The CP angle is an anatomically complex region. It houses numerous structures such as cranial nerves (V, VI, VII), blood vessels, and cerebrospinal fluid spaces. Understanding the normal anatomy is crucial for interpreting abnormalities in this region. Involvement of the various structures here may have independent and/or overlapping symptoms. For example, extending a CP angle mass into the Dorello canal, a bony channel through which the abducens nerve travels from the prepontine cistern to the cavernous sinus, may present with lateral rectus muscle palsy. Cerebellopontine angle lesions can be divided into tumor and non-tumor lesions. The most common tumor lesions -Vestibular schwannoma (acoustic neuroma), Meningioma, Epidermoid Cyst, Arachnoid Cyst, Ependymoma, Lipoma, Dermoid, Primary malignancy (Lymphoma and Melanoma), Metastatic disease, Facial nerve and Vestibular nerve schwannomasThe most common non-tumor lesions -Aneurysm/Vertebrobasilar Dolichoectasia and Anterior Inferior Cerebellar Artery Loop.Cerebellopontine lesions typically demonstrate differentiating imaging characteristics, mostly evaluated on MRI and CT Brain.

**TABLE OF CONTENTS/OUTLINE**

Normal cerebellopontine angle anatomy including surrounding structures.Involvement of the various structures in this region and their possible clinical presentations (table and image examples).Common and few less common cerebellopontine angle lesions and epidemiological /syndromic correlation, if present (table/chart). Masses and their characteristic imaging features (images/case examples). Non tumor cerebellopontine lesions (table/image examples ). Radiologic pitfalls.Take home points/summary. References.

## NREE-45 REVIEW OF THE LILIEQUIST MEMBRANE AND ITS SIGNIFICANCE IN NEUROIMAGING

Julie B. Guerin, MD (*Abstract Co-Author*) Nothing to Disclose
John C. Benson, MD (*Abstract Co-Author*) Nothing to Disclose
Edward Ahn, MD (*Abstract Co-Author*) Nothing to Disclose
V. Michelle Silvera, MD (*Abstract Co-Author*) Nothing to Disclose
Norbert G. Campeau, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Hayden Swartz, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. The Liliequist membrane (LM) is an important landmark for both neuroradiologists and neurosurgeons to identify on preoperative and intraoperative examinations for CSF diversion, masses involving the floor of the third ventricle, and endoscopic third ventriculostomy (ETV) patency. 2. The LM is best visualized using MRI with thin-section, heavily T2-weighted imaging such as with balanced steady-state free procession (bSSFP) sequences such as FIESTA and CISS. Flow signal through ETV sites is best demonstrated using spin echo-based techniques such as T2 FSE, T2 SPACE or CUBE sequences.

**TABLE OF CONTENTS/OUTLINE**

1. Defining the LM and its anatomy: Illustrate the three main components of the LM and their anatomic relationships with adjacent suprasellar and hypothalamic structures. 2. History of the LM. 3. Imaging technique: Emphasize the importance of thin-section, heavily T2-weighted imaging for anatomic visualization of the LM, and FSE-based techniques for functional assessment of flow through an ETV. 4. Review a series of cases in which the LM is visualized before and/or after endoscopic third ventriculostomy. 5. Review a series of cases in which the LM is indirectly depicted by subarachnoid contrast, subarachnoid hemorrhage, or by mass effect secondary to lesions in the suprasellar or prepontine cisterns.

## NREE-46 VARYING SHADES OF EPIDERMOID TUMORS - THE BLACK, THE WHITE AND EVERYTHING IN BETWEEN

Rita G. Bhatia, MD (*Abstract Co-Author*) Nothing to Disclose

Gaurav M. Saigal, MBBS (*Abstract Co-Author*) Nothing to Disclose
Hamilton Trinh, MD (*Abstract Co-Author*) Nothing to Disclose
Denver S. Pinto, MD, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

At the end of this exhibit, the reader should be able to:1. Identify key imaging features of epidermoid tumors and its subtypes2. Differentiate epidermoid tumors from its differential diagnoses3. Understand the clinical presentation and symptoms associated with epidermoid tumors

**TABLE OF CONTENTS/OUTLINE**

Pathophysiology of epidermoids - Anatomy and patterns of growth of epidermoid cystsClinical PresentationCase discussion with imaging findings with a focus on MRI findings especiallya) Diffusion restrictionb) White Epidermoids, Dark epidermoids and varying patterns of intermediate signalc) Sites of epidermoid tumor,Sites of epidermoids:Intradural:a) Extraparenchymal: Cerebello-pontine angle, Suprasellar cistern, Middle cranial fossa, Anterior cranial fossa, Interhemispheric fissureb) Intraparenchymal: Temporal lobe, frontal lobec) Intraventricular: Fourth ventricle,Extradural: Intradiploic, Intraorbital,Extradural sites: Calvarium,,Differential diagnosis: 1. Arachnoid cyst (for the extra-axial type) 2. Dermoid cyst, Neurenteric cyst (for the midline location) 3. Cystic Schwannoma (for the cerebellopontine angle) 4. Craniopharyngioma (For the skull base location) 5. Developmental neuro-epithelial tumor (DNET) and Multi-nodular and vacuolating neuronal tumor (MVNT) --> for the intra-parenchymal location 6. Ependymoma, Subependymoma, Medulloblastoma (for the intraventricular location),,Complications: 1. Malignant degeneration 2. Chemical meningitis/ aseptic meningitis with and without hydrocephalus 3. Spontaneous hemorrhage,,Goals of treatment:

## NREE-47 SPECTRUM OF NEUROIMAGING FINDINGS IN CNS LYMPHOPROLIFERATIVE DISORDERS

**Awards**
**Cum Laude**

**TEACHING POINTS**

1. Standard imaging signs of CNS lymphoproliferative disorders as revealed by MRI and CT. 2. Advanced imaging techniques such as MRI spectroscopy, diffusion-weighted imaging, and perfusion imaging are indispensable for distinguishing CNS lymphoproliferative disorders from other neurological disorders and assessing tumor aggressiveness. 3. These techniques provide intricate insights into the metabolic activity, cellular density, and vascularity of lesions, facilitating differentiation from other neurological pathologies and offering crucial information regarding tumor aggressiveness. 4. Accurate imaging interpretation informs treatment decisions and aids in monitoring therapeutic outcomes. 5. The precise interpretation of imaging findings serves as a cornerstone in guiding treatment strategies and monitoring therapeutic responses, highlighting the indispensable role of neuroradiologists in the comprehensive care of patients with CNS lymphoproliferative disorders.

**TABLE OF CONTENTS/OUTLINE**

1. Typical Presentation ○ Key Imaging Characteristics of CNS Lymphoma and Other Lymphoproliferative Disorders 2. Common Imaging Findings ○ Brain Manifestations of Lymphoma ○ Manifestations of Other Lymphoproliferative Disorders (*Intravascular Lymphoma, MALT Lymphoma of the Dura,*

*Lymphomatosis Cerebri*) 3. Atypical Presentations ○ Diverse Imaging Findings Across Unusual Sites: Eyes, Spinal Cord, Leptomeninges, Cerebellum/Brainstem, and Other Locations 4. Advanced Imaging Techniques ○ Application of MR Perfusion and MR Spectroscopy in Differential Diagnosis

## NREE-48 WRONG WHITE BRAIDS: UNRAVELING THE COMPLEXITY OF LEUKODYSTROPHIES FROM A RADIOLOGIST'S PERSPECTIVE

Juliana Duarte (*Abstract Co-Author*) Nothing to Disclose

Luiz Borella (*Abstract Co-Author*) Nothing to Disclose
GABRIELLE BACCARIN (*Abstract Co-Author*) Nothing to Disclose
Fabiano Reis (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Magnetic resonance imaging (MRI) plays a fundamental role in the diagnosis of leukodystrophies.Recognition of patterns on MRI includes differentiation between hypomyelinating and demyelinating patterns of white matter,distinguishing between diffuse and multifocal abnormalities,evaluating the predominant location of abnormalities,and identifying specific characteristics such as cystic degeneration of white matter,anterior temporal cysts,megalencephaly,increased perivascular spaces or small cysts,additional gray matter lesions,contrast enhancement,calcium deposits,microhemorrhages,spinal cord involvement,cranial nerves thickening and enhancement.Some spectroscopy findings may also suggest the diagnosis:in Canavan’s disease there is an increase in the NAA peak;a peak of alpha-glutamate concentrations (at 3.75 ppm) is observed in 18q Deletion Syndrome.MRI may lead to a specific diagnosis, suggest the appropriate genetic test to confirm the diagnosis,and have contributions in monitoring disease progression,and therapeutic responses.

### TABLE OF CONTENTS/OUTLINE

IntroductionCase-based review of leukodystrophies:Metachromatic leukodystrophyKrabbe diseaseX-linked adrenoleukodystrophyCanavan diseaseAlexander diseaseL-2-hydroxyglutarig acid uriaLeukoencephalopathy involving the brainstem and spinal cord with elevated lactate.Sjogren-Larsson syndromePropionic acidemia18q Deletion SyndromePOLR3B-related Hypomyelinating Leukodystrophy Adult-Onset Leukoencephalopathy with Axonal Spheroids and Pigmented GliaMegalencephalic leukoencephalopathy with subcortical cystsFinal remarks and take home messages

## NREE-49 HOW TO REPORT PITUITARY MACROADENOMAS

Nina Ventura, MD (*Abstract Co-Author*) Nothing to Disclose
Ferdinand D. Cabrera Filho, MD (*Abstract Co-Author*) Nothing to Disclose
Paula Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza Ambrozino, MD (*Abstract Co-Author*) Nothing to Disclose

Luiza A. Nahoum, MD (*Abstract Co-Author*) Nothing to Disclose
Luis A. Quevedo (*Abstract Co-Author*) Nothing to Disclose
Pedro A. Gama Carpentieri Primo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Importance of Structured Reporting- Emphasize the significance of a structured reporting format in providing comprehensive and consistent information to referring physicians and other healthcare providers. - Highlight how structured reports facilitate better understanding and interpretation of findings.2. Enhancing Communication - Encourage radiologists to use standardized terminology and formats to minimize ambiguity and misinterpretation of findings.3. Avoidance of Errors - Educate radiologists on errors in reporting pituitary macroadenomas, such as incomplete descriptions of tumor characteristics or failure to assess critical anatomical relationships.4. Clinical Decision Support - Highlight the role of structured reports in providing essential information for clinical decision-making, including tumor characteristics, proximity to critical structures, and potential treatment implications.

### TABLE OF CONTENTS/OUTLINE

1. Introduction- Overview of Pituitary Macroadenomas - Importance of Reporting and Diagnosis2. Characteristics of Pituitary Macroadenomas - Signal Intensity - Presence of Lobulation - Suprasellar Growth - Infrasellar Growth3. Relationship with Neighbor Structures - Optic Chiasm - Third Ventricle - Clivus - Sphenoid plane4. Remodeling of the Sellar Floor5. Type of Sphenoid Sinus Pneumatization6. Knosp Classification - Predicting Cavernous Sinus Invasion7. Presence and Importance of Onodi Cell8. Measure and Relevance of Intercarotid Distance9. Differential diagnosis - Red Flags that may point to other diagnosis10. Conclusion - Importance of Comprehensive and Structured Reporting - Clinical Implications

## NREE-5 INSIGHTS AND CONSIDERATIONS IN DEVELOPMENT AND PERFORMANCE EVALUATION OF GENERATIVE ADVERSARIAL NETWORKS (GANS): WHAT RADIOLOGISTS NEED TO KNOW

Kyung Mi Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Minjae Jang (*Abstract Co-Author*) Nothing to Disclose
Minjae Myung (*Abstract Co-Author*) Nothing to Disclose
Eui Jong Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Hyug-Gi Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Jeong Taek Yoon, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Deep learning has advanced AI in medical imaging, leading to significant improvements but also creating challenges like the need for extensive training data and laborious labeling. Generative Adversarial Networks (GANs) generate synthetic images for data augmentation and simplify medical image processing, enhancing efficiency and enabling unsupervised anomaly detection, thus reducing reliance on labeled datasets. Our investigation into GANs in medical imaging addresses their varied architectures, the considerations for selecting appropriate GAN models, and the nuances of model training and performance evaluation. This presentation aims to provide radiologists who are new to GAN technology with a thorough understanding, guiding them through the practical application and evaluation of GANs in brain imaging with two illustrative examples. It offers a comprehensive exploration of the transformative potential of GANs in medical imaging research. Ultimately, this paper strives to equip radiologists with the knowledge to effectively utilize GANs, encouraging further research and application within the field.

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. GAN architecture, hierarchy, and variants 3. Selecting the appropriate GAN for the research objectives 4. Input data training 5. Performance evaluation 6. Conclusion

## NREE-50 NOT EVERY DURAL BASE LESION REPRESENTS A MENINGIOMA: A PICTORIAL ESSAY ON SOLITARY FIBROUS TUMOR IN THE CENTRAL NERVOUS SYSTEM

Angelo D. Correa, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza A. Nahoum, MD (*Abstract Co-Author*) Nothing to Disclose

Paula Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza Ambrozino, MD (*Abstract Co-Author*) Nothing to Disclose
Luis A. Quevedo (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This education exhibit provides an analysis of solitary fibrous tumors involving the central nervous system (SFT-CNS), which can often be misdiagnosed as meningiomas due to their rarity and similar imaging characteristics. Through the analysis of 8 consecutive cases treated in our hospital between 2014 and 2024, this exhibit aims to highlight the clinical, histopathological, and MRI characteristics of SFT-CNS. The purpose of this study are - To discuss the clinical and histopathological characteristics of SFT-CNS. - To demonstrate the main magnetic resonance imaging (MRI) findings in SFT-CNS. - To present 8 consecutive cases with histopathological confirmation treated in our hospital between 2014 and 2024. - To compare the imaging findings of differential diagnoses. - To enhance recognition of this uncommon pathology among radiologists.

### TABLE OF CONTENTS/OUTLINE

- Introduction - Clinical and Histopathological characteristics of SFT-CNS. - Main imagen features of SFT-CNS. - Compare the imaging findings of differential diagnoses, particularly with those of meningioma. - Cases of Patients with a Histopathological Diagnosis of SFT-CNS.

## NREE-51 FROM DAWSONS FINGERS TO CENTRAL VEIN SIGN: A RADIOLOGIST'S PRIMER TO CLINICALLY RELEVANT CONVENTIONAL AND EMERGING MRI BIOMARKERS IN MULTIPLE SCLEROSIS

**Awards**
**Certificate of Merit**

Suradech Suthiphosuwan, MD (*Abstract Co-Author*) Nothing to Disclose
Aditya Bharatha, MD (*Abstract Co-Author*) Nothing to Disclose
Yusuf Alibrahim, BMedSc, MD (*Abstract Co-Author*) Nothing to Disclose
Jiwon Oh, FRCPC,PhD (*Abstract Co-Author*) Nothing to Disclose
Timothy Reynold U. Lim, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Pathologic features of multiple sclerosis (MS) include perivenular demyelination, inflammation and neurodegeneration; active lesions predominate in relapsing-remitting, and smoldering lesions and neuroaxonal loss in progressive forms.Conventional MRI findings, while currently still the most used imaging biomarkers, lack pathologic specificity and only moderately correlate with disease activity and disability in MS.MRI biomarkers more specific to MS pathology are emerging; the two furthest along in clinical development are the central vein sign (CVS) and paramagnetic rim lesions (PRLs).CVS reflects perivenular demyelination and is highly specific and sensitive for distinguishing MS from mimics.PRLs represent lesions with chronic active inflammation along the lesion edge are also useful for diagnosis and prognosis across the entire MS spectrum.Other biomarkers such as brain and spinal cord volumetric measures, cortical lesions and leptomeningeal enhancement have also shown prognostic utility in MS.

### TABLE OF CONTENTS/OUTLINE

A. Pathologic basis of imaging biomarkers in MSa. MS involves both gray and white matterb. Perivenular inflammatory demyelinationc. Neurodegeneration in MSi. Neuroaxonal lossii. Chronic active "smoldering" lesionsB. Conventional MRI biomarkersa. T2/FLAIR lesionsi. 2017 McDonald Criteriaii. Prognostic utility of T2 lesion burdeniii. Optic nerve as 5th location for DISb. Gadolinium-enhancing lesionsc. T1 black holesC. Emerging MRI biomarkersa. CVSb. Chronic active lesionsi. PRLii. Slowly expanding lesionsc. Cortical lesionsd. Leptomeningeal enhancemente. Volumetric measuresi. Brain (global / regional) atrophyii. Spinal cord atrophy

## NREE-52 NEURO BEHçET'S SCAR TISSUE: UNVEILING THE MANIFESTATIONS ON THE CENTRAL NERVOUS SYSTEM

### TEACHING POINTS

The purposes of this exhibit are: Review and illustrate the pathogenesis, imaging findings of neurological involvement of Behēet' disease, the differential diagnoses, and their correlation with clinical findings. Describe through illustrative presentations the benefits of MRI imaging approach to the diagnosis of Neuro-Behēet. Present challenging cases, such as venodural fistula and dural venous thromboses and differential diagnosis.

### TABLE OF CONTENTS/OUTLINE

Behēet pathogenesis and clinical findings. Imaging patterns on MR in different weighted sequences. Evaluation of complications such as venodural fistula and dural venous thromboses. Susceptibility weighted image (SWI)'s hole on detection of hemorrhagic findings in Neuro-Behēet.Imaging findings based on a pictorial review using representative cases from a Tertiary University Hospital database. A practical approach for better diagnostic accuracy and avoiding pitfalls. Final remarks.

## NREE-53 DECODING THE LOES SCORE: A STEP-BY-STEP REVIEW OF THE MRI SEVERITY SCORE FOR X-LINKED ADRENOLEUKODYSTROPHY

Clara Fiorot, MD (*Abstract Co-Author*) Nothing to Disclose
Angelo D. Correa, MD (*Abstract Co-Author*) Nothing to Disclose
Paulo V. Bahia, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ferdinand D. Cabrera Filho, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro A. Gama Carpentieri Primo, MD (*Abstract Co-Author*) Nothing to Disclose

Paula Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza Ambrozino, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza A. Nahoum, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Clinical importance of the MRI severity score for X-linked adrenoleukodystrophy (X-ALD)Introduce Dr. Loes and the rationale behind the development of this scoring system; Explain what the score is and its significance in X-ALD evaluation; Highlight the score's role in evaluating disease severity, disease monitoring, prognosis and treatment decision-making.Score overview, components and methodologyDetail the specific MRI findings that contribute to the score through a structured reporting template elaborated by the authors; Describe how the MRI severity score is calculated and interpreted through a case-based approach, through cases from the author's institution; Discuss scoring thresholds.Review of the cerebral anatomy commonly affected by X-ALDReview neuroanatomic locations by correlating MRIs from clinical cases and didactic schemes elaborated by the authors.

### TABLE OF CONTENTS/OUTLINE

IntroductionBrief overview of X-ALD; Challenges in disease assessment.Overview of the MRI severity scoreDevelopment rationale: the importance of objective assessment; Evidence supporting its use; Role in treatment decision-making; Structured template for reporting.Components of the score and scoring methodology with anatomic correlationWhite matter involvement and focal atrophy; Corpus callosum involvement and atrophy; Optic pathway involvement; Auditory pathway involvement; Projection fibers involvement; Cerebellum involvement and atrophy; Basal ganglia involvement; Global atrophy, brainstem atrophy and methods for assessmentConclusionCalculation and practical considerations; Addressing challenges, limitations and areas for further developments; Key takeaways.

## NREE-54 IMAGING INSIGHTS ON CHILDHOOD STROKE - SHEDDING LIGHT ON A CHALLENGING CONDITION

Luiz Borella (*Abstract Co-Author*) Nothing to Disclose
Fabiano Reis (*Abstract Co-Author*) Nothing to Disclose
Gustavo Yamada, MD (*Abstract Co-Author*) Nothing to Disclose
Thiago Costa Haiter, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Stroke in children raises concern to healthcare, due increasing incidence. The etiology is multifactorial, and this study emphasizes the main arterial etiologies of stroke, based on "The Childhood Arterial Ischemic Stroke Standardized Classification and Diagnostic Evaluation (CASCADE) criteria", searching for the best imaging findings, to assist accurate diagnoses. It subdivides into primary causes and secondary causes. Illustrated findings in original cases of "Moya-Moya" disease, carotid dissection in aortic/cervical arteriopathy, bacterial meningitis, viral infectious vasculitis (varicella zoster and COVID-19), occlusive vasculopathy due to Sickle Cell Disease and inflammatory vasculitis due to Behēet and Lupus are highlighted in the study, as well the main stroke mimics to keep in mind, especially hemiplegic migraine and posterior reversible encephalopathy syndrome (PRES). Ultimately, the study delves into the pitfalls, which must be considered to guarantee accurate diagnosis. The study seeks to improve diagnosis inchildren who can greatly benefit from an early diagnosis, allowing the expansion of future estudies and treatments, bringing greater quality of life to patients.

### TABLE OF CONTENTS/OUTLINE

- Introduction - Epidemiology of stroke in Children - The Childhood Arterial Ischemic Stroke Standardizes Classification and Diagnostic Evaluation(CASCADE) criteria Illustrated. - Main clinical manifestations - Diagnostic clues - Imaging investigation (cases and Imaging findings) in primary and secondary causes - Differential diagnoses and stroke mimics - Pitfalls

## NREE-55 EXPLORING NEURAL PATHWAYS - AI METHODS IN DIPY FOR ADVANCED NEUROANATOMICAL STUDIES

Serge Koudoro, MSc (*Abstract Co-Author*) Nothing to Disclose
Eleftherios Garyfallidis (*Presenter*) Nothing to Disclose

### TEACHING POINTS

As datasets expand and analysis methodologies evolve, the demand for sophisticated computational resources and techniques intensifies. The Diffusion Imaging in Python (DIPY) community has cultivated a robust open source software ecosystem designed for the analysis of structural and diffusion MRI data. Throughout this exhibit, we will embark attendees on a journey to: A) Explore advanced AI tools within DIPY (Diffusion Imaging in Python) for MRI data analysis. B) Highlight key methodologies addressing common research challenges. C) Showcase innovative techniques like EVAC+ for brain extraction. D) Discuss the role of generative AI in segmentation enhancement. E) Introduce Patch2Self2 for denoising and its extensions. F) Survey distortion correction methods, including style transfer. G) Present statistical analysis capabilities and tract analytics in DIPY. H) Demonstrate Tractometry with Bundle Analytics 2.0 and BundleWarp. E) Present a novel method for direct data harmonization.

### TABLE OF CONTENTS/OUTLINE

This exhibit offers a hands-on exploration of a community-driven open-source ecosystem (DIPY), vital for analyzing structural and diffusion MRI data. Attendees will deepen their understanding of MR imaging, gain insights into MR imaging and stay updated on the latest advancements. Specific topics like brain extraction techniques, distortion correction methods, and data harmonization will be covered. A focus on tractometry will demonstrate to attendees how to enable detailed group comparisons and identification of statistically significant differences in tract properties between populations. We wrap up with reflections on advancements made and future directions in MRI data analysis.

**TEACHING POINTS**

This educational exhibition provides a comprehensive overview of the imaging evaluation of pediatric patients with vascular intracranial emergencies. Imaging patterns, differential diagnoses, and potential pitfalls in imaging interpretation will be addressed, as well as etiology categorization and classifications for the most common vascular emergencies, aiming at a broad review of the theme. The purpose of this exhibition is to: Provide an overview of the imaging evaluation of pediatric patients with vascular intracranial emergencies. Highlight specific imaging patterns and features that may suggest the etiology discussing differential diagnosis and potential pitfalls in imaging interpretation. Use case studies to illustrate radiological challenges and diagnostic considerations.

