METHODS AND MATERIALS**

100 Marfan patients were prospectively included who underwent baseline aortic 4D flow MRI at 3T. Z-scores, degree of helical and vortical flow, wall shear stress (WSS), flow displacement (FD) and peak velocity were determined in the ascending aorta. Sex, age, BMI, antihypertensive medication, and presence of dural ectasia were recorded. Hierarchical cluster analysis was performed using 4D flow MRI-variables and Z-scores as input.

**RESULTS**

Cluster analysis revealed three distinct clusters distinguished by different Z-scores (mean ± SD; cluster 1: 0.4±1.1 vs. cluster 2: 3.1±1.1 vs. cluster 3: 3.6±1.9). These clusters exhibited significant variations in helical (global p=0.003) and vortical (global p<0.001) flow patterns, as well as WSS (0.49±0.11 vs. 0.44±0.12 vs. 0.37±0.09 N/m2, all pairwise ? p<0.037), FD (0.11±0.05 vs. 0.16±0.08 vs. 0.15±0.07, ? cluster 2 to cluster 1 and ? cluster 3 to cluster 1 p<0.009), and peak velocity (76.3±9.0 vs. 60.1±7.3 vs. 56.0±7.8 cm/s, all pairwise ? p<0.04). Patients in cluster 1 and 2 were notably younger compared to those in cluster 3 (32±14 vs. 33±13 vs. 40±15 years, all pairwise ? p<0.0297). Sex, BMI, antihypertensive medication, and presence of dural ectasia did not exhibit significant differences among the three clusters (all global p>0.2).

**CONCLUSION**

Using hierarchical cluster analysis with aortic 4D flow MRI and Z-scores, we identified three subgroups among Marfan patients, each exhibiting distinct hemodynamic profiles and clinical characteristics. Longitudinal follow up is warranted to determine whether our stratification based on 4D flow MRI and Z-scores can predict future aortic dilatation.

**CLINICAL RELEVANCE/APPLICATION**

Utilizing both Z-scores and 4D flow MRI-derived parameters could assist in identifying subgroups among Marfan patients, revealing different stages or phenotypes of aortic disease, thus allowing for tailored management strategies.

## T5A-SPBR-2 ENHANCING BREAST RADIOGRAPHERS' PERFORMANCE IN TOMOSYNTHESIS SCREENING WITH AN AI-BASED AUTOMATED EVALUATION SYSTEM

Ying Guo (*Abstract Co-Author*) Nothing to Disclose
Xuefei Lv (*Abstract Co-Author*) Nothing to Disclose
Fang Fang (*Abstract Co-Author*) Nothing to Disclose
Ellisa 1020 (*Presenter*) Nothing to Disclose

### PURPOSE

To improve breast radiographers' performance by using an AI-based system to automatically evaluate the breast positioning in tomosynthesis screening.

### METHODS AND MATERIALS

2396 images of digital mammography over three consecutive quarters were evaluated according to the standards regulated by the Mammography Quality Standards Act (MQSA) on a four-point-scale (1 = poor, 4 = excellent). Incidence of inadequate positioning, which was defined by AI system as any of the following errors were recorded and compared: incomplete gland coverage, incomplete pectoralis major muscle inclusion, over or insufficient exposure, skin fold, nipple not in the contour line, shoulder overlap shadow, abdominal skin, contralateral breast, and foreign body.The positioning data from the study acquired at the start of the project were used as baseline, while the data obtained over three consecutive quarters were used to compare with the first quarter. The percentage of views rated perfect or good and the percentage of views were used to assess changes in performance.

### RESULTS

For all quarters, the pass rates for CC views were significantly higher than MLO views. CC views achieved 100% pass rates for "abdominal skin included" and "pectoralis muscle not satisfactorily displayed." Compared to the second quarter, the positioning pass rates for CC views significantly improved in the third (OR=2.1, 95%CI:1.8-2.5) and fourth quarters (OR=2.5, 95%CI:2.1-3.0). MLO views exhibited a similar trend (third quarter OR=1.9, 95%CI:1.6-2.3; fourth quarter OR=2.7, 95%CI:2.2-3.3). There were significant differences in image score distributions across the three quarters ($P<0.001$), with the fourth quarter scoring significantly higher than the second ($P<0.001$). Within each quarter, CC view scores were significantly higher than MLO views (all $P<0.001$). Images score increases of 2.6 ($P<0.001$) and 3.5 ($P<0.001$) in the third and fourth quarters, respectively, compared to the second. CC view scores were 2.1 points higher ($P<0.001$) than MLO views.

### CONCLUSION

In all quarters, the positioning pass rates and image quality scores for CC views were significantly better than MLO views, potentially due to the higher technical difficulty of MLO views. Over time, the radiographer's positioning pass rates and image quality scores improved significantly for both CC and MLO views, reflecting the substantial improvement brought about by accumulated experience.

### CLINICAL RELEVANCE/APPLICATION

this study validates the application value of AI-assisted assessment in monitoring and improving mammographic image quality, providing strong evidence for promoting diagnostic quality, guiding continuous technologist education, and ensuring the overall efficacy of breast cancer screening.

## T5A-SPBR-3 ASSISTING RADIOLOGISTS FOR ACCURATE BREAST ULTRASOUND LESION DETECTION IN SCREENING USING DEEP LEARNING

Nan Zhang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to develop a breast lesion detection model for dynamic ultrasound videos using deep learning to assist physicians in accurately identifying lesions.

### METHODS AND MATERIALS

Our dataset included dynamic ultrasound videos from 2,141 patients. We developed a dynamic video detection model for breast lesion diagnosis. The model’s performance was evaluated using sensitivity rates and mean Average Precision (mAP). Additionally, to gauge the model’s impact on clinical diagnosis, a reader study with one senior and two junior physicians assessed the model’s diagnostic aid.

**RESULTS**

The model achieved a sensitivity rate of 98.4% for lesion detection and a frame-level mAP50 of 89.9%, indicative of its effectiveness. In the reader study, the model helped increase the sensitivity rates of a senior physician and two junior physicians from 87.27%, 78.51%, and 76.32% to 95.75%, 92.85%, and 90.71%, respectively, suggesting the model's potential in assisting physicians in breast lesion detection.

**CONCLUSION**

The deep learning model demonstrated high accuracy and sensitivity for breast lesion detection.

**CLINICAL RELEVANCE/APPLICATION**

It has the potential to support screening efforts and augment physicians' diagnostic skills. The integration of AI into diagnostics could promote earlier breast cancer detection and improve patient care.

Yan Chen, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Artificial intelligence (AI) has the potential to revolutionize breast cancer screening programs. In 2023, the RSNA hosted a Screening Mammography Breast Cancer Detection AI Challenge, where participants were invited to develop AI models to interpret mammograms. Here we assess the performance of the Top 7 ranked models and compare their performance to a commercially available AI model.

**METHODS AND MATERIALS**

RSNA Challenge teams were provided a training-set of 11,913 2-view 2D digital mammogram (2DDM) screening cases, from two institutions (US and Australia) for AI training. Models were tested using an independent test-set of 4,811 2DDM cases from the same source. In both sets, cancer cases were pathology proven and non-cancer cases had at least 1-year of normal follow-up. Performance of the Top 7 ranked challenge AI models (as per pF1 score in the RSNA Challenge https://www.kaggle.com/competitions/rsna-breast-cancer-detection/leaderboard) and ensemble models created from these is evaluated. A commercially available AI model for assessment of 2D screening mammograms also analyzed the cases from the independent test-set. The performance of the Top 7 ranked models, and combined ensemble models, was compared to the performance of the commercial AI model.

**RESULTS**

Across the Top 7 ranked algorithms, the mean recall rate (RR) was 1.6%, sensitivity 47.4%, specificity 99.4% and PPV 61.2%. Combining the Top 3 and Top 7 ranked algorithms into ensemble models demonstrated an increased RR (2.4% and 3.0%), while achieving a marked improvement in sensitivity (60.6% and 63.7%), with limited effect on specificity (98.8% and 98.2%, respectively). At the manufacturers' recommended recall threshold, the commercial AI model demonstrated a much higher RR of 8.3% compared to all individual top ranked models from the Challenge and their ensembles. However, the sensitivity of the commercial product was much greater at 75.6%, with a specificity of 93.0%.

**CONCLUSION**

The commercially available AI algorithm outperformed the Top ranked challenge algorithms and ensemble models in terms of sensitivity, equating to an additional 23 cancers detected compared to the Top 7 ensemble model.

**CLINICAL RELEVANCE/APPLICATION**

Cancer detection AI challenges can be a useful starting point for algorithm development, but products require more extensive testing and training before their performance is clinically or commercially useful.

## T5A-SPBR-6 COMPARING BREAST CANCER DETECTION CAPABILITIES OF MACHINE LEARNING MODELS TRAINED ON DCE PERFUSION VERSUS SINGLE EARLY POSTCONTRAST MR IMAGES

Sangam G. Kanekar, MD (*Abstract Co-Author*) Nothing to Disclose
Alison L. Chetlen, DO (*Abstract Co-Author*) Nothing to Disclose
Scott N. Hwang, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Michelle Le, BEng (*Abstract Co-Author*) Nothing to Disclose
Gavin Jones, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Machine Learning (ML) classification algorithms may play a role in the detection and diagnosis of cancer on MRI scans. Dynamic contrast-enhanced perfusion MRI (DCE-MRI) is a highly sensitive technique for breast cancer detection. Temporal enhancement data from DCE-MRI passes can be merged into the different channels of the red, green, and blue components of an RGB color image. Overlaying multiple passes of DCE-MR time points into a single RGB image may serve to augment the amount of data available to ML algorithms to aid in cancer detection. The aim of this study is to investigate whether ML models benefit from this incorporation of DCE data into training images by comparing them with models trained with single postcontrast images.

### METHODS AND MATERIALS

Using Microsoft Custom Vision, a commercially available ML tool, two types of classification models to detect breast cancer were created using a public dataset of 922 radiologist-annotated malignancies localized on DCE-MRI. Identical sets of images were used for training: one single postcontrast set and one DCE set. The set of DCE images was created by taking a single pre-contrast, early-postcontrast, and late-postcontrast slice and designating each pass to a different channel of an RGB image. Both models were verified with 5-fold cross-validation. Following validation, the performance of the models trained on single postcontrast and DCE images was compared using ROC curves.

### RESULTS

The AUCs for the single postcontrast and DCE models were 0.934 ± 0.010 and 0.968 ± 0.004 respectively (p-value=<0.001). At a probability threshold of 0.5, both models had comparable sensitivities of 0.913 ± 0.015 (single postcontrast) and 0.922 ± 0.009 (DCE). The DCE model had statistically significant improvement in both specificity (0.752 ± 0.064 vs 0.893 ± 0.037, p-value=0.005) and accuracy (0.833 ± 0.033 vs 0.907 ± 0.016, p-value=0.004).

### CONCLUSION

This study demonstrates that there is a benefit to utilizing DCE when creating ML models for the detection of invasive malignancies in breast cancer patients. Ultimately, both the models generated from single postcontrast and DCE-MR images function successfully as breast cancer screening tools. The use of DCE images did show improvement when compared to the model based on traditional grayscale MR images.

### CLINICAL RELEVANCE/APPLICATION

AI and ML models may serve as an adjunct to traditional evaluation methods for clinically detecting breast malignancies. Including perfusion imaging may also be helpful for assessing pathologies at other anatomical sites.

## T5A-SPBR-7 UNSUPERVISED MAMMOGRAM ANOMALY DETECTION WITH TRANSFORMER

Bhavik N. Patel, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Zhemin Zhang (*Abstract Co-Author*) Nothing to Disclose
Imon Banerjee, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Out-of-distribution (OOD) detection plays an important role in mammograms screening. For downstream models the OOD samples would have negative impact on accuracy. However, due to the limited number of labeled OOD samples, unsupervised learning is preferred. The existing methods for unsupervised OOD detection in medical imaging are predominately CNN based. Also few conduct research on mammograms. Inspired by hybrid architecture composed of CNN and transformer in other medical tasks, we are motivated to apply the hybrid architecture to mammogram OOD detection in unsupervised learning methods.

### METHODS AND MATERIALS

We propose an unsupervised anomaly detection model based on CNN and transformer architecture by incorporating reconstruction loss and discriminator loss trained with self-supervised fashion as anomaly score. A discriminator branch is added with six image augmentations to help the model to understand the in-distribution (ID) images. The image with augmentation is labeled 1, otherwise is labeled 0. The discriminator branch takes the latent space after the transformer to MLP to get predicted label score. During training, reconstruction loss updates the entire model. Discriminator loss between actual label and predicted value updates CNN encoder and transformer. At inference time, reconstruction error and discriminator predicted value are used together to get an anomaly score.

### RESULTS

The dataset is from RSNA mammography screening, and manually reviewed to remove OOD samples in the training. 11,722 samples are used for training. The internal test set includes 1,227 samples, including 302 ID, and 925 OOD samples. The external test set is from Mayo Clinic, with 77 ID samples, and 178 OOD samples. The hybrid model with the discriminator is compared against CVAD, f-AnoGAN, VQ-VAE, and hybrid architecture without discriminator. The hybrid model with the AUC score of 0.934 for internal evaluation outperforming the highest 0.929 from baseline f-AnoGAN. However, the f-AnoGAN AUC drop to 0.672 in external. The hybrid model with discriminator branch has AUC score of 0.73, which maintains the best performance for external evaluation.

### CONCLUSION

Our contribution includes 1) to the best of our knowledge, this is the first extensive study of experiments of various existing unsupervised anomaly detection techniques to mammograms. 2) the proposed hybrid model with discriminator has better performance to identify different categories of OOD samples both in internal and external evaluations.

### CLINICAL RELEVANCE/APPLICATION

The proposed method has better performance to detect OOD samples on internal and external performance across the other existing models, that to improve the downstream diagnosis tasks.

## T5A-SPBR-8 BMI PREDICTION FROM MAMMOGRAPHY IMAGES AND ITS IMPLICATIONS FOR BREAST CANCER RISK

Frank Li (*Abstract Co-Author*) Nothing to Disclose
Seyed Mohammadreza Chavoshi, MD (*Abstract Co-Author*) Nothing to Disclose
Bardia Khosravi, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Hari Trivedi, MD (*Abstract Co-Author*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*) Consultant, Softbrew Digital LTD
Theodorus Dapamede, MD, PhD (*Presenter*) Intern, MARS BioImaging Ltd

### PURPOSE

Traditional breast cancer risk models often underperform, especially in minority populations. Recent advances like the image-based deep learning models Mirai and Asymirai outperform these traditional models but lack explainability of the image features influencing their predictions. Body mass index (BMI) is a well-known, explainable risk factor for breast cancer, affecting pre- and post-menopausal women differently. This study aims to predict BMI from mammograms, potentially shedding light on explainable features within deep-learning-based breast cancer risk prediction models.

### METHODS AND MATERIALS

We acquired a dataset of 11,874 patients who had undergone 4-view screening mammography with corresponding BMI measurements from 2012 to 2021. Mammograms were labeled with the BMI at the time of the study and divided into 80/20 training and testing splits at the patient level. Bilateral images were created by stitching left and right images. We trained six ConvNext-based models for different views (LMLO, LCC, RMLO, RCC, BMLO, BCC) and assessed their performance using MAE and R^2 metrics, incorporating GradCAM++ for explainability. We conducted subgroup analyses based on race, sex, age, marital status, tissue density, and BIRADS score, and additionally predicted BIRADS and pathological severity from biopsy using the pre-logit model layer.

### RESULTS

All 6 models performed similarly, with mean R2 of 0.76 (SD: 0.03) and mean MAE of 2.5 kg/m2 (SD: 0.14 kg/m2). The RMLO model outperformed others with R2 of 0.80, suggesting sufficient BMI encoding in unilateral mammograms. Subgroup analysis on race revealed higher model performance in White patients compared to Black patients across all models, notably RMLO (R2=0.81 vs. R2=0.76, respectively). Model performance was lower in postmenopausal-age women (R2=0.70 vs. R2=0.76, respectively). BIRADS Breast Density C and BIRADS score 1 yielded the highest performance with R2=0.67 - 0.69 and R2=0.74, respectively. Finally, pre-logit prediction showed signal in predicting BIRADS scores with AUROC= 0.61 - 0.74.

### CONCLUSION

DL models demonstrate the ability to predict BMI, a risk factor in breast cancer, from mammography exams with acceptable performance. Models trained for BMI prediction were also able to predict BIRADS scores by a classification head on the last layer. This demonstrates common underlying signals that may contribute to performance of DL breast cancer risk prediction models.

### CLINICAL RELEVANCE/APPLICATION

As image based breast cancer DL models are deployed clinically, evaluation of explainability and confounders is critical to guarantee model robustness and equitable performance across groups, as the complexity and “black box” nature of these models continues to increase.

## T5A-SPBR-9 DEEP LEARNING MAMMOGRAPHY-BASED AGE PREDICTION: INSIGHTS INTO MODEL PERFORMANCE AND DEMOGRAPHIC DISPARITIES

Seyed Mohammadreza Chavoshi, MD (*Abstract Co-Author*) Nothing to Disclose
Bardia Khosravi, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Frank Li (*Abstract Co-Author*) Nothing to Disclose
Hari Trivedi, MD (*Abstract Co-Author*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*) Consultant, Softbrew Digital LTD
Theodorus Dapamede, MD, PhD (*Presenter*) Intern, MARS BioImaging Ltd

### PURPOSE

To develop and evaluate deep learning models for age prediction using bilateral and unilateral mammograms and to investigate model performance across various demographic subgroups.

### METHODS AND MATERIALS

A dataset of 84,968 mammograms from the EMBED dataset (71,816 training; 13,152 testing) was used. The mean age was 57.0 years for both sets. ConvNext-base CNN and DenseNet-121 models were trained on resized (512x512) and padded images to predict age using unilateral (left, right) and bilateral mammograms. Subgroup analyses were performed on race, marital status, tissue density, and BI-RADS. The penultimate model features were used to predict these demographic factors to see if these are considered by the model when predicting patients’ age.

### RESULTS

Bilateral mammograms yielded better age prediction (ConvNext: $R^2$=0.73, MAE=4.79; DenseNet: $R^2$=0.70, MAE=5.09) compared to unilateral (ConvNext: $R^2$=0.69, MAE=5.04; DenseNet: $R^2$=0.68, MAE=5.18). Subgroup analysis revealed lower performance for African-Americans ($R^2$=0.69) compared to Caucasians ($R^2$=0.76). The model performed best on married patients ($R^2$=0.73) and those with BI-RADS 1 ($R^2$=0.74) and tissue density type C ($R^2$=0.74). The penultimate model features predicted race and density with AUCs >0.90, except for density type B (AUC=0.86).

### CONCLUSION

Deep learning models can predict age from mammograms with high accuracy, and bilateral imaging yields superior results compared to unilateral. However, the models exhibit demographic disparities, with lower performance in African-American and non-married patients. Importantly, the penultimate features of the age prediction model can predict sensitive demographic information such as race and breast density with high AUCs, indicating that the model considers these factors during age prediction. This finding is alarming as it suggests potential bias in the model's predictions. Furthermore, the presence of pathology acts as a confounder, decreasing the model's performance in age prediction.

### CLINICAL RELEVANCE/APPLICATION

Age prediction from mammograms using deep learning has potential applications in identifying patients with accelerated aging or increased breast cancer risk, which could inform personalized screening strategies and risk assessment. However, the demographic disparities in model performance and the model's ability to predict sensitive patient information raise significant concerns about the fairness and transparency of these algorithms. These findings underscore the need for diverse training data, rigorous bias evaluation, and further investigation into the clinical implications of demographic differences in model performance.

## T5A-SPCA-1 THE ASSOCIATION BETWEEN RADIOMIC PHENOTYPE OF PERI-CORONARY ADIPOSE TISSUE AND ATRIAL FIBRILLATION

Wu Jingping (*Presenter*) Nothing to Disclose

### PURPOSE

Epicardial adipose tissue (EAT) contribute to atrial fibrillation (AF). We sought to explore the role of FAI (fat attention index), volume, fat radiomic profile (FRP) from peri-coronary artery adipose tissue (PCAT) on coronary computed tomography angiography (CCTA) in determining the presence of AF and differentiating AF types.

### METHODS AND MATERIALS

This study enrolled 300 patients underwent CCTA retrospectively and divided them into AF (n=137) and non-AF groups (n=163). The imaging parameters of FAI, volume and FRP were excavated and measured after PCAT segmentation. Every coronary artery extracted 853 radiomics and a total of 2559 radiomics were collected. Significant and relevant FRP was screened by random forest algorithm based on machine learning, and then compared three models of VF (FAI and volume), FRP and FRPC (FRP and clinical factors). Among AF individuals, the FRP and FRPC scores of persistent AF (PerAF, n=44) and paroxysmal AF (PAF, n=93) were compared with boxplot.

### RESULTS

In the test cohort, FRP score performed excellent distinctive ability to identify AF with an AUC of 0.89 compared with the model enrolling FAI and volume (AUC = 0.83), and FRPC model showed improved AUC of 0.98 combining clinical factors. Among AF types, FPR and FRPC scores are significantly higher in the PerAF than PAF patients ($p < 0.001$). And twenty most contributive features were selected in identifying AF.

### CONCLUSION

Textural radiomic features derived from PCAT on coronary CTA detect micro-pathophysiological information associated with AF, which may help identify and differentiate AF and provide a hopeful imaging target.

### CLINICAL RELEVANCE/APPLICATION

l This study mainly studied the association between peri-coronary arteries fat and atrial fibrillation.l The analysis of epicardial tissue around coronary arteries help identify and differentiate atrial fibrillation and its types. l Fat radiomic profiles derived from peri-coronary arteries fat could provide non-invasive tool for atrial fibrillation.

### PURPOSE

Positive remodeling in coronary atheroma is a precursor to macroscopic calcifications. This study evaluates the hypothesis that larger coronary artery cross-sectional area (CSA) in early adulthood predicts a greater incidence of subclinical coronary artery disease (CAD), as indicated by CT coronary artery

calcium (CAC) scores.

**METHODS AND MATERIALS**

The study participants were part of The Coronary Artery Risk Development in Young Adults (CARDIA) Study, a community-based study with initial recruitment in 1985-86. We conducted a prospective assessment of the CSA at the proximal left anterior descending artery (LAD-CSA) during the 2010-11 exam using non-contrast, ECG-gated CT. This report is a subset of 474 participants (315 females, 176 Black) who had CAC scores of zero at the 2010-11 exam and participated in the chest CT exams in 2020-22. The chest CT exams were analyzed using a deep-learning algorithm with additional expert review for the presence and amount of CAC. Logistic regression models, adjusted for demographic and clinical variables, evaluated the association between baseline LAD-CSA and incident CAC.

**RESULTS**

The mean participant age at baseline was 49.8 years (SD 3.6), BMI was 29.3 kg/m2 (SD 6.9), and LAD-CSA was 18.3 mm2 (SD 6.0). During the 10-year interval, 33.1% of participants developed any CAC. Each standard deviation increase in LAD-CSA was associated with 1.33 times (95% CI, 1.05-1.70; p=0.019) the odds of incident CAC after adjusting for study field center, race, sex, age, smoking, alcohol intake, physical activity, BMI, education, blood pressure, diabetes, total cholesterol, HDL cholesterol, C-reactive protein, and cholesterol and hypertension treatment.

**CONCLUSION**

Larger LAD-CSA in middle-aged adults free from CAC is associated with increased risk of developing subclinical CAD over ten years. These findings suggest that coronary artery remodeling, as measured by LAD-CSA, could serve as a non-invasive imaging biomarker to stratify CAD risk earlier in life and enhance the value of the CT CAC exam.

**CLINICAL RELEVANCE/APPLICATION**

The onset of coronary artery calcification (CAC) occurs at varying ages, impacting the timing, approach, and cost of strategies for cardiovascular disease prevention. LAD-CSA, as a marker of coronary remodeling, predicts development of CAC and subclinical CAD 10 years later, among those individuals negative for CAC, providing an enhanced approach for CAD risk management in middle-aged adults.

## T5A-SPCA-2 PROPOSED CT PERFUSION PROTOCOL: SUB-MILLISIEVERT APPROACH WITH FOUR-DIMENSIONAL SIMILARITY FILTER

Yusuke Kobayashi (*Abstract Co-Author*) Nothing to Disclose
Teruhito Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Takaaki Hosokawa (*Abstract Co-Author*) Nothing to Disclose
Yuta Yamamoto, MD (*Abstract Co-Author*) Nothing to Disclose
Yuki Tanabe (*Abstract Co-Author*) Nothing to Disclose
Tomoro Morikawa, MD (*Abstract Co-Author*) Nothing to Disclose
Kazuki Yoshida, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Two computed tomography perfusion (CTP) protocols are useful for diagnosing myocardial ischemia: dynamic CTP (multiple heartbeats of about 30 s) and static CTP (single-heartbeat). However, CTP leads to radiation exposure (particularly in dynamic CTP), has difficulty in capturing the optimal scan timing (static CTP), and shows low contrast compared with that of magnetic resonance imaging. A four-dimensional similarity filter (4D-SF) was developed using a similarity algorithm to reduce noise. At least four CTP images were required for proper operation. We analyzed if using a 4DSF would improve image quality and enable use of a new CTP protocol (named multi-static CTP (MS-CTP)) that reduces radiation dose compared with dynamic CTP with optimum timing for imaging in patients with obstructive coronary artery disease (CAD).

**METHODS AND MATERIALS**

Patients (n=28) who underwent dynamic myocardial CTP before invasive coronary CT were retrospectively included. Obstructive CAD was defined as the presence of severe (=70%) or moderate (50-69%) lesions with a fractional flow reserve of =0.8. Three CTP datasets (dynamic CTP, single-shot static CTP (SS-CTP), and MS-CTP) were reconstructed from dynamic CTP data. Dynamic CTP was reconstructed using iterative reconstruction (IR) and 4D-SF, and then the SS-CTP (IR alone) was cropped from dynamic CTP according to SCCT expert consensus. MS-CTP was obtained from five phases of CTP scanning (IR and 4D-SF).For quantitative image assessment, the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of SS-CTP and MS-CTP were compared. The diagnostic accuracy of MS-CTP (visual assessment) was compared with that of SS-CTP (visual assessment) and mean myocardial blood flow derived from dynamic CTP. The probability of capturing the optimum scan timing was compared between MS-CTP and SS-CTP.

**RESULTS**

The SNR and CNR in MS-CTP images (IR and 4D-SF) were significantly higher than those in SS-CTP (IR alone) (median SNR: 9.7 vs. 6.1; median CNR: 24.9 vs. 16.2, respectively; $p < 0.05$). Sensitivity and specificity were 83% and 86% for MS-CTP, 56% and 88% for SS-CTP, and 59% and 91% for dynamic CTP, respectively. MS-CTP showed the highest sensitivity ($p < 0.05$). MS-CTP had a higher probability of achieving optimal scan timing than did SS-CTP (96.4 vs. 7.1%; $p < 0.01$) and lower radiation dose compared with that of dynamic CTP (0.96 vs. 4.13 mSv; $p < 0.01$).

**CONCLUSION**

The MS-CTP protocol improved the image quality and probability of capturing the optimal scan timing compared with SS-CTP, with significantly higher sensitivity for obstructive CAD compared with dynamic those of CTP and SS-CTP.

**CLINICAL RELEVANCE/APPLICATION**

The MS-CTP protocol may reduce radiation exposure and increase CTP's clinical value in managing ischemic heart disease.

## T5A-SPCA-3 ELECTRICAL AND ANATOMICAL LEFT VENTRICULAR AXES IN PATIENTS UNDERGOING TAVR EVALUATION: INFLUENCE OF BASELINE CHARACTERISTICS, FUNCTIONAL AND STRUCTURAL PARAMETERS, AND ECG APPEARANCE

Mohamed Abdel-Wahab (*Abstract Co-Author*) Nothing to Disclose
Matthias Gutberlet, MD, PhD (*Abstract Co-Author*) Speaker, Siemens AG;Speaker, Koninklijke Philips NV;Speaker, Bayer AG;Speaker, Bracco Group;Author, Thieme Medical Publishers, Inc
Christian Krieghoff, MD (*Abstract Co-Author*) Proctor, Edwards Lifesciences CorporationSpeaker, Bracco Group
Florian Fahr (*Abstract Co-Author*) Nothing to Disclose
Patrick Seitz (*Abstract Co-Author*) Nothing to Disclose
Robin F. Gohmann, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

In this retrospective study, we compare the electrical axis to the anatomical left ventricular (LV) axis and determine the influence of base line characteristics, functional and structural parameters and ECG appearance.

**METHODS AND MATERIALS**

Overall, 1675 consecutive patients examined with CT before transcatheter aortic valve replacement (TAVR) were screened. For 981 patients, an electronically stored pre-interventional ECG was available and interpretable. ECGs were grouped into normal (n=301) and abnormal ECGs (n=680). Whenever possible, further ECG sub-characterization and subgroup analysis for hypertrophy were performed. Anatomical LV axis was measured on ECG-synchronized CT at end diastole (reconstruction at 70% of RR interval) perpendicular to the patients' long axis.

**RESULTS**

Mean electrical axis (55±15°, 0.3±57°, p<0.001) and proportion of female gender (178 [59%], 291 [43%], p<0.001) differed significantly between patients with normal and abnormal ECGs. No differences in anatomical or functional parameters were present. There was a weak correlation between the axes in normal ECGs ($R^2$=0.033, p=0.002), which was absent in the group and subgroups with abnormal ECGs. The subgroup with no hypertrophy and normal ECG showed a strong correlation ($R^2$=0.409, p<0.001). No correlation between LV mass and difference between electrical and anatomical axis was observed.

**CONCLUSION**

Electrical and anatomical LV axis seem to be connected in patients being evaluated for TAVR with normal ECGs. This correlation was weakened by conduction distortions caused by LV hypertrophy, frequently observed in patients before TAVR.

**CLINICAL RELEVANCE/APPLICATION**

The electrical frontal axis is a routine parameter in ECG interpretation. It has been reported to correlate with the anatomical LV axis, but the literature is conflicting.

## T5A-SPCA-4 MYOCARDIAL STRAIN COMBINED WITH CLINICAL RISK FACTORS IN THE PREDICTION OF IN-HOSPITAL HEART FAILURE AMONG PATIENTS WITH ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION

Lei Xu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jianlin Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Hui Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Hao Woo (*Abstract Co-Author*) Nothing to Disclose
Dong Yang, BMedSc, MMEd (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the predictive value of myocardial strain derived from cardiac magnetic resonance (CMR) combined with clinical indicators for in-hospital heart failure in STEMI patients.

**METHODS AND MATERIALS**

In all, 139 STEMI patients were included, with 28 in the heart failure group and 111 in the non-heart failure group, and clinical and laboratory data were collected. Left ventricular (LV) global radial strain (GRS), global longitudinal strain (GLS), global circumferential strain (GCS), left ventricular ejection fraction (LVEF), stroke volume (SV), and infarct size (IS) were assessed by CMR.

**RESULTS**

The heart failure group had worse GRS, GLS, GCS, LVEF, SV, larger IS , longer symptom to balloon time (SBT) and higher levels of high-sensitivity C-reactive protein (hs-CRP) and neutrophil percentage (N%) than the non-heart failure group (P<0.05). There was a strong correlation between GRS and LVEF (r=0.741, P<0.001). After adjustment for CMR and clinical risk factors, GRS<15.6%, LVEF<37.7%, symptom to balloon time (SBT)<350 min, hs-CRP>11.45 mg/L, and N%>74% were independently associated with heart failure. CMR model (GRS<15.6%+LVEF<37.7%) and clinical model (SBT<350 min+hs-CRP>11.45 mg/L+N%>74%) were associated with a lower diagnostic accuracy for predicting in-hospital heart failure in patients with STEMI than the co-model including CMR and clinical independent risk factors: area under the curve (AUC) for CMR model=0.759 (95% confidence interval[CI]=0.679-0.827; P<0.001), AUC for clinical model=0.824(95%CI=0.750-0.883; P<0.001), and AUC for CMR and clinical co-model =0.918(95%CI=0.859-0.957; P<0.001).

**CONCLUSION**

GRS combined with clinical risk factors, especially for LVEF, SBT, hs-CRP, and N% maybe an effectively predictor for in-hospital heart failure in patients with STEMI, and may provide new evidence for early prognosis assessment.

**CLINICAL RELEVANCE/APPLICATION**

Recent decades have witnessed continuous advancements in medical technology, enabling clinicians to derive increasingly comprehensive diagnostic evidence from imaging, serum markers, clinical history, among other sources. However, the challenge of timely and efficiently selecting the most relevant clinical indicators from dozens, sometimes hundreds, for diagnosis and treatment has emerged as a significant obstacle in clinical practice. Research on heart failure in patients with STEMI has historically concentrated on understanding the mechanisms underlying heart failure in adverse prognostic events and evaluating the predictive value of associated markers.

## T5A-SPCA-5 LEFT ATRIAL REMODELLING AND FIBROSIS QUANTIFICATION BY LATE ENHANCEMENT COMPUTED TOMOGRAPHY: A PILOT STUDY

Gudrun Feuchtner, MD (*Abstract Co-Author*) Nothing to Disclose
Pietro Giacomo Lacaita, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Left atrial (LA)-fibrosis mapping by CMR provides a roadmap for guidance of LA-catheter ablation. Cardiac CT may be a reasonable alternative. Therefore, the purpose of our pilot study was to evaluate late enhancement fibrosis mapping by CT.

### METHODS AND MATERIALS

Patients with atrial fibrillation (AF) who underwent 128-slice-dual-source high-pitch (3.2) ECG-synchronized CT-Angiography (CTA) prior to LA-catheter ablation between 2015 and 2019 were screened, and those who had both CTA and a late enhancement (LE) CT-scan 7 min after CTA (high-pitch,3.4; 80-100kV) were finally included.1) CTA: Left atrial wall thickness (LAWT) as marker for the severity of LA remodeling was measured at 3 sites along the LA-ridge.2) Late enhancement (LE) was quantified by placing 3 ROI co-axially aligned into LAWT on CTA. LE was defined as enhancement of more than 90HU. Focal and diffus LE, and mixed LE pattern were distinguished. Left atrial wall artifacts were recorded, distinguished subjectively from LE by an experienced observer, and quantified.

### RESULTS

Of 126 patients (age 59.8 years, 35 females (27.8%) screened), 95 with complete CTA and LE scans were finally included. 86/95 (90.5%) had a mean LAWT >1.5mm and 72/95 (75.8%) had LAWT >2mm. Of 86 patients with LAWT >1.5mm, 69 (80.2%) had LE, while the frequency of LE was significantly higher in LAWT >2mm with 68/72 (94.4%) (p= 0.014). Of 58 patients with LE, 42 (72.4%) had focal LE, 11 diffuse (19%) and 5 (8.6%) patients had mixed (focal+diffuse) LE pattern. Mean CT-density (HU) of focal LE was 106.91+/-17.5, and density of diffuse or mixed focal/ diffuse LE 97.6+/-4.4 HU, with a trend toward higher values for focal LE but not significant (p=0.086). LAWT was mean 2.6 +/-1.2 mm (max. 5.7mm), increasing LAWT and LE HU as marker for fibrosis density were mild positively correlated (r=0.257;p=0.031). Left atrial wall artifacts (mainly: beam hardening, streaks, motion) had higher HU (mean 154.11HU) as compared to LE (114.2 HU)(p=0.002;t-test). Mean radiation dose for the LE-CT scan was 0.95 mSv (range, 0.52-1.2mSv).

### CONCLUSION

Left atrial fibrosis mapping by LE-CT is feasible. Late enhancement is found more frequently in LAWT more than 2mm, and LE density correlated with increasing LA-remodelling.

### CLINICAL RELEVANCE/APPLICATION

Left atrial fibrosis mapping by CT may provide a reasonable alternative to CMR, for both the guidance of a more precise LA ablation, and as prognosticator for outcome in patients with atrial fibrillation.

## T5A-SPCA-6 CORRELATION BETWEENLEFT ATRIUM FRACTAL DIMENSION ANDCARDIAC FUNCTION INPATIENTS WITHATRIAL FIBRILLATION

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Mengyuan Jing (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the correlation between left atrial (LA) morphology and left ventricular (LV) systolic function in patients with atrial fibrillation (AF).

### METHODS AND MATERIALS

We studied 1066 patients admitted to our institution between December 2018 and December 2022 for AF. All patients underwent cardiac computed tomography angiography (CTA) and transthoracic echocardiography. LV systolic function was assessed using transthoracic echocardiography. On cardiac CTA images, we measured the LA diameter (LAD) and quantified LA morphology using the fractal dimension (FD). The correlations among LAD, LA FD, and LV systolic function were evaluated.

### RESULTS

Among the enrolled participants, 677 (63.50) were men and 389 (36.50) were women. The average age of all participants was 64.00 (55.00, 71.00) years. Correlation analysis showed that the LAD was negatively associated with the ejection fraction (EF) (r=-0.175, P<0.001) and fractional shortening (FS) (r=-0.172, P<0.001) and positively associated with end-systolic volume (ESV) (r=0.090, P=0.003). LA FD was negatively correlated with the EF (r=-0.092, P=0.003) and FS (r=-0.083, P=0.007) and positively correlated with end-diastolic volume (EDV) (r=0.086, P=0.005) and ESV (r=0.094, P=0.002). The restricted cubic spline (RCS) curves with four knots demonstrated a nonlinear correlation between LA FD and ESV (overall P=0.0459, nonlinear P=0.0345) and EDV (overall P=0.0019, nonlinear P=0.0001) and a linear relationship with EF (P=0.037, P=0.1249). Specifically, EDV and ESV decreased as LA FD increased, then increased and decreased again, whereas EF continuously decreased.

### CONCLUSION

The correlation between LV systolic function and LA FD suggests that LA shape may also be used as a tool to assess LV systolic function in patients with AF.

### CLINICAL RELEVANCE/APPLICATION

In the clinical setting, in addition to the left atrial diameter, the left atrial fractal dimension may also provide clues to altered left ventricular systolic function in this patient population.

## T5A-SPCA-7 CAD-RADS 2.0: AGREEMENT OF METHODS FOR ASSESSMENT OF PLAQUE BURDEN

Felix Heidrich (*Abstract Co-Author*) Nothing to Disclose
Ivan Platzek, MD (*Abstract Co-Author*) Nothing to Disclose
Ralf-Thorsten Hoffmann, MD (*Abstract Co-Author*) Nothing to Disclose
Stefanie Jellinghaus (*Abstract Co-Author*) Nothing to Disclose
Krzysztof Nocon (*Abstract Co-Author*) Nothing to Disclose
Suela Mema (*Presenter*) Nothing to Disclose

### PURPOSE

The current version of the Coronary Artery Disease Reporting and Data System (CAD-RADS 2.0) introduced a plaque burden sub-classification (P), which allows for values between P1 and P4. Three methods for assessing plaque burden are allowed: coronary artery calcium (CAC) testing, segment involvement score (SIS) and visual estimate.The aim of this study was to evaluate the agreement of the methods of coronary plaque burden assessment approved by CAD-RADS 2.0.

### METHODS AND MATERIALS

The RIS radiology information system (RIS) of our hospital was searched for patients who underwent coronary computed tomography angiography (CCTA) in November and December 2023 (including CAC testing).The CCTAs were evaluated by two board-certified radiologists, with 12 and 4 years of experience with CCTA, respectively. The total CAC score was automatically calculated according to the Agatston method. Each reader independently

determined the segment involvement score and the overall visual assessment score P (visual). The summary segment involvement score and visual assessment score were determined in consensus.Based on these findings, P (CAC), P (SIS) and P (visual) were determined for each patient according to CAD-RADS 2.0.The Friedman test was used to assess differences between the P scores determined based on the three different methods. A p value of 0.05 was considered statistically significant.Weighted kappa was used to quantify the agreement between the three different methods.

**RESULTS**

One hundred and thirty two consecutive patients were included in this retrospective study (mean age 62,8 y; 40 f, 82 m; age range 35 - 87 y).Agatston scores varied between 0 and 6351 (mean Agatston score 366,05 ± 968, 62). Segment involvement scores varied between 0 and 13 (median SIS 1).P (CAC) was 0 in 49 cases, 1 in 41 cases, 2 in 8 patients, 3 in 23 cases and 4 in 11 patients.P (SIS) was 0 in 47 cases, 1 in 33 cases, 2 in 22 cases, 3 in 13 patients and 4 in 17 patients.P (visual) was 0 in 47 cases, 1 in 43 patients, 2 in 20 cases, 3 in 9 cases and 4 in 13 patients.The Friedman test detected no significant differences between the three methods (p = 0.204). Weighted Kappa values for method agreement were 0. 743 for agreement between P(CAC) and P(SIS), 0.762 for agreement between P (CAC) and P(visual) and 0.853 for agreement between P(SIS) and P(visual).

**CONCLUSION**

The current study shows a good agreement between the three methods of plaque burden estimation allowed in CAD-RADS 2.0. Based on these results, we do not expect a significant impact of the choice of plaque estimation method on clinical recommendations based on plaque burden.

**CLINICAL RELEVANCE/APPLICATION**

When using CAD-RADS 2.0, the method for plaque burden estimation should be chosen based on local requirements and time available for scan evaluation.

## T5A-SPCA-8 DIAGNOSIS AND PROGNOSIS OF ISCHEMIA WITH NO OBSTRUCTIVE CORONARY ARTERY USING $^{13}$N-AMMONIA POSITRON EMISSION TOMOGRAPHY

Shuji Sakai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akiko Sakai, MD,PhD (*Abstract Co-Author*) Nothing to Disclose

Akihiro Inoue, MD (*Abstract Co-Author*) Nothing to Disclose
Koichiro Kaneko, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Michinobu Nagao, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Ischemia with no obstructive coronary arteries (INOCA) is a condition characterized by angina with no angiographic stenosis. INOCA is associated with an increased risk of cardiovascular morbidity and mortality. Endotypes include coronary spastic angina and coronary microvascular dysfunction, with both often coexisting. Comprehensive coronary artery function testing by invasive catheterization is needed to determine the endotype of INOCA and to select appropriate treatment. 13N-ammonia PET (NH3-PET) quantification can identify coronary microvascular dysfunction noninvasively. We investigated the usefulness of NH3-PET in diagnosing INOCA and predicting prognosis.

**METHODS AND MATERIALS**

A total of 433 consecutive patients with symptoms of angina pectoris who underwent adenosine-stress NH3-PET were enrolled. The NH3-PET assessments were summed stress score (SSS), myocardial flow reserve (MFR) reflecting vascular endothelial function under adenosine-stress, papillary muscle ischemia (PMI) on high-resolution cine imaging, and resting to stress ratio of the circumferential strain (strain ratio) exclusively for NH3-PET. Patients were divided into three groups based on comprehensive functional assessment of invasive coronary catheters: coronary artery disease (CAD), non-coronary artery disease (non-CAD), and INOCA. A prognostic study was conducted for INOCA and non-CAD groups with major adverse cardiac accidents (MACE) as the endpoint.

**RESULTS**

Finally, 293 patients were diagnosed with CAD, 95 with non-CAD, and 45 with INOCA. SSS for non-CAD (0.89±2.42) and INOCA (0.82±1.62) groups was significantly lower than that for CAD (9.85±7.96) group. MFR for CAD (2.08±0.66) and INOCA (1.84±0.54) groups was significantly lower than thar for non-CAD (2.68±0.67) group. The frequency of papillary muscle ischemia was significantly higher in INOCA group (40%) than in CAD (11%) and non-CAD groups (11%). Cox proportional hazards regression analysis of the factors that define MACE showed that a strain ratio lt;0.93 was obtained as an independent factor, even after adjusting for age and sex (Odds ratio 11.8, plt;0.007). In the Kaplan-Meier survival curve, INOCA patients with a strain ratio lt;0.93 had significantly more MACEs than the other patients.

**CONCLUSION**

NH3-PET findings in patients with INOCA are characterized by decreased MFR despite the absence of regional ischemia. Papillary muscle ischemia is more frequent, and the strain ratio reduction obtained from NH3-PET is useful in predicting MACE.