**TABLE OF CONTENTS/OUTLINE**

1 Clinical presentation and etiologyOverview of clinical presentation of pediatric intracranial vascular emergency divided by hemorrhagic, ischemic and thrombotic etiologies. 2 Ischemic Disorders: Inflammatory Arteriopathy Focal cerebral arteriopathy, Primary or Secondary vasculitis. 3 Ischemic Disorders: Non-Inflammatory Arteriopathy Dissection, Moyamoya patterns and Genetic etiologies. 4 Hemorrhagic disorders: Coagulation disorders and Germinal Matrix Hemorrhage. Aneurysm, Vein of galen aneurysmal malformation, Arteriovenous malformations, Germinal matrix hemorrhage, Cerebral proliferative angiopathy, Cavernous angiomas, Cerebrofacial arteriovenous metameric syndrome (CAMS), Dural arteriovenous fistula and Coagulation disorders 5 Cerebrovenous Thrombosis Cerebral Venous Sinus Thrombosis, Cortical Vein Thrombosis, Medullary Vein Thrombosis

## NREE-57 UNVEILING THE MYSTERIES OF THE PERIVASCULAR SPACES LESIONS

Thanh Binh Nguyen, MD (*Abstract Co-Author*) Nothing to Disclose
Santanu Chakraborty, FRCPC,MBBS (*Abstract Co-Author*) Nothing to Disclose
Maria Lucia Brun, MD (*Abstract Co-Author*) Nothing to Disclose

**TEACHING POINTS**

• Knowing the function and the role of the glymphatic system. • To discuss the normal anatomy of the perivascular spaces and variants.• To discuss the diverse types of causes and diseases affecting the perivascular spaces with highlight on the recently described and updated lesions.• To provide an approach describing lesions that mimics the perivascular spaces which will aid in appropriate management and guide in surgical intervention.

**TABLE OF CONTENTS/OUTLINE**

-Overview of the glymphatic system -Anatomy of the perivascular spaces and variants -Approach to diagnose neoplastic and non-neoplastic causes of dilated perivascular spacesA. Non enhancing causes.B. Enhancing causes. -Non enhancing causes• Small vessel diseases: cerebral amyloid angiopathy, CADASIL, hypertensive encephalopathy• Neurodegenerative: Parkinson disease, Alzheimer disease• Demyelination and Autoimmune disease: NMOSD, MS, SLE• Miscellaneous: Sener syndrome, mucopolysaccharidoses, traumatic brain injury -Enhancing causes• GFAP• Infection: Cryptococcus, PML-IRIS• Neoplastic: Intravascular lymphoma• Inflammatory: CLIPPERS, SLIPPERS, Intravascular Sarcoidosis -Diseases that mimics dilated perivascular spaces • Benign cysts: neuroglial cysts, arachnoid cysts, Neuroenteric cysts, choroidal cysts,• Vascular: Lacunar infarct, PVL in peds• Neoplastic: DENT, MVNT, low grade glioma (anterior temporal)• Infectious: Neurocysticercosis, Toxoplasmosis

## NREE-58 LOST IN THE LABYRINTH: REVIEW OF THE INNER EAR AND ITS CONGENITAL MALFORMATIONS

Andres F. Caliz Cabrales, MD (*Abstract Co-Author*) Nothing to Disclose
Julian M. Gandur, MD (*Abstract Co-Author*) Nothing to Disclose
Oreanna Quintero, MD (*Abstract Co-Author*) Nothing to Disclose
Jesus Eduardo Barreto Fernandez (*Abstract Co-Author*) Nothing to Disclose
Sara Gomez Milanes, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

This poster provides a review of the anatomy and embryology of the inner ear; this review aims to facilitate a better understanding of why congenital malformations occur and to aid in their identification. Additionally, each malformation will be reviewed, and an algorithm will be provided to assist in reaching a diagnosis easily. The poster also correlates these malformations with the most important syndromes associated with them, highlighting the importance of understanding genomics in the study of these malformations and their relationship with various genetic syndromes. The objective is to provide radiologists with a reference tool that simplifies the understanding of this topic, often considered a "labyrinth," and demystifies the inner ear by offering a clear and concise overview of its structure, embryonic development, and associated pathologies.

**TABLE OF CONTENTS/OUTLINE**

Objectives; Importance of timely identification of congenital malformations of the inner ear; Embryology; Anatomy; Congenital malformations of the inner ear and their classification systems; Concise review of each congenital malformation correlating them with their respective embryonic developmental failure and imaging cases. Including: Complete labyrinthine aplasia, Rudimentary otocyst, Cochlear aplasia, Common cavity, Cochlear hypoplasia, Incomplete partition, Enlarged vestibular aqueduct, Abnormalities in the bony canal and cochlear nerve; Diagnostic algorithm; Imaging cases resolved using the diagnostic algorithm; Link between inner ear development, brain, and body: Clues for many diagnoses; Gallery of normal images of the inner ear; Bibliography

## NREE-59 INSIGHTS FROM THE INSIDE: UPDATES ON TRANSCRANIAL ULTRASOUND IN GREY SCALE, DOPPLER, AND CONTRAST-ENHANCED TECHNIQUES

**TEACHING POINTS**

Transcranial ultrasound has emerged as a valuable modality in neuroimaging due to its versatility, non-invasive nature, and low cost, offering real-time evaluation of cerebral hemodynamics and pathologies.The purpose of this exhibit is to review current applications and advancements in transcranial ultrasound techniques for adults with actual case examples, emphasizing the clinical significance of Grey Scale, Duplex Doppler, and Contrast-Enhanced modalities.

**TABLE OF CONTENTS/OUTLINE**

Introduction to Transcranial Ultrasound a. Anatomy and Approaches b. Overview of ultrasound techniques: Grey Scale, Duplex Doppler, and Contrast-Enhanced UltrasoundClinical Applications of Transcranial Ultrasound in Adults a. Detection and monitoring of vasospasm in subarachnoid hemorrhage b. Evaluating cerebral stenosis with Duplex Doppler c. Management of sickle cell disease via flow velocity assessments d. Identification and implications of internal carotid artery occlusion e. Diagnosing brain death f. Real-time monitoring of emboli g. Detecting vascular lesions amenable to interventional treatment h. Assessing reperfusion post-thrombolysis i. Role in diagnosing vertebrobasilar insufficiency j. Contribution to the diagnosis of Parkinson's disease k. Detection and follow-up of raised intracranial pressure l. Identification of right-left shunt m. Assessment of cerebrovascular reserve capacityResearch Frontiers in Transcranial Ultrasound a. Quantifying brain perfusion with contrast-enhanced ultrasoundConclusion a. Summarize the impact of transcranial ultrasound on radiological practice and its potential future applications

## NREE-6 DOWN THE PATH OF NEURONAL INJURY AND AXONAL DEGENERATION: PATHOLOGIC MECHANISMS AND IMAGING FINDINGS BEYOND WALLERIAN CHANGES

**Awards**
**Cum Laude**

Nancy Margarita Gutierrez Castaneda, MD (*Abstract Co-Author*) Nothing to Disclose
Michelle Y. Gonzalez Putoy SR, MD (*Abstract Co-Author*) Nothing to Disclose
Griselda T. Romero Sanchez, MD (*Abstract Co-Author*) Nothing to Disclose
Carlos Zamora, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Angela M. Sosa, MD, MSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

After completing this exhibit, the viewer will be able to:Summarize the different types of axonal degeneration, including classic Wallerian degeneration versus non-Wallerian changes.Identify the main molecular mechanisms and pathways underlying axonal degeneration: NAD+ metabolism, mitochondrial dysfunction,and necroptosis.Describe axonal degeneration during aging and its critical role in the pathophysiology of neurodegenerative diseases,such as Alzheimer's disease,Parkinson's disease,amyotrophic lateral sclerosis.Recognize a spectrum of common and atypical imaging patterns of axonal degeneration utilizing a case-base approach.

**TABLE OF CONTENTS/OUTLINE**

1.overview of neuronal and axonal structure and function. 2.Types of neuronal degeneration.3.Cellular and molecular basis of axonal degeneration.4.Axonal degeneration in aging and neurodegenerative diseases.5. Case review including:a.Classic Wallerian degeneration along corticospinal tract(acute intramyelinic edema and chronic atrophic changes).b.Pontocerebellar axonal degeneration.c.Degeneration of cranial nerves.d.Cranial and caudal axonal degeneration in the spinal cord.e.Degeneration of mammillary bodies and fornix (e.g,temporal lobe, epilepsy/mesial temporal sclerosis).f. Optic nerve degeneration(e.g.,phthisis bulbi).g.Degeneration atrophy(e.g.,tongue[CNXII],masticador muscles[CNV],shoulder muscles[brachial plexus].hHypertrophic olivary degeneration.i.Neurodegenerative disease.

## NREE-60 PIECING TOGETHER THE PUZZLE OF NEUROTOXOPLASMOSIS: INSIGHTS FROM NEUROIMAGING

Fabiano Reis (*Abstract Co-Author*) Nothing to Disclose
Lazaro F. Amaral, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana T. Raeder, MD (*Abstract Co-Author*) Nothing to Disclose
Gustavo Yamada, MD (*Abstract Co-Author*) Nothing to Disclose
Lua P. Carvalho, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro Tiradentes (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Review and illustrate the imaging findings of neurotoxoplasmosis, discuss the differential diagnoses, and correlate them with pathological images. Describe, through illustrative presentations, the benefits of the multimodality imaging approach for diagnosing neurotoxoplasmosis. Present challenging cases, such as differentiating between neurotoxoplasmosis, primary CNS lymphoma, and other opportunistic infections. Highlight radiological diagnostic pearls of neurotoxoplasmosis.

**TABLE OF CONTENTS/OUTLINE**

Neurotoxoplasmosis epidemiology and parasite life cycle. Imaging patterns on MR and CT. Susceptibility-weighted imaging (SWI) as an auxiliary tool for calcified lesions. Spectroscopy and perfusion as valuable tools for differential diagnosis. Imaging findings of post-treatment response. Differential diagnoses derived from a visual examination utilizing illustrative cases sourced from a database at a Tertiary University Hospital. Neurotoxoplasmosis imaging pearls. Final remarks.

## NREE-61 UNVEILING BRAIN METASTASIS RESPONSES TO IMMUNOTHERAPY: MRI INSIGHTS

Laura Oleaga, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nuria Bargallo, MD (*Abstract Co-Author*) Nothing to Disclose
Gary Amseian, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- To illustrate the use of immune checkpoint inhibitors in treating brain metastases and the implications on MRI imaging.- To recognize both classical and novel immunotherapy-specific response patterns in brain MRI.- To highlight the importance of utilizing key radiological assessment criteria to standardize response evaluations and outline differences among them.

**TABLE OF CONTENTS/OUTLINE**

1. Overview of immune checkpoint inhibitors in the management of brain metastases. 2. Imaging Patterns of Response. A. Classical response patterns: i. Complete response ii. Partial response iii. Stable disease iv. Progression of disease. B. Immunotherapy-specific patterns: i. Pseudoprogression ii. Hyperprogression iii. Durable response. 3. Assessment criteria to standardize response evaluation: A. Comparison of traditional vs Immunotherapy-

specific criteria. B. The significance of timing in distinguishing pseudoprogression and durable response. C. Addressing ambiguities in response criteria. D. Impact of clinical data on MRI assessment: neurological status, systemic therapy, and local treatments. 4. Spotting immune-related intra- and extracranial adverse events on imaging. 5. Brain MRI protocols and the potential of advanced techniques. 6. Conclusion

## NREE-62 CRACKING THE FETAL CENTRAL NERVOUS SYSTEM MRI: THE BIG PICTURE FOR RADIOLOGIST TRAINEES

Samuel Castillo, MD (*Abstract Co-Author*) Nothing to Disclose
Aura Maria M. Gonzalez Peralta, MD, MD (*Abstract Co-Author*) Nothing to Disclose
Genier Fabian Castano Lizarazo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To assess the indications and techniques of neuro-fetal MRI in order to evaluate the main central nervous system anomalies.- To describe systematic evaluation of normal fetal central nervous system MRI. - To outline the main five fetal central nervous system pathologies as well as pearls and pitfalls that every radiologist must recognize.- To ilustrate through real-life cases assessment of fetal central nervous system pathologies at antenatal and postnatal follow-up MRI.

### TABLE OF CONTENTS/OUTLINE

1. Introduction to Central Nervous System fetal pathologies: epidemiology, indications, and MRI technique. 2. Evaluation of normal Central Nervous System fetal development at various gestational periods through MRI: A step-by-step guideline. 3. MRI assessment of the five main Central Nervous System fetal anomalies: pearls and pitfalls for radiologists trainees. 3a: Abnormal fetal Central Nervous System cortical layering, gyration, and sulcation. 3b: Fetal ventriculomegaly. 3c: Midline anomalies: holoprosencephaly, corpus callosum agenesis-dysgenesis. 3d: Posterior fossa anomalies. 3e: Spinal dysraphism. 4. Presentation of five captivating cases of cetal Central Nervous System pathologies antenatally diagnosed at a national perinatology ķnstitute with postnatal follow-up MRI. 5. Conclusions: what is the future of fetal Central Nervous System MRI?

## NREE-63 DIAGNOSTIC IMAGING OF PEDIATRIC SUPERFICIALLY/CORTICALLY-BASED BRAIN TUMORS: NAVIGATING COMMON AND COMPLEX CASES

Fabricio G. Goncalves, MD (*Abstract Co-Author*) Nothing to Disclose
Carmen Rosa Cerron Vela (*Abstract Co-Author*) Nothing to Disclose
Mario Mahecha, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1 Stress early and accurate diagnosis for better outcomes.2 Discuss challenges in diagnosing pediatric tumors like PXA and Ganglioglioma, focusing on their unique imaging features.3: Emphasize recognizing mimics like NCC and cortical tubers, detailing differentiation strategies with advanced MRI.4 Highlight MRI advancements for enhanced tumor visualization and diagnostic accuracy.5: Promote integrated diagnostic strategy, merging imaging, clinical assessment, and genetic profiling for precise and tailored diagnosis.

### TABLE OF CONTENTS/OUTLINE

Objective: Enhance diagnostic accuracy for pediatric brain tumors and mimics.OutlineIntroduction: Stress the importance of precise diagnosis in pediatric neuroimaging.Specific TumorsPXA Discuss MRI features to differentiate from high-grade gliomas.DNET Emphasize the "bubbly" appearance and its link to epilepsy.MVNT: Describe imaging characteristics that may appear aggressive.PLNTY Explain classification and MRI signals.DGONC Highlight difficulties in recognizing diffuse patterns.Ganglioglioma: Cover typical features including calcifications and cystic changes.DIG: Identify key diagnostic features like large cystic components and robust reaction.DLGNT: Discuss its presentation as diffuse leptomeningeal lesions, emphasizing diagnostic challenges.Cerebellar Hemangioblastomas Discuss association with VHL syndrome.Lhermitte Duclos Syndrome: Describe the "tiger-striped" MRI appearance and Cowden syndrome link.Tumor Mimics: Strategies for distinguishing mimics like neurocysticercosis and cortical tubers using advanced imaging.Cases: Present cases illustrating diagnostic challenges and typical scenarios.

## NREE-64 SPINAL CSF LEAKS: TYPICAL AND ATYPICAL APPEARANCES AT CT MYELOGRAPHY

**Awards**
**Magna Cum Laude**

Daniel J. Scoffings, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
David Butteriss (*Abstract Co-Author*) Nothing to Disclose
Neha Kallam, BSc, MBBS (*Abstract Co-Author*) Nothing to Disclose
Anoma Lalani Carlton Jones, MBBS, FRCR (*Presenter*) Nothing to Disclose

### TEACHING POINTS

After viewing this exhibit the learner will be to:1. Describe the different types of spinal CSF leak that lead to spontaneous intracranial hypotension.2. Recognise the most common appearances at CT myelography that occur in each type of spinal CSF leak.3. Evaluate some of the atypical imaging manifestations of spinal CSF leaks at CT myelography.

### TABLE OF CONTENTS/OUTLINE

OUTLINE: Spinal CSF leaks have gained increased recognition over the last decade with advances in myelography and scanning techniques, imaging resolution and scanner capabilities. Our understanding of the causative pathologies are ever evolving as new techniques come to light. Dynamic CT myelography is a useful tool for detection of such leaks provided that meticulous technique is utilized. This educational exhibit will review the range of pathologies that can be encountered in the adult and paediatric population with examples of all different types of leaks from ventral and dorsal dural tears, lateral leaks, CSF venous fistulas, with typical and more atypical appearances of each, as well some lesser known and recognized entities including loculated leaks and CSF venous malformations and genetic associations. CONTENTS (1) Classification of spontaneous spinal CSF leaks. (2) Types of dynamic CT myelography and when to use them. (a) Ultrafast dynamic. (b) Modified dynamic. (c) Lateral decubitus (3) Provocation maneuvers at CT myelography. (4) Appearances of spontaneous leak types at CT myelography. (a) Ventral (type 1) leaks. (b) Lateral (type 2) leaks. (c) CSF-venous fistulas. (5) Less common forms of spinal CSF leak. (a) CSF-venous malformation fistula. (b) Arachnoid ‘blebs’. (6) Pitfalls and mimics (7) The negative or equivocal CT myelogram.

## NREE-65 ‘FIND THE LEAK’: CURRENT CONCEPTS IN IMAGING AND INTERVENTIONS IN SPONTANEOUS INTRACRANIAL HYPOTENSION

Tony Rahul (*Abstract Co-Author*) Nothing to Disclose
Sai K. Deepalam JR, MD (*Abstract Co-Author*) Nothing to Disclose
Meghana Kancharla, MBBS (*Abstract Co-Author*) Nothing to Disclose

Shravan Reddy K, MBBS (*Abstract Co-Author*) Nothing to Disclose
Shreyas Reddy K, MBBS, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Spontaneous intracranial hypotension (SICH) is a clinical syndrome due to diminished intracranial pressure, leading to disruptions in the homeostasis among blood, cerebrospinal fluid (CSF), and cerebral parenchyma. • SICH stems from three primary causes: (1) CSF leak originating from a nerve root sleeve diverticulum; (2) CSF leak attributed to an osteophyte spur, and (3) CSF venous fistula (CVF). • A range of modalities is employed to assess the underlying condition, including computed tomographic (CT) myelography, dynamic CT myelography, digital subtraction myelography, magnetic resonance (MR) imaging, and MR myelography with intrathecal gadolinium. Selection among these modalities is contingent upon whether the leak is characterized as high or low flow. • A targeted epidural patch using autologous blood or fibrin glue is an effective intervention.

**TABLE OF CONTENTS/OUTLINE**

• Understanding the pathophysiology and clinical features of SICH. • Discuss in detail the brain and spine imaging findings of SICH, with emphasis on key findings. • Myelographic patterns of SCIH: Tips for identification. • Basics, step-by-step technical approach, and limitations of CT myelography, Dynamic CT myelography, Digital subtraction myelography and MR myelography. • Epidural blood patch: technique and limitations. • Diagnostic approach and management algorithm for SICH.

## NREE-66 THE DIFFERENT FACES OF FRONTOTEMPORAL DEMENTIA: CLINICAL, STRUCTURAL AND FUNCTIONAL CORRELATION

**TEACHING POINTS**

Through this pictorial essay will be made a review based on cases and original drawings about the pathologies of the carotid arteries. This will be addressed by typical imaging patterns to narrow down differential diagnoses. The purpose of this exhibition is to: - Review the anatomy of the carotid arteries; - Understand the advantages and limitations of the main imaging methods used to evaluate carotid pathologies; - Recognize the main imaging patterns of the most frequent carotid artery diseases.

**TABLE OF CONTENTS/OUTLINE**

ANATOMICAL CONCEPTS • Carotid arteries anatomy IMAGING ASSESSMENT METHODS • Ultrasound • Computerized Tomography • Magnetic Resonance Imaging CAROTID ARTERIES DISEASES • Imaging aspects of carotid pathologies • Teaching points to narrow down differential diagnoses INTERACTIVE CASE-BASED DIDACTICS • Sample cases to illustrate and solidify the concepts

## NREE-68 POSTOPERATIVE SPINAL IMAGING: KEEPING YOUR BEHIND OUT OF A BIND!

Ajay Malhotra, MD, MMM (*Abstract Co-Author*) Nothing to Disclose
Mihran A. Khdhir, MD (*Abstract Co-Author*) Nothing to Disclose
Dheeman Futela, MBBS (*Abstract Co-Author*) Nothing to Disclose
Shadi Ebrahimian, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Accurate interpretation of post lumbar spinal surgery images is critical for radiologist. This educational exhibit focuses on the following topics:1. What are the imaging protocols used in post spinal surgery evaluation?We will explain different modalities including radiographs, CT, and MRI and the protocols used on each modality.2. How to evaluate post-operative radiographs?Different radiographic postsurgical complications will be explained including hardware fracture, loosening, et. 3. What is considered as normal postsurgical changes on CT/MRI?Expected postsurgical findings will be explained. 4. What are the early postsurgical complications on CT/MRI? Early complications including fluid collection, intraoperative vascular and neural injuries, hardware malpositioning, and possible intracranial hemorrhage will be shown. 5. What are the late complications?Late postsurgical changes such as infection, failed back surgery syndrome, pseudoarthrosis, and hardware failure will be discussed. 6. What are the challenges in evaluation of postsurgical CT and MRIs and what are the strategies to overcome those challenges?Streak artifacts related to the hardware is one of the most common limitations in evaluation of postoperative CT and MRI scans. The strategies in reducing these artifacts will be discussed.

**TABLE OF CONTENTS/OUTLINE**

1. Commonly used modalities and protocols in postoperative imaging.2. Expected findings and postsurgical complications on radiographs.3. Normal post-surgical CT/MRI findings.4. Early complications on CT/MRI.5. Late complications on CT/MRI.6. Challenges in evaluation of postsurgical CT/MRI images.7. Strategies to reduce hardware related artifacts.

## NREE-69 UNVEILING IMMUNE EFFECTOR CELL ASSOCIATED NEUROTOXICITY SYNDROME (ICANS): WHAT EVERY RADIOLOGIST SHOULD KNOW

Marta Calvo-Imirizaldu, MD (*Abstract Co-Author*) Research Grant, Siemens AG
Manuel Rafael Lopez De La Torre Carretero (*Abstract Co-Author*) Nothing to Disclose
Pablo Del Nido Recio (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Carmen Mbongo, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To understand some key clinical and radiological manifestations of Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS).To provide clues for identifying imaging patterns suggestive of ICANS for prompt diagnosis and intervention.

**TABLE OF CONTENTS/OUTLINE**

Chimeric antigen receptor (CAR) T cells targeting the CD19 cell surface glycoprotein have emerged as a highly effective immunologic therapy in patients with certain refractory hematologic malignancies. The engagement of these two cell receptors causes a systemic cytokine release, which can compromise the blood-brain barrier and cause an immune effector cell-associated neurotoxicity syndrome (ICANS).ICANS is a pattern of neurotoxicity observed in patients following CAR T-cell infusion with associated neurologic symptoms, such as headaches and confusion. Neuroimaging is frequently obtained in patients who present with acute neurologic changes after infusion. This pictorial review aims to summarize some of the neuroimaging findings in ICANS through illustrative cases from our institution.1. Brief overview of the fundamentals of CAR-T cell therapy and ICANS pathophysiology.2. Clinical presentation and grading severity of ICANS (ASTCT consensus).3. Neuroimaging findings. While typically yielding negative results, imaging is advised when encountering suspected ICANS cases. Such imaging is crucial for detecting brain oedema and other abnormalities including stroke, haemorrhage, leptomeningeal enhancement, and mass effect, among others. - CT and brain MRI imaging findings. - Main entities to be considered in the differential diagnosis of ICANS.- Other CNS complications following CAR-T cell therapy.