**CLINICAL RELEVANCE/APPLICATION**

NH3-PET is a minimally invasive and safe technique with excellent reproducibility in INOCA diagnosis and monitoring the treatment progress.

## T5A-SPCH-2 RADIOMICS MODEL PREDICTS PATHOLOGIC RESULTS FOR LUNG CANCER SCREENING BASED ON THREE-DIMENSIONAL ULTRASHORT ECHO TIME (3D-UTE) AND T2-WEIGHTED (T2W)IMAGING

Jian-Xing Qiu, MD (*Abstract Co-Author*) Nothing to Disclose
Jiejin Yang (*Abstract Co-Author*) Nothing to Disclose
Rile Nai (*Abstract Co-Author*) Nothing to Disclose
Shuai Ma, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate radiomics techqiques based on 3D-UTE and T2-weighted (T2w) Imaging for a MR lung cancer screening program and compare the predict performances.

### METHODS AND MATERIALS

53 patients with 56 nodules (mean size 19.37mm) who had undergone chest MRI examination were retrospectively collected. Spiral UTE-MRI was performed using a MAGNETOM Aera 1.5T MR scanner (Siemens Healthcare, Erlangen, Germany). A prototype 3D Spiral UTE-MRI sequence was acquired in the coronal plane. The T2w multi-shot Turbo Spin Echo sequence (BLADE) was acquired in coronal orientation during breath-hold. The final surgical pathology was treated as gold standard for model construction. Radiomics features were extracted from 3D-UTE and T2ws. The radiomics models were constructed by using the machine learning methods (SVM, KNN, NaiveBayes and logistic regression) with five-fold cross validation, respectively. Two experienced radiologists independently rated multi-parameter MR images of each lesion. The final radiologists‘ diagnosis was reached by consensus and were compared with the radiomics models’ diagnostic outcomes. AUCs of the models were compared to evaluated the predict performance.

### RESULTS

The enrolled lesions were randomly divided into training and test dataset (8:2). The radiomics signature (build by LR method) with the best performance based on the 3D-UTE, T2w and merged models demonstrated AUCs of 0.85, 0.82 and 0.93, respectively. The merged model outperformed each single sequence competitors. Predict performance did not show a statistically difference between each radiomics model and radiologists (P values range from 0.06 to 0.80), while a tendency of superiority of merged radiomics was obvious concerning sensitivity, accuracy and AUC.

### CONCLUSION

The MR-based radiomics technique can serve as a promising radiation-free alternative to computed tomography,performing noninferiorior diagnostic efficacy compared with manual diagnosis, serving as a promising noninvasive predictor of lung cancer screening program for clinical decisions.

### CLINICAL RELEVANCE/APPLICATION

Our initial results suggest that radiomics information based on 3D-UTE and T2w both can be used to differentiate benign from malignant nodules, and the noninferiority was achieved when compared with radiologists concerning the diagnostic efficacy, which shows that the MR-based radiomics approach is at least equally appropriate for diagnosis of pulmonary nodules as compared to conventional manual diagnosis based on domain knowledge and enough experience.

## T5A-SPCH-3 AI-ENHANCED PREDICTION OF LUNG CANCER RISK FROM IMAGING BIOMARKERS IN CHEST RADIOGRAPHS: AN EXTERNAL VALIDATION STUDY

Theodorus Dapamede, MD, PhD (*Presenter*) Intern, MARS BioImaging Ltd

### PURPOSE

This study explores the potential of artificial intelligence to predict lung cancer risk using imaging features from chest radiographs (CXRs), independently of traditional risk factors like smoking history. This approach could serve as an early detection tool in populations lacking comprehensive patient histories.

### METHODS AND MATERIALS

This IRB-approved study utilized a dataset of 249,749 initial frontal non-portable CXRs (51.5% Black, 48.5% White) from 2008 to 2021 to identify patients with lung cancer via ICD10 codes. The dataset was divided 80/20 for training and testing. A pre-trained ICD-10 comorbidity CNN model predicted 10 risk factors, utilized by an XGBoost model for lung cancer prediction. Additionally, a logistic regression (LR) model served as a baseline. Model performance was evaluated using AUC, sensitivity, and specificity metrics. External validation was conducted on a geographically distinct dataset comprising 160,244 patients. SHAP values were employed for model explainability.

### RESULTS

For logistic regression (LR), the area under the curve (AUC) was 0.76 [95% CI: 0.74 - 0.79], with a sensitivity of 0.89, specificity of 0.53. The XGBoost (XGB) model showed slightly improved performance with an AUC of 0.79 [95% CI: 0.76 - 0.82], a sensitivity of 0.85, specificity of 0.58.. Furthermore, on the external dataset, the LR model demonstrated an AUC of 0.77 [95% CI: 0.76 - 0.79], sensitivity of 0.75, specificity of 0.68. The XGB model exhibited comparable results with an AUC of 0.79 [95% CI: 0.77 - 0.80], sensitivity of 0.73, specificity of 0.72.

### CONCLUSION

In conclusion, our study highlights AI's potential in forecasting lung cancer risk using CXR imaging biomarkers, providing a non-invasive method irrespective of conventional risk factors like smoking history.

### CLINICAL RELEVANCE/APPLICATION

The integration of AI-driven predictive models utilizing CXR imaging biomarkers offers a non-invasive and potentially transformative approach for early lung cancer detection, especially beneficial in populations with incomplete patient histories, ultimately enhancing screening effectiveness and patient outcomes.

## T5A-SPCH-5 SINGLE AND MULTIPARAMETRIC MOLECULAR INFORMATION FROM MRI: COMPARISON OF CAPABILITY FOR POSTOPERATIVE RECURRENCE PREDICTION WITH FDG-PET/CT IN STAGE I NON-SMALL CELL LUNG CANCER PATIENTS

### PURPOSE

To compare the quantitative prediction capability for postoperative recurrence of between FDG-PET/CT and MRI-based molecular information from chemical exchange saturation transfer (CEST) imaging and diffusion-weighted imaging (DWI) in stage I non-small cell lung cancer (NSCLC) patients.

### METHODS AND MATERIALS

79 pathologically diagnosed and surgically treated NSCLC patients underwent CEST imaging, DWI and FDG-PET/CT as preoperative examinations, follow-up and pathological examinations. According to the follow-up and pathological examination results, all patients were divided as recurrence (n=13) and non-recurrence (n=66) groups. In each lesion, magnetization transfer ratio asymmetry at 3.5ppm (MTRasym), apparent diffusion coefficient (ADC) and SUVmax of each nodule were assessed by ROI measurements. To compare all indexes between each two groups, Student’s t-test was performed. To determine the significant predictors, multiple logistic regression analysis was performed among all indexes. Then, ROC analysis was performed to compare distinguishing two groups among all indexes and combined significant predictors. Finally, sensitivity (SE), specificity (SP) and accuracy (AC) were compared among all methods by McNemar’s test.

### RESULTS

There were significant difference of each index between two groups ($p<0.05$). Multiple logistic regression analyses determined MTRasym (Odds ratio [OR]: 1.31, $p=0.03$) and ADC (OR: 0.002, $p=0.008$) as significant predictors in this setting. When applied each feasible threshold value, SPs and ACs of MTRasym (SP: 81.8%, AC: 82.2%), ADC (SP: 87.9%, AC: 86.1%) and combined predictors (SP: 89.4%, AC: 89.9%) were significantly higher than those of SUVmax (SP: 69.7%, $p<0.05$; AC: 72. %, $p<0.05$). Moreover, AC of combined predictors was significantly higher than that of MTRasym ($p=0.03$).

### CONCLUSION

MRI-based molecular information has better potential for prediction of postoperative recurrence than FDG-PET/CT in stage I NSCLC patients. Moreover, combined CEST and DWI information can improve prediction capability of CEST imaging in this setting.

### CLINICAL RELEVANCE/APPLICATION

MRI-based molecular information has better potential for prediction of postoperative recurrence than FDG-PET/CT in stage I NSCLC patients. Moreover, combined CEST and DWI information can improve prediction capability of CEST imaging in this setting.

## T5A-SPCH-6 NATURAL HISTORY AND CLINICAL CHARACTERISTICS OF SUBSOLID PULMONARY NODULES IN PEDIATRIC PATIENTS

Shushan Dong (*Abstract Co-Author*) Researcher, Koninklijke Philips NV
Jianlin Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Hong Yu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hua Ren, MMed (*Presenter*) Nothing to Disclose

### PURPOSE

The natural history of subsolid pulmonary nodules in pediatric patients remains unclear. There are no guidelines for optimal management of these subsolid nodules (SSNs). To investigate the natural course of SSNs in the pediatric patient population and to gain insights into the best mode of follow-up.

### METHODS AND MATERIALS

At least two CT follow-up records of patients aged 18 years or younger with SSNs were retrospectively reviewed and assessed between January 2010 and December 2020. The incidence of interval growth; clinical, radiologic, and pathological features; and follow-up outcomes of these SSNs were investigated. Growth of SSNs was judged by increase in the diameter of the entire nodule or solid portion of 2 mm or more or new appearance of solid portions within SSNs.

### RESULTS

A total of 35 patients (median age, 17 years; range, 13-18 years; 16 women) with 52 SSNs (including 49 pure ground-glass nodules [PGGNs] and 3 part-solid nodules [PSNs]) were analysed and evaluated. One of the 52 SSNs (2.2%) (one PSN) showed interval growth. The PSN showed an increase in nodule size without any change in the size of the solid component. The interval from the initial computed tomography examination to growth was 20 months. Four SSNs (7.7%) (three PGGNs and one PSN) in four patients disappeared within 2-7 months during follow-up. Among the 21 SSNs (18 PGGNs, 3 PSNs) in 19 studied individuals who underwent pulmonary resection, eight were invasive adenocarcinomas, seven minimally invasive adenocarcinomas, five adenocarcinomas in situ, and one bronchiolar adenoma. All the patients survived without recurrence.

### CONCLUSION

Only 2.2% of SSNs in pediatric patients with no history of malignancy showed subsequent growth. The much higher likelihood of persistent SSNs in pediatric patients that represent a primary lung tumour rather than metastasis or infectious causes should be followed up with long intervals and appropriate surgical treatment after thoughtful discussion.

### CLINICAL RELEVANCE/APPLICATION

A follow-up strategy involving a long interval and appropriate surgical treatment after thoughtful discussion should be considered for SSNs in pediatric patients.

## T5A-SPCH-7 MAGNETIC RESONANCE OF PULMONARY NODULES IN ONCOLOGICAL PATIENTS

Bruno Hochhegger, MD,PhD (*Abstract Co-Author*) Nothing to Disclose

Bruce Steinberg (*Abstract Co-Author*) Nothing to Disclose
Ronak Kundalia (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to assess the accuracy of pulmonary nodule detection via magnetic resonance imaging (MRI) compared to the gold standard, computed tomography (CT), in patients with cancer.

### METHODS AND MATERIALS

During a 2-year period, MRI of the chest was performed on oncological patients for staging of extrathoracic cancer and subsequently compared to their CT. Only the largest nodule was considered in patients with multiple nodules. Nodule size and malignancy were recorded for each modality, as well as the presence of interstitial lung disease (ILD), adenopathy, cardiomegaly, pleural effusion, pericardial effusion, and vertebral fracture. All cases were read by 2 thoracic radiologists and any discrepancies were resolved by discussion.

### RESULTS

A total of 154 nodules >3 mm in diameter were found in 241 participants (mean age: 59 years [11-105]). No nodules were found in the remaining 91 patients. Average nodule diameter was 11.5mm (range: 3.9 - 29.1mm; SD: 8.1mm). MRI detected all nodules greater than 5mm. Malignancy was detected in 37 nodules. The sensitivity, specificity, and accuracy values of MRI for all nodules were 90.9%, 100%, and 94.8%, respectively. For ground glass nodules (n = 11), the values were 43.6%, 100%, and 65.0%, respectively. When compared to CT, long-axis diameter measured by MRI was underestimated by 9 ± 2.3% (P < .001). There was a strong correlation between measurements of CT and MRI (? = 0.70-1.00). Furthermore, MRI accurately detected the presence ILD (92.8%), adenopathy (95%), cardiomegaly (96.7%), pleural effusion (97.4%), pericardial effusion (100%) and bone lesions (99.3%). Accuracy of diffusion-weighted imaging to detect nodule malignancy was 93.75%.

### CONCLUSION

These findings suggest that lung MRI accurately detected pulmonary nodules and other thoracic pathologies commonly observed in oncological patients.

### CLINICAL RELEVANCE/APPLICATION

Lung MRI may serve as a substitute to CT for oncological patients undergoing routine extra-thoracic surveillance, thereby decreasing radiation exposure.

## T5A-SPCH-8 DEEP LEARNING RECONSTRUCTION IMPROVES PULMONARY NODULE DETECTION AND MEASUREMENT ACCURACY FOR ULTRA-LOW-DOSE CHEST CT COMPARED TO HYBRID ITERATIVE RECONSTRUCTION

Lan Song, MD (*Abstract Co-Author*) Nothing to Disclose
Wei Song, MD (*Abstract Co-Author*) Nothing to Disclose
Xin Sui, MD (*Abstract Co-Author*) Nothing to Disclose
Jinhua Wang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the image quality and pulmonary nodule detectability and measurement accuracy between deep learning reconstruction (DLR) and hybrid iterative reconstruction (HIR) of chest ultra-low-dose CT (ULDCT).

### METHODS AND MATERIALS

Participants who underwent chest standard-dose CT (SDCT) followed by ULDCT from October 2020 to January 2022 were prospectively included. ULDCT images reconstructed with HIR and DLR were compared with SDCT images to evaluate image quality, nodule detection rate, and measurement accuracy using a commercial deep learning-based nodule evaluation system. Detected nodules with long diameter and volume measured by SDCT were used as

references. Nodules with long diameter =3 mm but <30 mm were categorized into three subgroups (3-6 mm; 6-10 mm; =10 mm) and three types (subsolid, solid, and calcified). To analyze differences between the measured data and the reference data, the systematic percentage error (SPE) and absolute percentage error (APE) of long diameter and volume were calculated. Bland-Altman analysis and Wilcoxon signed-rank test were used to evaluate the differences between ULDCT and SDCT images.

**RESULTS**

Eighty-four participants (54 ± 13 years; 26 men) were finally enrolled. The effective radiation doses of ULDCT and SDCT were 0.16 ± 0.02 mSv and 1.77 ± 0.67 mSv, respectively (P < 0.001). The mean ± standard deviation of the lung tissue noises was 61.4 ± 3.0 HU for SDCT, 61.5 ± 2.8 HU and 55.1 ± 3.4 HU for ULDCT reconstructed with HIR-Strong setting (HIR-Str) and DLR-Strong setting (DLR-Str), respectively (P < 0.001). A total of 535 nodules were detected. The nodule detection rates of ULDCT HIR-Str and ULDCT DLR-Str were 74.0% and 83.4%, respectively (P < 0.001). The SPEs in nodule volume from that of SDCT was 17.1% in ULDCT HIR-Str versus 8.5% in ULDCT DLR-Str ( P < 0.001). The APEs in nodule volume from that of SDCT was 19.5% in ULDCT HIR-Str versus 17.9% in ULDCT DLR-Str (P < 0.001).

**CONCLUSION**

DLR was superior to HIR in terms of image noise and image quality at ultra-low-dose settings. DLR also increased the lung nodule detection rate and improved measurement accuracy of nodule volume in comparison with HIR.

**CLINICAL RELEVANCE/APPLICATION**

The study prospectively evaluated the performance of DLR applied to chest ultra-low-dose CT for image quality improvement and lung nodule assessment using a deep learning-based nodule evaluation system.

## T5A-SPCH-9 A MACHINE LEARNING MODEL BASED ON DUAL-LAYER DETECTOR SPECTRAL CT TO PREDICT AND CLASSIFY INVASIVENESS OF LUNG ADENOCARCINOMA

Lian Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Bingxin Gong (*Abstract Co-Author*) Nothing to Disclose
Peng Sun, MD,MD (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Shen Gui (*Abstract Co-Author*) Nothing to Disclose
Zhen Quan (*Abstract Co-Author*) Nothing to Disclose
Jiayu Wan (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the utility of a machine learning (ML) model based on dual-layer detector spectral CT (DLCT) parameters for predicting the invasiveness of lung adenocarcinoma manifesting as ground glass nodules (GGNs) prior to surgical intervention.

**METHODS AND MATERIALS**

In a retrospective study, 300 patients with lung adenocarcinoma were included, comprising 160 cases of invasive adenocarcinomas (IA) and 140 cases of pre-invasive minimally invasive adenocarcinoma (MIA). These patients were subsequently divided into a training group (n=190) and a test set (n=110). The study focused on the automated detection and segmentation of each lesion. Four ML models were developed using three DLCT parameters: conventional, electron density, and effective atomic number. The predictive performance of each ML classifier was evaluated using equivalent hyper parameters on the test set, and the diagnostic effectiveness was assessed by calculating the area under the receiver operating characteristic curve (AUC), along with sensitivity, specificity, and overall accuracy of the ML algorithm.

**RESULTS**

Ten important features were derived from ML model based on different DLCT parameters. The conventional plus electron density model performed better than ML models with other DLCT parameters, achieving AUC values of 0.930 and 0.955 in the training and test sets, respectively. The clinical model, which included age, sex, smoking, and alcohol history, had AUCs of 0.667 and 0.736 in the training and test sets, respectively. The clinical model and rad-score were incorporated into a logistic regression to construct a model (joint model), with the AUC of the joint model being 0.964 and 0.959 in the training and test sets, respectively.

**CONCLUSION**

The ML model based on DLCT parameters can help predict the invasiveness of GGNs, classifying GGNs as different risk grade.

**CLINICAL RELEVANCE/APPLICATION**

This study investigates the medical imaging characteristics of DLCT and its correlation with the invasiveness of lung adenocarcinoma. Furthermore, this study established a ML model that significantly aids in predicting the invasiveness of lung adenocarcinoma and guides radiologists in predicting and classifying the invasiveness of this condition.

## T5A-SPER-2 PULMONARY TUMOR THROMBOEMBOLIC MICROANGIOPATHY: IMPORTANT RADIOLOGIC FINDINGS WITH CLINICAL MANIFESTATION

Sung-A Chang (*Abstract Co-Author*) Nothing to Disclose
Min Yeong Kim, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Pulmonary tumor thromboembolic microangiopathy (PTTM) is a change of pulmonary microvasculature by microscopic tumor cell emboli, and which leads to a rapid progression of dyspnea, pulmonary hypertension, right heart failure and death. This study was purposed to evaluate CT findings of PTTM with clinical manifestation.

### METHODS AND MATERIALS

Among chest CT scans of emergency room (ER) from 2013 to 2021, twenty-five patients were found to have PTTM after review of medical records including echocardiography. Analysis of CT findings included ratio of the right ventricle (RV) to the left ventricle (LV), diameter of main pulmonary artery (MPA), visible pulmonary arterial thromboembolism (PTE), centrilobular GGOs, vascular tree in bud appearance, and mismatched perfusion defects on dual energy iodine maps.

### RESULTS

The most common primary cancer was sex dependent, with seven out of 14 women having breast cancer and five out of 11 men having stomach cancer. The ratio of RV to LV more than 1 were observed in 21 patients, MPA more than 2.9 cm were in 22 ones. Only 2 CT scans revealed PTE in segmental branches. Centrilobular GGOs were found in 15 patients, 10 of them diffusely involved both lungs. Vascular tree in bud appearance was found in 9 patients. Sixteen CT exams performed with dual-energy CT scanner and included iodine perfusion map, all of which revealed various degree of mismatched perfusion defects. Severity of pulmonary hypertension was moderate in 22 patients, severe in 2 ones. Sixteen patients died within a week and only two patients have been alive more than one year after immediate chemotherapy with adequate cardiologic management.

### CONCLUSION

Most cases of PTTM tend to be found in ER due to rapid clinical progression and its mortality rate within 7 days was more than 60%. The diagnosis of PTTM begins with CT scanning and the CT findings are very specific to proper diagnosis.

### CLINICAL RELEVANCE/APPLICATION

To avoid rapid progress to death by PTTM, both radiologists and ER physicians should be aware of PTTM for early diagnosis and proper management.

## T5A-SPGI-1 RADIOMICS ANALYSIS BASED ON GD-EOB-DTPA-ENHANCED MRI FOR PREDICTING EARLY RECURRENCE IN HEPATOCELLULAR CARCINOMA AFTER PARTIAL HEPATECTOMY

Yuxi Tao (*Abstract Co-Author*) Nothing to Disclose
Zichang Ma (*Abstract Co-Author*) Nothing to Disclose
Yaqin Zhang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Hanqiu Zeng (*Presenter*) Nothing to Disclose

### PURPOSE

Hepatocellular carcinoma (HCC) has a high incidence and poor prognosis, with surgical resection being the primary treatment method. Early recurrence is a major cause of death in HCC patients who undergo curative liver resection. Identifying high-risk patients for early recurrence preoperatively and implementing adjuvant therapy can improve prognosis and increase survival rates. However, there is currently no comprehensive, intuitive, and reliable tool for predicting early recurrence in clinical practice.

### METHODS AND MATERIALS

In this bicentric study, 239 patients with HCC who underwent Gd-EOB-DTPA-enhanced MRI before resection were divided into training (n = 168) and validation (n = 71) sets. Radiomics features were extracted from multi-sequence MR (mp-MR) images using FAE. Consistency analysis was used to select stable features, Spearman rank correlation coefficient test was used to eliminate redundant features and reduce feature dimensions, and the least absolute shrinkage and selection operator algorithm was used to select radiomics features with the most predictive value for early recurrence. Univariate and multivariate logistic regression analysis to determine independent risk factors associated with early recurrence and construct a clinical-radiologic prediction model. A combined nomogram was built by incorporating radiomics features and significant clinical-radiologic variables to achieve early recurrence prediction.

### RESULTS

The radiomics model based on mp-MRI outperformed all other radiomics models in the training set and validation set. Age, AST, rim arterial phase hyperenhancement, mosaic architecture, and satellite tumors were independent risk factors for early recurrence. The combined nomogram outperformed the radiomics model and the clinical-radiologic model in the training set (0.783 vs. 0.753 vs. 0.744) and validation set (0.734 vs. 0.691 vs.0.704). Excellent calibration was achieved in the combined nomogram. Decision curve analysis confirmed the clinical usefulness of combined nomogram.