## NREE-7 CNS CAVERNOUS MALFORMATIONS IN CHILDREN, SPECTRUM OF DISEASE

**Awards**
**Certificate of Merit**

Paul J. Farnsworth, DO (*Abstract Co-Author*) Nothing to Disclose

V. Michelle Silvera, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Cavernous malformations (CMs) are slow flow vascular malformations most commonly found in the brain and spinal cord. The clinical significance of CMs lies in their potential to cause various neurological symptoms and complications such as bleeding, seizures, neurological deficits, and headaches. Once a CM is diagnosed, the risk of bleeding needs to be addressed, the likelihood of which depends on factors such as location and the presence of certain genetic mutations in the patient. Diagnosing a CM on imaging can be challenging if atypical imaging features are present and when CMs are very large (giant) or infiltrative. Treatment options include observation with surveillance imaging, surgical resection, stereotactic radiosurgery, and laser interstitial thermal therapy (LITT). TEACHING POINTS:1. CMs can lead to a range of neurological symptoms and complications, such as bleeding, seizures, neurological deficits, and headaches. 2. Specific genetic mutations may result in Familial Cerebral Cavernous Malformation Syndrome (FCCM), increasing the likelihood in children of developing CMs throughout their lives. 3. CMs located in critical areas such as the brainstem are at higher risk to bleed, rebleed, and cause neurological deficits. 4. Giant and infiltrative CMs are often misdiagnosed and not considered in the list of potential diagnoses before surgery.

**TABLE OF CONTENTS/OUTLINE**

1. Define CMs and describe their typical imaging appearance. 2. Discuss atypical imaging features that complicate CM diagnosis. 3. Review FCCM and illustrate the three main types with case examples. 4. Review the imaging features of Giant CMs 5. Demonstrate the imaging features of Infiltrative CMs.

**TEACHING POINTS**

1. Photon-counting detector (PCD-) CT offers unique advantages over traditional energy-integrating detector (EID-) CT in neuroradiology. 2. The primary inherent benefit of PCD- over EID-CT is the ultra high spatial resolution, with slice thickness on the order of 0.2mm. 3. High yield diagnostic applications in neuroradiology include temporal bone CT, CT angiography (CTA) of the head and neck, CT venography (CTV) of the head, and CT myelography (CTM). 4. Other/emerging applications include head CT and face/sinus/orbit CT.

**TABLE OF CONTENTS/OUTLINE**

I. Brief review of relevant physics aspects of PCD-CT, compared to EID-CT. II. PCD-CT in temporal bone imaging a. Anatomy b. Case based pathology III. PCD-CTA a. Head CTA anatomy b. Distinguishing infundibula and aneurysms c. Evaluating aneurysms, both untreated and treated d. Assessing arterial stenoses e. Other (additional case based pathology) IV. PCD-CTV a. Anatomy b. Dural venous sinus thrombosis c. Idiopathic intracranial hypertension V. PCD-CTM a. Lateral decubitus imaging of CSF-venous fistulae b. Dynamic imaging of high-flow CSF leaks VI. Emerging applications (case based anatomy and pathology) a. Head CT b. Face/sinus/orbit CT

## NREE-71 THE NEW ERA OF GALLIUM-68 DOTATATE PET IMAGING TO EVALUATE INTRACRANIAL MENINGIOMAS: A PICTORIAL REVIEW

Nelson F. Ferreira, MD (*Abstract Co-Author*) Nothing to Disclose
Ana C. Ottaiano, MD (*Abstract Co-Author*) Nothing to Disclose
Tomas Freddi, MD (*Abstract Co-Author*) Nothing to Disclose
Larissa Freitas, MD (*Abstract Co-Author*) Nothing to Disclose

Marilia Assuncao Jorge (*Abstract Co-Author*) Nothing to Disclose
Ronaldo Belz (*Abstract Co-Author*) Nothing to Disclose
Efraim Ferreira, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The main goal of this pictorial essay is:- To discuss the potential impacts of PET images using 68Gallium-DOTATATE as radiotracer on diagnostic confirmation and treatment management of meningiomas.- To demonstrate PET imaging follow-up for meningiomas that are unresectable, recurrent, incompletely resected, and/or higher-grade meningiomas, where radiation therapy (RT) may be preferred.- To describe and illustrate the radiological patterns of 68Gallium-DOTATATE PET images in posttreatment changes, as well as its correlation to other imaging modality, such as computed tomography (CT) and magnetic resonance imaging (MRI).

**TABLE OF CONTENTS/OUTLINE**

- Introduction- Imaging modalities- Pre-treatment imaging findings- Post-treatment follow-up findings- Practical tips and Pitfalls- Conclusion/Take home message

## NREE-72 ANTENATAL AND POSTNATAL IMAGING IN CONGENITAL POSTERIOR FOSSA ANOMALIES: PATTERN RECOGNITION AND DIAGNOSTIC APPROACH

**Awards**
**Certificate of Merit**

Elka Miller, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Neetika Gupta, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Pradeep Krishnan, MD (*Abstract Co-Author*) Nothing to Disclose
Shivaprakash B. Hiremath, DMRD, FRCR (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To review the anatomy and embryology of the posterior fossa on fetal and postnatal MRI. 2. To describe congenital anomalies of the posterior fossa with emphasis on non-cystic anomalies, describing their distinctive imaging features and accompanying effects on the cerebellum and the brainstem. 3. To advance understanding of non-cystic posterior fossa anomalies by highlighting specific imaging phenotypes and pattern-based approaches on antenatal and postnatal MRI.

**TABLE OF CONTENTS/OUTLINE**

1. Discuss various disease entities resulting in posterior fossa anomalies. 2. Identify salient imaging features of non-cystic posterior fossa disorders in the fetal and postnatal brain to reach a specific diagnosis. 3. Describe a systematic pattern-based imaging approach to help guide appropriate management and genetic evaluation.

## NREE-73 READ MY MIND: IMAGING CEREBRAL SMALL VESSEL DISEASE

Hediyeh Baradaran, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Bryan L. Bishop, MD (*Abstract Co-Author*) Nothing to Disclose
Keena Li (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. We will provide an overview of CSVD including criteria for diagnosis2. We will closely examine common imaging features of CSVD and their classification schemes and rating scales3. We will walk through imaging led examples and cases of CSVD to highlight key imaging features4. We will present data on the associations of each of these imaging findings to future stroke, cognitive impairment, and mortality.

**TABLE OF CONTENTS/OUTLINE**

1. Review of CSVD and diagnostic criteriaa. Epidemiology and risk factors2. Overview of common imaging features of CSVDa. White Matter Hyperintensitiesb. Covert Brain Infarctionsc. Cerebral Microbleedsd. Enlarged Perivascular Spaces3. White Matter Hyperintensitiesa. T2/FLAIR hyperintensity in periventricular/deep cerebral white matter, subcortical gray matter, BG, brainstemb. Various Established Imaging Scalesc. Imaging examples and casesd. Clinical associations with future stroke, dementia, mortality4. Covert Brain Infarctionsa. Imaging detected infarcts in asymptomatic patientsb. Covert brain infarction schema i. Specific examples of each classification ii. Lacunar, subcortical, corticalc. Clinical associations with future stroke, dementia, mortality5. Cerebral Microbleedsa. Small round or ovoid lesions (<10mm diameter) of marked hypo intensity with blooming on T2*b. MARS and BOMB criteriac. Imaging examples and casesd. Clinical associationsPerivascular spacesExtensions of extra cerebral fluid space covered by Pia mater surrounding cerebral vessels from brain surface into and through brain parenchymab. Potential classification schemasc. Imaging examples and casesd. Clinical associations7. Summary

## NREE-74 CAROTID PLAQUES RISK STRATIFICATION: THE APPLICABILITY AND LIMITATIONS OF THE PLAQUE-RADS

Francinne Santos, MD (*Abstract Co-Author*) Nothing to Disclose
Bruna Gontijo, MD (*Abstract Co-Author*) Nothing to Disclose
Leandro T. Lucato, MD (*Abstract Co-Author*) Nothing to Disclose
Cleiton A. Freitas, MD (*Abstract Co-Author*) Nothing to Disclose
Paula Arantes (*Abstract Co-Author*) Nothing to Disclose
Alcivan Morais Filho, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Effective reporting of carotid plaque risk is no longer limited to stenosis measurement and is essential for communication prior treatment decisions. Critical characteristics of plaque, such as ulceration or irregularity, and internal hemorrhage are revealed by axial contrast imaging techniques. These characteristics add to a complete analysis of plaque instability and the risks of the following complications. Plaque-RADS (PR) aims to standardize radiologists, clinicians, and surgeons' communication about carotid plaques. In this system, plaques are divided into: normal vessel walls (PR1); plaques with Maximum Wall Thickness (MWT) <3 mm (PR2); MWT = 3 mm without complications (PR3); thick Fibrous Cap (FC) (3a), thin or invisible FC (3b), and healed ulcers (3c); complicated plaques (PR4) with ulcerations (4a), intraplaque hemorrhage (4b), or intraluminal thrombus (4c). PR has drawbacks, even with its advantages. It may misclassify the risk associated with these plaques since it assumes that those lacking a visible FC are thin-capped. The limitations of fibrous cap visibility make it difficult to classify Categories 3c and 4b, both of which show visible ulceration. The obligation to attribute a category, even under suspicion of limited evaluation, can also be detrimental. Although the system may need to address some of these limitations in order to increase its applicability, it is worthy in order to improve communication.

**TABLE OF CONTENTS/OUTLINE**

Presentation with Plaque-RADS and cases of limitations.

## NREE-75 THE WHOLE SPECTRUM OF MOYAMOYA DISEASE: FROM DIAGNOSIS TO POST-TREATMENT FOLLOW-UP

Daniel L. Cardoso, MD (*Abstract Co-Author*) Nothing to Disclose
Claudia D. Leite, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Maria Martin, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Marcos F. Docema, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Julia M. Brunelli, MD (*Abstract Co-Author*) Nothing to Disclose
Cesar Gabriel Rocha Da Costa Paloschi, MD (*Abstract Co-Author*) Nothing to Disclose
Thiago Jose Pinheiro Lopes, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Moyamoya is a chronic occlusive, non-inflammatory and non-atherosclerotic cerebrovascular disorder, which affects mainly the intracranial portions of the distal internal carotid artery and the proximal anterior and middle cerebral arteries. The development of compensatory collateral circulation provides the angiographic appearance of a "puff of smoke", which translates to Moyamoya in Japanese and gives the disease its name. Radiological imaging plays a central role in the diagnosis of this disease and the recognition of resulting ischemic and hemorrhagic events. Our goal is to first review the imaging features of Moyamoya and then discuss the different surgical techniques developed to treat it, how to identify them on imaging studies, and what to expect from post-treatment imaging evaluation.

**TABLE OF CONTENTS/OUTLINE**

1) Introduction. 2) Pathophysiological mechanism and anatomical correlation. 3) Angiographic classification of Moyamoya disease. 4) Vascular and parenchymal findings. 5) Surgical management: revascularization techniques and postoperative image characterization. 6) Assessment of pre- and post-treatment cerebral perfusion. 7) Challenges, pearls and pitfalls in differential diagnosis. 8) Future directions. 9) Take home messages.

**TEACHING POINTS**

This pictorial essay explores the 2021 WHO classification of astrocytic tumors, with a particular focus on the integration of molecular and genetic profiling, which now plays a pivotal role in the categorization of these neoplasms.Through a series of illustrative clinical cases, accompanied by insightful diagrams and educational illustrations, the key objectives of this review are to explain the updated classification, showcase practical applications in clinical settings,

discuss important molecular markers, provide insights on neuroimaging interpretation, address challenges in adopting the new system, review prognostic implications, and explore future trends.

**TABLE OF CONTENTS/OUTLINE**

2021 WHO classification for astrocytic tumors- Explaining the Updated Classification- Importance of molecular and genetic profiling in tumor categorization Important Genes and Molecular profiles - Discussion on key markers and their significance in differentiating astrocytic tumor subtypes Illustrative Cases - Presentation of select cases to demonstrate practical applications - Use of diagrams and illustrations to enhance understanding- Highlighting the use of molecular and genetic markers in diagnosis, prognostication, and therapy Exploring Future Trends - Anticipation of evolving trends in neuro-oncology - Discussion on how advancements in molecular genetics may impact future updates to tumor classification

## NREE-77 ASSESSMENT OF TREATMENT RESPONSE IN ADULT GLIOMAS: A PRIMER FOR RADIOLOGISTS

Bruna G. Dutra (*Abstract Co-Author*) Nothing to Disclose
Raquel A. Moreno, MD (*Abstract Co-Author*) Nothing to Disclose
Luis F. Godoy, MD (*Abstract Co-Author*) Stockholder, Johnson & Johnson;Stockholder, Illumina, Inc;Stockholder, UnitedHealth Group
Heitor C. Alves, MD (*Abstract Co-Author*) Nothing to Disclose
Murilo Vega, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro Oertel D'Amico, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Understanding the relevance of establishing criteria for defining treatment response status in patients with glioma.Brief history of the RANO criteria and it’s previous versions.Understanding the importance of updated criteria (RANO 2.0 from 2023), with a focus on the limitations of previous versions.Becoming familiar with how to apply the RANO 2.0 criteria in practice.

**TABLE OF CONTENTS/OUTLINE**

INTRODUCTIONResponse Assessment in Neuro-Oncology (RANO) overview.GENERAL RECOMMENDATIONS IN RANO 2.0Intended use for RANO 2.0:Patient population and tumor types.Imaging protocol definition, including choice of modality and recommended study parameters.DISEASE ASSESSMENT RECOMMENDATIONS IN RANO 2.0Method of measurement: two-dimensional and volumetric assessment.Definition of measurable and nonmeasurable disease.Definition of target and nontarget lesions.ASSESSMENT OF TREATMENT RESPONSE STATUS IN RANO 2.0Selection of baseline study for comparison.Criteria for definition of treatment response status as complete response, partial response, stable disease and progressive disease.Definition and use of “sum of bideminsional products”.Illustrative cases focusing on practical application of RANO 2.0 criteria.Special considerations:Pseudoprogression and confirmatory scans (which settings require confirmatory imaging and appropriate confirmation timing).Pseudoresponse (associated tumor and treatment).Nonenhancing glioblastoma IDH-wildtype.FUTERE PERSPECTIVESBT-RADS:Overview of intended use.Limitations.Advanced imaging:Current uses for advanced imaging in the setting of adult glioma.Trends in the literature for validation in treatment response assessment.

## NREE-78 STARING INTO THE BRAINS ABYSS: NAVIGATING THROUGH CORTICAL MALFORMATIONS

Kevin Kurt Mac Allister (*Abstract Co-Author*) Nothing to Disclose
Cristina H. Besada SR, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Federico M. Olivera Plata, MEd (*Abstract Co-Author*) Nothing to Disclose
Manuel S. Perez Akly, MD (*Abstract Co-Author*) Nothing to Disclose
Stefania Solanot, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Cortical malformations must be ruled out in essentially every pediatric patient with developmental delay or epilepsy.MRI is certainly recommended as the most important imaging method in the evaluation of MCD, thanks to its optimal delineation of grey and white matter structures.Neuroimaging plays a crucial role in the prenatal and postnatal diagnosis of malformations of cortical development, since pathological tissue is not always available except for surgeries or autopsies. Radiologically, cortical malformations exhibit distinct imaging features such as abnormal cortical lamination, dysplastic gyri, and heterotopias.CT misses the abnormality in more than 30% of cases.Radiologists should also obtain detailed information from the referring clinicians regarding the size of the head, possible syndromic clinical features, epilepsy semiology, and EEG findings (particularly, location of origin of spikes) before reporting the examination

**TABLE OF CONTENTS/OUTLINE**

Role of imaging in the diagnosis of malformation of cortical development Normal cortex developmentClassification according to the affected stage of normal cortex development Description of the most important disorders and radiological findingsConclusion References

## NREE-79 GLAND FINALE: POST-OPERATIVE PITUITARY INSIGHTS

Rebeca O. Francelino, MD (*Abstract Co-Author*) Nothing to Disclose
THARYN Goncalves FRANCO DE GODOY (*Abstract Co-Author*) Nothing to Disclose
Raquel A. Moreno, MD (*Abstract Co-Author*) Nothing to Disclose
Paula Arantes (*Abstract Co-Author*) Nothing to Disclose
Guilherme Almeida (*Abstract Co-Author*) Nothing to Disclose
Taisa M. Guarilha, MD (*Abstract Co-Author*) Nothing to Disclose
Luis Antonio Tobaru Tibana, MD (*Abstract Co-Author*) Nothing to Disclose
Lucas G. Braga, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

In this presentation, we delve into the critical aspects of post-operative image acquisition protocols, focusing on timing and sequences essential for optimal imaging outcomes. Additionally, we explore the typical postoperative changes that occur following pituitary surgery. These changes encompass various factors, including anatomical distortions, the utilization of common surgical materials, the presence of hematic residues, gas foci, and local artifacts. Moreover, we emphasize the importance of recognizing specific imaging changes indicative of residual lesions and complications. Understanding and identifying these changes are paramount in postoperative imaging, as they provide valuable insights into the patient's recovery process and are crucial for prompt intervention and management.

**TABLE OF CONTENTS/OUTLINE**

1. Contemporary Protocol for Pituitary Assessment. 2. Routes of Intervention in Pituitary Lesions: highlight transsphenoidal route particularities and other main intervention routes. 3. Primary Surgical Inclusion Materials and MRI Characteristics: describe MRI characteristics of surgical materials and common imaging artifacts. 4. Common Changes After Surgical Removal of Pituitary Adenomas. 5. Notable Complications: discuss regional hemorrhage,

cerebrospinal fluid leakage, ischemia, among others. 6. Characterizing Residual Pituitary Adenoma Lesions on MRI: focus on distinct gadolinium enhancements for identifying residual lesions. 7. Current Protocol for Postoperative Pituitary Adenoma Surveillance via MRI. 8. Main Items in the Imaging Report: highlight essential components for clinical and imaging follow-up alterations.

## NREE-80 ACUTE SPINAL TRAUMA MRI: A PRACTICAL GUIDE FOR BEGINNERS

David Castanedo SR, MD (*Abstract Co-Author*) Nothing to Disclose
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*) Nothing to Disclose
Silvia Revuelta Gomez, MD (*Abstract Co-Author*) Nothing to Disclose
Ana Berasategui Criado, MD (*Abstract Co-Author*) Nothing to Disclose
Sofia Bretos Azcona, MD (*Abstract Co-Author*) Nothing to Disclose
Alejandra Somoano Marfull (*Abstract Co-Author*) Nothing to Disclose
Rodrigo Sutil (*Abstract Co-Author*) Nothing to Disclose
Marina Arroyo Olmedo, MD (*Abstract Co-Author*) Nothing to Disclose
Celia Cantolla, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To know the basic spinal Magnetic Resonace Imaging (MRI) protocol in the traumatic context.- To identify the potential injuries that can occur in spinal trauma, both at the spinal cord and extramedullary area.- To know the Schaeffer and Basic classifications to assess the severity of spinal injuries

### TABLE OF CONTENTS/OUTLINE

A) Imaging techniques in spinal traumaB) Main MRI protocol and special sequences (in case of lesion at the craniocervical junction, lesion in the dura mater of the thecal sac, vertebral arteries, radicular lesion or spinal cord infarction)C) Types of injuries- Ligamentary lesions (anterior and posterior longitudinal ligament, ligamentum flavum, supra and interspinous ligaments)- Disc damage and acute herniations- Vascular injuries- Extramedullary haemorrhage- Cord damage: cord edema, haemorrhage, spinal cord section. Schaeffer and Basic classifications.

## NREE-82 FROM PIXELS TO PRACTICE: IMPACTFUL NEUROIMAGING ADVANCES IN THE CLINICAL MANAGEMENT OF CEREBRAL AMYLOID ANGIOPATHY

**Awards**
**Certificate of Merit**

Eduardo D. Valadares, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Clara Zanon Zotin (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Cerebral Amyloid Angiopathy (CAA) is a the second most prevalent form of cerebral small vessel disease, with devastating clinical consequences.The pattern of distribution of MRI-visible lesions aids in the distinction between CAA and other prevalent forms of sporadic cerebral small vessel diseases, such as hypertensive arteriolosclerosis.The Boston Criteria v2.0 offers high positive predictive value for the diagnosis of CAA. Edinburgh Criteria is useful in the characterization of CAA-related ICH in CT studies. Hemorrhagic markers, especially cortical superficial siderosis, more strongly predict the risk of first-ever or recurrent intracerebral hemorrhage, compared to non-hemorrhagic markers, which are more strongly associated with cognitive impairment, but are often outperformed by advanced techniques, such as diffusion-based markers.

### TABLE OF CONTENTS/OUTLINE

• Introduction: Pathophysiology, clinical spectrum, and classification of CAA.• Neuroimaging features: Hemorrhagic (cerebral microbleeds, cortical superficial siderosis, intracerebral hemorrhage, intragyral hemorrhages, convexity subarachnoid hemorrhage) and Non-hemorrhagic (perivascular spaces in the centrum semi-ovale, cortical cerebral microinfarcts, white matter hyperintensities in a multifocal subcortical pattern• Diagnostic value: Boston criteria (versions 1.0, 1.5, and 2.0) and Edinburgh criteria • Prognostic value: Risk of first-ever and recurrent intracerebral hemorrhage; Risk of transient focal neurological episodes; Risk of cognitive decline• Impact of neuroimaging markers of CAA in clinical management of patients with stroke.• CAA diagnosis in the era of anti-amyloid treatmento Risk of ARIA

## NREE-83 SMALL HEADS BIG TROUBLES NEONTAL CEREBRAL HYPOXIC-ISCHEMIC INJURY

Paola A. Lara Rodezno, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The assessment of the radiological signs in hypoxia in the full-term neonate are characteristic and different from older children; on the other hand, the alterations in premature neonates are different from those in full-term neonates. Assessment of signs of hypoxic damage on neonatal brain imaging requires attention to a number of specific signs. It is important for the radiologist to know the normal findings according to the gestational age of the neonate and to differentiate between severe or total hypoxia, prolonged or partial and mixed hypoxia. Brain MRI was evaluated in premature and term infants looking for 4 interrelated fundamental signs grouped under the term "1-2-3-4 sign" with findings of total severe hypoxia such as: increase in signal intensity of the basal ganglia and thalamus in T1W, posterior arm sign absent in full-term neonate, signs of diffusion hypoxia; signs of prolonged hypoxia such as hyperintensity of the cerebral cortex on T1W.

### TABLE OF CONTENTS/OUTLINE

The most frequent finding was hyperintensity of the basal nuclei, followed by hyperintensity of the gyri and lamellar cortical necrosis.

## NREE-84 A 360 DEGREE REVIEW OF THE POWER OF LOW INTENSITY FOCUSED ULTRASOUND (LIFUS) IN MANAGEMENT OF BRAIN TUMORS

Jody L. Tanabe, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha Pisani Petrucci, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nolan Dang (*Abstract Co-Author*) Nothing to Disclose
Natalie Serkova, PhD, MBA (*Abstract Co-Author*) Nothing to Disclose
Parisa Khoshpouri, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Understanding LIFUS Mechanisms Explore the fundamental mechanisms underlying Low Intensity Focused Ultrasound (LIFUS) and its unique features in affecting the blood brain barrier. 2. Explaining the Safety Profiles: Evaluate the safety profile of LIFUS in diagnosis and management of brain tumors facilitating drug delivery, emphasizing key considerations for clinical implementation. 3. Clinical Application and Ongoing Trials: Discuss the current clinical

applications of LIFUS in approaching brain lesions and highlight ongoing trials investigating its efficacy, aiming to delineate its potential role as a therapeutic modality in combination with oncologic treatments.

**TABLE OF CONTENTS/OUTLINE**

• Introduction to LIFUS and its Mechanism of Action: Briefly introduce the concept of Low Intensity Focused Ultrasound (LIFUS) and the underlying mechanism of LIFUS, focusing on how it interacts with neural tissue and disrupts the BBB. its potential applications in neuroradiology and targeting brain tumors. • Safety Profile: Highlight the safety considerations associated with LIFUS, including its non-invasive nature, potential side effects, and current safety protocols. • Ongoing Clinical Trials: Provide an overview of ongoing clinical trials investigating the use of LIFUS in various neurological conditions, including the objectives, methodologies, and preliminary findings. • Conclusion: Summarize the potential of LIFUS as a promising tool in neuroradiology and neuromodulation, highlighting its role in advancing the field and addressing unmet clinical needs.