### CONCLUSION

The radiomics model based on preoperative Gd-EOB-DTPA-enhanced MRI can effectively predict early recurrence in HCC patients. The combined nomogram incorporating clinical-radiologic features and radiomics features demonstrates superior predictive performance.

### CLINICAL RELEVANCE/APPLICATION

The nomogram developed based on this provides a simple and intuitive tool for preoperatively predicting early recurrence in HCC, identifying high-risk patients, guiding the development of personalized treatment plans, optimizing postoperative monitoring strategies, and improving the prognosis of HCC patients.

## T5A-SPGI-10 MULTIPLE MAGNETIC RESONANCE DIFFUSION MODELS FOR PREOPERATIVE PREDICTING MACROTRABECULAR MASSIVE HEPATOCELLULAR CARCINOMA

Wenjian Wang (*Abstract Co-Author*) Nothing to Disclose
Ke Xue (*Abstract Co-Author*) Nothing to Disclose
Zhe Wang (*Abstract Co-Author*) Nothing to Disclose
Ye Jing (*Abstract Co-Author*) Nothing to Disclose
Martin R. Prince, MD, PhD (*Abstract Co-Author*) Patent agreement, General Electric Company;
Xianfu Luo (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the feasibility of intravoxel incoherent motion (IVIM) and fractional order calculus (FROC) models in characterizing macrotrabecular massive hepatocellular carcinoma (MTM-HCC).

### METHODS AND MATERIALS

168 patients suspected of HCC prospectively underwent liver MRI scanning on a 3.0-tesla scanner. All patients receive routine liver scanning protocol and an additional 12 b-values(0-2000s/mm²) diffusion-weighted imaging. Patients with tumor resection histologically confirmed HCC were divided into MTM-HCC and non-MTM-HCC groups. The IVIM and FROC models derived parameters including true diffusion coefficient (Dt), pseudo diffusion coefficient (Dp), perfusion fraction (f), diffusion coefficient (D), fractional order parameter (ß), and microstructural quantity (μ) were calculated, and compared in MTM and non-MTM HCC groups. Apparent diffusion coefficient (ADC) values were also included in the comparison. Image features including arterial phase hypovascular and maximum tumor diameter (=5cm) were also compared in the two groups by using an independent student t-test or Mann-Whitney U test. The prediction performance was evaluated by receiver operating characteristic (ROC) analysis and areas under ROC curves (AUC)s were compared by the DeLong test.

### RESULTS

A total of 58 HCC patients including 16 MTM and 42 non-MTM HCC patients were enrolled in this study. The arterial phase hypovascular component and the maximum tumor diameter were statistically significant differences between MTM and non-MTM HCC (P=0.040, 0.036). Dp, f, ß, and μ showed no significant difference. While ADC, Dt, and D between the MTM and non-MTM HCC groups were statistically significant (P=0.047, 0.010 and 0.008). MTM-HCC group showed lower Dt values [(0.93±0.14) ×10-3 mm2/s vs. (1.27±1.36) ×10-3 mm2/s ], and lower D values [(1.05±0.16)×10-3mm2/s vs. (1.20±0.19)×10-3mm2/s ], along with lower ADC values [(0.96±0.11)×10-3mm2/s vs. ( 1.03±0.14 )×10-3mm2/s ]. The AUC values of arterial phase hypovascular component, maximum tumor diameter, ADC, Dt, and D were 0.647, 0.653, 0.656, 0.720, and 0.722, respectively.

### CONCLUSION

IVIM and FROC models-based parameters showed promising ability in identifying MTM-HCC and were superior to ADC and MRI imaging features.

### CLINICAL RELEVANCE/APPLICATION

Multiple magnetic resonance diffusion models were feasible for preoperative predicting the more aggressive subtype of hepatocellular carcinoma, specifically macrotrabecular massive hepatocellular carcinoma (MTM-HCC).

## T5A-SPGI-2 THE VALUE OF R2* COMBINED WITH AUTOMATIC QUANTIFICATION OF INTRATUMORAL MAGNETIC SENSITIVE SIGNAL IN PREDICTING THE EARLY CURATIVE EFFECT OF HEPATOCELLULAR CARCINOMA AFTER TACE

Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Mingrui Zhuang (*Abstract Co-Author*) Nothing to Disclose
Ying Zhao JR (*Abstract Co-Author*) Nothing to Disclose
Jun Li (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the value of R2 * combined with automatic quantification of intratumoral magnetic sensitive signal (ITSS) in predicting the early efficacy of TACE in HCC.

### METHODS AND MATERIALS

The clinical and imaging data of patients with HCC who received TACE for the first time in our hospital from October 2011 to April 2023 were collected. All patients underwent 1.5T MRI examination of upper abdomen before TACE. According to the mRECIST standard, the postoperative efficacy of TACE was divided into complete remission (CR), partial remission (PR), disease stability (SD) and disease progression (PD). CR and PR were recorded as effective group (n=45), SD and PD as ineffective group (n=35). ESWAN sequence images generate amplitude map, phase map and R2* map on the workstation. Two observers referred to the T2WI image and placed three equal regions of interest (ROI) on the R2 * image of the largest plane of the tumor and recorded the average value. Using AntopySketch software, the tumor outline was drawn on the largest plane of the tumor and the septum between the upper and lower poles on the amplitude map, and the ITSS ratio was obtained automatically. Intra-group correlation coefficient (ICC) was used to compare the consistency of the measured data between the two observers; Kolmogorov-Smirnov test was used to test the normality of parameters; independent sample t-test or Mann-WhitneyU test was used to compare the differences between the two groups; subjects operating characteristic (ROC) curve was used to evaluate the prediction performance; Logistic regression was used to construct a joint prediction model; Delong test was used to compare the prediction efficiency of each parameter and the joint model.

### RESULTS

The R2* and ITSS ratios measured by the two observers were in good agreement (ICC > 0.75). The R2 * value and ITSS ratio in the effective group were significantly lower than those in the ineffective group (P < 0.001). The R2* and ITSS ratio in the effective group were significantly lower than those in the ineffective group (P < 0.001). The area under the curve (AUC) of R2*, ITSS and the combination of R2* and ITSS to predict the early outcome after HCC were 0.773, 0.766 and 0.839 respectively. There was no significant difference between the prediction efficiency of R2* and ITSS (P = 0.911). The prediction efficiency of the combination of R2* and ITSS was better than that of the single parameter of ITSS (P = 0.040).

### CONCLUSION

Both R2* and ITSS can predict the early curative effect after TACE in patients with HCC, and the predictive efficiency is improved after the combination of R2* and ITSS.

### CLINICAL RELEVANCE/APPLICATION

This study helps clinicians to make individualized treatment plans and improve the survival rate of patients with liver cancer.

## T5A-SPGI-6 THE VALUE OF ENHANCED T2 * WEIGHTED IMAGING IN PREDICTING EARLY RECURRENCE OF HEPATOCELLULAR CARCINOMA AFTER HEPATECTOMY

Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Ying Zhao JR (*Abstract Co-Author*) Nothing to Disclose
Jun Li (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the value of enhanced T2 * weighted angiography (enhancedT2-starweightedangiography,ESWAN) in predicting early recurrence of hepatocellular carcinoma (HCC) after hepatectomy.

## METHODS AND MATERIALS

29 patients with hepatocellular carcinoma who underwent upper abdominal MRI (including ESWAN sequence) and underwent hepatectomy (15 cases of early recurrence (ER) and 14 cases of early non-recurrence (NER)) were collected retrospectively. In AW4.6 workstation (GEHealthcare), ESWAN quantitative parameter maps, including amplitude map, phase map, R2* map and T2* map, are automatically generated by Functool software. According to the T2WI images, three equal-sized circular regions of interest (ROI) were placed in the tumor, the peri-tumor area (1cm) and the distal peri-tumor normal liver parenchyma (5cm) at the maximum level of the lesion, and the amplitude, phase, R2* and T2* values were recorded. The average values of 3 ROI were used for statistical analysis. Kolmogorov-Smirnov test was used to evaluate the normality of the parameters, and independent sample t-test or Mann-WhitneyU test was used to compare the differences of quantitative parameters between the two groups. The diagnostic performance was evaluated using subject operating characteristics (ROC) analysis.

## RESULTS

The amplitude value (tumor), peri-tumor value, liver value, R2* (tumor), R2* (peritumor) and R2* (liver) in ER group were significantly higher than those in NER group. There was no significant difference in other quantitative parameters between the two groups ($P > 0.05$). The area under the curve (AUC) of amplitude value (tumor), amplitude value (peri-tumor), amplitude value (liver), R2 * (tumor), R2 * (peri-tumor) and R2 * (liver) for predicting early recurrence were 0.590, 0.600, 0.681, 0.890, 0.924 and 0.929, respectively. When amplitude value (tumor), amplitude value (peri-tumor), amplitude value (liver), R2* (tumor), R2* (peritumoral) and R2* (liver) parameters were combined, the predictive efficiency increased (AUC=0.971).

## CONCLUSION

Multiple quantitative parameters of ESWAN sequence have certain value in predicting early recurrence of hepatocellular carcinoma after hepatectomy.

## CLINICAL RELEVANCE/APPLICATION

Help clinicians to develop individualized treatment plans

## PURPOSE

This study aimed to determine diagnostic accuracy of combining contrast-enhanced ultrasound (CEUS) and CT/MRI Liver Imaging Reporting and Data System (LI-RADS) major imaging features for the improved classification of indeterminate liver observations.

## METHODS AND MATERIALS

A retrospective analysis using a database from a prospective study conducted at 11 centers in North America and Europe from 2018 through 2022 included a total of 109 participants at risk for hepatocellular carcinoma (HCC) who had liver observations with indeterminate characterization on both CEUS and CT/MRI (LR3, LR-4, and LR-M). The individual LI-RADS major features for HCC on both CEUS and CT/MRI were extracted and analyzed in various combinations. Biopsy, explant histology, and follow-up CT/MRI were used as the final reference standard. The diagnostic performance of LI-RADS major features combinations for definitive diagnosis of HCC (LR-5) were calculated. A reverse, stepwise logistical regression sub-analysis was also performed.

## RESULTS

This study included 114 observations indeterminate on both CT/MRI and CEUS. These observations were initially classified as LR-3 (n=37), LR-4 (n=41), and LR-M (n=36) on CT/MRI and LR-3 (n= 48), LR-4 (n= 36), LR-M (n= 29), and LR-TIV (n=1) on CEUS. Of them, 43.0% (49/114) were confirmed as HCC, 37.3% (43/114) were non-malignant, and 19.3% (22/114) were non-hepatocellular malignancies. The highest diagnostic accuracy among the combinations of imaging features was achieved in CT/MRI LR-3 observations, where the combination of CEUS arterial phase hyper-enhancement (APHE) + CT/MRI APHE had 96.7% specificity, 75.0% positive predictive value and 86.5% accuracy for HCC. CEUS APHE was the variable that showed synergism between benign versus malignant and HCC versus any other observation.

### CONCLUSION

The combination of LI-RADS major features on CT/MRI and CEUS showed higher specificity, positive predictive value, and accuracy compared to individual modalities' assessments, particularly for CT/MRI LR-3 observations. These combinations can produce a definitive diagnosis of HCC in a small percentage of cases with inconclusive imaging on individual modalities.

### CLINICAL RELEVANCE/APPLICATION

By using the combination of CEUS and CT/MRI LI-RADS major features, a definitive diagnosis of HCC can be achieved in cases where individual modalities produce inconclusive results, particularly in LR-3 observations. This comprehensive approach may lead to early intervention.

## T5A-SPGI-8 NEOPLASTIC VERSUS BLAND PORTAL VEIN THROMBOSIS IN HEPATOCELLULAR CARCINOMA: QUANTITATIVE ANALYSIS BASED ON MR DIFFUSION-WEIGHTED IMAGING

Maimoona Siddique, FRCR, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

We investigated to establish specific criteria to diagnose PVT in patients with hepatocellular carcinoma (HCC), based on MR diffusion-weighted imaging (DWI). Our aim was to distinguish the bland from neoplastic PVT by doing quantitative analysis between attenuation values on Triphasic Computed Tomography (TP-CT) and Apparent Diffusion Coefficient (ADC) values on MR DWI.

### METHODS AND MATERIALS

A total of 47, age and sex-matched, HCC patients with PVT, classified based on Doppler ultrasound and TP-CT imaging-based criteria of PV expansion and venous contrast filling defect, were selected. Correlative MR images were reviewed independently. Visual analysis of diffusion restriction was based on signal intensity change. Quantitative parameters including ADC values for regions of interest drawn over thrombus, background liver parenchyma, and dominant HCC lesion, as well as the ratios of the thrombus to liver and tumor (T:L ADC and T:T ADC, respectively) values, were recorded. Receiver operator curve analysis (ROC) was used to define cut off ADC values to differentiate malignant from benign PVT.

### RESULTS

Of the total 47 cases with PVT [32 males, 15 females; mean age 48 years±10.2], the mean Alpha-Fetoprotein level was 2173 ±946 ng/ml. On TP-CT, neovascularity and early arterial enhancement of PVT were depicted in 36/47 cases with malignant PVT and non-depicted in 11/47 cases with benign PVT. PVTs were complete in 40 patients and partial in seven. In all cases, the venous contrast filling defects on TP-CT showed correlative signal involving the entire width of the portal vein lumen or its segmental which approximated (with T1 weighting) and exceeded (with T2 weighting) the intensity of the hepatic parenchyma while the hepatic veins showed a complete flow void. There was slightly lower sensitivity for detecting segmental PVT compared with that of major PVT in the malignant PVT cases, possibly related to partial volume effect. There was a statistically significant [P value < 0.05] difference between ADC and ADC ratio values of the benign versus malignant PVT. ROC curve revealed cutoff value (& 7;1), with sensitivity (100%), and specificity (84%).

### CONCLUSION

MR DWI has an excellent diagnostic yield in the differentiation of malignant from benign PVT in HCC. However, the sensitivity is limited in cases with segmental PVT, particularly in cases with curative intent.

### CLINICAL RELEVANCE/APPLICATION

Diffusion weighted limited MR liver imaging can serve as a better substitute for equivocal cases of malignant portal venous thrombosis on dynamic CT imaging, or those with a history of iodinated contrast allergy.

## T5A-SPGI-9 PREDICTION OF TREATMENT EFFICIENCY OF HCC PATIENTS AFTER TRANSCATHETER ARTERIAL CHEMOEMBOLIZATION BASED ON IVIM TEXTURE ANALYSIS

Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
SHUO ZHANG (*Abstract Co-Author*) Nothing to Disclose
Ying Zhao JR (*Abstract Co-Author*) Nothing to Disclose
Qianyu Zhang (*Abstract Co-Author*) Nothing to Disclose
SIQI WANG (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the value of texture analysis based on IVIM images in predicting the efficacy of hepatocellular carcinoma (HCC) after transcatheter arterial chemoembolization (TACE).

### METHODS AND MATERIALS

A retrospective analysis of 76 patients with HCC at our hospital from June 2015 to October 2018 was performed. For the IVIM analysis, Maps were reconstructed of the IVIM parameters (fast mono, slow mono, fraction of fast mono and standard ADC). They were randomly divided into a training group and a test group (7:3). The enrolled patients were divided into an objective response group and non-objective response group according to the treatment effect after TACE according to the mRECIST standard. Lesions of all the HCC patients were delineated manually through ITKSNAP software. Observers used United Imaging uAI Research Portal platform and FeAture Explorer Pro (FAE, V 0.5.2) on Python (3.7.6) to extract texture parameters. Analysis of variance (ANOVA) were used for feature selection to construct the predictive model. The linear discriminant analysis (LDA) method was used to combine texture parameters. The predictive performance of the test texture parameters was analyzed by receiver operating characteristic curve (ROC).

### RESULTS

A total of 1184 texture features were obtained after IVIM-based texture analysis of each patient, 5 significant texture features were selected after screening to construct the predictive model.1 feature was from fast mono;4 features were from fraction of fast mono. The AUC, sensitivity and specificity scores of training group were 0.7918(95%CI, 0.6684-0.9151), 83.87% and 63.64%. The AUC, sensitivity and specificity scores of test group were 0.600(95%CI, 0.3155-0.8845),92.31% and 60.00%.

### CONCLUSION

Texture analysis of IVIM images have potential clinical value in predicting the treatment effect of HCC patients after TACE. It is of feasibility to provide guidance for better clinical individual treatment.

## CLINICAL RELEVANCE/APPLICATION

It may be possible to provide guidance regarding better clinical treatment for patients who undergo TACE by analyzing IVIM texture images.

## T5A-SPGU-1 EVALUATION OF SPLIT RENAL FUNCTION USING MR-DERIVED STRUCTURE AND ARTERIAL SPIN-LABELED PERFUSION FEATURES IN CHRONIC OBSTRUCTIVE NEPHROPATHY

Wenhao Guan (*Abstract Co-Author*) Nothing to Disclose
Jinzhi Yang (*Abstract Co-Author*) Nothing to Disclose
Xiancheng Li (*Abstract Co-Author*) Nothing to Disclose
Yang Dong (*Abstract Co-Author*) Nothing to Disclose
Yuqing Cai (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the value of magnetic resonance arterial spin-labeled (ASL) imaging and renal structural characteristics in quantitative evaluation of the split renal function (SRF) in obstructive nephropathy.

### METHODS AND MATERIALS

Consecutive forty-six patients with obstructive hydronephrosis were recruited for a 3-T conventional and ASL-MRI examination from January 2022 to August 2023 prospectively. The 92 independent kidneys were divided into 3 groups based on split GFR obtained by renal scintigraphy (RS). (1) normal renal function: GFR=40ml/min, renal parenchymal radioactivity uptake and clearance is good; (2) mild to moderate impairment: 20ml/min= GFR<40ml/min, a mild or moderate reduction in renal parenchymal radioactivity uptake; (3) severe impairment or no function: GFR<20ml/min, there is a marked reduction in renal parenchymal radioactivity uptake, with thinning of the cortex or little or no renal parenchyma. Renal blood flow (RBF) and renal parenchymal thickness (RPT), renal pelvic dilation (RPD) were assessed on ASL and T1WI maps. One-way analysis of variance (ANOVA) and Kruskal-Walli's test was used to analyze the differences among the three groups. Pearson and Spearman rank correlation analysis approach were adopted to analyze the correlation between RBF, RPT, RPD and GFR, and ROC curve was used to compare their efficacy.

### RESULTS

Renal cortical RBF, RPT, and RPD could distinguish the SRF pairwise subgroups with different renal function impairments ($p<0.001$). The correlation coefficients were 0.767, 0.635, and -0.589, respectively. ROC curve analysis showed that RBF, RPT, and RPD could distinguish the renal function grades with obstructive hydronephrosis. The combination of RBF, RPT and RPD achieved the highest diagnostic efficacy in distinguishing different degrees of renal dysfunction. The AUC valves were 0.869 (95% CI, (0.768-0.937)), 0.883 (95% CI, (0.756-0.959)) and 0. 994 (95% CI, (0.931-1.00)) in normal and mild to moderate impairment groups, mild to moderate impairment group and severe impairment or no function group, normal and severe impairment or no function group, separately.

### CONCLUSION

MR structural and ASL imaging enables quantitative measurements of RPT, RPD, and renal cortical RBF. They were correlated with RS and SRF. The combination of which achieved high diagnostic efficacy and demonstrated clinical potential in noninvasive evaluation of SRF in obstructive nephropathy.

### CLINICAL RELEVANCE/APPLICATION

MR structural features and ASL-RBF are correlates with SRF obtained by RS in obstructive nephropathy. RBF combines with RPT and RPD can improve the diagnostic efficiency of split renal impairment furtherly. MRI provides a non-invasive quantitative measurement method for assessing split renal function.

## T5A-SPGU-2 INTERMEDIATE PI-RADS LESIONS: IS THERE A ROLE FOR THE PRIMARY SCORE?

James Shi, MD (*Abstract Co-Author*) Nothing to Disclose
Maryam Rahmani, MD (*Abstract Co-Author*) Nothing to Disclose
Vahid Yaghmai, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Garrett G. Ward, MD (*Abstract Co-Author*) Nothing to Disclose
Seyedeh Niloufar Rafiei Alavi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

While PI-RADS has greatly improved tumor localization and biopsy guidance, a significant portion of patients still receive intermediate results. We evaluated role of PRIMARY score on PSMA PET/CT in patients with PIRADS=3

### METHODS AND MATERIALS

Patients with intermediate mpMRI results (PIRADS=3) who also had available PSMA-PET/CT scans were evaluated. We reviewed the PSMA PET/CT results and scored prostate findings using the PRIMARY score—a novel standardized scoring system for interpreting PSMA PET/CT within the prostate. PI-RADS

scores were upgraded to PIRADS=4 if the PRIMARY score was 3 or higher, or downgraded to PIRADS=2 if PRIMARY score was 1-2. Final lesion diagnoses were correlated with pathology results, with clinically significant prostate cancer defined as a Gleason Score =7. We calculated sensitivity and specificity for detecting clinically significant PCa by combining mpMRI and PSMA PET/CT. ROC curve analyses was performed to calculate the area under the curve for PRIMARY and compare it to two previously described methods for classification of PIRADS=3 lesions

**RESULTS**

We identified 42 PIRADS=3 lesions in patients who also had undergone PSMA PET/CT. Biopsy results revealed that 26/42 (62%) of these lesions were clinically significant PCa (GS =7), while 8/42(19%) were GS=3+3, and 8/42 (19%) were benign. Using PRIMARY, all benign lesions were correctly classified as PRIMARY=2, and only 25% of favorable medium-risk lesions (GG=3+4) were missed. The use of PSMA PET/CT for PIRADS 3 lesions resulted in a sensitivity of 88% and specificity of 81.25% for detecting clinically significant PCa on mpMRI. ROC analyses showed higher diagnostic accuracy for the PRIMARY score (AUC= 0.829 [0.691-0.967]) compared to PSA density cutoff (> 0.15) (AUC=0.464 [0.283-0.644]), and SUVmax cutoff (>5) alone (AUC=0.683 [0.516-0.850]).