## NREE-85 AN EDUCATIONAL EXHIBIT OF THE DIFFERENT IMAGING CHARACTERISTICS OF HR- VWI MRI AND MRA ON PATIENTS WITH CONFIRMED INFECTIOUS VASCULITIS

Javier M. Romero, MD (*Abstract Co-Author*) Stockholder, TMA Precision Medicine
Suely F. Ferraciolli, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Odette Ganem (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

HR- VWI has been recently utilized as an excellent sequence to detect inflammation of the intracranial circulation when vasculitis is suspected. Although imaging characteristics have been well defined in patients with primary central nervous system vasculitis, infectious or secondary vasculitis has been less well described. Many Infectious etiologies may result in vasculitis, including viral, bacterial, or fungal etiologies.In this pictorial review, we would like to highlight the local changes on the vascular wall and the predominant vascular territories compromised in infectious diseases viewed on High-resolution vessel wall imaging (HR-VWI) MRI and magnetic resonance angiography (MRA).

**TABLE OF CONTENTS/OUTLINE**

- Introduction- Clinical presentation of Infectious Vasculitis: Viral, Bacterial, and Fungal - Radiographic characteristics of infectious vasculitis on MRA and HR VWI MRI - Differential Diagnosis with other causes of CNS Vasculitis (with schematic drawing)- Conclusion

## NREE-86 EX VIVO HIGH-RESOLUTION CAROTID PLAQUE MRI WITH EMPHASIS OF QUANTITATIVE SUSCEPTIBILITY MAPPING: IMMUNOHISTOPATHOLOGICAL CORRELATION

Ryo Toya, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tomoki Nakano, MD (*Abstract Co-Author*) Nothing to Disclose
Ayano Ishiyama, MD (*Abstract Co-Author*) Nothing to Disclose
Hideki Ishimaru (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Many studies using in vivo carotid plaque MRI have highlighted its usefulness in the detection of clinically unstable plaques. However, in vivo MRI is often plagued by motion artifacts, such as carotid artery pulsation, and offers lower spatial resolution than microscopic histopathology specimens. Consequently, accurately assessing signals related to different components within carotid plaques can be difficult. Ex vivo MRI presents advantages such as eliminating motion artifacts and providing higher-resolution images that can be accurately correlated with histopathology. Quantitative susceptibility mapping (QSM), a recently developed technique for measuring tissue susceptibility, is expected to characterize the carotid plaque composition. In this presentation, we provide new insights from ex vivo high-resolution carotid plaque MRI, including QSM, and identify discrepancies with previous in vivo imaging results while also raising important issues that require further attention.

**TABLE OF CONTENTS/OUTLINE**

-Immunostaining is useful for diagnosing carotid plaque components -Can intraplaque hemorrhage and lipid-containing components be distinguished? -Is it the only calcification that shows a low signal in all imaging sequences? -Is it practically possible to diagnose fibrous cap? -What signals do the fibrous component and loose matrix exhibit? -Key challenges to be solved.

## NREE-87 DIAGNOSTIC ACCURACY OF CONTRAST ENHANCED FLUID-ATTENUATED INVERSION RECOVERY (CE-FLAIR) MRI IN DIAGNOSIS OF INFECTIOUS MENINGITIS TAKING CSF ANALYSIS AS GOLD STANDARD”

Urooj Kanwal, DMRD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Shaista Shoukat, MBBS (*Abstract Co-Author*) Nothing to Disclose
Sumera Shahbaz, MBBS (*Abstract Co-Author*) Nothing to Disclose
Sumaira Roohi, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Meningitis, an inflammation of the meninges, can be caused by various infectious agents. Early and accurate diagnosis is vital for effective treatment. Cerebrospinal fluid (CSF) analysis is the standard method, but Contrast Enhanced Fluid-Attenuated Inversion Recovery (CE-FLAIR) MRI shows potential for improved visualization of meningeal inflammation. However, its diagnostic accuracy compared to CSF analysis needs clarification. This study aims to address this gap.

**TABLE OF CONTENTS/OUTLINE**

STUDY DESIGN Cross-Sectional Descriptive Study RESULTSThe mean age was calculated to be 35.4 + 14.7 years with 145 male participants (51.60%) and 136 female participants (48.40%).The diagnostic accuracy of CE-FLAIR MRI was further delineated in Figure No. 5. Sensitivity, specificity, positive predictive value, and negative predictive value were calculated as 96.05%, 92.23%, 94.71%, and 94.06%, respectively. The overall diagnostic accuracy of CE-FLAIR MRI was determined to be 94.51%. CONCLUSION This study provides valuable insights into the diagnostic accuracy of contrast enhanced fluid-attenuated inversion recovery (CE-FLAIR) MRI in meningitis diagnosis. The results underscore the potential of CE-FLAIR MRI as a noninvasive tool with comparable diagnostic accuracy to the gold standard cerebrospinal fluid (CSF) analysis.

## NREE-88 CLINICAL SIGNIFICANCE OF OUTER CONTOUR ASSESSMENT OF INTRACRANIAL VESSELS USING 3D HEAVILY T2 WEIGHTED MR CISTERNOGRAPHY

Hideki Ishimaru (*Abstract Co-Author*) Nothing to Disclose
Tomoki Nakano, MD (*Abstract Co-Author*) Nothing to Disclose
Ryo Toya, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Chika Somagawa, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

3DMR cisternography is a high spatial resolution image with heavy T2 contrast (cerebrospinal fluid is visualized as a high signal and the other as a low signal). Imaging methods based on fast spin echo and fast gradient echo are mainly used and are effective in the diagnosis of cerebrospinal fluid leaks, hydrocephalus, and the relationship between tumors and normal structures. This method can also be used to evaluate intracranial vascular contours and can be applied to a variety of vascular diseases. The purpose of this exhibit is to provide clinical applications of 3D MR cisternography in various intracranial vascular diseases, with an emphasis on the outer contour assessment of intracranial vessels.

**TABLE OF CONTENTS/OUTLINE**

Sequence for 3D MR cisternography-Imaging parameters and image contrast-Case based presentation-A. Arterial contours (arterial course in acute arterial occlusion, evaluation of outer diameter of occluded blood vessels in moyamoya disease, aplastic/twig-like MCA)-B. Venous contours (involvement in neurovascular compression, draining veins in dural arteriovenous fistula)-C. Estimation of vascular wall pathology by comparison with TOF (atherosclerotic plaque, arterial dissection, cerebral vasospasm, etc)-D. Location of cerebral aneurysm (distal dural ring and paraclinoid aneurysm)-E. Others-F. Limitations and Pitfalls-

## NREE-89 DON'T GET LOST, USE THE BONE. A COMPREHENSIVE GUIDE OF THE ANTERIOR CONDYLAR CONFLUENCE ANATOMY USING CONE-BEAM CT

**Awards**
**Certificate of Merit**

Orlando M. Diaz, MD (*Abstract Co-Author*) Nothing to Disclose
Fernando Ahumada (*Abstract Co-Author*) Nothing to Disclose
Kristina Ramirez Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Valeria Ortega, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Review the anatomy of the anterior condylar confluence and the related network of vein structures. 2) Describe the cone-beam CT utility in arteriovenous fistulas at the anterior condylar confluence and adjacent bone structures.3) Recognize the landmarks and identify differences between the arteriovenous fistulas of the anterior, posterior, and lateral condylar veins.

**TABLE OF CONTENTS/OUTLINE**

1) Cone-beam CT: Importance in describing bone anatomya) Previous literature utilization of cone-beam CTb) Cone-beam CT's role in understanding the anterior condylar confluence and adjacent venous structures2) Posterior fossa venous drainage overview3) Anterior condylar confluence anatomy 4) Anatomy review with cone beam CT: Structures related to the anterior condylar confluence5) How to identify anterior condylar vein6) Anterior condylar vein arteriovenous fistulasa) Case 1b) Case 27) How to identify posterior condylar vein8) Posterior condylar vein arteriovenous fistulasa) Case 3b) Case 49) How to identify lateral condylar vein10) Lateral condylar vein arteriovenous fistulasa) Case 3b) Case 411) Conclusion

## NREE-9 MANAGEMENT OF INTRACRANIAL METASTASES: WHAT THE RADIOLOGIST NEEDS TO KNOW

Miral D. Jhaveri, MD, MBA (*Abstract Co-Author*) Royalties, RELX
Surjith Vattoth, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Santhosh Gaddikeri, MD (*Abstract Co-Author*) Nothing to Disclose
Ken Tatebe, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shehbaz M. Ansari, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Brian Mu, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Review imaging findings associated with intracranial metastases, with an emphasis on features that are germane to management decisions.2. Discuss the major modalities for treatment of intracranial metastases including radiation therapies, systemic treatments (chemotherapy immunotherapy), and surgical approaches with a focus on clinical issues relevant to an interpreting radiologist.3. Review post-treatment imaging of intracranial metastases and the major complications associated with each treatment modality.4. Role of advanced imaging to differentiate residual/recurrent metastasis vs treatment related changes.

**TABLE OF CONTENTS/OUTLINE**

Significant advancements have been made in the diagnosis and treatment of intracranial metastases, improving outcomes but complicating their clinical landscape and evaluation on imaging. To generate cogent reporting, radiologists should understand the clinical implications of different imaging characteristics of metastatic lesions and have basic familiarity with when and how major treatment modalities are used. The exhibit focuses on the routine neuroimaging task of evaluating intracranial metastases both before and after treatment. The role of advanced imaging techniques beyond conventional MRI is discussed, particularly in the differentiation of true residual or recurrent metastastic disease from pseudoprogression or radiation necrosis. Additionally, a wide range of complications including postoperative, parenchymal and vascular post-radiation, and chemotherapy and immunotherapy related complications are also reviewed.

## NREE-91 POST-THROMBECTOMY IMAGING FINDINGS: WHAT THE GENERAL RADIOLOGIST NEEDS TO KNOW

**Awards**
**Magna Cum Laude**

Ranliang Hu, MD (*Abstract Co-Author*) Stockholder, Moderna, Inc;Stockholder, Pfizer Inc
Dan I. Cohen-Addad, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander D. Bode, MD (*Abstract Co-Author*) Nothing to Disclose
Michael Nance, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Saumya Gurbani, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Describe the clinical indications for mechanical thrombectomy and the TICI classification scale for assessing reperfusion after thrombectomy.2. Illustrate normal imaging findings and complications following mechanical thrombectomy, including a review of the clinical relevance of these findings.3. Discuss the use of different modalities to differentiate blood products from contrast staining, including dual energy CT and MRI.

**TABLE OF CONTENTS/OUTLINE**

Mechanical thrombectomy is an effective intervention for ischemic stroke and relies on multimodal imaging for post-procedure follow-up. With increasing prevalence, the general radiologist should be familiar with the spectrum of post-thrombectomy imaging. In this article, we describe expected and unexpected imaging findings via a case review of patients who underwent mechanical thrombectomy for ischemic stroke.- Clinical guidelines for mechanical thrombectomy and TICI classification of reperfusion.- Review expected post-thrombectomy findings: clot resolution, contrast staining, subarachnoid hemorrhage.- Review unexpected imaging findings and their clinical relevance, including: residual clot, re-occlusion, access site dissection and pseudoaneurysm, vasospasm, hemorrhagic conversion, contrast-induced neurotoxicity.- Discuss use of dual energy CT and MRI to differentiate hemorrhage from contrast staining

## NREE-92 JOURNEY TO THE CENTER OF THE HEAD - IMAGING REVIEW OF CAVERNOUS SINUS TUMORAL LESIONS

**Awards**
**Certificate of Merit**

Marta Calvo-Imirizaldu, MD (*Abstract Co-Author*) Research Grant, Siemens AG
Manuel Rafael Lopez De La Torre Carretero (*Abstract Co-Author*) Nothing to Disclose
Elida Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Pablo D. Dominguez, MD (*Abstract Co-Author*) Nothing to Disclose
Jose Miguel Escudero-Fernandez, MD (*Abstract Co-Author*) Nothing to Disclose
Reyes M. Garcia-Eulate (*Abstract Co-Author*) Nothing to Disclose
Carmen Mbongo, MD (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• To evaluate the different tumoral entities that can involve the cavernous sinuses (CS), including intrinsic and extrinsic lesions.• To describe perineural paths and anatomic relationships, such as the skull-base foramina, that are important in secondary invasion of the CS.

**TABLE OF CONTENTS/OUTLINE**

Many crucial vascular and nervous structures converge in the CS, including the internal carotid artery -ICA- and the cranial nerves III, IV, V1, V2 and VI. The CS can be damaged by tumoral lesions of distinct origins.Neoplasms can primarily arise within the CS, secondarily invade it from adjacent structures, by perineural spread through skull base foramina or by metastatic disease.• Intrinsic tumors include:- Meningioma: it produces luminal narrowing of the ICA and shows homogeneous enhancement after contrast administration.- Cavernous Hemangioma: it does not produce luminal narrowing of the ICA.- Schwannoma: it shows heterogeneous enhancement, and cystic or hemorrhagic areas can be observed.- Plexiform Neurofibroma: the target sign is a typical finding of these tumors.- Other tumors: Solitary Fibrous Tumor and Melanoma.• Extrinsic tumors can be classified according to their location:- Sellar and suprasellar region: Pituitary macroadenoma invades the CS when it contacts more than 67% of the diameter of the ICA. A Craniopharyngioma can show cystic and calcified areas in children.- Oral / Maxillary region: Nasopharyngeal Carcinoma, Juvenile Nasopharyngeal Angiofibroma, Adenoid Cystic Carcinoma, Rhabdomyosarcoma, Esthesioneuroblastoma.- Bone malignancies: Chordoma, Chondrosarcoma, Osteosarcoma.- Systemic malignancies: Lymphoma, Multiple Myeloma and Metastases.

## NREE-93 BRIDGING THE GAP: LIFE-SIZE 3D PRINTED PEDIATRIC TO ADULT NEUROVASCULAR AND CRANIAL ANATOMY

Jonathan M. Morris, MD (*Abstract Co-Author*) Consultant, Medtronic plc;Speaker, Medtronic plc;Consultant, Merit Medical Systems, Inc;Speaker, Merit Medical Systems, Inc;Consultant, Landauer Inc;Speaker, Johnson & Johnson
David F. Black, MD (*Abstract Co-Author*) Nothing to Disclose
Hayden Swartz, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Pediatric neurovascular anatomy is a series of small and complex arteries and veins overlapping critical neuroanatomic structures. Foundational knowledge begins in medical school with adult cadaveric dissections, two-dimensional (2D) medical illustrations, and progresses through cross sectional imaging and angiographic evaluation during training. 2. Current resources provide limited conceptual models of the small and complex pediatric neurovascular and neuroanatomic relationships. 3. Cadaveric dissections provide valuable understanding, however, are destructive and not widely available due to ethical factors, limited autopsy exposure, and rarity of pathology. 4. By combining coregistered computed tomography (CT), CT angiography, and gadolinium bolus magnetic resonance venogram with three-dimensional (3D) computer aided design software, 3D printing pioneers a practical solution to teach age-dependent, patient-specific, life-size neurovascular anatomy and the overlying cranial vault in normal patients ages 0-18. 5. 3D printed models offer several advantages including an ethical nondestructive means to acquire, manufacture, and teach neurovascular anatomy, including haptic perception, unattainable by current resources, critical for radiology trainees.

**TABLE OF CONTENTS/OUTLINE**

1. Background of pediatric neurovascular anatomy. 2. Current state of educational tools and gap. 3. Benefits of patient and age specific 3D printed models from imaging. 4. Future directions of 3D neurovascular education.

## NREE-94 JOURNEY TO THE CENTER OF THE HEAD - IMAGING REVIEW OF CAVERNOUS SINUS NON-TUMORAL LESIONS

Jose Miguel Escudero-Fernandez, MD (*Abstract Co-Author*) Nothing to Disclose
Elida Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Pablo D. Dominguez, MD (*Abstract Co-Author*) Nothing to Disclose
Marta Calvo-Imirizaldu, MD (*Abstract Co-Author*) Research Grant, Siemens AG
Reyes M. Garcia-Eulate (*Abstract Co-Author*) Nothing to Disclose
Carmen Mbongo, MD (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

; To evaluate the different non-tumoral entities that can invade the cavernous sinuses (CS).; To learn the most important imaging features of each lesion and how to make an adequate differential diagnosis with neoplastic etiologies.; To describe anatomic relationships, such as the skull-base foramina, that are important in secondary invasion of the CS.

**TABLE OF CONTENTS/OUTLINE**

Unlike neoplasms, non-tumoral lesions tend to show low signal on T2-weighted imaging. They can be classified according to their etiology:; Vascular etiologies: Carotid-cavernous fistula, Internal carotid artery Aneurysm and CS thrombosis. They all produce similar clinical features; the CS syndrome (exophthalmos, ophthalmoplegia, chemosis, etc). Digital subtraction angiography plays a dual role in their diagnosis and management.; Infectious

etiologies: Fungal sinusitis produces narrowing and thrombosis of the internal carotid artery and the CS, with infarction of paranasal and nasal tissues (producing the typical "black turbinate sign"). Tuberculous pachymeningitis manifests as nodular and enhancing lesions.; Inflammatory etiologies: include Granulomatosis with Polyangiitis, Tolosa-Hunt Syndrome, Sarcoidosis and IgG4 Disease. Granulomatosis with polyangiitis affects paranasal sinus, nasal cavities and orbits and may produce hypertrophic pachymeningitis with CS involvement, ICA stenosis and vasculitis. Tolosa-Hunt syndrome is a diagnosis of exclusion and involves the CS region, the superior orbital fissure and the orbital apex of the same side.; Miscellaneous: Arachnoid, Epidermoid, Dermoid Cysts and Pseudocysts. Epidermoid cysts do not enhance and show diffusion restriction.

## NREE-95 DEFINING THE CENTRAL ROLE OF RADIOLOGY FOR SAFE AND EFFECTIVE ANTI-AMYLOID THERAPY IN EARLY ALZHEIMER'S DISEASE

Joseph M. Mettenburg, MD (*Abstract Co-Author*) Nothing to Disclose
Riddhi Patira (*Abstract Co-Author*) Nothing to Disclose
Saurab Faruque, MPH (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Anti-amyloid (AA) monoclonal antibodies rapidly emerged as an approved treatment for Alzheimer's disease (AD) dementia. Efficacious and safe treatment requires robust clinical data to accurately classify patients at initiation and to monitor throughout treatment. Radiologists directly contribute to this process through acquisition and interpretation of baseline and serial screening MRI and careful collection of cerebrospinal fluid (CSF) samples. This educational exhibit aims to prepare radiologists for their central role in AA therapy programs.The educational objectives of this exhibit are to understand:- Factors affecting CSF AD biomarker analysis and the recommended pre-analytical protocol for mitigating variability- Conditions and imaging features that exclude patients from AA therapy, and radiographic pitfalls and mimics- The role of MRI parameters in serial amyloid-related imaging abnormality (ARIA) assessment- Imaging characteristics of ARIA-H (hemorrhage) and ARIA-E (edema)- Monitoring timelines for ARIA, and circumstances and recommendations for adjustments to monitoring and treatment

### TABLE OF CONTENTS/OUTLINE

1. AD pathophysiology therapeutic targets2. The radiologist’s role in treatment initiationa. Baseline MRI-detectable exclusionary conditions criteria, and their imaging characteristics mimicsb. Rationale recommendations for standardized CSF sample collection3. The radiologist’s role in monitoring managementa. Overview of ARIA-H ARIA-Eb. Considerations for selecting MRI sequence type field strengthc. Recommended monitoring protocol timelined. Evaluating ARIA radiographic severitye. Adjustments to monitoring therapy after detection of ARIA

## NREE-96 MRI “ARTIFACTS” WITH CLINICAL RELEVANCE IN STROKE EVALUATION

### TEACHING POINTS

-To review the physical origins of MRI signs including Fluid Attenuated Inversion Recovery (FLAIR) Hyperintense Vessel Sign (HVS), Susceptibility Weighted Imaging (SWI) Brush Sign (BS) and the Arterial Spin Labeling (ASL) Arterial Transit Artifact (ATA). -Then describe the imaging features of these artifacts in MRI. -We will then review the associations of these findings with acute stroke.

### TABLE OF CONTENTS/OUTLINE

1. Introduction2. The FLAIR hyperintense vessel sign (HVS).a, The physics of hyperintense vessels on FLAIR.b, Imaging appearance. c, Clinical Associations - scoring FHV ASPECT.3. SWI brush sign (BS)a, The origin of the brush sign on SWI.b, Imaging appearance. c, Clinical associations.4. ASL arterial transit artifact (ATA)a, The origin of the arterial transit artifact. b, Imaging appearance.c, Clinical associations.

## NREE-97 FUNCTIONAL MRI TECHNIQUES TO DETECT, UNDERSTAND, AND PROGNOSTICATE DISORDERS OF CONSCIOUSNESS

David Fischer (*Abstract Co-Author*) Nothing to Disclose
Jeffrey Ware, MD (*Abstract Co-Author*) Nothing to Disclose
Azfar Basunia, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Disorders of consciousness (DoC) are believed to occur due to disruption of key awareness and arousal brain networks. Conventional clinical assessments have major limitations and suffer high misdiagnosis rates, posing challenges to decision making over the withdrawal of life-sustaining care. In this exhibit, we aim to:1. Highlight limitations of current clinical assessments and conventional imaging in neuroprognostication.2. Illustrate fMRI techniques to detect and differentiate between levels of consciousness and prognosticate on future recovery.3. Review current society guidelines and possible implementation strategies.

### TABLE OF CONTENTS/OUTLINE

1. Overview of disorders and levels of consciousness.2. Current clinical assessments and conventional imaging techniques (CT, MRI) a. Limitations in accurate DoC detection and neuroprognostication b. Need for novel techniques based on the neurobiology of coma.3. Functional MRI (fMRI) for understanding and prognosticating on DoC and detecting covert consciousness such as covert cortical processing and cognitive motor dissociation a. Task-based fMRI b. Stimulus-based fMRI c. Resting-state fMRI - (i) Functional network integrity for neuroprognostication (ii) Frequency domain analysis (iii) Emerging techniques such as dynamic functional connectivity.4. Practical considerations for fMRI implementation a. Acquisition and pre-processing strategies, including novel techniques to improve patient-level reliability b. Post-processing approaches and interpretation c. Considerations for scanning critically ill patients (safety, sedation, etc).5. Current society guidelines and expert consensus on DoC neuroprognostication with fMRI.

## NREE-98 INTRACRANIAL VESSEL WALL MRI: WHAT YOUR LUMEN IS NOT TELLING YOU

Keena Li (*Abstract Co-Author*) Nothing to Disclose
Hediyeh Baradaran, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Bryan L. Bishop, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. We will provide an overview of what VWI entails and which patient populations are most likely to benefit from this type of advanced imaging. 2. We will provide an in-depth review of imaging techniques and protocols for high quality VWI in a timely manner which can be easily transitioned to clinical practice. 3. We will provide a clear, stepwise approach for interpreting vessel wall MR. 4. We will review specific scenarios in which VWI is a useful tool and adjunct to standard imaging.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction and overview of what vessel wall imaging means and who may benefit from this technique. a. Allows visualization of vessel wall rather than lumen alone. b. Differentiating etiologies of intracranial luminal stenosis. c. Identifying source of symptomatic disease which does not result in luminal stenosis and is not detected on standard imaging. 2. Imaging protocol for VWI. a. Review of various imaging techniques and protocols for VWI. b. Practical information on specific sequences and timing. 3. Stepwise approach to interpreting VWI in the clinical setting. a. Identify vessel narrowing on TOF MRA. b. Classify pattern of narrowing. c. Evaluate T2 weighted sequence. d. Evaluated for presence of and pattern of enhancement. 4. Scenarios in which VWI is a useful adjunct to standard neuro imaging. a. Non-stenosing Atherosclerotic Plaque i. Vessel wall enhancement, remodeling, plaque thickness and surface irregularity, intraplaque hemorrhage. b. CNS Vasculitis i. Concentric wall thickening and enhancement which persist over multiple examinations. c. Moyamoya i. VWI can be helpful to differentiate MMD, A-MMS, and V-MMS. d. CAA (A Beta Angiitis) i. Wall inflammation can be seen in inflammatory CAA.