**CONCLUSION**

PSMA PET/CT provides valuable information for assessing the risk of malignancy in PIRADS 3 lesions. Incorporating PSMA PET/CT prostate findings can reduce false positives and false negatives in MRI-guided prostate biopsies.

**CLINICAL RELEVANCE/APPLICATION**

The incorporation of PSMA PET/CT and the PRIMARY scoring system into the assessment of PI-RADS 3 lesions enhances the diagnostic accuracy for detecting clinically significant prostate cancer, reducing unnecessary biopsies, and optimizing patient management.

## T5A-SPGU-3 FOLLOW-UP OF NON-PALPABLE INCIDENTALOMAS <1CM: DOES GROWTH RATE ALLOW DISTINGUISH BETWEEN MALIGNANT AND NON-MALIGNANT LESIONS?

Pietro Pavlica, MD (*Abstract Co-Author*) Nothing to Disclose
Paul S. Sidhu, BSc, FRCR (*Abstract Co-Author*) Consultant, Samsung Electronics Co, Ltd;Speaker, Samsung Electronics Co, Ltd;Speaker, Bracco Group;Consultant, Itreas Ltd;Speaker, Siemens AG

Irene Campo (*Abstract Co-Author*) Nothing to Disclose
Gianluca Visalli, MD (*Abstract Co-Author*) Nothing to Disclose
Jia Cheng Yuan, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

a) to substantiate whether small, incidentally detected testicular lesions can be safely followed up; b) to assess the growth rate of surgically proven benign, malignant and non-neoplastic lesions; c) to investigate whether a threshold could be identified for a reliable differentiation between benign/non neoplastic lesions and malignant tumours based on growth characteristics.

**METHODS AND MATERIALS**

From October 2001 to November 2021, 127 patients with nonpalpable testicular lesions <1cm were monitored in seven diagnostic centers. Patients had negative tumor markers, and cysts were excluded. High-frequency, broadband probes were used for ultrasound. For patients with multiple lesions, the largest was considered. Follow-up, adhering to ESUR recommendations, was mostly every three months for 12 months then annually. Surgery was scheduled for 39 lesions due to growth or patient/urologist preference.

**RESULTS**

Among 127 initially followed-up testicular lesions, 6 disappeared, 8 reduced, 85 remained stable, and 28 grew. Follow-up duration ranged from 1 to 22 years. Histology was available for 39 operated, 11 stable, and 28 growing lesions. Among stable ones, 1 was benign, 10 non-neoplastic; among growing, 18 malignant, 8 benign, 2 non-neoplastic. Initial volumes didn't statistically differ between malignant and non-malignant. Growth rates were significantly higher for malignant tumors. Best indicators to differentiate malignancy were specific growth rate, doubling time, and growth in maximum and average diameters. All malignant tumors were removed within 18 months, all stage IA.

**CONCLUSION**

This retrospective study represents the first attempt to estimate the growth rate of testicular incidentalomas, to identify thresholds to differentiate surgical from non-surgical lesions, and benign from malignant lesions. We found that benign and malignant lesions can be effectively differentiated based on growing parameters, even though superimposition exists. These results are promising, but the strength of the evidence suffers from the retrospective design of the study. Prospective multicenter studies with a larger number of lesions are necessary to substantiate them, leading to an evidence-based paradigm shift in the management of small testicular incidentalomas.

**CLINICAL RELEVANCE/APPLICATION**

Our data suggest that malignant small, non-palpable incidentalomas are mostly seminomas (17/18 in our series, 94%). All were identified and removed within 18 months after discovery, and all were stage IA tumours.

## T5A-SPGU-4 IMPACT OF THE USE OF ENDORECTAL COIL ON DIAGNOSTIC ACCURACY OF MRI FOR EXTRAPROSTATIC EXTENSION IN PROSTATE CANCER

Mason Belue, MD (*Abstract Co-Author*) Nothing to Disclose
Omer Esengur, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the impact of endorectal coil (ERC) use on MRI accuracy in detecting extraprostatic extension (EPE) in prostate cancer patients by comparing National Cancer Institute EPE grading with post-radical prostatectomy (RP) pathology findings.

**METHODS AND MATERIALS**

In this retrospective study, 956 consecutive patients (median age=62 [IQR: 57-67], median PSA=9.7 ng/mL [IQR: 4.8-10.5]) who underwent prostate MRI with ERC (ERC+) or without (ERC-) between January 2007 and March 2024 were included. Prospectively reported EPE grades of ERC+ and ERC- patients were compared with EPE status on post-RP histopathology. Diagnostic metrics were calculated at EPE grade =1 and =3 cutoffs for ERC+ and ERC- groups. Additional statistical analysis was done using Fisher's exact test, receiver operating characteristic curve (AUC), and DeLong's test.

**RESULTS**

A total of 228 patients out of 956 (24%) were found to have EPE on histopathology. In the entire study sample, the sensitivity was 70%, specificity was 69%, PPV was 41%, NPV was 88% and accuracy was 69% for the EPE grade=1 threshold. At EPE grade=1 cutoff, sensitivity (75% vs 63%) and NPV (90% vs 84%) were higher for ERC+ compared to the ERC- group. Specificity was found to be similar across the ERC+ and ERC- groups at both EPE grade=1 (67% vs 72%) and EPE grade=3 (94% vs. 95%) thresholds. NPV was found to be high across all settings, especially for EPE grade=1 (90% for ERC+, 84% for ERC-). Accuracy was found to be similar at EPE grade=1 (69% for ERC+, 70% for ERC-) and slightly higher for ERC+ (80%) compared to ERC- (75%) EPE grade =3. Detection of EPE on MRI was significant across EPE thresholds of =1 and =3 in ERC+ and ERC- patients ($p<0.05$). The AUC was 0.742 for ERC+ and 0.697 for ERC- ($p=0.25$).

**CONCLUSION**

While ERC improves detection of EPE and reliability in correctly identifying patients who do not have EPE, it does not significantly enhance MRI accuracy. This suggests that routine ERC use may not be justified in clinical practice, especially considering the cost and patient discomfort associated with its use.

**CLINICAL RELEVANCE/APPLICATION**

Considering the minimal impact of ERC on improving diagnostic outcomes, its routine use in prostate MRI may not be warranted, potentially reducing both costs and patient discomfort.

## T5A-SPGU-5 IMPACT OF PROSTATE MR IMAGE QUALITY ON PROSTATE CANCER DETECTION: IS BEAUTY IN THE EYE OF THE BEHOLDER?

Andrei S. Purysko, MD (*Abstract Co-Author*) Contract, Profound Medical Inc;Research support, Blue Earth Diagnostics Ltd;Consultant, KOELIS;
Ryan Ward, MD (*Abstract Co-Author*) Nothing to Disclose
Jennifer Bullen, MSc (*Abstract Co-Author*) Nothing to Disclose
Emily Knott (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine if a prostate MR Image quality improvement initiative increased the sensitivity and negative predictive value of prostate MRI for clinically significant prostate cancer (grade group [GG] =2).

**METHODS AND MATERIALS**

Single-center prospective study included patients who underwent PI-RADS compliant prostate MRI followed by MRI-guided biopsy for prostate cancer detection before and after implementation of image quality improvement measures. PI-QUAL and PI-RADS scores were performed as part of routine clinical care by 1 of 19 abdominal radiologists. MRI-targetd and/or systematic prostate biopsies were performed by 1 of 6 urologists using a transperineal approach.

**RESULTS**

There were 288 MRIs pre-intervention (before 6/5/2023) and 689 MRIs post-intervention (after 8/31/2023). Image quality improvement interventions included measures to reduce artifacts from motion and rectal gas, such as dietary restrictions and enema prior to the MRI. Scans with PI-QUAL score = 4 significantly increased after the interventions (figure 1). Compared to pre-intervention, post-intervention scans were similar with respect to patient age, scanner vendor, model, and magnetic field. The sensitivity for GG = 2 cancer detection increased from 85% (40/47) to 89% (139/157). The negative predictive value pre and post interventions was 90% (63/70 and 162/180, respectively).

**CONCLUSION**

Image quality improvement interventions resulted in a small increase in sensitivity for prostate cancer detection while the negative predictive value remained unchaged.

**CLINICAL RELEVANCE/APPLICATION**

In practice, expert readers can achive high performance for clinically significant prostate cancer detection in PI-RADS compliant MR exams, despite artifacts from motion and rectal air.

## T5A-SPGU-6 FAST PROSTATE MRI VS CONVENTIONAL MULTIPARAMETRIC PROSTATE MRI: COMPARISON AND OUTCOMES

Hussein D. Aoun, MD (*Presenter*) Reviewer, Galil Medical Ltd

**PURPOSE**

To assess whether fpMRI can potentially be utilized as a screening tool in early prostate cancer, as well as its association with PSA and available targeted biopsy results.

### METHODS AND MATERIALS

This is an IRB approved single institution retrospective review of 100 men between the ages of 50 and 80 who underwent mpMRI exams from January 2016 to May 2021. The patient population included 50 African American (AA) and 50 non-African American (non-AA) men. The mpMRI exams selected came from three categories: Group A (PI-RADS 1-2); Group B (PI-RADS 3); and Group C (PI-RADS 4-5). There were 20, 30, and 50 studies in groups A, B, C, respectively. The axial high resolution T2 weighted images and axial diffusion weighted images (fpMRI sequences) from each mpMRI exam were separated and de-identified. Two masked radiologists (R1 and R2) assigned each fpMRI case the highest possible lesion PI-RADS score. The collected fpMRI scores were then compared to the mpMRI results, PSA values, and available targeted biopsy outcomes.

### RESULTS

The median age for AA men and non-AA men was 66.5 and 66.0, respectively. The median PSA for AA men and non-AA men was 8.19 and 6.59, respectively. Median PSA for selected mpMRI groups A, B, C for AA men were 9.98, 6.79 and 8.05, respectively and 4.82, 7.15 and 7.40 for non-AA men. The concordance rates between the two fpMRI reviewers and mpMRI for groups A B, C were 0.69 (95% confidence interval [CI], 0.62 to 0.75). The Kappa statistics between the two fpMRI reviewers and mpMRI for groups A, B, C were 0.51 (95% CI,0.41 to 0.62). There were slight differences in median PSA values across groups A, B, C whether those PI-RADS groups were determined by mpMRI, by R1 fpMRI, or by R2 fpMRI. The positive predictive value (PPV) of group C for Gleason score (GS) > 7 for mpMRI, for R1 fpMRI, and for R2 fpMRI was 0.76 (= 35/46; 95% CI, 0.61 to 0.87), 0.76 (= 34/45; 95% CI, 0.60 to 0.87), and 0.79 (= 30/38; 95% CI, 0.63 to 0.90), respectively. The PPV of groups B or C combined for GS > 7 for mpMRI, R1 fpMRI, and R2 fpMRI was 0.62 (= 40/64; 95% CI, 0.50 to 0.74), 0.67 (= 40/60; 95% CI, 0.53 to 0.78), and 0.72 (= 39/54; 95% CI, 0.58 to 0.84), respectively. The negative predictive value (NPV) of group B or C combined for GS = 7 on mpMRI, R1 fpMRI, and R2 fpMRI was 100% (= 3/3; 95% CI, 29 to 100%), 100% (= 7/7; 95% CI, 59 to 100%), and 92% (= 12/13; 95% CI, 64 to 100%), respectively.

### CONCLUSION

The concordance rates, PPV and NPV between the mpMRI and fpMRI results for groups B and C were moderately high, moderately high, and very high, respectively. This pilot study suggests that a larger prospective study might be beneficial to help establish fpMRI as a screening tool for prostate cancer.

### CLINICAL RELEVANCE/APPLICATION

This study was performed to assess the overall concordance of fpMRI protocol versus mpMRI protocol.

## T5A-SPGU-7 FROM PIXELS TO REALITY: RADIOMICS-DRIVEN MACHINE LEARNING FOR ISUP CLASSIFICATION IN CLEAR CELL RENAL CELL CARCINOMA AND SHAP EXPLAINABILITY FOR FEATURE IMPORTANCE

M. Milagros Otero-Garcia, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Alejandra Garcia Baizan, MD (*Abstract Co-Author*) Nothing to Disclose
Paolo N. Franco, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Inmaculada Aymerich Lopez (*Presenter*) Nothing to Disclose

### PURPOSE

Radiomic features were widely used to develop predictive models to support clinical decisions in different pathologies. Concerning clear cell renal cell carcinoma (ccRCC), studies for its classification according to Fuhrman grade were published. However, the ISUP grade is currently used and more research should be done in that direction.The objective of this work is to determine the ISUP grade of ccRCC from the nephrographic series of abdominal CT using machine learning models with radiomic features. SHAP values will be employed to enhance explainability of the model and feature importance.

### METHODS AND MATERIALS

This is a retrospective observational study with the approval of the Local Ethics Committee. 109 patients were recruited from 2019 to 2021. Subjects with contrast-enhanced CT prior to nephrectomy as well as pathological confirmation of the diagnosis were included. The nephrographic phase of each study was selected. Tumor volumes were segmented and 105 radiomic variables for each VOI were extracted. For feature selection, the intraclass correlation coefficient of each feature was calculated using the segmentation of three radiologists. Only features with an excellent ICC were selected. Then, highly correlated variables were avoided and the MRMR (maximum relevance minimum redundancy) algorithm was used. Then, different machine learning models were trained and their performance was evaluated. SHAP values were calculated to assess the importance of the features in each decision. Python software was used.

### RESULTS

After calculating the ICC of the 105 radiomic features, 65 had an excellent ICC value. Of these, 20 were selected, as the rest were highly correlated with each other. These features were ordered according to their highest degree of relevance and least redundancy and the 5 most relevant were selected. Several machine learning models were trained with these features, using 8-fold and grid search to optimize the model hyperparameters. Among them, logistic regression was the one that had the best metrics (accuracy 81.8%, AUC 0.86). SHAP values were computed, demonstrating that Major axis length is the feature that contributed the most to the prediction.

### CONCLUSION

The ISUP grade of ccRCC can be predicted from a selection of radiomic features extracted from the CT nephrographic series. These features acted as biomarkers within a machine learning model based on logistic regression.

### CLINICAL RELEVANCE/APPLICATION

Clinical implementation of models for ISUP grade prediction of ccRCC holds promise in enhancing patient care since it could provide insight into the aggressiveness of the tumor before biopsy or surgical intervention, offering valuable guidance for clinicians in determining optimal and personalized therapeutic strategies.

## T5A-SPGU-8 IMPACT OF PROSTATE MRI IMAGE QUALITY ON DIAGNOSTIC PERFORMANCE FOR CLINICALLY SIGNIFICANT PROSTATE CANCER (CSPCA)

Yue Cheng (*Abstract Co-Author*) Nothing to Disclose
Yao Niu (*Abstract Co-Author*) Nothing to Disclose
Liang Wang, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the image quality of the main sequences in PI-RADS base on several subtle image differences and explore it’s effects on clinically significant prostate cancer(csPCa) detection, positive predictive value(PPV) and radiologist’s diagnosis in different sequences and prostate zones.

## METHODS AND MATERIALS

This single-center retrospective study included 306 patients undergoing prostate MRI prior to biopsy. All pathological specimens were reported by dedicated urogenital pathologist. csPCa was considered as Gleason=7(ISUP=2). Three readers evaluated the image quality of different aspects of each MRI sequence and compared with the PI-RADS score before biopsy and pathological results. Diagnostic accuracy and statistical significance were calculated with Wilson’s 95% confidence intervals.

## RESULTS

High-quality images had higher diagnostic accuracy and PPV of csPCa, which was more significant in T2WI and DWI. PI-RADS 3 had more poorer quality images and DWI-related image quality had a significant effect on PI-RADS classification. Regarding the relationship between prostate zone and image quality, csPCa detection rates showed statistical differences between high- and low-quality images only at the peripheral zone, while this difference was not significant at the transition zone or lesions involved both transition and peripheral zones.

## CONCLUSION

Prostate MRI quality may have an impact on the diagnostic performance. The poorer image quality is associated with lower csPCa detection rates and PPV, which can lead to an increase in radiologist’s ambiguous diagnosis (PI-RADS 3), especially for the lesions located at the peripheral zone.

## CLINICAL RELEVANCE/APPLICATION

These findings emphasize the importance of sufficient quality control of MRI scan based on the patient's own situation and clinical needs, as well as the necessity of adjusting the doctor's diagnostic strategy appropriately based on scan quality, which can be used to guide more helpful and relevant clinical decisions.

### PURPOSE

Congenital isolated middle ear malformation (CIMEM) is extremely rare. This study aims to analyze which middle ear structural abnormalities of CIMEM can be diagnosed preoperatively on multi-slice computed tomography (MSCT) and which cannot.

### METHODS AND MATERIALS

This was a retrospective study. Patients diagnosed with CIMEM during surgery at the Affiliated Hospital of Zunyi Medical University from January 2018 to June 2023 were enrolled. All patients underwent temporal bone CT scanning before surgery using the GE Optima CT680 Series under the following conditions: 140 kV, 300 mA, slice thickness of 0.625 mm, with bone algorithm. Imaging studies were interpreted by consensus of two neuroradiologists.

### RESULTS

A total of 36 patients were included in this study, including 24 males (66.6%) and 12 females (33.3%), with a median age of 16.5 years (range: 6-48 years). A total of 43 ears underwent surgery, with 7 bilateral surgeries and 29 unilateral surgeries. Preoperative MSCT demonstrated a 100% detection rate for complete absence or deformity of the stapes superstructure, absence of the incudial long process, abnormal position of the incudial long process, abnormal or absent incudial body, absence of the incudial short process, malleus malformation, displacement and bifurcation of the tympanic segment of facial nerve canal, and adherence of the facial nerve canal to the ossicular chain. The CT detection rate for absence of the stapedial footplate and concomitant oval window atresia was 92.9%. Incudomalleolar joint fusion was observed in only 41.7% of cases on CT. Situations where CT was unable to determine included soft tissue connection between the incudial body and long process, soft tissue connection between the incudostapedial joint, and fixation of the stapedial footplate.

### CONCLUSION

Preoperative MSCT can effectively demonstrate the absence or deformity of ossicular chain components, oval window atresia, and displacement and bifurcation of the tympanic segment of facial nerve canal. However, MSCT has a lower detection rate for incudomalleolar joint fusion and cannot assess situations such as soft tissue connection between ossicles and fixation of the stapedial footplate.

### CLINICAL RELEVANCE/APPLICATION

This study can provide imaging guidance for clinical doctors in the preoperative management of CIMEM.

## T5A-SPHN-4 SPONTANEOUS CUTANEOUS EXTRUSION OF PAROTID GLAND STONE: A CASE REPORT AND LITERATURE REVIEW

Mashael M. Alharthi, MBBS,MBBS (*Abstract Co-Author*) Nothing to Disclose
Ghouth A. Waggass, MBBS (*Abstract Co-Author*) Nothing to Disclose
Abdulmalik Abumohssin, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

The parotid gland is an exocrine salivary gland composed of superficial and deep lobes within a facial capsule.The formation of stone within the salivary ducts is termed sialolithiasis; 5-20 percent arise in the parotid glands. Clinically present with pain and swelling but may be asymptomatic. Diagnostic workups include imaging and direct visualization with sialoendoscopy. Treatment regimens include parotid gland resection, extracorporeal shock-wave lithotripsy (ESWL), and transoral duct surgery (TDS).

### METHODS AND MATERIALS

The purpose of the study is to discuss a case of parotid gland stone migration with cutaneous extrusion and provide a literature review.Literature review: searched using PubMed, Google Scholar, and ScienceDirect, along with a manual review of references. Articles were limited to those in the English language.

**RESULTS**

A 50-year-old male with a background of hypertension was referred to the ENT clinic at our hospital due to left-side recurrent parotitis for the last two years that was treated by antibiotics. The patient presented with painless swelling. The clinical exam showed stable vital signs, a small firm, non-tender, palpable 1-2 cm mass on the left parotid areas, and no palpable lymph nodes. The facial nerve is intact, and the bimanual exam didn't show any purulent discharge. CT Neck from outside was provided, and two small stones were shown along the course of the left parotid duct. A 16-month follow-up CT scan shows cutaneous migration and extrusion of the previously described stone. Otherwise, there are no signs of acute inflammation. Ultrasound correlation showed calcified subcutaneous focus in the area of concern with a small amount of fluid collection. The sialogram showed complete occlusion of the Stenson's duct on the left without visualization of the parotid gland. On operation day, the patient brought the stone intact in a box. It was spontaneously extruded without the intention of removing it. The texture was hard with a trace of blood stain on it; the wound site did not completely heal, but there were no signs of active infection or bleeding.

**CONCLUSION**

Parotid gland stones are rare entities compared to submandibular stones.Our case is seventh in the medical literature.CT scan can be used for stone localization and follow-up.

**CLINICAL RELEVANCE/APPLICATION**

Conservative management can be considered in uncomplicated parotid gland stones.

## T5A-SPHN-5 FEASIBILITY OF ELECTRON DENSITY MAP DERIVED FROM UNENHANCED DUAL-ENERGY CT FOR DETECTING PERITONSILLAR ABSCESS

**PURPOSE**

To evaluate the feasibility of electron density (ED) map derived from unenhanced dual-energy CT (DECT) for detecting peritonsillar abscess.

**METHODS AND MATERIALS**

This study included 116 consecutive patients who were clinically suspected of peritonsillar abscess and underwent DECT (99 abscesses and 17 tonsillitis). The final diagnosis of peritonsillar abscess was determined by typical imaging findings on contrast-enhanced CT. A board-certified radiologist evaluated the presence or absence of peritonsillar abscess on unenhanced conventional 120-kVp images (CTconv), 70- and 40-keV virtual monochromatic images (VMIs), and ED map by using a 4-point diagnostic score as follows: 4, highly likely; 3, likely; 2, unlikely; and 1, highly unlikely. For each image, cases rated as 3 or 4 on the diagnostic s score were defined as with peritonsillar abscess, while those rated as 1 or 2 were defined as without abscess. The contrast-to-noise ratio (CNR) of abscess lesions was calculated using the following formula: CNR= [adjacent tonsils - abscess center]/ [standard deviation in adjacent tonsils]. In cases confirmed to have peritonsillar abscess, the diagnostic score was compared between unenhanced CTconv and DECT images using the Mann-Whitney U test. CNR was also compared using the paired t-test. In addition, sensitivity, specificity, and diagnostic accuracy of peritonsillar abscess were calculated for each image and their diagnostic performances were compared by the McNemar test.