## NREE-99 CURRENT STATUS OF GLYMPHATIC IMAGING: PERSPECTIVES AS OF 2024

Toshiaki Taoka, MD, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation

**TEACHING POINTS**

Since its introduction in 2012, the glymphatic system hypothesis has gained attention through animal studies showing its role in conditions like Alzheimer’s disease, Parkinson’s disease, stroke or head trauma. Human evaluation remains challenging due to the unavailability of fluorescent tracers and the unapproved use of intrathecal gadolinium-based contrast agents (GBCA). As an alternative, the Diffusion Tensor Image Analysis aLong the Perivascular Space (DTI-ALPS) method has gained traction for its noninvasive nature and simple interpretability through the ALPS-index. However, recent critiques question its reliability due to sensitivity to imaging conditions and issues like fiber crossing. This exhibit will introduce the concept of glymphatic system, detail the DTI-ALPS method along with its limitations, and explore additional non-invasive techniques such as choroid plexus volume, perivascular space volume assessment, and evaluations of blood-brain barrier or venous wall permeability using GBCA, offering a comprehensive overview of current methodologies for glymphatic system evaluation.

**TABLE OF CONTENTS/OUTLINE**

1. Overview of the Glymphatic System- Introduction to the Glymphatic System Hypothesis- Importance of the Glymphatic System in Neurological Diseases2. Detailed Analysis of the DTI-ALPS Method-Description of the DTI-ALPS Technique and the ALPS Index-Limitations and Critiques of the DTI-ALPS Method3. Other Non-Invasive Assessment Techniques for Glymphatic System-Non-Contrast Techniques (e.g., choroid plexus volume assessment)-Contrast-Enhanced Techniques (e.g., evaluation of blood-brain barrier)

## OVERVIEW OF TEMPORAL LOBE PLUS EPILEPSY AND ANATOMIC SUBSTRATES: INSULA, THALAMUS, OLFACTORY, AND CINGULATE SYSTEMS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Aline Herlopian (*Abstract Co-Author*) Nothing to Disclose
Chong Zhou, MD (*Abstract Co-Author*) Nothing to Disclose
Irene Dixe de Oliveira Santo, MD (*Abstract Co-Author*) Nothing to Disclose
Richard A. Bronen, MD (*Abstract Co-Author*) Nothing to Disclose
Justin Sindoni, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Discuss temporal lobe plus epilepsy (TLE+) and its importance2. Review pertinent anatomy of TLE+ (e.g., connections to the insula, thalamus, olfactory, and cingulate)3. Review cases of pathologies of TLE+ structures involved in refractory epilepsyBackground: Temporal lobe epilepsy is the most common type of epilepsy and accounts for about half of all cases of focal epilepsy. Over the last few decades, it has been recognized that epilepsy may be the result of “network” changes in the brain rather than from a focal abnormality influencing an “epileptogenic zone.” Temporal lobe plus epilepsy (TLE+) is a term coined to discuss the network of extratemporal structures involved in refractory temporal lobe epilepsy, including the insula, thalamus, olfactory connections, and cingulate. In this exhibit we will discuss the anatomy and connections of the structures involved in TLE+ in the context what is important for the radiologist to know and evaluate. We will review imaging of both normal anatomy and cases illustrating pathology in patients with TLE+. The ultimate goal is to assist the radiologist in providing optimal care in the diagnosis and successful treatment of epilepsy, particularly with helping targeting for recent therapies such and neuromodulation and laser ablation treatments.

### TABLE OF CONTENTS/OUTLINE

1. Introduction2. Discussion of structures and connections of TLE+ (e.g. the insula, thalamus, olfactory connections, and cingulate)3. Imaging evaluation of normal TLE+ structures4. Case examples of pathology involving TLE+ structures5. Summarize TLE+ and future directions for the radiologist’s role in the multidisciplinary approach to epilepsy treatment

Azza Reda, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Lucia Brun, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To recognize and differentiate between cases of stroke and differential considerations based on imaging findings.- To recognize specific imaging patterns and signs associated to common and uncommon stroke mimics on imaging.- To understand the importance of accurate differentiation for timely and appropriate patient management.

### TABLE OF CONTENTS/OUTLINE

Mimics account for nearly half of all hospital admissions for suspected strokes. Stroke mimics may present as functional disorders or may be symptomatic of underlying neurological or medical conditions. A significant number of patients continue to receive thrombolysis unnecessarily, resulting in inherent risks and avoidable costs. Thus, accurate diagnosis is of utmost importance. A non-contrast CT scan alone is often insufficient for diagnosis, and multimodal CT or MRI scans are typically required.Imaging Pattern-Based Approach Through Cases:- Segmental gray and white matter: Stroke, Seizures, Migraine, HSV encephalitis, Venous thrombosis, TGA, Hypoglycemia, Tumor, MELAS- Cortical and deep gray matter: HII, Hepatic encephalopathy, CJD, Wernicke's encephalopathy.- Deep gray matter: Stroke, HII, CO poisoning, extrapontine myelinolysis, CJD, Nonketotic Hyperglycemia, Venous thrombosis, Wernicke's.- White matter: CADASIL, Susac's, demyelination, metronidazole and methotrexate toxicity, Heroin.- Watershed zones: Stroke, RCVS, PRES, Moya-Moya, Hyperperfusion syndrome.- Scattered Foci: Fat emboli, DAI Embolic infarcts, Mets.- Corpus Callosum: CLOCCs, Seizures, Marchiafava-Bignami. <!--EndFragment-->

Noelia Bravo Alcobendas, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

After reviewing this exhibit, the reader should: - Understand the pathophysiology of spontaneous intracranial hypotension and be able to explain and correlate it with the imaging findings. - Properly describe the findings in the studies performed to patients affected by this condition. - Learn the MRI sequences that are most useful for detecting the different findings leading to disease diagnosis and to identifying underlying causes, being aware of the differential diagnosis suggested by each of the described findings. - Be familiar with the complex diagnostic and therapeutic process of the disease: recognizing situations warranting a high clinical suspicion for this condition, determining appropriate screening tests, identifying circumstances in which invasive procedures are needed for further evaluation, and customizing treatment approaches for individual scenarios.

### TABLE OF CONTENTS/OUTLINE

-Introduction - Clinical presentation - Differential diagnosis - Causes - Work-up algorithm - Diagnostic imaging : initial approach o Brain MRI o Spine MRI - Diagnostic imaging : investigating the etiology o CT-Myelography o Non invasive MR-Myelography o Fluoro-Myelography - Treatment o Conservative treatment o Targeted treatment - Conclusions

## PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA: IMAGING AND FEATURES AND DIFFERENTIAL DIAGNOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Diogo G. Correa, MD (*Abstract Co-Author*) Nothing to Disclose
Lara Mori, MD (*Abstract Co-Author*) Nothing to Disclose
Gabriela A. Ribas, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Imaging Modalities: Teach about the imaging modalities commonly used in diagnosing PCNSL.
- Typical Imaging Features: Highlight the typical imaging features of PCNSL on MRI and CT scans.
- Differential Diagnosis: Emphasize the importance of considering differential diagnoses when evaluating imaging findings suggestive of PCNSL in immunocompetent and immunocompromised patients.
- Key Differentiating Factors: Teach about the key differentiating factors between PCNSL and other brain lesions on imaging.
- Advanced Imaging Techniques: Introduce advanced imaging techniques such as diffusion-weighted imaging (DWI), perfusion-weighted imaging (PWI), and magnetic resonance spectroscopy (MRS), which may aid in differentiating PCNSL from other brain lesions based on specific metabolic and hemodynamic features.

### TABLE OF CONTENTS/OUTLINE

Introduction to PCNSL: Definition and incidence and clinical presentation. Histophatological analysis: Overview of WHO classification diffuse large B-cell lymphoma (DLBCL) and other lymphoid neoplasms in the CNS. Role of Imaging in PCNSL Diagnosis: Importance of MRI in PCNSL diagnosis, clinical applicability and data provided by MRI. Imaging Features of PCNSL: Tumor metabolism, water molecule diffusion, cell density and blood-brain barrier permeability. Differential Diagnosis of PCNSL: Importance of distinguishing differential diagnoses, defining biopsy location. Atypical Forms of PCNSL: Extra-axial PCNSL, intravascular lymphoma, lymphomatosis Cerebri and skull lymphoma. Conclusion: Radiologist role is to contributed to the PCNSL diagnosis, treatment planning, and patient care.

Jeffers Nguyen, MD (*Abstract Co-Author*) Nothing to Disclose
Long H. Tu, MD (*Abstract Co-Author*) Nothing to Disclose
Christopher J. Hamilton, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The lumbosacral plexus is a complex network of nerves formed by the ventral rami of the lumbar and sacral spine, with end branches innervating the pelvic sidewall and lower limbs. Despite its clinical significance, lumbosacral plexus MRI examinations are infrequently performed, and instances of imaged pathologies are even rarer. Consequently, radiologists may lack the exposure and expertise needed to effectively evaluate these examinations.Our objective is two-fold: 1) to delve into the anatomy and present cases illustrating key findings of lumbosacral plexus pathologies that we have drawn from the past 25 years at our academic tertiary center showcasing a wide range of etiologies, including neoplastic, infectious, inflammatory and traumatic causes; and 2) to highlight the key MRI sequences and demonstrate our search pattern while providing a step-by-step framework to assist in the interpretation of this uncommonly performed exam.

### TABLE OF CONTENTS/OUTLINE

1.Review the anatomy of the lumbosacral plexus2.Identify the indications for MRI evaluation of the lumbosacral plexus in clinical practice3.Familiarize with the MRI techniques and sequences utilized for optimizing the imaging of the lumbosacral plexus4.Develop a systematic search pattern and highlight key elements that should be documented in every radiologist’s report5.Discuss and illustrate various pathologies affecting the lumbosacral plexus, including neoplastic, infectious/inflammatory, traumatic and degenerative etiologies

Hajime Sakuma, MD, PhD (*Abstract Co-Author*) Research Grant, Eisai Co, Ltd;Research Grant, FUJIFILM Holdings Corporation;Research Grant, Guerbet SA;
Maki Umino, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Iron rim lesions (IRLs) and central vein sign (CVS) on SWI have been reported to be useful for the diagnosis and monitoring of multiple sclerosis (MS). Here we demonstrate the importance of these findings regarding diagnosis and clinical relevance in MS patients. We aimed to1) Understand what IRLs indicate in MS pathology. 2) Learn about the pathology of CVS, which shows inflammation-dependent remodeling of blood vessel walls (lumen enlargement and collagen deposition). 3) Learn how specific IRLs and CVS are for MS lesions and what the differential diagnosis is. 4) Learn the relationship between IRLs and other MRI findings/clinical findings.

### TABLE OF CONTENTS/OUTLINE

1. Pathology of IRLs: IRLs represent a rim of iron-laden macrophages/microglial cells at the lesion edge (i.e., chronic active lesion). 2. Diagnostic value of IRLs and CVS: IRLs are unique to MS except for Susac syndrome. CVS is unique to MS except for Behēet's disease. 3. IRLs and other MR findings: ring enhancement and hypointense ADC rim may predict progression from acute to IRL. 4. Combination of IRLs and CVS: a great impact on the prediction of clinically isolated syndrome patients' conversion to definite MS. 5. Clinical relevance of IRLs: IRLs may serve as a marker of persistent low-level inflammation in adjuvant therapy targeting insidious clinical decline.

## IDENTIFICATION AND CLINICAL SIGNIFICANCE OF PLAQUE ULCERATIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Luca Saba, MD (*Abstract Co-Author*) Nothing to Disclose
Brett Cucchiara (*Abstract Co-Author*) Nothing to Disclose
Jae W. Song, MD, MS (*Abstract Co-Author*) Nothing to Disclose
David Yang (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. We provide criteria for defining plaque ulcerations based on image modality.2. We correlate the anatomy of a plaque ulceration to its appearance on imaging and clarify the concept of an ulceration as a crater in plaque rather than an outpouching of the blood vessel wall.3. We describe the stages of how plaque develops and ulcerations form.4. We review the literature on the significance of plaque ulcerations and high risk with stroke and cardiac events.5. We provide examples of common image interpretation pitfalls that may mimic plaque ulcerations, including faint plaque calcifications, carotid webs, and intimal flaps from arterial dissections.

### TABLE OF CONTENTS/OUTLINE

1. Identification of plaque ulceration. (a) Criteria for defining plaque ulceration in the vascular beds. (b) Classification of carotid artery ulceration types. (c) Anatomy of plaque ulceration and imaging appearances.2. Mechanism and pathophysiology of plaque ulceration.3. Clinical significance of plaque ulcerations in the aorta, coronary arteries, carotid arteries, and intracranial arteries. (a) Prevalence. (b) Histology. (c) Clinical associations with stroke or cardiac events. (d) Multimodality image examples on ultrasound/echocardiograms, CTAs, and MRAs.4. Image interpretation pitfalls of identifying plaque ulcerations. (a) Example of focal calcification. (b) Example of carotid web versus dissection

Diogo G. Correa, MD (*Abstract Co-Author*) Nothing to Disclose
Elissandra M. Lima, MD (*Abstract Co-Author*) Nothing to Disclose
Celso Hygino, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To elucidate the neuroradiological manifestations of arbovirus infections, emphasizing characteristic imaging features across different modalities. To enhance understanding of the pathophysiological impact of arboviruses in the CNS, facilitating early diagnosis and effective intervention. To discuss the evolution of imaging in tracking the progression and support treatment response of arbovirus infections, highlighting their pivotal role in clinical decision-making.

### TABLE OF CONTENTS/OUTLINE

1. Overview of arboviruses, focusing on physiopathology and clinical findinds. 2. Epidemiology of arboviruses, focusing on those that frequently cause neurological manifestations 3. Discussion on the physiopathology of CNS invasion and typical progression. 4. Radiological signatures of dengue fever, West Nile virus, Chikungunya, Japanese Encephalitis, Saint Louis Encephalitis, and Zika, including cortical lesions, white matter changes, spinal cord findings, neural root involvement, and hemorrhagic presentations. 5. Associated complications: post Yellow-Fever Vaccination lesions, Guillain-Barré Syndrome. 6. Discuss the diagnosis challenges, using a combination of imaging features, clinical correlation, and laboratory confirmation. 7. Overview of current support treatments and prevention available for arbovirus infections and the role of neuroradiology in monitoring treatment efficacy and neurologic recovery. Implications of imaging findings on therapeutic decisions, particularly in severe cases requiring aggressive treatment. 8. Take-home messages: summary of the critical contributions of imaging to understanding, diagnosing, and managing arbovirus infections in the CNS.

### TEACHING POINTS

To illuminate the neuroradiological manifestations associated with Chikungunya virus (CHIKV) infections in adults, emphasizing specific imaging features that aid in diagnosis. To delineate the clinical relevance of these imaging findings, enhancing the understanding of CNS involvement. To advocate for integrating neuroradiological evidence with clinical diagnostics to optimize the prevention and management of CHIKV.

### TABLE OF CONTENTS/OUTLINE

1.Brief overview of Chikungunya virus, including virology, transmission, and global epidemiology. 2.Discuss typical clinical presentations, focusing on neurological symptoms that prompt neuroradiological evaluation. 3.Comprehensive review of neuroradiological findings in CHIKV-infected patients, detailed descriptions of patterns observed in MRI and CT, including encephalitis, myelitis, and perinatal mother-to-child transmission. 4.Description of the spectrum of neurological complications associated with CHIKV, ranging from mild headache and vertigo to more severe complications like Guillain-Barré syndrome and acute disseminated encephalomyelitis. 5. Typical and atypical radiological features, such as meningeal enhancement, cerebral and spinal cord involvement, acute disseminated encephalomyelitis-like lesions, and Guillain-Barré syndrome. 6.Discussion on the role of imaging in differentiating CHIKV neurological manifestations from those caused by other arboviruses. 7.Prevention and discussion on the role of neuroradiology in monitoring treatment efficacy and neurological recovery. 8.Recap the significance of neuroradiological approaches in diagnosing and managing Chikungunya's neurological manifestations.

Diogo G. Correa, MD (*Abstract Co-Author*) Nothing to Disclose
Elissandra M. Lima, MD (*Abstract Co-Author*) Nothing to Disclose
Celso Hygino, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To elucidate the benefits of topographic approach in imaging and classification of spinal cord lesions, enhancing diagnostic precision and therapeutic targeting.To showcase the integration of neuroimaging, clinical and laboratory data, with topographic lesions mapping to provide a comprehensive overview of lesion features. To better understand how topographic data can inform prognosis and guide rehabilitation strategies, improving outcomes.

### TABLE OF CONTENTS/OUTLINE

1.Introduction to topographic approach of spinal cord lesions, emphasizing the value of detailed anatomical and functional mapping. 2.Classification system based on topographic data that categorizes injuries by segments of the spine, adjacent structures and specific neural elements affected. 3.Imaging the spinal lesions, including epidural abscess, lymphoma, angiomyolipoma, cytomegalovirus, syphilis, schistosomiasis, CIDP, melanoma, Guillain-Barré syndrome, post-vaccination myelitis, chemical radiculitis, sarcoidosis, subacute combined degeneration, copper deficiency, HIV, ADEM, NMOSD, tuberculosis, fungus, vasculitis, CLIPPERS, viral encephalitis, spinal cord ischemia, COVID myelitis. 6. Gadolinium enhancement patterns of the spinal cord diseases. 7.Examine how specific topographic features correlate with patient prognosis, potential for recovery and risk of complications. 8.Discuss how topographic information can guide surgical interventions, the choice of rehabilitation techniques, and the development of targeted therapies. 9. summary of the pivotal role that topographic mapping plays in transforming the landscape of spinal cord injury diagnosis and management.

### TEACHING POINTS

The intricate anatomical structures comprising the scalp, skull, and dura mater serve as potential loci for lesions capable of traversing multiple compartments. The purpose of this educational exhibit is to explore the various facets of transcalvarial lesions, including their clinical and imaging characteristics, in order to equip radiologists with the tools necessary to significantly narrow the spectrum of potential diagnoses.

### TABLE OF CONTENTS/OUTLINE

1. Definition of a transcalvarial lesion.2. Overview of the anatomical structures that compose the scalp, cranial vault, and dura mater.3. Discussion of the main differential diagnosis: Meningioma, Lymphoma, Metastasis and Plasmacytoma.4. Patterns of calvarial invasion on CT.5. Miscellaneous: Demonstration of rare lesions that can manifest as transcalvarial masses: CNS Tuberculosis, Solitary Fibrous Tumor and Dermatofibrosarcoma Protuberans.

### TEACHING POINTS

1. The endoscopic endonasal approach (EEA) is a surgical technique that allows for direct access to a variety of tumors centered at the anterior skullbase. By operating through the nose and paranasal sinuses, EEA minimizes brain retraction, and manipulation of neurovascular structures that occur with transfacial and transcranial approaches.2. Knowledge of conventional pre-operative skullbase anatomy and typical postoperative appearance of nasoseptal flap reconstruction on CT and MRI is crucial to assess for possible complications of EEA.3. The most common type of complication is flap failure, which can manifest radiologically as CSF leak from flap migration/dehiscence, flap necrosis, and infection. Other less common complications involve injury to the internal carotid artery (ICA) and other adjacent skullbase structures. These complications can be evaluated with skullbase CT and MRI, cisternograms, and cerebral angiograms.

### TABLE OF CONTENTS/OUTLINE

1. Overview of the endoscopic endonasal approach: general technique and comparison of EEA to transfacial/transcranial approaches.2. Normal postoperative findings on CT and MRI: intact nasoseptal flap and fat graft.3. Postoperative Complications on Imaging A. Flap: flap migration with brain herniation, CSF leak, flap necrosis with infection. B. Vascular: ICA dissections, pseudoaneurysms, cavernous sinus thrombosis, air embolism to intracranial vessels.

## THE ART OF MISMATCH: A DIAGNOSTIC KEY IN CNS TUMOR IMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Roy Riascos, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Carlos H. Torres, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Andres F. Rodriguez, MD (*Abstract Co-Author*) Nothing to Disclose
Paulo C. Puac Polanco, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Maria Lucia Brun, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1.To improve the ability to recognize and interpret various types of mismatches in CNS tumor imaging, leading to more accurate diagnoses. 2.To foster a deeper comprehension of the different scenarios where mismatch patterns can be valuable in the diagnostic process of CNS neoplasms. 3. To emphasize the importance of interdisciplinary collaboration in the initial approach of brain tumors and their evaluation after treatment.

### TABLE OF CONTENTS/OUTLINE

In the realm of CNS neoplasm diagnosis, the emergence of mismatch scenarios offers a compelling dimension to the diagnostic process.The nuanced interplay between clinical presentations, diverse imaging modalities, and difficulties/limitations of imaging techniques unveils challenges for an accurate diagnosis where different types of mismatches can be found. The ability to recognize and interpret these deviations from the expected unlocks precision in diagnosing CNS neoplasms, ultimately leading to better patient care and outcomes.Outline: 1. Clinico-radiological mismatch: Pseudoprogression. Pseudo response. 2. Imaging-imaging mismatch: T2/FLAIR mismatch. Advanced-basic imaging mismatch. Mistmatch within imaging features. 3. Imaging-technique mismatch. 4. Imaging-surgical findings mismatch: Imaging. Conclusion: Understanding the pivotal role of mismatch scenarios in the diagnostic process of CNS neoplasms is key. We must emphasize the importance of interdisciplinary collaboration.

## MAPPING THE MAZE: NEUROIMAGING INSIGHTS INTO IMMUNOCOMPROMISED PATIENTS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Faisal A. Alsugair, MD,FRCPC (*Abstract Co-Author*) Nothing to Disclose
Paulo C. Puac Polanco, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Azza Reda, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Immunocompromised patients represent a vulnerable group that can be affected by numerous neurological conditions.• The impairment of the body's immune system in this population can alter their ability to prevent diseases, particularly infections.• Other less common complications can be seen in immunocompromised patients, such as infection-induced neoplasms, paradoxical inflammatory reactions to treatment, or metabolic conditions. . There are several primary immune deficiencies and a wide number of secondary causes that include advanced age, metabolic conditions, infection (e.g., HIV), malnutrition, and chronic disorders such as diabetes and systemic lupus erythematosus

### TABLE OF CONTENTS/OUTLINE

Approach for diagnosing Complications in Immunocompromised patientsA. Opportunistic infectionsB. Treatment-related complicationsC. NeoplasmsD. Miscellaneous A. Opportunistic infections- Toxoplasmosis- Fungal infections: Candida albicans, Cryptococcal meningoencephalitis, Cryptococcosis Gelatinous pseudocysts, choroid plexitis, Invasive fungal sinusitis- Viral infections: Ramsay-Hunt syndrome, herpes zoster virus, Herpes zoster ophthalmicus- Nocardia- CD8 encephalitis B. Treatment-related complications- PML- PML-IRIS C. Neoplasms- EBV-induced 1ry CNS Lymphoma - Miscellaneous- Vasculitis- Infarction

## CONTRAST-INDUCED ENCEPHALOPATHY: AN UNDERESTIMATED COMPLICATION AFTER ENDOVASCULAR PROCEDURES?

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Salome Bosshart, MD (*Abstract Co-Author*) Nothing to Disclose
Rosario Pascarella, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Luisa Zedde, MD (*Abstract Co-Author*) Nothing to Disclose
Nathalie Nierobisch (*Abstract Co-Author*) Nothing to Disclose
Nicolin Hainc (*Abstract Co-Author*) Nothing to Disclose
Alexander Stebner, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

I) Pathophysiology, epidemiology, and clinical presentation II) Typical radiographical signs of Contrast-Induced Encephalopathy (CIE) on CT and MRI. III) Distinguishing CIE from other differential diagnoses/frequent post-endovascular procedures complications.

### TABLE OF CONTENTS/OUTLINE

What is CIE? It is a rare sporadic condition of neurotoxicity after intravascular administration of iodine contrast. It evolves rapidly and causes temporary neurological deficits/seizures shortly after contrast administration, sometimes within hours. Patients usually recover within days without residual findings on imaging, but cases of incomplete remission with permanent deficits and rarely death have been reported. It is assumed that the breakdown of the blood-brain barrier with contrast-leakage causes altered excitability and thus neuronal dysfunction. Typical imaging findings? Cortical and sulcal hyperdensities on CT not corresponding to blood but contrast agent and vasogenic edema resulting in mass effect. These findings typically resolve completely within hours to days on follow-up imaging. Pearls, pitfalls, and differential diagnoses: Is it blood or contrast? - Dual-Energy CT is a useful tool to differentiate iodine from blood! Is the swelling a sign of stroke progression? - Sometimes you will need CTA to exclude residual or recurrent vessel occlusions, or MRI to look for diffusion restriction in acute stroke patients and FLAIR/T1w/SWI for blood, as iodine contrast should not be visible on MRI! Am I missing something? - Time will tell: After excluding acute conditions like subarachnoid hemorrhage and acute ischemic stroke, CIE will resolve typically quickly with conservative supportive treatment.

## PICTORIAL REVIEW OF INTRAVENTRICULAR BRAIN TUMORS IN ADULTS AND CHILDREN - A PRIMER FOR RESIDENTS AND FELLOWS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Laiz Godoy, MD (*Abstract Co-Author*) Nothing to Disclose
Otavio Augusto Ferreira Dalla Pria, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Intraventricular brain tumors encompass myriad presentations in both clinical symptomology and radiological findings and frequently represent a challenge for the radiologist since multiple imaging features overlap among these tumors. Nevertheless, they account for a relevant incidence in our daily practice regardless of being an experienced neuroradiologist or a junior resident taking calls. Given their importance, a constant review of these entities is mandatory to succeed in general or neuroradiology. Moreover, this exhibit aims: 1. To review the literature concerning adult and children's intraventricular brain tumors; 2. To describe multi-modality imaging findings helpful in narrowing the differentials and relevant clinical presentations based on location, age, sex, etc. 3. To depict cases of typical and atypical supra and infratentorial intraventricular brain tumors in adults and children.

### TABLE OF CONTENTS/OUTLINE

1. Concise exposition delineating the embryology, anatomical configuration, and physiological attributes pertinent to the ventricular system; 2. Illustration of diverse cases featuring intraventricular cerebral neoplasms, including but not limited to ependymoma, subependymoma, central neurocytoma, subependymal giant cell tumor, choroid plexus neoplasm, meningiomas, juxtaposed with a comprehensive examination of potential differentials such as colloid cysts, atypical teratoid/rhabdoid tumors, and other pathologies. Furthermore, incorporation of cases initially presumed to originate intrinsically but ultimately diagnosed within the extraventricular ambit due to semblant radiological manifestations; 3. Conclusion and take-home messages, 4. References

## UNRAVELING THE UNUSUAL: A CASE REVIEW OF UNIQUE TRIGGERS FOR TRANSIENT ISCHEMIC ATTACKS (TIAS)

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Mansi N. Jantre III, MBBS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Transient Ischemic Attacks (TIAs) are often precipitated by conventional risk factors such as hypertension, diabetes, or hypercholesterolemia. However, there exists a subset of cases where atypical triggers play a significant role. This review examines the radiological features and diagnostic challenges associated with these unusual triggers for TIAs. Through a series of case studies and imaging modalities including CT, MRI, and angiography, we elucidate the role of radiology in understanding these atypical triggers is crucial for accurate diagnosis, timely intervention, and improved patient outcomes.

### TABLE OF CONTENTS/OUTLINE

-Introduction - Case: Parapharyngeal abscess with secondary involvement of carotid sheath- Case; Stylocarotid syndrome in Eagles syndrome-Case: Subclavian steel syndrome-Case; ICA pseudoanuysm triggering TIA and Horners syndrome-Case; Floating unstable plaque in ICA

## WHEN TO WORRY ABOUT INTRACRANIAL CALCIFICATIONS: OVERVIEW ON CT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Guilherme C. Martins, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Calcifications within the brain parenchyma or vasculature are typical finding in all ages, present in the radiologist's daily routine. They can be age-related or pathological with a wide spectrum of presentations. Even with the introduction of Magnetic Resonance Imaging (MRI), non-contrast computerized tomography (NCCT) scan is the choice for detection and characterization. They can be classified into patterns with related terminology, ranging from dots, lines, stippled, blush, gyriform to conglomerates, as well as divided into pathological subtypes: vascular, genetic, infectious, inflammatory or neoplastic diseases. Pathological conditions can be linked to the radiological phenotype, taking into account anatomical location, distribution, dimensions and morphology, in association with clinical history and age. When identified in the appropriate clinical setting, the characteristic features allow the radiologist to facilitate the differential diagnosis and avoid practical errors.

### TABLE OF CONTENTS/OUTLINE

Optimizing the approach based on the radiological patterns, dividing them with related terminology and pathological subtypes thru a summary facilitates diagnosis, understanding and clinical management.

## DON'T BE VEIN: INTRACRANIAL VENOUS PATHOLOGY - A PRIMER FOR THE RADIOLOGIST

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Ashok Srinivasan, MD (*Abstract Co-Author*) Nothing to Disclose
Grant E. MacKinnon, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Understanding typical intracranial venous anatomy and common variants is essential to develop an effective search pattern and avoid misinterpretation, a common pitfall for the training radiologist.2. Recognizing patterns of venous thrombosis and hemorrhage will aid in rapid diagnosis and the potential need for additional imaging.3. Identifying venous malformations helps guide patient management and avoid unnecessary workup.

### TABLE OF CONTENTS/OUTLINE

I. Typical intracranial venous anatomy a) Unique features of intracranial veinsII. Common intracranial venous variants a) High riding jugular bulb b) Jugular diverticulum c) Jugular dehiscenceIII. Venous thrombosis a) Risk Factors b) Venous territories i) Dural venous sinus thrombosis ii) Deep venous thrombosis iii) Superficial venous thrombosis c) Imaging features signs d) Complications i) Infarction ii) Dural arteriovenous fistula e) Mimics i) Hypoplastic/stenotic transverse sinus ii) Arachnoid granulations iii) PolycythemiaIV. Venous hemorrhage a) Venous epidural hematoma i) Common subtypes (1) Anterior temporal (2) Vertex (3) Clival b) Germinal matrix hemorrhage i) Risk Factors ii) Grading c) Perimesencephalic (nonaneurysmal) subarachnoid hemorrhageV. Venous malformations a) Cavernous malformation b) Developmental venous anomaly c) Capillary telangiectasia d) Sinus pericranii

## BRAIN MRI PROTOCOLS: A USER GUIDE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Matthew F. Glasser, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Robert C. McKinstry III, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Arash Nazeri, MD (*Abstract Co-Author*) Nothing to Disclose
Michelle Wegscheid, MD,PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Brain MRI protocols can be overwhelming for trainees. A foundational understanding of the physical principles of brain MR sequences is important for effective clinical deployment and accurate diagnostic interpretation. Furthermore, understanding MR parameters as customizable variables will inform patient and pathology-specific protocol optimization. The purpose of this exhibit is to: 1) Discuss the basic physics principles underlying sources of tissue contrast and image quality. 2) Provide an overview of acquisition methods, pulse sequences, and acceleration techniques commonly used in brain MR protocols. 3) Illustrate clinical applications and limitations of MR parameters through case examples. 4) Detail an approach to optimizing MR protocols for patient needs and pathology-specific questions.

### TABLE OF CONTENTS/OUTLINE

Tissue contrast: i) Sources of contrast: T1, T2, T2*, ? (susceptibility), PD, fat/water content, magnetization transfer, motion, ii) Weighting vs. quantitative mapping, iii) Fat saturation methodsImage quality spatial resolution, SNR, CNR, image fidelity, artifactsImage acquisition methods: i) Read-out: cartesian vs. non-cartesian k-space sampling, 2D vs. 3D, EPI, ii) Common pulse sequences: spin echo, gradient echo, SSFP, inversion recovery, DWI, perfusion, BOLD, flow sensitive, iii) Acceleration techniques: multi-coil parallel imaging (GRAPPA/SENSE, CAIPIRINHA and wave-CAIPI), simultaneous multi-slice, k-t acceleration methods for dynamic imaging, compressed sensing, deep learning methods, geometry factor (g-factor), iv) Reduced FOV (e.g., ZOOMit)Hardware: magnetic field strength, radiofrequency coils, gradient strength and slew rate, b0 and b1 shimming

### TEACHING POINTS

Hypophysitis is an inflammation of the pituitary gland and a rare cause of hypopituitarism. It can be primary (autoimmune or idiopathic) or secondary to sellar, suprasellar, and parasellar lesions, systemic diseases, or drugs. The most common primary hypophysitis is lymphocytic. Regardless of the etiology, patients with hypophysitis present symptoms and signs caused by inflammation that can lead to hypopituitarism with or without diabetes insipidus, and/or symptoms related to mass effect on the pituitary stalk, hypothalamus, or optic chiasm. The diagnosis relies on clinical, laboratory, and radiological findings. MRI with contrast is the preferred imaging modality, often necessitating follow-up studies to discern changes aiding in differentiation from pituitary adenomas. Treatment primarily entails hormonal replacement, with glucocorticoids reserved for cases presenting with compressive symptoms. Surgical intervention is seldom warranted.

### TABLE OF CONTENTS/OUTLINE

1. Hypophysitis is recognized as a rare inflammatory condition affecting the pituitary gland.2. Lymphocytic hypophysitis is the most prevalent form of primary hypophysitis.3. Diagnosis of hypophysitis can be challenging, but MRI plays a crucial role in confirming the diagnosis and preventing misinterpretation that might lead to unnecessary surgical interventions.4. Treatment strategies primarily involve hormone replacement therapy and the use of high-dose glucocorticoids to alleviate mass effect and manage symptoms effectively.

### TEACHING POINTS

• Review the most common, uncommon, and easily missed causes of epilepsy.• Discuss types of seizures, MRI epilepsy protocol and sequences.• Describe the most important pearls, pitfalls, and causes of misses that the radiologist should know regarding each of the conditions described.

### TABLE OF CONTENTS/OUTLINE

1. Prevalence and causes of epilepsy.2. Types of seizures: simple partial, complex partial, and generalized.3. Indications for imaging in adults and children with epilepsy.4. Imaging findings of the multiple etiologies with cases from our institution.5. Common misses and pitfalls.6. Pearls and systematic approach to increase the sensitivity of the radiologist to these conditions and improve detection of even the most subtle findings, including:a. Important information to review in the patient’s chart.b. Useful imaging modalities including but not limited to MRI, CT, and nuclear medicine.c. MRI technique recommendations.d. Vital MRI sequences according to suspected etiology and patient’s agee. Appropriate level and windowing.

## IMAGING PATTERNS OF SKULL BASE LESIONS ON CT/MR AND THEIR MIMICS: A SIMPLIFIED SYSTEMATIC APPROACH TO ANALYZE COMPLEX SKULL BASE LESIONS AND NARROW YOUR DIFFERENTIALS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Rita G. Bhatia, MD (*Abstract Co-Author*) Nothing to Disclose
Natalya Nagornaya, MD (*Abstract Co-Author*) Nothing to Disclose
Julieta Aristizabal Baron, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Review pertinent anatomy of the skull base. 2. Provide a simple systematic approach and review the differential diagnosis of benign and malignant lesions of the skull base and common "pseudolesions" based on anatomic subdivisions, characteristic imaging features and patterns of growth allowing radiologists to narrow down the differential diagnosis. 3. Review specific roles and use of different imaging modalities for accurate diagnosis, localization, and staging when appropriate of most common skull base lesions.4. Highlight key points in the imaging findings that should be included in the radiology report as critical information for the pre-operative planning. 5. Highlight key imaging features of most common "pseudolesions" to help differentiate them from their potential pathologic mimics or "true lesions" and to avoid unnecessary biopsies and treatment.

### TABLE OF CONTENTS/OUTLINE

1. Pseudolesions, normal variants, and developmental anomalies: fibrous dysplasia, arrested pneumatization of the sphenoid sinus, juvenile ossifying fibroma, aneurysmal bone cyst, petrous apex cephalocele, dermoid cyst, white epidermoid cyst, neuroenteric cyst and ecchordosis physaliphora. 2. Expansile benign skull lesions: lateral sphenoid meningocele, allergic fungal sinusitis, mucocele, and cholesterol granuloma. 3. Central skull base tumors: giant cell tumor, spindle cell hemangioma, clival chordoma, invasive pituitary adenoma, and plasmacytoma. 4. Petro-clival lesions: chordoma and chondrosarcoma. 5. Vascular lesion and mimics: petrous Internal carotid artery aneurysm, carotid canal sympathetic plexus schwannoma, and cavernous sinus capillary hemangioma.

**Certificate of Merit**

Mariko Kurokawa, MD (*Abstract Co-Author*) Nothing to Disclose
Noriko Doki (*Abstract Co-Author*) Nothing to Disclose
Yasunobu Takaki (*Abstract Co-Author*) Nothing to Disclose
Koichiro Mori (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- CNS complications in leukemia are diverse and can significantly impact patient outcomes.
- MRI plays a crucial role in the early diagnosis and management of CNS lesions in leukemia patients.
- Recognizing characteristic MRI findings can help differentiate various CNS complications and guide appropriate treatment.

### TABLE OF CONTENTS/OUTLINE

• Introduction
- Overview of CNS complications in leukemia
- Importance of MRI in diagnosis and management • Malignancy
- CNS infiltration and recurrence
- Post-transplant lymphoproliferative disorders • Infections
- Viral, bacterial, fungal and other infections • Cerebrovascular events
- Hemorrhage and thrombosis • Drug (and/or Radiotherapy)- related neurotoxicity
- Chemotherapy and radiotherapy-induced complications • Immune-mediated neurotoxicity
- CAR T-cell therapy and associated neurotoxicity syndromes • Conclusion
- Significance of a comprehensive MRI approach in leukemia patients

### TEACHING POINTS

Photon-counting detector (PCD) CT provides CT angiography (CTA) with higher spatial resolution and less noise than energy-integrating detector (EID) CT. Metals, such as clips, coils, stents, and liquid embolic materials, used during neurosurgery or endovascular surgery cause beam-hardening artifacts, which strongly degrade images. To settle this issue, we should optimize the reconstruction techniques including field-of-view (FOV), matrix size, kernel setting, use of iterative reconstruction (IR) and metal artifact reduction algorithms (MAR). PCD-CT also provides the retrospective use of virtual monoenergetic imaging. This presentation covers the advantages and pitfalls of PCD-CT over EID-CT, and discusses the causes and types of metal artifacts, and various reconstruction techniques. We also demonstrate latest advances in PCD-CT with case-based reviews.

### TABLE OF CONTENTS/OUTLINE

1. Principles and advantages of PCD-CT, and image quality of CTA using PCD-CT. 2. Overview of artifacts in general and explanation of the mechanisms and types of metal artifacts. 3. Reconstruction techniques to reduce metal artifacts. 4. Case-based review of cases in which reconstruction techniques to reduce metal artifacts were useful. 5. Discussion for utilities of PCD-CT for metal artifact reduction with advantages, disadvantages, and pitfalls.

### TEACHING POINTS

Diffusion-weighted imaging (DWI) is an essential MRI technique for assessing neurological disorders. Single-shot echo-planar imaging (SS-EPI) is the most widely used DWI technique; however, EPI-based DWI techniques are prone to susceptibility artifacts in areas of B0 field inhomogeneity. Therefore, many DWI techniques have been developed to overcome distortion caused by magnetic susceptibility. The aims of this presentation are (1) to introduce DWI techniques for distortion correction, (2) to realize the improvement of distortion in clinical cases, and (3) to discuss their clinical application. Furthermore, (4) techniques to reduce acquisition time, making these technologies more clinically useful, will also be presented.

### TABLE OF CONTENTS/OUTLINE

1. History and techniques of distortion correction in DWI.2. Clinical applications: We demonstrate examples of DWIs with distortion correction. The discussion will be categorized into the following two types of DWI techniques.(a) The methods to reduce distortions in EPI-based DWI, including Reverse encoding Distortion Correction (RDC) -DWI, etc. (b) The methods to reduce distortions using fast spin echo (FSE), including TGSE-BLADE DWI (2D turbo gradient- and spin-echo diffusion-weighted imaging with non-Cartesian BLADE trajectory), etc. 3. The techniques to reduce acquisition time for clinical applications: Specifically, they are parallel imaging, simultaneous multi-slice acceleration technique, and noise reduction technique. Noise reduction techniques include Deep Learning Reconstruction (DLR) techniques.

## TRACTOGRAPHY 101: A GUIDE TO SEGMENTATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Karla D. Fuentes Badillo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Axon fibers, the fundamental components of neural communication, are classified into three main groups: commissural fibers, association fibers, and projection fibers. This classification is crucial for understanding the complex network of the brain. Projection fibers: white matter tracts that connect the cortex with other areas in the CNS. They may be efferent (motor) or afferent tracts (sensory), e.g., corticospinal tract, anterior thalamic radiations. Association fibers: connect different areas in the same hemisphere. There are two types of association fibers: long-range and U-fibers (short-range), e.g., arcuate fasciculus, inferior fronto-occipital fasciculi, cingulum (limbic system fibers), uncinate fasciculus. Commissural fibers: a type of white matter tract that crosses the midline, connecting the same cortical area in opposite hemispheres (right-left hemispheric connections), e.g., forceps minor and major. Three diffusion tensor imaging techniques in common use are the fractional anisotropy map, the principal diffusion direction map, and fiber-tracking maps. Axonal tracts are commonly mapped using a deterministic method called FACT (fiber assignment by continuous tracking). In this method, the user selects "seed voxels" in a particular area of the brain, and automated software computes fiber trajectories in and out of that area.

### TABLE OF CONTENTS/OUTLINE

Introduction Basics Tractography Inferior Longitudinal Fasciculus (ILF) Inferior Fronto-Occipital Fasciculus (IFO) Arcuate Fasciculus (AF) Uncinate Fasciculus (UF) (forceps major, FMA) (forceps minor, FMI) Cingulum (CBT, CBD) Fornix (FX) Corticospinal Tract (CST) Anterior Thalamic Radiations (ATR) Conclusion

### TEACHING POINTS

To categorize the diverse etiologies of intracranial hemorrhage (ICH) and elucidate their radiological hallmarks.To explore the latest advancements in methodologies and imaging technologies for accurately pinpointing the causes of ICH.To highlight the critical role of radiological findings in guiding therapeutic strategies and prognostication for patients with ICH.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: an overview of intracranial hemorrhage. 2. Etiologies of Intracranial Hemorrhage: the prevalent and less common primary and secondary causes of ICH, such as hypertension, cerebral amyloid angiopathy, aneurysms, arteriovenous malformations, cavernous malformations, trauma, coagulopathies, tumors, vasculitis, and venous sinus thrombosis. 3. Radiological Identification of ICH Etiologies: the roles of CT, MRI, and digital subtraction angiography (DSA) in discerning the origin of the hemorrhage and the age of the clot. How imaging features, like the location and pattern of hemorrhage and associated findings, can indicate specific etiologies. ICH classification systems, including Fisher grading for subarachnoid hemorrhage, Zabramski classification for cavernous malformations, and Boston criteria for cerebral amyloid angiopathy. 4. Radiology-Guided Management and Therapeutic Approaches: how radiological findings, including the spot and swirl signs, influence active ICH management strategies, including surgical interventions. 5. Advancements in Imaging Techniques and Future Directions: recent technological innovations in radiology that improve the detection and characterization of ICH. 6. Take-home Messages.

### TEACHING POINTS

The orbit is a sophisticated anatomical area encompassing vital structures such as the eye globe, optic nerve, and extraocular muscles. Thus, the precise interpretation of orbital imaging findings necessitates a comprehensive understanding of its complex anatomy and the interrelationships among these structures. The specific objectives are as follows: To delineate the orbital anatomy and highlight the critical anatomical relationships for clinical practice. To showcase the primary imaging findings associated with orbital disorders, tailored to the anatomical specifics of each compartment. To present the detailed orbital anatomy and its interconnected structure, ensuring accurate interpretation of imaging results.

### TABLE OF CONTENTS/OUTLINE

1. Overview of Imaging Modalities, Protocols, Pitfalls, Principles, and Techniques Specific to Orbital Imaging. 2. Bony Landmarks and Foramina Within the Orbit. 3. Anatomy and Functional Aspects of the Orbital Septum. 4. Detailed Examination of the Eye Globe: Anatomy, Function, and Imaging Assessments of Disorders. 5. The Optic Nerve and Sheath: Detailed MRI Characteristics and Associated Pathologies. 6. Diagnostic Imaging of Extraocular Muscles: Anatomy and Pathological Conditions. 7. Structural and Functional Analysis of Intraconal and Extraconal Spaces: Tools for Diagnostic Imaging of Related Disorders. 8. Assessment of the Nasolacrimal Apparatus. 9. Pathological Conditions Specific to Orbital Compartments: Infections, Tumors, and Inflammatory Diseases. 10. Clinical and Surgical Perspectives: Presentation and Management Strategies for Orbital Disorders, Including Surgical Techniques. 11. Take-Home Messages.

Laura C. Magalhaes, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The primary objective of this abstract is to delve into the evolving landscape of stroke management, emphasizing the extended window for treatment beyond the traditionally accepted timeframe. It aims to shed light on the latest neuroradiological advancements and clinical trials that support this paradigm shift. Key objectives include: To analyze the impact of recent research on extending the treatment window for ischemic stroke, including the implications for radiological practices. To evaluate the role of conventional and advanced imaging techniques in identifying patients who can benefit from treatment in the extended window phase. To discuss integrating radiological innovations into clinical guidelines, focusing on time to treat and the potential for improved recovery rates.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: historical context of the "golden hour" in stroke treatment and its limitations. 2. Pivotal studies (ex: DAWN, DEFUSE 3) that challenge the traditional treatment window, extending the time frame for eligible thrombectomy patients. 3. "Brain window" vs. "time window" — how patient-specific factors influence treatment eligibility. 4. How MRI and CT perfusion techniques have become instrumental in identifying salvageable brain tissue beyond the conventional treatment window. 5. Radiological Innovations and Clinical Trials: Overview of ongoing clinical trials exploring the limits of stroke intervention timings, including thrombectomy and intravenous thrombolysis. 6. Future Directions: The potential for further expanding the treatment window with continuous advancements in the imaging diagnosis assessment. 7. Take-home messages.

## THE NOVEL DUAL INJECTION CONE BEAM CT FOR ASSESSMENT OF THE ANGIOARCHITECTURE OF INTRACRANIAL DURAL ARTERIOVENOUS FISTULAS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Yoichi Morofuji, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Understanding the complex dural arteriovenous fistula (dAVF) anatomy, especially in identifying the feeders and shunt patterns in relation to the affected sinus and cortical veins, is crucial for determining treatment approaches and predicting clinical outcomes and possible complications. We developed dual injection cone beam computed tomography (CBCT) that enabled the simultaneous identification of feeders, fistulous points, and drainers.

### TABLE OF CONTENTS/OUTLINE

Our dual injection CBCT is a novel imaging modality for assessing the angioarchitecture of dAVFs. Although 3D-DSA reveals the morphological anatomy, all vessels are depicted uniformly, making it difficult to recognize feeders, fistulous points, and drainers. In contrast, in dual injection CBCT, the presence of diluted contrast media in the drainers and undiluted contrast medium in the feeders not only makes it easier to recognize the feeders and drainers but also enables detailed evaluation of the fistulous point. Identifying fistulous points and shunt patterns is crucial for determining the treatment approaches and avoiding possible complications. Cross-sectional imaging in dual injection CBCT can provide superior information on small arterial feeders and fistulous points compared to other modalities, such as 3D-DSA, CTA, and MRI, because the gradation of the contrast media in dual injection CBCT clearly demonstrates feeders and drainers. To the best of our knowledge, our dual injection CBCT is the first report to provide the images to distinguish the feeders, fistulous points, and drainers of shunt diseases simultaneously.