**RESULTS**

The diagnostic score for detecting peritonsillar abscess and CNR for ED map were significantly greater than those for CTconv (both, $p < 0.001$). The sensitivity, specificity, and accuracy for diagnosing peritonsillar abscess were 62.2%, 83.3%, and 65.5% for CTconv, respectively; and 78.6%, 83.3%, and 79.3% for ED map. The accuracy of ED map was significantly greater than that of CTconv ($p < 0.001$).

**CONCLUSION**

ED map derived from unenhanced DECT may enable efficient identification of peritonsillar abscess without the use of contrast agents.

**CLINICAL RELEVANCE/APPLICATION**

ED map provides useful information to detect peritonsillar abscess without the use of contrast agents.

### PURPOSE

Synthetic data generation plays a crucial role in enhancing model explainability and performance improvement in medical imaging. We present an open-source diffusion model capable of generating multi-resolution chest radiographs conditioned on radiology reports, serving as a model-as-a-dataset for the research community to leverage and develop upon.

### METHODS AND MATERIALS

A Matryoshka diffusion model was developed and trained on the MIMIC-IV dataset containing 220,000 chest radiographs. The model generates multi-resolution images (642, 2562, 10242) and can be extended to higher resolutions. Conditioning is based on the findings section of radiology reports embedded using the publicly available OpenAI large embedding model, which enables more detailed image descriptions compared to previous works conditioned only on the impression section. The model was trained to support positive and negative prompts, allowing for the disentanglement of image attributes and removal of confounding factors. Additionally, the model's output is post-processed by an image de-identification algorithm to ensure robustness and remove potential PHIs.

### RESULTS

It cost $2.14 to embed the 16 million tokens of all MIMIC-IV CXR reports. Generating 1000 images (all three resolutions) takes 14.8 minutes. A review of 50 generated 10242 images and 50 real cases revealed a discrimination rate of 58%. The Fréchet Inception Distance (FID) of 5,000 generated images, a metric quantifying the quality and diversity of the generated images (lower is better), was 2.4 for 642, 6.8 for 2562, and 18.7 for 10242 images. These FID scores significantly outperform the previously reported value of 54.9. Additionally, the model’s capabilities in inpainting were evaluated based on text prompts; whereby an area of the CXR is marked by the user and asked to be filled with a specific pathology.

### CONCLUSION

We developed an open-source multi-resolution chest X-ray diffusion model with granular conditioning on radiology reports findings, demonstrating high-quality image generation, with low FID. This model-as-a-dataset approach enables researchers to generate synthetic chest X-rays with desired characteristics, facilitating model explainability and performance improvement.

### CLINICAL RELEVANCE/APPLICATION

The proposed model serves as a valuable tool for radiologists and researchers, enabling the generation of diverse, high-resolution chest X-rays with specific pathologies and characteristics. Besides its educational value, this can aid in the development and validation of computer-aided diagnosis systems and support research on rare pathologies. The open-source nature of the model fosters collaboration and accelerates advancements in the field of medical imaging.

## T5A-SPIN-3 MODEL-AGNOSTIC EXPLANATIONS FROM A DEEP-LEARNING COX MODEL SUGGEST THAT FIRST-ORDER AND GRAY-LEVEL RADIOMIC FEATURES ARE THE BEST PREDICTORS OF SURVIVAL IN PATIENTS WITH NON-SMALL CELL LUNG CANCER

Suhrud Panchawagh (*Abstract Co-Author*) Nothing to Disclose
Ashish L. Atre, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Lung cancer is the highest cause of mortality among all cancers. Literature suggests that the 5-year survival rate for non-small cell lung cancer ranges from 17% to 37%. Given the aggressive nature of the malignancy, counseling the patients and their relatives regarding survival times takes precedence. Radiomics involves extracting large quantities of features from medical images using data-characterization algorithms, aiding in disease diagnosis and treatment predictions. We propose a deep-learning survival model relying on radiomic high-resolution computed tomography features to estimate survival time.

**METHODS AND MATERIALS**

We comprehensively analyzed 422 CT scans from the NSCLC-Radiomics dataset from The Cancer Imaging Archive. Expert radiologists meticulously segmented primary neoplasms. Using PyRadiomics, we extracted 2446 radiomic features and retained 104 after ensemble feature selection. We used a Cox proportional hazards (Cox PH) framework, parameterized with a multi-layer perceptron neural network, to analyze survival data by adjusting the baseline hazard function based on the provided covariates. Model hyperparameters were optimized using a validation set. Local interpretable model-agnostic explanations (LIME) were used to explain model predictions.

**RESULTS**

The median age of the participants was 69 years, and 31% were females. The median survival time was 1.53 years, and 89% of deaths occurred during the study duration. The model achieved a time-dependent concordance score of 0.98, an integrated Brier score of 0.011, and an integrated negative binomial log-likelihood score of 0.04. LIME revealed that the gray-level size zone matrix, gray-level dependence matrix, and first-order features passed through original and local binary pattern filters were the most responsible for survival.

**CONCLUSION**

Our multi-layer perceptron survival model revealed excellent performance metrics. Tumor heterogeneity and coarseness explained patient survival the most. Further model refinements can be done using more extensive multicentric data, hand-crafting feature selection, tuning model hyperparameters well, and observational studies using this model in clinical settings.

**CLINICAL RELEVANCE/APPLICATION**

Current tools estimating survival times rely primarily on subjective estimates, considering clinical features, imaging, and histopathological examination. To the best of our knowledge, no quantitative objective estimate exists to estimate survival times specific to the patient. Integrating such robust models into clinical practice could substantially enhance the accuracy of survival predictions, thereby supporting more personalized treatment planning.

## T5A-SPIN-4 ACUTE PULMONARY EMBOLISM RISK STRATIFICATION BASED ON IMAGING, LABORATORY AND CLINICAL DATA USING MACHINE LEARNING: A PILOT STUDY

Jiri Weichet, MD (*Abstract Co-Author*) Nothing to Disclose
Hana Malikova, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Michal Buk, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Scoring systems for acute PE (pulmonary embolism) risk assessment, such as the Simplified Geneva Score (SGS), pulmonary embolism rule-out criteria (PERC) or age-adjusted D-Dimer value (DD), are together with clinical experience commonly used to indicate CT pulmonary angiography (CTPA), the gold standard diagnostic test for PE. However, they are based mainly on empirical evidence and domain knowledge and are inherently simplistic, disregarding relative importance and relationships between clinical and/or laboratory parameters they are based on. This commonly leads to overuse of CTPA, meaning unnecessary burden of the patient with ionizing radiation and iodine contrast, and associated costs. The aim of this study is to use clinical and laboratory data of patients who underwent CTPA for suspected PE and construct a model using machine learning for predicting high risk PE patients.

**METHODS AND MATERIALS**

Our dataset contained 690 patients with suspected PE who underwent clinical and laboratory examination and subsequent CTPA. In total 27 clinical and laboratory parameters were gathered. An experienced radiologist assessed the CTPA for presence of PE and assigned a score according to the most proximal level of the pulmonary vasculature where PE was present, which served as the ground truth. For the training group, 551 patients were randomly selected, and the remaining 139 served as the test group. A classification model using the XGBoost algorithm was trained to assess the probability of PE, using a threshold value to label high risk patients. Using the same test group, the SGS was also calculated, labeling the patient as high risk in case of SGS = 3 and/or elevated age-adjusted DD.

**RESULTS**

Using SGS in combination with DD to estimate high risk PE patients yielded 27 true positive, 95 false positive, 15 true negative and 2 false negative results, which translates to 93.1 % sensitivity and 13.64 % specificity. Using our model to predict high risk PE patients yielded 35 true positive, 59 false positive, 44 true negative and 1 false negative result, which translates to 97.22 % sensitivity and 42.72 % specificity. When comparing these two, there were 22.86 % more true positive, 61.02 % less false positive, 65.91 % more true negative and 100 % (1 case) less false negative results using our model.

**CONCLUSION**

On our test group, our model outperforms the gold standard of SGS and DD for selecting high risk PE patients, mainly producing significantly less false positive results, therefore having much higher specificity, and slightly increased sensitivity.

**CLINICAL RELEVANCE/APPLICATION**

When applied to clinical practice using this model might reduce the number of unnecessary CTPA examinations and could be more precise than previous empirically based PE risk assessment tools.

## T5A-SPIN-5 CONSTRUCTION OF A SYSTEM TO PREVENT CONTRAST AGENT MISADMINISTRATION USING A.I. AND COMPARISON BETWEEN SMART GLASSES AND FIXED-POINT CAMERAS

Michimasa Suzuki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Satoru Kawai (*Abstract Co-Author*) Nothing to Disclose
Noboru Hojo (*Abstract Co-Author*) Nothing to Disclose
Chinatsu Ozawa (*Abstract Co-Author*) Nothing to Disclose
Kenzo Muroi (*Abstract Co-Author*) Nothing to Disclose
Shinsuke Kyogoku, MD,PhD (*Abstract Co-Author*) Nothing to Disclose

TAKASHI OMINO (*Abstract Co-Author*) Nothing to Disclose
Kazuya Abe (*Presenter*) Nothing to Disclose

**PURPOSE**

Iodine contrast media used in CT and other procedures can cause serious side effects such as anaphylactic shock. If a patient has had an adverse reaction to a contrast agent in a previous examination, the use of the same contrast agent is contraindicated due to the risk of recurrence of the adverse reaction. Therefore, the patient is interviewed and the history of side effects is checked prior to the examination, and a different contrast agent is used if there is an adverse reaction and its use is clinically unavoidable. However, there have been incidents in which the same contrast agent was administered as the one with a history of side effects due to insufficient confirmation. Currently, there is no system specifically designed to prevent such incidents. Therefore, we have developed a system that analyzes images from a fixed-point camera and smart glasses, and sounds an alarm when a specified contrast syringe is used. We compared the two systems and report the results.

**METHODS AND MATERIALS**

The real-time object detection algorithm YOLO (You Only Look Once), which is deep learning, was used for detection. The contrast syringe used to construct the model was a four-material type adopted by the hospital. The fixed-point camera was set up so that the CT system and the bed could be seen and the examination room could be seen widely. The patient wore smart glasses, held the contrast syringe in his hand, and moved around the bed to take images. A total of 377-412 images were prepared for the study. The Microsoft annotation tool Vott was used to annotate the images. These images were used to build the model. The alert sounding system was created in Python.

**RESULTS**

All formulations were more detectable with the smart glasses than with the fixed-point camera. In addition, data trained with both images performed better than data trained with each image alone.

**CONCLUSION**

The system was developed and verified to prevent misadministration. Smart glasses were superior to fixed-point cameras in detection. If the fixed-point camera can also sufficiently satisfy factors such as installation location, it will be possible to reduce the misadministration of contrast media.

**CLINICAL RELEVANCE/APPLICATION**

Currently, there is no system specifically designed to prevent the administration of contraindicated contrast agents. Being able to identify the syringe from the video image would be a protective barrier to prevent human error.

## T5A-SPIN-6 HIPAA-COMPLIANT OPEN-SOURCE LARGE LANGUAGE MODELS (LLMS) FOR RADIOLOGY REPORT ANNOTATION: A COMPREHENSIVE ANALYSIS OF MODEL SIZE, PROMPTING STRATEGIES, AND PATHOLOGY COMPLEXITY

Hari Trivedi, MD (*Abstract Co-Author*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;
Saptarshi Purkayastha, PhD (*Abstract Co-Author*) Nothing to Disclose
Bardia Khosravi, MD, MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the impact of model size and chain-of-thought (CoT) prompting on the performance and efficiency of open-source, HIPAA-compliant large language models for annotating chest radiograph reports with varying degrees of pathology complexity.

**METHODS AND MATERIALS**

A random subset of 2,000 chest radiograph reports from MIMIC-IV, a publicly available dataset, was manually annotated. These were used to evaluate the performance of open-source LLMs: Phi-3 (3B), Zephyr-beta (7B), Llama-3 (8B and 70B variants). The reports were annotated for three pathologies with increasing complexity: pneumothorax (simplest; explicitly mentioned in text), rib fracture (moderate; requires distinguishing from other fractures like scapula), and cardiomegaly (most complex; necessitates deduction from patient results, e.g., enlarged cardiac silhouette). Models were tested with and without CoT prompting on an A100 GPU, assessing performance metrics and compute time.

**RESULTS**

Without CoT, Phi-3, Zephyr, and Llama-3-8B processed each report (with three pathologies) in 0.6s, while Llama-3-70B took 2.6s (4 times slower). With CoT, each report was analyzed in 32.3s with Llama-3-70B, 13.8s by Zephyr and Llama-3-8B, and 10.8s by Phi-3. Larger models generally outperformed smaller ones, with the 70B model achieving the highest F1 scores and NPVs across all pathologies. CoT improved average sensitivity by 0.44% to 1.73% for larger models (7-70B) but decreased it by 19.03% for the smallest model (3B), likely due to hallucinations based on the generated reasonings. For the simplest pathology (pneumothorax), medium-sized models (7B and 8B) performed very well, with sensitivities >95%, suggesting their adequacy for easier pathologies that involve simple text searches.

**CONCLUSION**

Model size significantly influenced performance, especially for complex pathologies like cardiomegaly. While CoT prompting slightly enhanced performance for larger models, the gains were negligible. Compute time increased with model size and CoT usage, presenting a trade-off between performance and efficiency.

**CLINICAL RELEVANCE/APPLICATION**

Our research provides insights into optimizing open-source LLM selection and prompting strategies for automated radiology report annotation while maintaining HIPAA compliance. Researchers can make informed decisions when implementing these technologies in their workflows by considering pathology complexity, model size, and computational resources. While we recognize the potential of large, open-source language models for various radiology tasks, there is no one-size-fits-all highlighting a need for careful model selection and prompting.

## T5A-SPIN-7 STUDY ON THE TEXT-CNN CLASSIFICATION OF DIAGNOSIS REPORT ON LUNG CT AND THE RECOMMENDATION OF ACR ENCODING

Zhangzhen Shi (*Abstract Co-Author*) Nothing to Disclose
Lihui Zu (*Abstract Co-Author*) Nothing to Disclose
Jingxin Liu (*Abstract Co-Author*) Nothing to Disclose
Dong-Hong An (*Presenter*) Nothing to Disclose

### PURPOSE

To use text-CNN to automatically classify the conclusions of lung CT report, and to automatically recommend ACR coding of Radiology Diagnostic conclusions in local language.

### METHODS AND MATERIALS

A total of 80,000 lung CT diagnostic reports (2017-2023), were downloaded from the RIS-PACS system of the hospital's data center. The conclusion part of the diagnostic report in local language was subjected to text preprocessing, including text cleaning, word segmentation in local language, and word frequency analysis. According to the local language version of ACR encoding, obtain the training grouping scheme for diagnostic disease name corresponding to the keywords in local language. The content includes 10 common lung diseases, including nodules, calcification, inflammation, fibrosis, fluid accumulation, emphysema, bullae, fractures, deposition, tuberculosis, etc. Chunk the conclusion of the report according to periods or semicolons. Query and group a single sentence according to the above 10 disease groups, generate a single label dataset, and obtain a total of 255,026 samples. Quantify each sentence in the text. Complete the sample dataset and divide it into training and validation sets in an 8:2 ratio. Train the text-CNN model. Also, We compared the text-CNN classification and ACR code recommendation with the fast-CNN model which were generated simultaneously. In the experiment, Python 3.7, tensorflow 2.0, pandas 1.3.5, sklearn 1.0, jieba 0.42.1, seaborn 0.12.2, etc. were used.

### RESULTS

By Training, fine-tuning, we obtained a text-CNN model, which embedding dimension is 20, number of convolution kernels is 32, and convolution kernel size is [2,3,4]. For the validation set, the recognition rate can reach 75%. The recognition rate of the fast-CNN model is 72%

### CONCLUSION

Machine learning methods such as text-CNN can be used to automatically recommend ACR codes for conclusions of radiology diagnostic reports in local language and accelerate the encoding speed of report's conclusions in the RIS system . Clarify the accumulated data on the daily RIS stock over the past decade. Improve RIS-PACS data reuse performance. Create a good conditions for the clinical, educational, and scientific application of RIS-PACS data. Specially creating a good conditions for the jointed training of text-image AI models in RIS-PACS.

### CLINICAL RELEVANCE/APPLICATION

This research may improve reuse performance of RIS-PACS data and create a good conditions for the clinical, educational, and scientific application of RIS-PACS data.

## T5A-SPIN-8 CHATGPT ON ACR APPROPRIATENESS CRITERIA: CAN CONTEXTUALIZED GPT OUTPERFORM HUMANS IN ASSESSING MUSCULOSKELETAL MRI SCAN REQUEST APPROPRIATENESS?

Jin Rong Tan, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Gita Y. Karande, MMEd, FRCR (*Abstract Co-Author*) Nothing to Disclose
Keefe Lai, FRCR,MBBS (*Abstract Co-Author*) Nothing to Disclose
Lai-Peng Chan, FRCR,MBBS (*Abstract Co-Author*) Nothing to Disclose
Anh N. Tran (*Abstract Co-Author*) Nothing to Disclose
May S. Mak, MBChB, FRCR (*Abstract Co-Author*) Nothing to Disclose
Sudharsan Madhavan, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Large Language Models (LLM) are potentially useful clinical decision support tools, especially when grounded with domain-specific knowledge. In radiology, there is currently limited evidence regarding LLM solutions to assess imaging appropriateness. The purpose of this study is to evaluate a contextualized LLM's performance in assessing musculoskeletal MRI scan request appropriateness, and to compare LLM performance against humans across a range of clinical experience.

### METHODS AND MATERIALS

A contextualized LLM with GPT-4 to validate the appropriateness of MRI scan orders within clinical contexts was developed. To mitigate hallucination and enhance LLM knowledge, a retrieval-augmented generation framework was used to equip the LLM with a domain-specific knowledge base constructed from 33 American College of Radiology Appropriateness Criteria guidelines for musculoskeletal conditions. A test dataset of 70 fictional case scenarios was created based on the same guidelines, including cases with insufficient clinical information to justify a scan request. Quantitative evaluation using the McNemar mid-P test was performed, comparing standard GPT-4, contextualized GPT-4, and human clinicians, including two subspecialist radiologists, two radiology trainees, and an orthopaedic surgeon. Qualitative assessment compared the output of standard (non-RAG) GPT-4 with the contextualized model.

### RESULTS

The contextualized model achieved an accuracy of 88.57%, and demonstrated statistically significant superior performance compared to the human radiology trainees, orthopaedic surgeon and standard GPT-4 model. It had numerically superior performance compared to two radiologists, although not statistically significant. The standard GPT-4 model achieved an accuracy of 55.71%, and demonstrated inferior performance compared to the subspecialist radiologists and a radiology trainee. Notably, the contextualized model correctly identified all cases which had insufficient clinical information, whereas the standard GPT-4 LLM could not.

### CONCLUSION

A contextualized LLM is more effective than a standard LLM in assessing scan appropriateness based on ACR guidelines. Contextualized LLM outperformed human respondents including subspecialist radiologists, emphasizing their potential as a clinical decision support tool.

### CLINICAL RELEVANCE/APPLICATION

A chatbot grounded with domain-specific knowledge of imaging appropriateness guidelines is more effective than a standard model, and outperformed human respondents including subspecialist radiologists in assessing musculoskeletal MRI scan appropriateness.

## T5A-SPIR-5 TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT COMBINED WITH VARICEAL EMBOLIZATION REDUCES THE RISK OF REBLEEDING FOR PATIENTS WITH POST-TIPS PPG GREATER THAN 12 MMHG

Chuansheng Zheng, MD (*Abstract Co-Author*) Nothing to Disclose
Yaowei Bai (*Presenter*) Nothing to Disclose

### PURPOSE

The consensus on whether Transjugular intrahepatic portosystemic shunt (TIPS) should be combined with variceal embolization in the treatment of portal hypertension bleeding has not yet been reached. This study aimed to compare the difference in rebleeding incidence between TIPS and TIPS combined with variceal embolization and to analyze the optimal population for variceal embolization.

### METHODS AND MATERIALS

Clinical data of 721 patients undergoing TIPS creation were retrospectively collected. After screening based on inclusion and exclusion criteria, 406 patients were included. Patients were divided into two groups according to whether TIPS combined with variceal embolization was performed: TIPS group (n=155) and TIPS+E group (n=251). Kaplan-Meier (KM) curves were used to analyze prognostic differences between the two groups, and subgroup analysis was conducted based on post-TIPS portal pressure gradient (PPG) exceeding 12 mmHg.

### RESULTS

After TIPS placement, the mean PPG significantly decreased for all patients (27.4±6.1 mmHg vs. 12.2±4.6 mmHg, P<0.001). A total of 51 patients (12.6%) experienced rebleeding, with 24 cases (15.9%) in the TIPS group and 27 cases (10.6%) in the TIPS+E group. There was no significant difference in cumulative rebleeding incidence between the TIPS+E and TIPS groups (HR=0.69, 95%CI=0.39-1.21, Log-rank P=0.18). In the subgroup with post-TIPS PPG greater than 12 mmHg, the cumulative rebleeding incidence was significantly lower in the TIPS+E group compared to the TIPS group (HR=0.47, 95%CI=0.24-0.93, Log rank P=0.026). In the subgroup with post-TIPS PPG less than 12 mmHg, there was no significant difference in cumulative rebleeding incidence between the two groups.

### CONCLUSION

For patients with post-TIPS PPG exceeding 12 mmHg, simultaneous variceal embolization with TIPS placement is recommended to significantly reduce the risk of post-TIPS rebleeding.

### CLINICAL RELEVANCE/APPLICATION

For patients with post-TIPS PPG exceeding 12 mmHg, simultaneous variceal embolization with TIPS placement is recommended to significantly reduce the risk of post-TIPS rebleeding.