Gabriela A. Ribas, MD (*Abstract Co-Author*) Nothing to Disclose
Laura C. Magalhaes, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To explore the intricate landscape of high-flow vascular malformations within the brain, emphasizing the crucial role of radiologic imaging in their diagnosis, classification, and treatment planning. To provide a detailed overview of the types and characteristics of high-flow vascular malformations in the brain. To highlight the advancements in imaging techniques that have transformed the detection, understanding, and intervention strategies for these conditions. To explore the multidisciplinary approach to managing high-flow vascular malformations, focusing on integrating radiologic findings into arteriographic therapeutic decisions.

### TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Classifying brain high-flow vascular malformations: arteriovenous malformations and cerebral proliferative angiopathy, their grading systems, risks, differentiation, and the implications for treatment. Overview of dural arteriovenous fistulas, including classification based on location, venous drainage patterns, and associated risks. Pial arteriovenous fistulae: epidemiology, radiographic features, complications, therapeutics, and prognosis. 3. Imaging: CT angiography, MRI angiography, 4D flow MRI, and digital subtraction angiography. 4. Challenges in imaging diagnosis: differentiating between various types of vascular malformations. The role of imaging in assessing the risks of bleeding and neurological deficits. 5. Treatment planning and radiologic guidance: endovascular treatment, surgery, and radiosurgery. 7. Clinical outcomes: the predictive value of imaging findings. 8. Take-home messages.

### TEACHING POINTS

The primary aim of this abstract is to dissect the intricate world of congenital malformations of the posterior fossa, emphasizing the groundbreaking role of radiological imaging in their diagnosis, classification, and management. This exploration intends to: Illuminate the diverse spectrum of congenital malformations within the posterior fossa, highlighting their clinical relevance and challenges in diagnosis. Detail the advancements in radiological techniques that have revolutionized the detection and understanding of these malformations. Foster a comprehensive approach to managing these conditions, leveraging imaging findings to guide therapeutic decisions and predict outcomes.

### TABLE OF CONTENTS/OUTLINE

1. Overview of the posterior fossa's anatomy and its critical role in neurological function. 2. Introduction to the complexity of congenital malformations in this region and their impact on patient morbidity and mortality. 3. Comparative analysis of CT, MRI, and ultrasonography in the context of prenatal and postnatal imaging. 4. MRI protocol. 5. Classification of common malformations, including Dandy-Walker malformation, Chiari malformations, and arachnoid cysts, along with rarer entities like rhombencephalosynapsis and pontocerebellar hypoplasia. 6. Embryological origins and potential genetic underpinnings of these conditions. 7. Exploration of how the extent and nature of malformations as seen on imaging correlate with neurological outcomes. 8. Potential areas for future research, like genetic markers and their imaging correlates. 9. Take-home messages.

## CAROTID WEB: IMAGING FEATURES AND ENDOVASCULAR MANAGEMENT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Yeray Aguilar Tejedor (*Abstract Co-Author*) Nothing to Disclose
Alejandro Santana Hernandez, MD (*Abstract Co-Author*) Nothing to Disclose
Cristina Candelaria Linares Bello, MD (*Abstract Co-Author*) Nothing to Disclose
Ernesto Santana, MD (*Abstract Co-Author*) Nothing to Disclose
Carmen Rodriguez Fuentes, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To remember the craniocervical vascular anatomy. To describe the physiopathology of the carotid web and the different imaging findings. To explain the endovascular management in the treatment (stenting).

### TABLE OF CONTENTS/OUTLINE

Carotid web is a rare and under-recognized cause of stroke, especially in young patients with a high recurrence rate. It presents as a linear membrane that extends from the posterior aspect of the carotid bulb or internal carotid artery into the lumen, and is considered an atypical form of fibromuscular dysplasia. This entity predisposes to thrombus formation due to blood stasis and platelet activation. A complete clinical history and physical examination are crucial for its diagnosis. Digital subtraction angiography is the gold standard diagnosis procedure. Endovascular procedures, such as stenting, plays an important role in its management.

Stacey Danica L. Gosiaco, MD (*Abstract Co-Author*) Nothing to Disclose
Randall S. Teh, MD (*Abstract Co-Author*) Nothing to Disclose
Kevin Ryan T. Yu, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Lacunar stroke syndromes represent a distinct subset of ischemic strokes, characterized by small subcortical infarcts resulting from occlusion of deep penetrating arteries. Difficulty may be encountered on imaging due to their small size unless there is a high index of suspicion. Correlation with the clinical presentation and imaging findings is paramount to diagnosis. The objectives of this exhibits are: 1) Understand the intricate relationship between neuroanatomy, vascular pathology, and clinical manifestations, 2) Recognize imaging features and patterns of lacunar stroke syndromes, 3) Develop a clinical approach to detecting infarct in acute brain imaging

### TABLE OF CONTENTS/OUTLINE

IntroductionA. Definitions and NeuroanatomyB. Mechanism of Lacunar InfarctionC. Clinical PresentationD. Imaging ConsiderationClassic Lacunar SyndromesA. Pure Motor HemiparesisB. Ataxic HemiparesisC. Pure Sensory StrokeD. Sensorimotor StrokeE. Dysarthria-Clumsy Hand SyndromeAtypical Lacunar SyndromesA. Internuclear OpthalmoplegiaB. Isolated DysarthriaC. Hemichorac/HemiballismusD. ## ALTERED VISUALIZATION OF DEEP MEDULLARY VEINS IN VARIOUS INTRACRANIAL DISORDERS: A STUDY OF SWI

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Eun Ja Lee, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To understand the physics of susceptibility-weighted MR imaging (SWI) and the venous anatomy on SWI.To investigate the fine anatomic structure of medullary veins of cerebral white matter on SWI.To describe various intracranial disorders in which the medullary veins play a major role in disease development.To assess the clinical significance of altered visualization of deep medullary veins in various intracranial disorders

### TABLE OF CONTENTS/OUTLINE

1. General overview of SWI, including assessment of venous hemodynamics 2. Understanding the overall venous anatomy and anatomic structure of medullary veins in the cerebral hemisphere 3. Exploring the fine radiologic anatomy of the medullary veins using SWI. 4. Discussion of disorders related to altered visualization of deep medullary veins 1) changes of deep medullary veins in patients with acute and subacute ischemic stroke 2) changes of deep medullary veins in patients with moyamoya disease 3) changes of deep medullary veins in patients with cerebral venous sinus thrombosis - major dural sinuses / cortical veins / deep veins4) changes of deep medullary veins in vascular anomaly or malformation - developmental venous anomaly / Sturge Weber syndrome / dural arteriovenous fistula 5) hemorrhagic disorders related to deep medullary veins - diffuse vascular injury due to trauma / deep medullary vein engorgement or thrombosis in neonates 6) changes of deep medullary veins in cerebral small vessel disease 7) changes of deep medullary veins in cognitive impairment 8) changes of deep medullary veins in patients with brain death 9) post-operative changes of deep medullary veins 10) others 5. Summary and conclusion

### TEACHING POINTS

Cysts are often seen in brain imaging. Distinguishing between these cysts based solely on imaging findings can be difficult due to their varied presentations. A location-based approach and specific imaging features can help in making a more precise diagnosis.1) To review imaging findings of brain cystic lesions.2) Recognize the different types of brain cystic lesions, categorized on the basis of their causes and localization.3) A practical approach to interpreting these conditions systematizing the evaluation based on main neurologic imaging findings and clinical features.4) Formulate a differential diagnosis for a cystic-appearing lesion in the central nervous system, considering its location or site of origin and imaging features.

### TABLE OF CONTENTS/OUTLINE

1) Introduction.2) Localization of brain cystic lesions: Extra-axial x Intra-axial.3) Cystic lesions and other neurological imaging findings tips.4) Visual systematization of different types of cystic lesions.5) Main differential diagnosis for a cystic-appearing lesion.6) Take home messages.

Takeshi Yoshizako, MD (*Abstract Co-Author*) Nothing to Disclose
Yasushi Kaji, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Aiko Gobara, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Varicella zoster virus (VZV) infection causes several neurological complications, which can be severe because VZV reactivation is associated with a compromised immune system. Diagnosis of VZV is difficult in the absence of a characteristic rash, but is important because of the need for early antiviral therapy. MRI is a non-invasive diagnostic tool that can help reveal the neurological complications of VZV disease. Here, we review the neurological complications of VZV and discuss their diagnosis, differential diagnosis and validated imaging modalities.1. To provide a clinical and radiological review of the central nervous system (CNS) and peripheral nervous system (PNS) complications of VZV infection.2. To provide an anatomical and pathological review of the mechanisms by which CNS and PNS complications of VZV infection occur and spread, and to correlate these with imaging findings.3. To describe effective methods for the detection of neurological complications of VZV infection by imaging.

### TABLE OF CONTENTS/OUTLINE

A. Epidemiology and clinical features of neurological complications in VZVB. Radiological review of CNS and PNS complications of reactivated VZV and differential diagnosis of each 1. Meningoencephalitis 2. Cranial nerve palsies 3. Vasculopathy 4. Myelitis 5. Other neurological complications such as optic neuritis and perineuritisC. Effective Conventional MR imaging of brain, spinal cord, and peripheral nerve lesionsD. Advanced MR imaging methods for neurological complication detectionGd 3D-FLAIR, vessel wall imaging, 3D MR neurography

## THALAMIC INFARCTS: CLINICAL PRESENTATION WITH REVIEW OF ANATOMY AND VASCULAR SUPPLY OF RELEVANT THALAMIC NUCLEI

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Rishi K. Gosalia, MD (*Abstract Co-Author*) Nothing to Disclose
Liam M. O'Neill, MD (*Abstract Co-Author*) Nothing to Disclose
Patrick Taggart, DO (*Abstract Co-Author*) Nothing to Disclose
Tamim Sultani, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Most common cause of unilateral thalamic infarcts is microvascular disease with less common causes to include large vessel arterial plaque disease and embolic infarcts. Microvascular disease related thalamic infarcts usually occur in the ventrolateral territory while large vessel plaque infarcts involve the posteromedial territories. Bilateral thalamic infarct etiology includes artery of Percheron occlusion, top of basilar artery occlusion and deep venous sinus thrombus.

### TABLE OF CONTENTS/OUTLINE

The exhibit is formatted as 2 clinical cases. The first case is an 86-year-old female who presented with abnormal sensation in the corner of mouth and ipsilateral hand and foot found to have an acute infarct in the contralateral thalamus within the VPM/VPL nuclei consistent with Cheiro-Oral Pedal Syndrome. The second patient is a 47-year-old male who presented with numbness and pain in left forehead, maxilla, neck, chest and thigh with stabbing headache behind the eyes. This patient was also found to have an acute lacunar infarct within the VPL nucleus of the right thalamus and was diagnosed with thalamic pain syndrome. The affected thalamic nuclei in these cases are the ventral posteromedial (VPM) and ventral posterolateral nuclei (VPL). Infarcts in this region of the thalamus can present with myriad of symptoms including sensorimotor deficits with sudden onset and severe symptoms. Sensory loss and decreased levels of consciousness are also commonly seen in VPM/VPL thalamic nuclei infarcts. These regions of the thalamus are predominately supplied by paramedian or thalamic perforators from P1 and P2 segments of the PCA. The VPL nucleus is supplied by the posterior choroidal artery, a branch of the P2 segment PCA.

## THE MERGE OF BONES: DELVING INTO SYNOSTOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Leandro T. Lucato, MD (*Abstract Co-Author*) Nothing to Disclose
Douglas M. Nunes (*Abstract Co-Author*) Nothing to Disclose
Claudia D. Leite, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Thiago Luiz P. Scoppetta, MD (*Abstract Co-Author*) Nothing to Disclose
Diego C. Fragoso (*Abstract Co-Author*) Nothing to Disclose
Carlos Jorge da Silva, PhD, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The development of the face and skull is orchestrated by a complex three-dimensional morphogenetic process involving hundreds of genes controlling a coordinated pattern of tissue proliferation, and differentiation from different embryological origins.Imaging characteristics allow differentiation between positional plagiocephaly and that resulting from craniosynostosis.Tomographic studies with 3D reconstruction are the gold standard for imaging in the diagnosis and classification of craniosynostoses for potential surgical planning, as they allow for great detail of the bone structure.MRI studies provide a better assessment of the brain parenchyma, especially in patients with syndromic craniosynostoses, where other findings may be present.In some cases, imaging markers allow for the diagnosis of a specific disease or at least a group of diseases.

### TABLE OF CONTENTS/OUTLINE

IntroductionTo review (1) normal suture anatomy and (2) pattern of suture closureGenetic and Pathophysiological PerspectivesTo depict genetic and embryology of cranial suturesImagingTo discuss the main imaging modalities, including their strengths and weaknessTo guide radiologists in the differentiation between positional plagiocephaly from true synostosisTo demonstrate the imaging spectrum of craniosynostosis, involving single versus multiple suture fusionTo identify the main imaging markers that enable a confident diagnosis of a specific disease or a group of related diseasesTo highlight potential associated abnormalities

## COMPARATIVE EVALUATION OF HABENULAR VOLUME AND IRON CONTENT USING MANUAL AND NORMALIZED SEGMENTATION TECHNIQUES IN STAGE SEQUENCES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

E. Mark Haacke, PhD (*Abstract Co-Author*) Research Grant, Biogen Idec Inc ;President, Magnetic Resonance Innovations, Inc
Lei Zhang (*Abstract Co-Author*) Nothing to Disclose

Bingyang Bian (*Abstract Co-Author*) Nothing to Disclose
Xingchen Pan (*Abstract Co-Author*) Nothing to Disclose
TAO LI (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Using different segmentation methods to study the intergroup differences in the volume and iron content of the habenula between patients with first episode depression (FED) and control group. All subjects underwent STAGE sequence magnetic resonance imaging (MRI). Volume measurement included two methods, the first involved manual segmentation using ITK-SNAP (Figure 1), and the second used a habenular brain template created from a high-resolution, high-contrast template comprised of a total of 990 brain scans, followed by post-processing with FSL software to obtain the volume of the habenula (Figure 2). Due to poor matching of QSM to the MNI 152 space, iron content was measured only through manually segmented brain templates in the QSM sequence.There were no differences in gender or age between patients with FED and the control group ($p > .05$) (Table 1). Using manual segmentation, there were no differences in volume or iron content of the bilateral habenula between FED patients and the control group ($p > .05$). However, standardized segmentation of the habenula showed intergroup differences, with a larger habenula volume in FED patients ($p < .05$). Furthermore, we compared the results of manual segmentation and standardized segmentation, finding intergroup differences in the right habenula ($p < .05$) (Table 2).The above results indicate that manual segmentation involves a certain level of subjectivity, while standardized segmentation is more sensitive in detecting intergroup differences. This suggests the need for applying more refined segmentation techniques in this field to achieve superior segmentation results in the future.

### TEACHING POINTS

To illustrate the anatomical landmarks of the conus medullaris, filum terminale and cauda equina.To show the spectrum of pathologies affecting these structures using a case-based approach.To review the various pathological processes and their imaging features, based on magnetic resonance imaging (MRI).Provide differential diagnosis of lesions according to congenital, inflammatory/ infectious/ demyelinating auto-immune, neoplastic and vascular etiologies.

### TABLE OF CONTENTS/OUTLINE

The conus medullaris represents the tapered terminus of the spinal cord, is a vital anatomical landmark in diagnostic radiology. The filum terminale is a small thin filament of connective tissue that extends inferiorly from the apex of the conus medullaris to the sacrum. Cauda equina is the collective term given to nerve roots distal to the conus medullaris, which occupy the lumbar cistern. A thorough grasp of its anatomy, common anatomical variations, and the diagnostic challenges associated with lesions in this area is crucial for radiologists. This pictorial essay provides a detailed review of the anatomy as well as the broad differential diagnosis of lesions located in these topographies. Differential diagnoses were addressed by etiology and divided into the following groups: congenital, vascular, inflammatory/ infectious, neoplastic and miscellaneous.MRI is the method of choice for evaluating these lesions, as it provides better tissue and contrast resolution in the analysis. The knowledge of the anatomy and imaging patterns of lesions located in these areas is crucial for radiologists to be able to narrow the differential diagnosis, guiding a more efficient therapeutic approach to patients.

## IMAGING FOLLOW-UP OF THE LONG-TERM THERAPEUTIC MECHANISM OF VERMICULITE NANOSHEETS ON ISCHEMIC STROKE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Feng Lishuai (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Intraventricular injected vermiculite (VMT) enter into brain parenchyma through damaged cerebrospinal fluid brain barrier.VMT were swallowed by microglia and then reduced the release of proinflammatory factor by microglia through regulating upstream signaling pathways.VMT also improved survival rate of neuron and the integrity of BBB after ischemic stroke, reduced the "no-reflow" after reperfusion.All these protective effects of VMT is demonstrated by MRI and ultrasound super-resolution imaging technology.

### TABLE OF CONTENTS/OUTLINE

Ischemic stroke is a common neurological disorder and a major cause of permanent disability in patients. So far, few therapeutic drugs that can treat neurological damage in stroke. Therefore, protecting nerves and promoting neural function recovery remain an urgent research area. In this study, we adopted the method of intraventricular injection of VMT nanosheets. By comparing the areas of abnormal diffusion weighted imaging (DWI) signals with VMT nanosheets entering the brain, and using techniques such as biological transmission electron microscopy and immunofluorescence, we elucidated the passive targeted delivery characteristics of VMT nanosheets at different time points after stroke. Furthermore, the multi-target protective effects and prognosis of VMT nanosheets on neurons, glial cells, and cerebral blood vessels after stroke were explored through motor and cognitive-behavioral studies, MRI, ultrasound super-resolution in vivo imaging techniques, and brain tissue samples validation. These results demonstrated the enormous potential of VMT nanosheets in the application of ischemic stroke.

## THESE GO TO ELEVEN: SERIOUS SPINAL TAP COMPLICATIONS YOU SHOULD KNOW ABOUT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Alvaro Jose de la Iglesia Salas, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This exhibit intends• To acquaint the reader with the most crucial intracranial and spinal complications after lumbar puncture (LP) through a series of cases in a multimodality fashion.• To discuss the significance of dura-arachnoid enhancement after LP.• To review the technique, risk factors, and contraindications for LP.The main teaching points are• LP is a generally safe diagnostic and therapeutic procedure.• The rate of severe complications is low, but radiologists may encounter some in their careers. Familiarization with these adverse effects will grant a timely and correct diagnosis.• Chief risk factors are traumatic or non-sterile technique, bleeding diathesis, raised intracranial pressure, and challenging anatomy.• CT and MRI should be scrutinized for signs of intracranial and spinal hemorrhage, cerebrospinal fluid leak, intracranial hypotension, herniation, and dural sinus thrombosis.• Meningitis, abscess, arachnoiditis, epidermoid cyst, and foreign body constitute more unusual sequelae to be mindful of.• Diffuse dura-arachnoid enhancement should likely not be a concern for delaying LP since it is not prevalent without intracranial hypotension, strongly advising to exclude other causes first when present.

### TABLE OF CONTENTS/OUTLINE

• Introduction: relevant anatomy, LP technique, general indications.• General contraindications and risk factors for complications following LP.• LP complications: spinal and intracranial hemorrhage, cerebrospinal fluid leak, intracranial hypotension, cerebral and cerebellar herniation, dural sinus thrombosis, arachnoiditis, meningeal infection, abscess, epidermoid cyst, foreign body.• Dura-arachnoid enhancement after LP.• Conclusion.

Claudia Muns, MD (*Abstract Co-Author*) Nothing to Disclose
Alejandra Cardona Del Valle, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Review the grading of Arteriovenous Malformations (AVMs) as defined by the Spetzler-Martin classification. Provide anatomical diagrams of Grade I-V of AVMs. Contribute case examples with pathognomonic imaging findings of grade I-V AVMs on CT, MRI, and angiography studies. Define the possible complications of AVMs and their corresponding management. Provide a self-assessment tool for the classification of AVMs as defined by the Spetzler Martin classification.

### TABLE OF CONTENTS/OUTLINE

Educational Objectives Introduction. Arteriovenous Malformations (AVMs) Spetzler-Martin classification - Grade I-V Anatomical Diagrams, CT, MRI, and Angiography Imaging Findings and Treatment Options. Complications of AVMs. Self-assessment with multiple cases in quiz format. Conclusion. Brain AVMs are vascular lesions characterized by a connection between feeding arteries and a draining venous network without an intervening capillary bed. Clinically, AVMs can exhibit variable initial presentations and may result in serious outcomes such as intracranial hemorrhages, seizures, neurological deficits, and death. While diagnosis is made through different imaging modalities, management is mostly surgical. Thus, understanding AVM structure and location becomes relevant for planning appropriate interventions and anticipating potential complications. This exhibit will review the grading of AVMs as defined by the Spetzler-Martin classification using a pictorial depiction of lesions along with their appearance on various imaging modalities such as MRI, CT, and angiography. We will also discuss complications associated with AVMs, and address the role of radiology in guiding treatment decisions.

### TEACHING POINTS

1. 7-Tesla MRI (7T) offers high spatial and contrast resolution with a superior signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) than conventional field strengths, enhancing clinical application by improving the detection and characterization of both normal and abnormal structures. This exhibit showcases clinical advantages of 7T. 2. High spatial and contrast resolution plays a role in imaging for trigeminal neuralgia, where 7T MRI has the potential to improve diagnosis associated with pathologies like masses, local vascular alterations, and microstructural changes. 3. The anatomy of the skull base poses a challenge for imaging of skull base tumors. 7T could play a crucial role in enhancing comprehensive preoperative tumor assessment, vital for precise surgical planning for achieving adequate tumor resection and minimizing morbidity. 4. 7T enhances noninvasive diagnosis of focal epileptogenic lesions and associated microstructural features with precise trigger point detection in patients with nondiagnostic conventional field studies which expedites targeted treatment planning. 5. The identification of cortical lesions, white matter plaques, and characterization of imaging biomarkers such as central vein sign in Multiple Sclerosis could be significantly enhanced by 7T, addressing challenges often seen with conventional MRI. 6. 7T may play a promising role in the diagnosis and follow-up of Alzheimer’s disease by better elucidating structural changes and accompanying pathologies such as cerebral microbleeds with superior resolution.

### TEACHING POINTS

1. Review pertinent anatomy of the limbic system underlying temporal lobe epilepsy (ex. hippocampus, fornix, parahippocampal gyrus, cingulate).2. Review potential limbic anatomy variants that may be mistaken for pathology.3. Review cases of pathologies associated with temporal lobe epilepsy.Abstract: Temporal lobe epilepsy (TLE) is the most common type of epilepsy and accounts for about half of all cases of focal epilepsy. Diagnosis of epilepsy related radiological abnormalities often depends on identification of subtle imaging features involving the temporal lobe or limbic structures which can precipitate temporal lobe seizures. Accurate interpretation can be prone to error because unlike other neurological diseases such as tumors and demyelinating lesions, abnormalities in TLE may not involve significant MRI signal changes or distortion of brain anatomy. Additional normal individual differences in sulcal and gyral positioning and anatomy pose additional challenges. This exhibit will review normal anatomy, variant anatomy that may be confused with pathology, and pathologies that should be identified in the initial evaluation for TLE. We will review the concept of the limbic network and its functions and connections. Ultimately, this exhibit will serve as a primer for practicing radiologists in assessing complex and less recognized findings in medically refractory TLE.