## T5A-SPIR-6 MANAGEMENT OF MALIGNANT BILIARY OBSTRUCTION BY IMPROVING BILIARY STENTING WITH ZINC-SIROLIMUS-LOADED BIODEGRADABLE STENTS

Jung-Hoon Park, PhD (*Abstract Co-Author*) Nothing to Disclose
Yubeen Park (*Abstract Co-Author*) Nothing to Disclose
Dong-Sung Won, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Biodegradable biliary stents (BDBS) have emerged as a potential alternative, addressing concerns regarding stent removal in patients with unresectable malignant biliary obstruction (MBO). However, stent-induced tissue hyperplasia and biofilm formations challenges for removal. Drug-eluting multifunctional stents, incorporating silver nanoparticles, sirolimus (SRL), and paclitaxel have been demonstrated potential to mitigating these obstacles; however, translating these benefits into clear clinical efficacy remains challenging. This study aims to assess the efficacy and safety of Zn-SRL-loaded BDS in inhibiting tissue hyperplasia and bacterial activity in the rabbit common bile duct (CBD).

### METHODS AND MATERIALS

Polycaprolactone (PCL) composite with silica was fabricated with BDBS using a 3D printing system, subsequently coated with either SRL or Zn-SRL. The multi-functionalized stents were comprehensively characterized, including evaluation of surface properties, mechanical behavior, degradation and drug release kinetics, antibacterial efficacy, and cellular biocompatibility. Twenty male New Zealand white rabbits were divided into four groups: PCL, fPCL, SRL@fPCL, and Zn-SRL@fPCL. Hematological examination, cholangiography, and histological analysis were performed to evaluate mucosal changes and stent patency.

**RESULTS**

The multi-functionalized stents were exhibited tunable mechanical properties and sustained released kinetics to inhibit the bacterial activity and cytotoxicity. Stent placement was successful in all cases without complications. Jaundice was observed at 10-18 d in six rabbits in the PCL (n = 3), fPCL (n = 2), and SRL@fPCL (n = 1) groups. Cholangiography showed luminal narrowing and sludge formation in the PCL and fPCL groups, and stent patency was well preserved in the Zn-SRL@PCL group than in SRL@PCL group. Hematological and histological findings differed significantly among the groups ($p < 0.05$).

**CONCLUSION**

Application of SRL and Zn in fPCL significantly inhibited tissue hyperplasia and biofilm formation, resulting in well preserved stent patency without hepatobiliary dysfunction in rabbit CBD. Multi-functionalized BDBSs offer therapeutic potential of preventing stent-related complications and obviating the need for stent removal in inoperable patients.

**CLINICAL RELEVANCE/APPLICATION**

Zn-SRL-loaded BDBS show promise in reducing stent-induced tissue hyperplasia and biofilm formation in biliary stenting, potentially improving patency and decreasing complications in patients with MBO.

## T5A-SPIR-7 3D AUTOMATIC BODY COMPOSITION ANALYSIS TO PREDICT THE RISK OF POST-TIPS OVERT HEPATIC ENCEPHALOPATHY: A MULTICENTER STUDY

Xiaoqiong Chen (*Abstract Co-Author*) Nothing to Disclose
Shuoling Zhou (*Abstract Co-Author*) Nothing to Disclose
Jinqiang Chen (*Abstract Co-Author*) Nothing to Disclose
Yujie Zhao (*Abstract Co-Author*) Nothing to Disclose
Meiyan Huang (*Abstract Co-Author*) Nothing to Disclose
Sirui Fu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Hepatic encephalopathy (HE) after transjugular intrahepatic portosystemic shunt (TIPS) placement is highly prevalent and refractory; therefore, patients should be screened preoperatively. This study aimed to construct a malnutrition model based on a three-dimensional (3D) automatic assessment of skeletal muscle and fat tissues to predict overt HE post-TIPS.

**METHODS AND MATERIALS**

A total of 459 patients undergoing TIPS from five hospitals were divided into training (N=308) and external validation (N=151) groups. For subsequent comparison of the self-developed 3D (T12 to the L3 vertebrae) and existing two-dimensional (2D; at the middle level of the L3 vertebrae) assessment methods, we performed 3D automatic and 2D manual segmentation of muscle and fat tissues using preoperative computed tomography images, respectively. Next, we extracted their morphological and radiomic features and constructed the 3D-auto and 2D-manual MF Models. After comparing the two models via discrimination and calibration, we selected the better-performing method. Based on 26 clinical indicators, 26 morphological features, and 2,102 radiomic features, we developed the Clinical, 3D-auto MF, and Integrated Models, using LASSO and logistic regression. The optimal model was determined via discrimination and calibration.

**RESULTS**

First, for the assessment method of muscle and fat tissues, in discrimination the area under the curve (AUC) of the 3D-auto compared to the 2D-manual Model was 0.769 vs. 0.666 in the training set and 0.763 vs. 0.597 in the validation set. Meanwhile, the 3D-auto method performs better in terms of calibration curves. Therefore, we selected 3D-auto segmentation as the final assessment method for muscle and fat tissues. The Clinical Model incorporated two indicators. The 3D-auto MF Model incorporated nine indicators: four morphological and five grayscale-related radiomic features. The Integrated Model combined all these 11 indicators. Among these three models, the Integrated Model had a higher AUC than the Clinical and 3D-auto MF Models, both in the training (0.813 vs. 0.684 vs. 0.769) and validation sets (0.801 vs. 0.672 vs. 0.763); the Integrated Model also showed superior performance in the Delong test, net reclassification improvement, and integrated discrimination improvement. Similar results were observed for calibration.

**CONCLUSION**

We successfully developed a high-performance predictive model for overt HE post-TIPS, based on 3D automatic muscle and fat tissue assessment.

**CLINICAL RELEVANCE/APPLICATION**

Compared to 2D manual assessment, 3D automatic assessment of skeletal muscle and fat tissues could provide further information for the prediction of overt HE post-TIPS, thereby assisting in better patient selection for TIPS.

## T5A-SPIR-9 EFFICACY OF UTERINE ARTERY EMBOLIZATION USING GELATIN SPONGE PARTICLES FOR THE TREATMENT OF UTERINE LEIOMYOMA - A SYSTEMATIC REVIEW AND META-ANALYSIS

Obaid Ur Rehman (*Abstract Co-Author*) Nothing to Disclose
Eeshal Fatima (*Abstract Co-Author*) Nothing to Disclose
Zain Nadeem (*Abstract Co-Author*) Nothing to Disclose
Arsalan Nadeem, MBBS (*Abstract Co-Author*) Nothing to Disclose
Eeman Ahmad (*Abstract Co-Author*) Nothing to Disclose
Umar Akram (*Abstract Co-Author*) Nothing to Disclose
Ali Husnain, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Uterine leiomyoma is a benign tumor that, in addition to medical and surgical interventions, can be treated by uterine artery embolization (UAE). One of the embolic agents used for UAE is gelatin sponge particles. We aim to conduct a systematic review and meta-analysis to assess the efficacy of UAE using gelatin sponge particles.

**METHODS AND MATERIALS**

We reviewed PubMed, Embase, Scopus, and Google Scholar from the inception of the databases to April 2024. The inclusion criterion was the use of gelatin sponge particles for UAE in leiomyoma patients. Studies reporting outcomes such as mean reduction in the dominant leiomyoma volume and improvement in menorrhagia, dysmenorrhea, and bulk-related symptoms were included.

## RESULTS

Five studies involving a total of 391 participants were included in the analysis. Pooled proportion of mean reduction in the dominant leiomyoma volume was 42.17% at 3 months (95% CI: 33.65-50.68), 53.37% at 6 months (95% CI: 47.89-58.86), and 58.71% at 12 months (95% CI: 47.38-70.04). Pooled proportion of improvement in menorrhagia was 88% (95% CI: 85-91) at 3 months, 95% at 6 months (95% CI: 70-100), and 98% at 12 months (95% CI: 92-100). Pooled proportion of improvement in dysmenorrhea was 90% at 3 months (95% CI: 53-100), 96% at 6 months (95% CI: 66-100), and 89% at 12 months (95% CI: 61-100). Pooled proportion of improvement in bulk-related symptoms was 90% at 3 months (95% CI: 74-99) and 99% at 6 (95% CI: 92-100) as well as at 12 months (95% CI: 95-100).

## CONCLUSION

UAE using gelatin sponge particles is an effective treatment option for managing uterine leiomyoma. It significantly improves menorrhagia, dysmenorrhea, and bulk-related symptoms, which are symptoms related to increasing tumor size.

## CLINICAL RELEVANCE/APPLICATION

UAE using gelatin sponge particles for treating uterine leiomyoma is a promising intervention. This meta-analysis establishes its efficacy in reducing the tumor burden, in addition to improving menorrhagia, dysmenorrhea, and bulk-related symptoms.

## T5A-SPMK-1 ASSOCIATION OF TIBIAL SLOPE ALTERATIONS WITH ANTERIOR CRUCIATE LIGAMENT (ACL) INJURY AND MUCOID DEGENERATION

Shuda Xia (*Abstract Co-Author*) Nothing to Disclose
Avneesh Chhabra, MD, MBA (*Abstract Co-Author*) Consultant, ICON plc;Consultant, Treace Medical Concepts, Inc;Author with royalties, Wolters Kluwer nv;Author with royalties, Jaypee Brothers Medical Publishers Ltd;Speaker, Siemens AG;Medical Advisor, ImageBiopsy Lab;Research Grant, ImageBiopsy Lab
Flavio Duarte Silva (*Abstract Co-Author*) Nothing to Disclose
Mahad Rehman, BS, BA (*Abstract Co-Author*) Nothing to Disclose
Varun Ravi, BA (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the association of tibial slope (TS) alterations at the knee with ACL lesions by comparing radiographic measurements of lateral TS (LTS), medial TS (MTS), and coronal TS (CTS) with MRI defined intact, injured, and mucoid-degenerated native ACL knees and determine inter-reader reliability.

### METHODS AND MATERIALS

Patient records from two years at tertiary care hospitals were reviewed for individuals aged 18-100 who underwent both 3-Tesla knee MRI and radiographs. Two randomly selected cohorts, control, and pathologic ACLs on MRI with 86 patients each, were matched by age, gender, and BMI. A fellowship trained musculoskeletal radiologist revaluated all curated images, and characterized the ACL as normal, partially torn, completely torn, or having mucoid degeneration considering available reports from electronic health records. Two trained medical students independently collected clinical information and measured slopes on radiographs, blinded to the clinical and MRI findings. Intra-class correlation coefficient (ICC) estimates and case-control matching were done with the SPSS statistical package. ICC and analysis of variance were used for comparisons.

### RESULTS

Among 172 patients with 172 MRIs and radiographs, there were 86 controls and 86 ACL lesions. There were 108/172 (62.79%) males and 64/172 (37.21%) females. ICCs were 0.966 for MTS, 0.975 for LTS, and 0.978 for CTS. Mucoid degeneration patients had a higher BMI and were older than our controls ($p < .05$) or completely torn ($p < .001$) ACL patients. There was no difference in TS between normal and pathologic ACLs, however, LTS-MTS differences were larger with partial tears (2.5 +/- 4.9) than normal ACLs by 4.5 degrees (+/-1.2, $p < .001$), complete tears by 4.5 degrees (+/- 1.3, $p < .001$) and mucoid degeneration by 4.9 degrees (+/- 1.5, $p = .001$).

### CONCLUSION

Our results show that patients with partial ACL tears have a greater lateral-to-medial slope difference compared to patients with normal ACLs or other types of ACL pathologies. Additionally, patients with mucoid degeneration of the ACL tend to be older and have higher BMIs compared to patients with normal or completely torn ACLs. Furthermore, XR seems to be a reliable modality for separately measuring the medial, lateral, and coronal tibial slope.

### CLINICAL RELEVANCE/APPLICATION

These findings underscore the importance of considering biomechanical factors in ACL injury risk assessment and may inform future research endeavors aimed at elucidating the mechanisms underlying ACL pathology.

## T5A-SPMK-2 EFFICACY OF KNEE MR AI ALGORITHM IN PREDICTING CLINICAL SYMPTOMS OF PATELLAR INSTABILITY

Pascal Zille (*Abstract Co-Author*) Employee, Incepto Medical
Guillaume Herpe (*Abstract Co-Author*) Medical Officer Incepto-France Grant, Guerbet

Tom Vesoul (*Abstract Co-Author*) Nothing to Disclose
Gaspard d'Assignies, MD, PhD (*Presenter*) Founder, Incepto Medical SAS;Employee, Incepto Medical SAS;Stockholder, Incepto Medical SAS

### PURPOSE

Patellar instability is a common pathology that leads to patellar dislocations during acute phases, potentially resulting in progressive cartilage damage and severe arthritis if not adequately treated. Magnetic resonance imaging (MRI) serves as the primary diagnostic tool to identify anatomical patterns contributing to patellar instability. However, the laborious and time-consuming measurements related to these patterns are often underreported in

radiological reports. Artificial intelligence algorithms facilitate the automatic extraction of this crucial information. This study aims to investigate the relationship between reported symptoms of instability and the occurrence of high-risk patterns in images based on an analysis of over 10,000 MRI cases.

**METHODS AND MATERIALS**

In a prospective controlled study, we have extracted, using regular expression tools, the examinations performed for patients consulting for clinical symptoms of patellar instability from our external validation database of 11,074 MRI knee studies ( comparative arm ). A control arm containing patients without symptoms of patellar instability was included in the analysis. The selected exams were analyzed with our CE-marked automatic knee MRI AI algorithm. We analyzed all of the following parameters from the 3 knee compartments : Cartilages, Meniscus, ligaments, bone edema, TT-TG, trochlear sulcal depth, trochlear lateral inclination, Patellar height (Caton Deschamps index and Insall Salvati), joint effusion and Trochlear asymmetry ratio. Statistical Analysis : A univariate analysis was performed : for each variable, a logistic regression model was trained to predict the "patellar instability" class. This metric measures the ability of each individual variable to linearly predict the "patellar instability" class.

**RESULTS**

175 MRI were included in the comparative arm ( mean age, sex ratio ) and 175 in the control arm ( mean age, sex ratio ). The results of the analysis assessed the respective predictive accuracy : Trochlear sulcal depth ( 0.70 ), trochlear sulcus angle ( 0.70 ), trochlear lateral inclination ( 0.69 ), patellar height using Insall Salvati (0.65 ), patellar height using Caton Deschamps ( 0.60). The other variables resulted in accuracy values under 0.60.

**CONCLUSION**

Trochlear bone biometric features are the most predictive and the best correlated with symptoms. Given the time-consuming nature of the measurement, AI seems ideal in this context. However, AI must also adapt to the features most commonly used in clinical practice and those that have the most impact on patient management before adoption.

**CLINICAL RELEVANCE/APPLICATION**

Clinical symptom prediction of patellar instability can be achieved using automated AI measurment.

## T5A-SPMK-4 IMPACT OF THIGH MUSCLE AND FAT VOLUME ON THE 4-YEAR PROGRESSION OF KNEE OSTEOARTHRITIS IN OBESE PARTICIPANTS WHO ENGAGE IN PHYSICAL ACTIVITY

John A. Lynch, PhD (*Abstract Co-Author*) Nothing to Disclose
Gabby B. Joseph (*Abstract Co-Author*) Nothing to Disclose
Thomas M. Link, MD, PhD (*Abstract Co-Author*) Research Consultant, General Electric Company
Richard B. Souza, PhD (*Abstract Co-Author*) Nothing to Disclose
Upasana U. Bharadwaj, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the impact of thigh muscle and subcutaneous fat volume on the 4-year progression of knee osteoarthritis (OA) in obese participants who engage in physical activity, stratified by the type of activity.

**METHODS AND MATERIALS**

A total of 357 participants with BMI >= 25 kg/mm2 who engaged in various types of physical activity: ball sports (n=57), bicycling (n=58), elliptical trainer (n=84), jogging (n=67), racquet sports (n=37), and swimming (n=54) were selected from the Osteoarthritis Initiative cohort. Participants with Kellgren-Lawrence grade (KLG) > 3, missing knee MRI at baseline or 48-month follow up, missing thigh MRIs, or those who did not engage in any physical activity were excluded. Progression of knee OA was characterized using the difference in Whole-Organ Magnetic Resonance Imaging Score (WORMS) between baseline and 48-month knee MRI. A deep learning segmentation pipeline was used to compute subcutaneous fat and muscle volumes as well as cortical thickness from the corresponding axial T1-weighted thigh MRI at baseline. Associations were evaluated using linear regression adjusted for age, sex, BMI, KLG.

**RESULTS**

Significant association was found between the volume of quadriceps and 4-year progression of WORMS for meniscus (T=-2.19, p=0.03) across all activities; no significant associations were found for other muscle groups or subcutaneous fat. The bicycling group showed significant association for quadriceps (T=-2.69, p=0.01) and hamstrings (T=-2.01, p=0.04) with WORMS meniscus; as well as for quadriceps (T=-2.06, p=0.04) and cortical thickness (T=-2.27, p=0.03) with WORMS bone marrow lesions. The jogging group showed significant association for subcutaneous fat volume and WORMS cartilage (T=2.09, p=0.04). The racquet sports group showed significant association for cortical thickness (T=-2.09, p=0.04) and WORMS bone marrow lesions. No significant associations were found for elliptical, swimming, or ball sports.

**CONCLUSION**

Lower quadriceps volume was significantly associated with 4-year progression of WORMS meniscus across all activities. Bicycling, jogging, and racquet sports showed significant association for WORMS progression whereas elliptical, swimming, and ball sports did not show any progression.

**CLINICAL RELEVANCE/APPLICATION**

These results can potentially inform clinical management; namely, strengthening quadriceps and reducing subcutaneous fat volume in those engaging in rigorous activities such as bicycling, jogging, and racquet sports may delay progression of knee osteoarthritis.

## T5A-SPMK-6 MULTICENTER AND CROSS-DISCIPLINARY VALIDATION OF AI-BASED KELLGREN-LAWRENCE GRADING MODEL FOR KNEE OSTEOARTHRITIS ON PLAIN RADIOGRAPHY

Chang Ho Kang, MD (*Abstract Co-Author*) Nothing to Disclose
Jae-Joon Lee (*Abstract Co-Author*) CEO, Crescom Inc
Seungbong Han (*Abstract Co-Author*) Nothing to Disclose
Chong Bum Chang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyung-Sik Ahn, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
SANGUN KIM, MD (*Abstract Co-Author*) Nothing to Disclose
Kyu-Chong Lee, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To validate the multicenter reading efficacy of AI based Kellgren-Lawrence (KL) grading model for knee osteoarthritis (OA) and investigate the differences based on specialty and clinical experience.

## METHODS AND MATERIALS

The AI-based KL grading model, capable of detecting osteophytes and joint space narrowing, was developed using NASNet. For multicenter validation, a total of 458 matched subjects who undertaken knee radiographs in two tertiary hospitals were enrolled. Ground truth was built by the consensus of 4 experts with more than 10 years of experience. First, model performance was evaluated by AUC, accuracy, and reliability (?) compared with ground truth. Second, for user-oriented model validation, 4 trainees (2 radiologists and 2 orthopedic surgeons) with less than 5 years of experience evaluated KL grades in two sessions: with and without AI assistance. This validation compared AUC and ? of 4 users with and without software assistance. Finally, KL interpretation differences were evaluated using ? based on specialty and clinical experience.

## RESULTS

For model performance, the overall AUC, accuracy, and ? of the model were 0.918, 0.923.and 0.845, respectively. For user-oriented validation, AUCs of 4 users were increased with model assistance in entire KL grades. The overall ? of two expert radiologists and two expert orthopedic surgeons were 0.8629, and 0.7077, respectively and the difference ? (0.1550) was statistically significant (p=0.001). Especially, for KL 01 and 2, indicative of mild OA, the ? of the expert radiologists was significant higher (0.736 vs 0.505, p=0.0081, and 0.872 vs. 0.660, p=0.0068, respectively). Institution A, with less cumulative clinical experience had a significant lower ? (0.3883) than institution B (?=0.5592) without AI assistance. Furthermore, the improved ? values of institution A and B with AI assistance were 0.4594, and 0.2342, respectively, indicating a significantly higher improvement in institution A with lower clinical experience (difference=0.2253, p<0.001). Finally, one resident showed significantly higher improvement in AUC compared to the other three fellows, with the maximum increase in AUC approximately doubling (0.470 to 0.903).

## CONCLUSION

The AI-based KL grading model has equivalent accuracy to human experts. Additionally, the AI model appears to enhance the accuracy and reliability of both radiologists and orthopedic surgeons, especially for doctors with less clinical experience.

## CLINICAL RELEVANCE/APPLICATION

The newly developed AI model is useful for KL grading with feasible accuracy. Furthermore, this program could reduce different interpretations between the radiologists and orthopedic surgeons and is particularly beneficial for doctors with less clinical experience.

Francesca Pasquazzo, MD (*Abstract Co-Author*) Nothing to Disclose
Eda Bardhi (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze neoplastic tissue adjacent to radiofrequency thermal ablation (RFA) areas to demonstrate early perfusion anomalies and to suggest the synergic role of ablative techniques with chemotherapy treatments.

### METHODS AND MATERIALS

In this prospective study, a total of 10 mice were subjected to a colon-carcinoma cell implantation and after the tumor colonization, the RFA procedure was performed. All mice underwent a 7T MRI including 2D single-echo single-shot dynamic-contrast-enhanced (DCE) sequences with intravenous injection of gadolinium-based contrast agent (CA), before and after 72 hours from RFA treatment. Data-driven segmentation of the tumor mass enabled the identification of three ROIs with peculiar pharmacokinetic profiles of CA uptake: (i) VTA, viable tumor area; (ii) PNA, partial necrotic area; (iii) CNA, complete necrotic area. Within these ROIs, permeability (K-trans and extravascular-extracellular volume fraction, Ve) and perfusion (time to peak, TTP) indices were evaluated with non-parametric paired samples Wilcoxon tests.

### RESULTS

Robust increase of Ve (PNA and VTA, $p=0.014$, $p<0.001$, respectively) and TTP (VTA, $p<0.01$) is consistent with severe cellular and vascular damage induced by RFA.