### TABLE OF CONTENTS/OUTLINE

1. Introduction2. Background - Seizure workup with clinical context3. Normal anatomy of structures involved in temporal lobe epilepsy4. Examples of pathology involving limbic structures with clinical cases Summary of search pattern for TE seizure evaluation

## ARTERIAL SPIN LABELING ASSESSMENT OF CEREBRAL ARTERIOVENOUS FISTULAE AND MALFORMATIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Abraham Noorbakhsh, MD,MPH (*Abstract Co-Author*) Nothing to Disclose
Divya S. Bolar, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Usha Trivedi, MD, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Arterial spin labeling (ASL) is a noninvasive MRI technique that magnetically labels blood for use as an endogenous tracer for to assess cerebral perfusion. ASL is exquisitely sensitive for detecting arteriovenous fistulae (AVF) and arteriovenous malformations (AVM) via arterialized signal in the venous system and/or nidus. ASL can identify subtle AV shunt lesions and provides valuable insight into the progression or resolution of these lesions on follow-up imaging. However, mimics of AV shunt lesions on ASL, such as jugular venous reflux and venous thrombosis, can confound interpretation and warrant additional imaging for confirmation. This educational exhibit showcases the utility of ASL for diagnosing and assessing AVF and AVM and provides examples of mimics of which the neuroradiologist should be aware.

### TABLE OF CONTENTS/OUTLINE

1. Vascular Shunt Lesions - Review of arteriovenous malformations (AVM) and arteriovenous fistulae (AVF) 2. Current Methods of Assessing Shunt Lesions - Imaging methods to evaluate AVM and AVF 3. Discussion of Arterial Spin Labeling (ASL) - Review on acquisition and interpretation of ASL in the setting of AV shunting - Comparison of ASL with other techniques to assess shunt lesions 4. Cases of AVM with ASL - Examples of large and small AVMs 5. Cases of AVF with ASL - Examples of carotid cavernous fistula - Examples of dural arteriovenous fistula 6. ASL to Assess Follow up Studies - Progression and improvement of AVF and AVM on ASL 7. Pitfalls of ASL - Mimics of arterialized signal, including jugular venous reflux and venous sinus thrombosis 8. Summary of ASL and its utility for evaluating AVM and AVF

### TEACHING POINTS

Review the anatomy of the medulla oblongata, its specific structures, connections with other parts of the central nervous system, and main functions. Detail in step-by-step how and which weighted magnetic resonance imaging (MRI) sequences contribute to the identification of the main pathologies that affect the medulla oblongata. Demonstrate the importance of accurate diagnosis of bulbar pathologies for planning surgical and therapeutic interventions, and adequate monitoring of the disease in order to avoid further neurological damage.

### TABLE OF CONTENTS/OUTLINE

The medulla oblongata is a small segment of the brain stem that contains structures fundamental to life, such as the vital autonomous cardiovascular and respiratory centers that control heart rate, blood pressure, and breathing. Although isolated bulbar injuries are rare, late diagnosis and inadequate treatment can lead to disability or death. In this context, magnetic resonance imaging (MRI) plays a central role in accurate and early diagnosis, and it is essential for radiologists to have in-depth knowledge and a focused look at image findings to identify anatomical structures, recognize pathological changes, differentiate similar conditions and correlate radiological findings with clinical symptoms. The step-by-step analysis of the medulla oblongata using magnetic resonance allows the optimization of analytical reasoning in the evaluation, helping to obtain a detailed understanding of the changes expected in each disease, contributing to an accurate diagnosis and, consequently, an adequate treatment that obtain the best clinical outcomes.

## TARGETED NEUROSURGICAL INTERVENTIONS: THE ROLE OF NEUROIMAGING IN LITT, DBS, AND HIFU

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Evgeny Pavlushkov, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Jay Starkey, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Explore new neurosurgical techniques and their applications
- Understand the role of neuroimaging in pre-and post-operative settings
- Discuss the anatomy and targets for LITT, DBS, and HIFU procedures
- Highlight the importance of neuroimaging in guiding and evaluating these treatments

### TABLE OF CONTENTS/OUTLINE

- Introduction
- Laser Interstitial Thermal Therapy (LITT)
- Principles and mechanisms
- Indications and targeted pathologies
- Pre-operative imaging: planning and target identification
- Intra-operative imaging: real-time monitoring and guidance
- Post-operative imaging: assessing treatment response and complications
- Deep Brain Stimulation (DBS)
- Overview of DBS
- Targets for DBS:
- Ventral Intermediate Nucleus (VIM) for essential tremor
- Globus Pallidus internus (GPi) for dystonia and Parkinson's disease
- Subthalamic Nucleus (STN) for Parkinson's disease
- Pre-operative imaging: anatomical and functional mapping
- Intra-operative imaging: electrode placement and verification
- Post-operative imaging: evaluating lead position and stimulation effects
- High-Intensity Focused Ultrasound (HIFU)
- Principles and mechanisms of action
- Applications in neurosurgery, focusing on the VIM for essential tremor
- Pre-operative imaging: target localization and treatment planning
- Intra-operative imaging: real-time monitoring and guidance
- Post-operative imaging: assessing treatment efficacy
- Integration of Advanced Imaging Techniques
- The role of functional MRI, diffusion tensor imaging, and tractography
- Advances in intra-operative imaging: MRI-guided neurosurgery
- Future Directions and Challenges
- Emerging applications of LITT, DBS, and HIFU
- Potential limitations and risks
- Conclusion

## TEMPORAL LOBE ENCEPHALOCELES ASSOCIATED EPILEPSY - SUBTLE LESIONS YOU DO NOT WANT TO MISS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Richard A. Bronen, MD (*Abstract Co-Author*) Nothing to Disclose
Derek Nitz, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Temporal Lobe Encephaloceles Associated Epilepsy - Subtle Lesions You Do Not Want to Miss Temporal Lobe Encephaloceles (TLenc) are herniations of brain parenchyma through dural defects in the middle cranial fossa and have been identified as a cause of medically refractory epilepsy. Identification of these lesions is imperative because surgical resection can be curative. However, there are challenges to the diagnosis of TLenc, which include lack of awareness of the lesion (particularly prior to 2015) and subtle findings on MR and CT imaging. TLenc are often small, isointense to brain tissue, and difficult to distinguish from normal TL undulations or adjacent subjacent extracranial tissue, particularly if thin high resolution imaging protocols are not utilized. At the conclusion of this exhibit, the learner will be able to do the following: Describe TLenc and their clinical significance. Will be aware of the current imaging protocol to optimize the detection of TLenc. Highlight key imaging features to identify TLenc. Identify typical and subtle cases of TLenc.

### TABLE OF CONTENTS/OUTLINE

Background of TLenc: Define TLenc. Discuss clinical significance. Review current management of TLenc. Review pitfalls in the diagnosis of TLenc on imaging. Review recommended imaging protocol: Review HARNESS MRI imaging protocol. Discuss optimal sequences and view for identification of TLenc. Discuss key imaging features to identify TLenc. Review cases of typical and subtle TLenc.

## CONGENITAL CRANIOFACIAL ANOMALIES: A PICTORIAL REVIEW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Lauren J. Ehrlich, MD (*Abstract Co-Author*) Nothing to Disclose
Namita Bhagat, MD (*Abstract Co-Author*) Nothing to Disclose
Gaurav Cheraya, MD (*Abstract Co-Author*) Nothing to Disclose
Jordan Hughes, MD (*Abstract Co-Author*) Nothing to Disclose
Anisa A. Chowdhary, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Craniofacial malformations can be either isolated or part of a defined genetic syndrome. Early diagnosis of these malformations has vital clinical significance because some may present as acute emergencies in the postnatal period, whereas others may require long-term treatment. Some may also be associated with brain anomalies. The diagnostic value of three-dimensional reconstructed images by computed tomography (3D-CT) is particularly high in individuals with complex craniofacial deformities, and in patients with congenital malformations. 3D-CT imaging is the method of choice for understanding the pathologic morphology of the patients and in the preparation for craniofacial surgery.

### TABLE OF CONTENTS/OUTLINE

Introduction: Craniofacial malformation is one of the most commonly encountered birth defects in the prenatal and postnatal periods. Facial cleft cleft lip (CL) with or without cleft palate (CP), is the most common congenital craniofacial malformation. Craniofacial syndromes commonly associated with craniosynostis include Apert syndrome, Crouzon syndrome, and Pfeiffer syndrome, which are secondary to mutations of fibroblast growth factor receptor (FGFR). Purpose: The purpose of this study is to assess the clinical and CT imaging patterns of Craniofacial syndromes with correlating the abnormalities such as bone abnormalities of the face, cranium and the skull base.

## CHRONIC SUBDURAL HEMATOMA: ADVANCED IMAGING OF THE MEMBRANES AND THE ROLE OF MIDDLE MENINGEAL ARTERY EMBOLIZATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Uttam Bodanapally, MBBS (*Abstract Co-Author*) Speakers Bureau, Siemens AG;Travel support, Siemens AG;Research support, Siemens AG
Dheeraj Gandhi, MBBS, MD (*Abstract Co-Author*) Research Grant, Stryker CorporationResearch Grant, Medtronic plc
Athanasios Pavlou, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Chronic subdural hematoma (cSDH) is a complex immunological and angiogenic process that is initiated by minor trauma to the dural membranes. Based on hematoma morphology, cSDHs are classified on unenhanced CT scans for triage and treatment. Certain hematoma morphologies benefit from membrane imaging by either contrast enhanced MRI or contrast enhanced dual energy CT (DECT) that provides valuable information to guide further management. With increasing accessibility and significant shorter scan time, DECT not only provides an excellent means for the depiction and grading of membranes, but also provides functional information by estimating the amount of iodine exudation through the immature capillaries present in the membranes. Conventional surgical management of cSDH can quickly decompress the hematoma but recurrence and complication rates are high. Middle meningeal artery embolization (MMAE) can restrict arterial supply to the membranes to induce necrosis, target neo-vasculature and the cycle of inflammation which are thought to be responsible for propagation and postoperative recurrence. In addition, MMAE can also be potentially used as a standalone method to induce resorption and resolution without surgical evacuation.

### TABLE OF CONTENTS/OUTLINE

Epidemiology and health care burden. Pathophysiology as it pertains to advanced imaging methods. Role of CT imaging with emphasis on dual energy techniques for membrane imaging. Use of advanced imaging to guide surgical management with or without adjunct middle meningeal artery embolization. Discussion of the utility of sole middle meningeal artery embolization. Future prospects in the diagnosis and treatment of chronic subdural hematomas

## BEYOND THE BASICS OF PREOPERATIVE SPINE IMAGING: WHAT ARE THE FINDINGS THAT CHANGE MANAGEMENT?

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Carol P. Geer, MD (*Abstract Co-Author*) Nothing to Disclose
Edwin A. Stevens, MD (*Abstract Co-Author*) Nothing to Disclose
Scott D. Wuertzer, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Caroline Wilson, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica Hinaman, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Review cross-sectional spine imaging, highlighting the importance of CT for assessing fracture morphology and MRI for evaluating soft tissue injuries. 2. Describe additional, often overlooked, findings and anatomic considerations in the cervical, thoracic, and lumbar spine that affect patient management and should be included in all radiology reports. 3. Review these findings through a case-based approach with CT and MRI examples.

### TABLE OF CONTENTS/OUTLINE

Review of Basics. Fracture morphology - value of CT. Soft tissue injury - value of MRI. Cervical Spine. Traumatic - Traumatic disc herniation. Extent of ligamentous injury. Integrity of the transverse ligament. Discoligamentous competency at C2/C3. Angulation of odontoid. Extent of fracture with underlying diffuse idiopathic skeletal hyperostosis or ankylosing spondylitis. Non-traumatic - Soft foraminal disc herniation or disc-osteophyte complex. Ossification of posterior longitudinal ligament. Alignment. Anatomic Consideration - location of vertebral artery position relative to C2 pars. Thoracic and Lumbar Spine. Traumatic - Traumatic disc herniation. Extent of ligamentous injury. Extent of fracture with underlying DISH or AS. Non-traumatic - Location of disc herniation. Etiology of post-surgical stenosis (recurrent disc, osteophyte, or scar). Prior decompressive surgery. Anatomic Consideration - location of iliac vein bifurcation complex to L4/L5 and L5/S1.

## UNRAVELING THE MIDLINE: SELLAR AND PARASELLAR LESIONS FROM A RADIOLOGIST'S PERSPECTIVE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Fernanda V. Pereira, MD (*Abstract Co-Author*) Nothing to Disclose
Caio Silveira, MD (*Abstract Co-Author*) Nothing to Disclose
Gustavo Yamada, MD (*Abstract Co-Author*) Nothing to Disclose
Fabiano Reis (*Presenter*) Nothing to Disclose

### TEACHING POINTS

There is a myriad of sellar and parasellar lesions, and they are not uncommon. They are found especially in the pediatric population, accounting for approximately 10% of all pediatric intracranial tumors, and thus represent a routine diagnostic challenge for the radiologist. This educational exhibit aims to: review the normal anatomy and embryology of the midline of the brain, especially the pituitary gland, the suprasellar cistern and the hypothalamus; summarize the imaging characteristics of the sellar region on CT and MRI; review pituitary adenomas and their main mimicking entities, differential diagnoses and common pitfalls through a set of illustrative clinical cases.

### TABLE OF CONTENTS/OUTLINE

(1) Introduction; (2) Anatomy and embryology of the brain midline (sella turcica and pituitary gland, parasellar region, suprasellar cistern and hypothalamus); (3) Case-based review of pituitary adenomas, and its main mimickers and differential diagnoses: pituitary carcinoma, granular cell tumor of the neurohypophysis, meningioma, pituitary metastasis, intrasellar plasmacytoma, pituitary apoplexy, aneurysms, pilocytic hypothalamic/chiasmatic astrocytoma, craniopharyngioma, sellar xanthogranuloma, hypothalamic hamartoma, clivus chordoma, sarcoidosis, surgical manipulation, carotid-cavernous fistula, epidermoid cyst; (4) Final remarks and take-home messages.

David Tirschwell, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Mona Kharaji, MD (*Abstract Co-Author*) Nothing to Disclose
Javid Azadbakht, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Embolic stroke of undetermined source (ESUS) is a diagnosis of exclusion and relies on luminal imaging to assess arteriogenic causes.• Growing evidence points towards non-stenotic atherosclerotic plaques as a potential stroke etiology.• Vessel wall imaging (VWI) can potentially detect these non-stenotic lesions better than luminal imaging.• Evaluating plaque features of vulnerability in VWI may better stratify risk for secondary stroke prevention.• If incorporated as part of standard-of-care in IS work-up, VWI can offer targets for more appropriate treatment in certain ESUS patients.• Optimizing VWI and stroke MRI protocols for time efficiency and image quality, while also engaging with ordering providers can lead to acceptance and understanding of the value of VWI in stroke work-up and secondary stroke prevention.

### TABLE OF CONTENTS/OUTLINE

1. Etiologies of IS 2. Luminal imaging in IS2.1. Disadvantages of luminal imaging in evaluating small or outward remodeling plaques as potential arteriogenic causes of IS3. ESUS3.1. Definition3.2. Epidemiology and prognosis3.3. Traditional imaging and clinical evaluation paradigms4. Vessel wall imaging (VWI) in ESUS 4.1. Added value over luminal imaging4.2. Recommended protocols for efficiency and optimal image quality4.3. Identifying non-stenotic plaques (NSPs) upstream from the stroke territory4.4. VWI NSP mimics and imaging pitfalls4.5. Imaging features of high risk NSPs and their correlation with IS4.6. Incorporating carotid and intracranial VWI as part of standard-of-care in stroke work-up5. Technical and clinical challenges impeding the utility of VWI in ESUS 6. Future directions for addressing challenges for VWI implementation and interpretation

### TEACHING POINTS

The purposes of this exhibit are:- Review the main neuroimaging patterns of MOGAD through clinical cases.- Discuss and describe the imaging features at the heterogeneous phenotypes in MOGAD patients, focusing in MRI findings, such as optic neuritis, transverse myelitis, supratentorial and infratentorial involvement.

### TABLE OF CONTENTS/OUTLINE

1. Imaging patterns of MOGAD disorder with epidemiological features in adult and pediatric population.- Neuroimaging patterns such as supratentorial and infratentorial involvement, optic neuritis and transverse myelitis. 2. Supratentorial and infratentorial most common imaging patterns in MOGAD patients illustrated by clinical cases.- Supratentorial involvement showed by clinical cases with heterogenous imaging patterns such as acute disseminated encephalomyelitis (ADEM), flair-hyperintense lesions in anti-MOG associated encephalitis with seizures (FLAMES) and other patterns.- Infratentorial involvement in MOGAD illustrated by a clinical case 3. The overlap of the imaging and neurological patterns of ADEM and FLAMES- Clinical case illustrating the alternance of ADEM and FLAMES imaging patterns 4. Transverse Myelitis in MOGAD patients.- Clinical cases showing the spinal cord involvement in MOGAD disease. 5. Optic neuritis imaging pattern in MOGAD- Imaging pattern of MOGAD optic neuritis and the differences of the optic nerve involvement in the most common differential diagnosis.

### TEACHING POINTS

- The normal brain is not perfectly symmetrical.- Brain asymmetries are characterized by enlargement or atrophy of all or part of a cerebral hemisphere.- They can be physiological or non-physiological (congenital or acquired).

### TABLE OF CONTENTS/OUTLINE

Brain asymmetry has been observed for over a century in humans in terms of structure, function, and behavior and is characterized by enlargement or atrophy of all or part of a cerebral hemisphere. They can be physiological or non-physiological (congenital or acquired). Physiological asymmetries reflect evolutionary, hereditary, developmental, experiential, and pathological factors. The specialization of the left hemisphere for language was one of the earliest observations of brain asymmetry. Among the most prominent observations of brain asymmetry are the right frontal and left occipital petalia (when one of the lobes protrudes towards the contralateral side, leaving impressions on the inner surface of the skull). Other common physiological asymmetries include gyral-sulcal patterns, distribution of grey and white matter and ventricular asymmetry. On the other hand, various diseases, whether congenital or acquired, present disproportion between one cerebral hemisphere or lobe and the other. A pratical approach to assessment, considering the dimensions of the affected hemisphere (enlarged or reduced), the size of the lateral ventricles on the diseased side, and the pattern of involvement between the cerebral lobes, can help narrow down the list of differential diagnoses.

### TEACHING POINTS

• Caudal Regression Syndrome (CRS) is a rare genetic disorder characterized by total or partial agenesis of the lower vertebral, sacral, and thoracolumbar spine.• The clinical presentation of CRS varies based on the extent of malformations, common features include a short intergluteal cleft, foot deformities, and lower extremity muscular atrophy. Neurological deficits correlate with the level of vertebral anomaly, while gastrointestinal and genitourinary abnormalities pose significant diagnostic challenges.• Antenatal ultrasound is sensitive for detecting hypoplasia of the lower extremities and sacral or lumbosacral agenesis.• Fetal MRI confirms the diagnosis and assesses the level of the terminal medullary cone. Postnatally, imaging modalities like ultrasonography, bone survey, CT scan, and MRI are utilized for confirmation and detailed assessment.• CRS is divided into two subgroups: Group 1, characterized by high agenesis with cord termination above the lower border of L1, while Group 2, features low agenesis below L1, and often presents a low-lying conus, predisposing to progressive neurological deterioration.• Additionally, Renhaw's classification categorizes sacral agenesis into four types, providing insights into the anatomical variations seen in CRS.

Javier M. Romero, MD (*Abstract Co-Author*) Stockholder, TMA Precision Medicine
Arash Kamali, MD (*Abstract Co-Author*) Nothing to Disclose
David E. Timaran Montenegro, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Demonstrate the role of black blood MR imaging (BB-MRI) in detecting and interpreting arterial wall diseases in intracranial vessels. • Depict the clinical applications and pitfalls of BB-MRI in neurovascular diagnosis. • Provide insights into the pathology beyond luminal abnormalities, enabling the differentiation of causes of stenosis, such as intracranial atherosclerotic disease, vasculitis, and reversible cerebral vasoconstriction syndrome, through BB-MRI. • Highlight interpretive pitfalls, including artifacts from slow flow, enhancing veins mimicking arterial wall enhancement, and vasa vasorum enhancement mimicking vasculitis.

### TABLE OF CONTENTS/OUTLINE

Atherosclerosis: Clear visualization of vessel walls and enabling precise assessment of atherosclerotic plaque morphology and burden. Vasculitis: concentric vessel wall thickening and enhancement. Notably, the "tram track sign," observed as a hyperintense line with hypointense rims, is a hallmark of vasculitic involvement. Dissection: intramural hematoma as a characteristic imaging finding in dissection, along with the eventual visualization of mural thrombus. Moyamoya Disease: Characteristic terminal intracranial internal carotid artery stenosis without enhancement. Intracranial Saccular Aneurysms: Stability of aneurysms can be predicted by absence of enhancement in the vessel wall. Vasospasm: Narrowing of vessel lumen without enhancement. Reversible Cerebral Vasoconstriction Syndrome (RCVS): Mild enhancement or no enhancement with thickened vessel walls. Giant Cell Arteritis: Helps in determining where to perform a biopsy on the temporal artery and predicting biopsy results.

### TEACHING POINTS

Postoperative evaluation of the sella turcica is a major challenge, even for experienced neuroradiologists. The objective of this presentation is to promote a review on the topic and propose solutions for the standardized evaluation of these exams, with the aim of increasing the precision and confidence of radiologists when faced with them.

### TABLE OF CONTENTS/OUTLINE

- It is necessary to know the characteristics of pre-operative exams and how the surgical procedure was performed.- An examination with the appropriate technique must be performed, focusing on T2 and post-contrast T1-weighted sequences. Performing a dynamic sequence and post-contrast T1 3D fast spin echo sequences may be useful.- Careful evaluation of these studies should initially look for postoperative complications, such as bleeding, ischemia and CSF leak.- The assessment of residual lesion and progression must be carried out with caution, always using all available comparative exams, to identify slow growth.- Some post-treatment expected changes should also be observed, such as insinuation of the supra sellar cistern and herniation of the optic chiasm.

## HIDING IN THE CORNER: A SIMPLIFIED APPROACH TO CEREBELLOPONTINE ANGLE LESIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Joshua Russell (*Abstract Co-Author*) Nothing to Disclose
Madhurya Amirapu, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The CP angle is an anatomically complex region. It houses numerous structures such as cranial nerves (V, VI, VII), blood vessels, and cerebrospinal fluid spaces. Understanding the normal anatomy is crucial for interpreting abnormalities in this region. Involvement of the various structures here may have independent and/or overlapping symptoms. For example, extending a CP angle mass into the Dorello canal, a bony channel through which the abducens nerve travels from the prepontine cistern to the cavernous sinus, may present with lateral rectus muscle palsy. Cerebellopontine angle lesions can be divided into tumor and non-tumor lesions. The most common tumor lesions -Vestibular schwannoma (acoustic neuroma), Meningioma, Epidermoid Cyst, Arachnoid Cyst, Ependymoma, Lipoma, Dermoid, Primary malignancy (Lymphoma and Melanoma), Metastatic disease, Facial nerve and Vestibular nerve schwannomasThe most common non-tumor lesions -Aneurysm/Vertebrobasilar Dolichoectasia and Anterior Inferior Cerebellar Artery Loop.Cerebellopontine lesions typically demonstrate differentiating imaging characteristics, mostly evaluated on MRI and CT Brain.

### TABLE OF CONTENTS/OUTLINE

Normal cerebellopontine angle anatomy including surrounding structures.Involvement of the various structures in this region and their possible clinical presentations (table and image examples).Common and few less common cerebellopontine angle lesions and epidemiological /syndromic correlation, if present (table/chart). Masses and their characteristic imaging features (images/case examples). Non tumor cerebellopontine lesions (table/image examples ). Radiologic pitfalls.Take home points/summary. References.

## REVIEW OF THE LILIEQUIST MEMBRANE AND ITS SIGNIFICANCE IN NEUROIMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Julie B. Guerin, MD (*Abstract Co-Author*) Nothing to Disclose
John C. Benson, MD (*Abstract