### CONCLUSION

Perfusion MRI enables robust detection of significant modulation of the microvasculature within 72 hours from radiofrequency-induced ablation in a murine model of colon carcinoma. This opens a potentially new time window for the evaluation of therapeutic effects of RFA-enhanced chemotherapy.

### CLINICAL RELEVANCE/APPLICATION

Percutaneous treatments are increasingly used to manage different malignancies, with the purpose of being potentially curative. Remarkable modification of perfusion and permeability state of tumor’s growth were found after radiofrequency ablation, according to the neoplasia’s inner features. Considering a possible human application, assessment of perfusion changes in the ablated-zone and their quantification with DCE-MRI could help to identify a viable cell area with improved permeability and a potential target for further therapeutic approaches after thermal-ablation.

## T5A-SPMS-2 DEEP LEARNING BODY COMPOSITION ANALYSIS OF STAGING CT SCANS PREDICTS OUTCOMES AND FRAILTY IN GERIATRIC ONCOLOGY PATIENTS

James Hallinan, MBChB (*Abstract Co-Author*) Nothing to Disclose
Andrew Makmur, MD (*Abstract Co-Author*) Nothing to Disclose
Desmond Lim Shi Wei, MBBS, FRCR (*Presenter*) Nothing to Disclose

### PURPOSE

The body composition of an elderly cancer patient can be determined from staging CT scans using deep learning segmentation tools. Utilising the model “Total Segmentator”, we derived quantitative measurements including total muscle and fat volume along with qualitative analysis of fatty infiltration within muscle groups.We compared these body composition biomarkers against validated geriatric assessment scores (used to determine frailty in elderly patients), and survival outcomes.

### METHODS AND MATERIALS

We recruited 189 patients aged 70 years or older with newly diagnosed cancer. Each patient received a Geriatric Assessment in accordance with the American Society of Clinical Oncology. Each patient's staging CT scan (CT Thorax, Abdomen Pelvis) was put through a deep learning tool for organ

segmentation (Total Segmentator) to derive volumes and average intensities (in Houndsfield Units, HU) for each segmented organ including fat and muscle. All patients were categorised into groups according to their frailty status (fit vs frail) and their outcome (survival vs death during the study). T-tests were used to identify differences between the body composition biomarkers against clinical groups.

## RESULTS

The median age was 75 years old (70 - 90). The range of diagnoses included: gastrointestinal cancers (34.8%), lung cancers (18.7%) and breast cancers (12.6%), etc. At diagnosis 59.6% were receiving palliative intent treatment. Comparing between the fit vs frail group, there were significant differences (p-value less than 0.05) in the following biomarkers: extent of fatty infiltration of the paraspinal muscles (32HU vs 20HU, p-value = 0.003), gluteus muscles (29HU vs 18HU, p-value = 0.003) and all truncal muscles (HU34 vs HU29, p-value = 0.001), ratio of gluteus muscle volume against total muscle volume (0.020 vs 0.018, p-value = 0.003). Comparing between patients who survived vs died during the study (2 years duration), there were significant differences in the: average iliopsoas intensity (HU54 vs HU51, p-value = 0.01) and total subcutaneous fat (8.9L vs 7.9L, p-value = 0.049).

## CONCLUSION

Frail and fit elderly cancer patients show significant differences in some aspects of body composition which can be derived from staging CT scans.

## CLINICAL RELEVANCE/APPLICATION

A multivariable prognostication tool can be developed using CT derived body composition biomarkers and clinical scoring. This can be used to identify elderly cancer patients which may benefit from interventions to improve body composition and thus change outcome.

## T5A-SPNMMI-1 VEGFR2 TARGETED BIOSYNTHETIC NANO GAS VESICLES-BASED ULTRASOUND MOLECULAR IMAGING IMPROVING THE DIAGNOSTIC SENSITIVITY OF CANCER

Jianhua Zhou, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Xiaoxin Liang, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The vascular endothelial growth factor receptor 2 (VEGFR2) is not only a key effector in angiogenesis and cancer progression, but also expressed on the tumor cells, leading to tumor initiation. In recent years, microbubbles targeted to VEGFR2 have proven to improve the efficacy of ultrasound molecular imaging (USMI) of cancer. However, these microbubbles are restricted within the vasculature due to their relatively large particle size. Herein, we developed a VEGFR2-targeted gas vesicles (V2-GVs) with the particle size about 200 nm for tumor cells targeting in MB49 subcutaneous tumor mice and DEN/CCl4-induced orthotopic liver cancer mice.

### METHODS AND MATERIALS

V2-GVs were prepared by conjugating VEGFR2 antibody to the surface of GVs by amide reaction. The contrast-enhanced imaging features of non-targeted control GVs (Con-GVs) and V2-GVs were compared in MB49 subcutaneous tumor mice and DEN/CCl4-induced orthotopic liver cancer mice. The expression of CD31 and VEGFR2 of different sizes of tumors were assessed by fluorescence immunohistochemistry. The difference of signal intensity of V2-GVs and Con-GVs at 10 min were plotted to analyze the correlation between the USMI signal and the cell expression levels of VEGFR2 or CD31. The penetration ability of V2-GVs in tumor tissues was assessed by fluorescence immunohistochemistry.

### RESULTS

We found VEGFR2-targeted nanobubbles based USMI could successfully distinguish different lesions in diameter of 3-15 mm. The in vivo USMI experiments showed that V2-GVs produced stronger and longer retention in the subcutaneous bladder cancer and DEN/CCl4-induced liver cancer than that of the non-targeted Con-GVs (All $P < 0.05$). In addition, small lesions in diameter of 3-5 mm showed more expression of CD31 than those over 5 mm ($P < 0.0001$). However, the larger lesions in diameter > 10 mm showed more expression of VEGFR2 ($P < 0.001$). Moreover, the difference of signal intensity of V2-GVs and Con-GVs at 10 min showed a good linear correlation with the cell expression levels of VEGFR2 rather than CD31 (All $R2 > 0.82$, $P < 0.05$). Fluorescence immunohistochemistry confirmed that V2-GVs could penetrate the tumor vascular into the interstitial space of the tumors.

### CONCLUSION

VEGFR2-targeted nanobubbles have huge prospects for monitoring angiogenesis and tumor progression in different tumors.

### CLINICAL RELEVANCE/APPLICATION

VEGFR2-targeted nanobubbles based USMI have huge potential for clinical application of different cancers, providing the foothold for future studies on the imaging screening of this patient population.

## T5A-SPNMMI-2 REVERSE MAGNETIC RESONANCE TUNING NANOPLATFORM WITH HEIGHTENED SENSITIVITY FOR NON-INVASIVELY MULTISCALE VISUALIZING FERROPTOSIS-BASED TUMOR THERAPY

Zhongling Wang (*Abstract Co-Author*) Nothing to Disclose
Yi Zhu (*Presenter*) Nothing to Disclose

### PURPOSE

Ferroptosis-based therapy has garnered considerable attention for their ability to kill drug-resistant cancer cells. Consequently, it holds great significance to assess the therapeutic outcomes by monitoring ferroptosis-related biomakers. Nevertheless, conventional imaging technology suffer from limitations including reduced sensitivity and difficulty in achieving real-time precise monitoring. Therefore, we need a high-sensitive biological quantitative imaging for MR-guided multiscale dynamic tumor-related ferroptosis therapy.

### METHODS AND MATERIALS

We introduced a tumor acidic-microenvironment-responsive nanoplatform with “Reverse Magnetic Resonance Tuning (ReMRT)” property that is coupled with calculus-based “Area Reconstruction” for specific and quantitative imaging of ferroptosis. The T1 mapping image was turned “ON” when in the acidic TME, while the T2 mapping image was turned “Reverse ON”. R1 value increased gradually with an increase in acidity, whereas the R2 value decreases gradually, thereby leading to a more pronounced contrast between the R1 and R2 values, demonstrating the so-called ReMRT properties. Then, we will conduct a correlation analysis between this reverse MR mapping change and ferroptosis-related biomarkers.

## RESULTS

We present a simple yet powerful strategy with ReMRT property that enables versatile non-invasive imaging of the ferroptosis process in breast tumors, encompassing the evaluation of ROS yield and drug release. Acidity-triggered release of iron ions acted as an effective ferroptosis inducer because it increased ROS production through the Fenton's reaction to produce ·OH, and at the same time depleted endogenous GSH. Notably, the difference between R1 and R2 becomes more obvious as the acidity increases. We show that ?R1 and ?R2 values are sensitive for the determination of ROS yield and DOX release, and that the ReMRT nanoprobe in neutral microenvironment show little or no such correlation.

## CONCLUSION

This ReMRT nanoplatform is a highly efficacious chemo-ferroptosis agent and provides a superior tool for identifying intracellular hallmarks during ferroptosis by utilizing the relationship between relaxation time and ROS expression. Furthermore, implementing the "Area Reconstruction"method presents significant improvements in sensitivity of MR analysis, ensuring greater visualization than conventional MR R1/R2 values.

## CLINICAL RELEVANCE/APPLICATION

Collectively, these results demonstrate the translational potential of this biocompatible probe, which in the future may serve as a breast cancer therapeutic and valuable tool to quantify variances in the pH levels within the tumor microenvironment to evaluate treatment potential and tumor burden.

Darrys Reese (*Abstract Co-Author*) Nothing to Disclose
Kevin Dao, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Although most health plans are required to cover screening mammography (SM) for women 40 and over without cost sharing, out-of-pocket costs (OOPC) for indicated diagnostic tests after a positive SM potentially deter the completion of SM and follow-up care. In our study, we aimed to investigate public preferences for health insurance benefit design to enhance adherence to the entire breast cancer screening process.

### METHODS AND MATERIALS

A prospective discrete choice conjoint survey was administered to English-speaking, US-resident, female Amazon Mechanical Turk respondents aged 40-74 in April 2024. Participants were presented with six tasks and asked to select the best of three hypothetical scenarios in which they would undergo SM (in addition to the option to forgo SM). In each scenario, we paired two attributes at three varied levels: [1] OOPC for SM (free, $5, and $20) and [2] OOPC for follow-up imaging (free, $200, unknown ranging from $0 to $2000). Data were analyzed using Hierarchical Bayesian conjoint analysis to derive attribute importance and preference for each of the nine scenarios.

### RESULTS

A total of 103 female participants with a mean age of 48 years (SD = 6) were included. 81 (79%) were White, 20 (19%) were Asian, and 2 (2%) were American Indian/Alaskan Native. 32 (31%) identified as Hispanic, Latinx, or of Spanish origin. The participants were insured by Medicare (45; 44%), Medicaid (39; 38%), private insurance (17; 16%), and VA (1; 1%). One participant was uninsured (1;1%). The relative attribute importance of "OOPC for follow-up imaging" was significantly greater than "OOPC for SM" (62%; 95% CI: 58-67 vs 38%; 95% CI: 33-42). Public preferences were highest for the scenarios offering $5 SM and $0 follow-up imaging (14.5%; 95% CI: 13-16) and $5 SM and $200 follow-up imaging (14.5%; 95% CI: 12-17). Preferences were lowest for scenarios offering $0 SM and unknown follow-up imaging OOPC (7.7%; 95% CI: 6-9) and $20 SM and unknown follow-up imaging OOPC (7.5%; 95% CI 6-9).

### CONCLUSION

These findings suggest that it is more important for participants considering breast cancer screening to be informed about OOPC for follow-up diagnostic care. Public preferences align with an episode-based cost sharing model that provides upfront OOPC for the entire breast cancer screening process, from initial screening to final diagnosis.

### CLINICAL RELEVANCE/APPLICATION

Understanding patient preferences for health insurance design is crucial for policymakers, insurers, and healthcare providers in developing strategies to promote preventive care use. Our findings suggest that episode-based cost sharing could be a promising approach to enhance adherence to recommended breast cancer screening services.

## T5A-SPNPM-2 ASSOCIATION BETWEEN PRICE TRANSPARENCY AND PATIENT DECISION TO COMPLETE OUTPATIENT IMAGING

Thao Pham (*Abstract Co-Author*) Nothing to Disclose
Gelareh Sadigh, MD (*Abstract Co-Author*) Nothing to Disclose
Diya Garg (*Abstract Co-Author*) Nothing to Disclose
Aldo Arce (*Abstract Co-Author*) Nothing to Disclose
Ali Rashidi, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the prevalence of price estimator tool utilization for outpatient imaging appointments and the association between patients' price estimator use and imaging appointment completion.

## METHODS AND MATERIALS

In this retrospective study, all adult patients aged 18 years or older who were scheduled for an outpatient radiology examination between August 2022 and 2023 at a tertiary academic imaging center were included. Data regarding the generation of out-of-pocket price (OOPP) estimates for imaging encounters in patient portal, view of such estimate by patient, appointment status, and patients' demographic characteristics were extracted. Generalized estimation equation (GEE) models were used to assess the association between patients' price estimator use and imaging appointment completion.

## RESULTS

A total of 470,422 imaging encounters (mean age: 55.6 ± 19.1; 57.5% female; 56.3% white) were included. A total of 70,437 (14.97%) OOPP estimates were generated (99.9% by staff and 0.1% by patients). Only 149 (0.21%) of estimates were viewed by patients prior to imaging; 498 (0.70%) were viewed after imaging completion, and 99.09% were never viewed. There was a significantly higher number of uninsured among patients who viewed OOPP prior to imaging (55.4%), vs. those who viewed after imaging (33.5%) vs. those who never viewed the price (3.7%) ($P<0.001$). A higher proportion of patients who viewed the OOPP estimate prior to imaging had OOPP >$295 (88.6%), vs. those who viewed after imaging (57.8%) and those who never viewed the price (24.5%) ($P<0.001$). In patients for whom OOPP estimate was generated (regardless of viewing of price), the odds of imaging completion were higher than those without OOPP (OR 1.91; 95%CI: 1.87, 1.95; $P < 0.001$). However, in patients who viewed the OOPP on the portal prior to exam, the chance of imaging completion was significantly lower vs. those who did not view it (OR, 0.35; 95%CI: 0.23, 0.53; $P < 0.001$).

## CONCLUSION

Price estimator tools are more commonly used among patients who are self-pay or expecting higher OOP payments. Viewing of the OOPP estimate prior to imaging is associated with decreased imaging completion in the same imaging center. Completion of exams at other imaging centers with lower OOPP estimates is not clear. Increased imaging completion among those with an OOPP generation, might be due to patients not knowing the price vs. the price being communicated by staff.

## CLINICAL RELEVANCE/APPLICATION

Viewing OOPP estimates prior to imaging can impact the decision to complete the exam at the same imaging center. Direct communication of OOPP estimates as opposed to having the patient view OOPP on their own might be a better solution to improve decision-making.

## T5A-SPNR-10 IDENTIFYING DISCRIMINATIVE FEATURES OF ESSENTIAL TREMOR USING MACHINE LEARNING RANDOM FOREST MODEL

Xueyan Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

Due to the lack of effective biomarkers, the diagnosis of ET relies predominantly on clinical symptoms. This study aims to extract discriminative features of essential tremor combined with a machine learning random forest model.

### METHODS AND MATERIALS

In this study, 127 ET patients and 120 HCs were scanned through resting-state functional magnetic resonance imaging (Rs-fMRI). After image processing, a total of 13366 resting-state functional connectivity features were extracted from each participant. Firstly, we randomly separated all subjects into a training set and a test set according to the ratio of 7:3 (training set = 172, testing set = 75). Then, we performed dimensionality reduction on our feature matrices to eliminate unnecessary features, reduce computational complexity, prevent over-fitting during classifier training and increase classification performance. Finally, 44 resting-state functional connectivity features were selected for the construction of the random forest model to identify ET from HCs. The accuracy, sensitivity, specificity and the area under the curve (AUC) were used to evaluate the classification performances., Also, we can extract important features using the "feature_importances_" property of the random Forest Classifier function.

### RESULTS

The demographic characteristics of the clinical subjects included in the study are shown in Table 1. For the classification of ET and HCs, the random forest model gives an accuracy of 90.67%, specificity 86.11%, sensitivity 94.87%, and AUC of 0.919 (the confusion matrix results is shown in Figure 1. Figure 2 highlights the top ten features generated in ranking order of importance.

### CONCLUSION

The random forest model achieves high accuracy to identify ET patients from HCs. The most resting-state functional connectivity features were mainly located within or across the typical motor network and some selected some also involved in non-motor areas.

### CLINICAL RELEVANCE/APPLICATION

Several discriminative features may assist in the identification of essential tremor patients.

## T5A-SPNR-11 VOXEL-BASED ANALYSIS OF THE TEMPORAL EVOLUTION OF MULTIPLE SCLEROSIS LESIONS

Sangam G. Kanekar, MD (*Abstract Co-Author*) Nothing to Disclose
Jack Quillen (*Abstract Co-Author*) Nothing to Disclose
Scott N. Hwang, PhD, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Assess the temporal evolution of multiple sclerosis (MS) lesions based on MRI with a focus on the voxels that transition from brain to lesion or lesion to brain. These may relate to active versus smoldering MS plaques.

### METHODS AND MATERIALS

MR images (FLAIR, MPRAGE, proton-density, and T2) were obtained from The 2015 Longitudinal MS Lesion Segmentation Challenge. Provided preprocessing of images include inhomogeneity-correction using N4, skull/dura-stripping, and rigid registration to a 1 mm isotropic MNI template. Each contributor was imaged 4 or 5 times at approximately 1 year intervals. Image masks showing lesion segmentation were manually generated by two experienced raters for 5 datasets at all timepoints. 14 additional datasets are provided without masks.Voxels were classified into 4 groups as brain voxels which remain brain, lesion voxels which remain lesion, brain voxels which become lesion, and lesion voxels which become brain at each of the timepoints compared to the earliest images. Differences in voxel intensities were assessed. Processing was performed with plugins written in Java on Fiji, an open-source program for image analysis. Pairwise Mann-Whitney U Tests were performed to assess for significant differences and the Bonferroni correction was applied.

### RESULTS

While some lesions enlarge, others contract, possibly secondary to smoldering lesions. Statistically significant differences are present with relative FLAIR hyperintensity in normal-appearing (to the human eye) brain voxels which become lesion voxels compared to brain voxels which do not change

($p<0.001$). The differences are significant for transitions at 1, 2, and 3 years after baseline. Subtle hypointensity is also present in lesion voxels which transition to brain compared to lesion voxels which do not change ($p<0.001$).

**CONCLUSION**

Statistically significant differences can be identified between normal-appearing brain voxels which stay normal and normal brain voxels which become lesion voxels. This is true at for voxel transitions between baseline and at 1-3 years later. Subtle differences are also present between voxels which transition from lesion to normal-appearing brain, mostly at the periphery of what may represent smoldering lesions.

**CLINICAL RELEVANCE/APPLICATION**

Defining response to disease-modifying therapy (DMT) in MS patients can be difficult, relying on the number of clinical attacks or new MRI-detected lesions. Voxel-based early detection of subtle abnormalities may provide a means of predicting transitions from normal-appearing brain to lesions before they become overt and may thus provide useful metrics for managing treatment. Early identification of potential transitions may also help characterize smoldering lesions.

## T5A-SPNR-13 WHITE MATTER HYPERINTENSITY SEGMENTATION IN MULTIPLE SCLEROSIS AND NEUROMYELITIS OPTICAL SPECTRUM DISORDERS USING 2.5D FRC-RESUNET

Chunjie Guo, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The study aims to develop a precise segmentation method to evaluate the multiple and irregularly shaped white matter hyperintensity (WMH) lesions in the brain, occurring in patients with multiple sclerosis (MS) and neuromyelitis optical spectrum disorder (NMOSD). This method is essential for accurate diagnosis, effective treatment, and prognosis of these conditions.

**METHODS AND MATERIALS**

In this study, we propose a 2.5D FrC-ResUnet deep learning algorithm for segmenting WMH in the brains of patients with MS and NMOSD. This algorithm utilizes a Spectral Encoder to extract global information, enabling the accurate segmentation of dispersed lesions. Additionally, the model incorporates the Selective Features Module (SFM) and the Convolutional Block Attention Module (CBAM) to enhance the differentiation of lesion background and provide a clear outline of the pathology. The study utilized a public dataset from the MICCAI 2016 MS Lesion Segmentation Challenge and local datasets for MS and NMOSD, which included 36 MS and 33 NMOSD subjects.

**RESULTS**

Our approach was assessed on both the public and local datasets for MS and NMOSD. In comparison to U-Net, ResUNet, FC-DenseNet, AttentionUNet, and LPA algorithms, the 2.5D FrC-ResUnet demonstrated the highest Dice Similarity Coefficient (DSC) on three different datasets, with values of 0.710, 0.667, and 0.822, respectively.

**CONCLUSION**

The 2.5D FrC-ResUnet demonstrates accurate and robust segmentation of NMOSD brain WMH. Meanwhile, the model excels in segmenting MS brain WMH, especially when confronted with irregularly shaped and dispersed lesions.

**CLINICAL RELEVANCE/APPLICATION**

The clinical application of the 2.5D FrC-ResUnet model promises for advancing the imaging analysis of WMH in patients with MS and NMOSD, which could potentially enhance clinical outcomes by improving diagnostic and therapeutic strategies.

## T5A-SPNR-14 AN EXPERIMENTAL EVALUATION OF THE RELATIONSHIP BETWEEN THE INDUCED RADIOFREQUENCY HEATING NEAR AN IMPLANTED CONDUCTIVE MEDICAL DEVICE DURING MRI, SCANNER-REPORTED B1+RMS, AND SCANNER REPORTED AVERAGE TRANSMIT POWER

John T. Vaughan, PhD (*Abstract Co-Author*) Nothing to Disclose
Devashish Shrivastava (*Abstract Co-Author*) Nothing to Disclose
David Gultekin, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Time-varying radiofrequency (RF) fields necessary to perform magnetic resonance imaging (MRI) may induce excessive heating near implanted conductive medical devices during MRI. Both time and space-averaged root mean square of the effective magnetic field (B1+rms) and whole-body average specific absorption rate (SAR) (time-averaged RF power per unit body weight) have been proposed as metrics to control the induced heating and avoid unintended thermal injury. The purpose of this study is to experimentally evaluate the relationship between the induced RF heating near an implanted conductive medical device, scanner-reported B1+rms, and scanner-reported RF power.

**METHODS AND MATERIALS**
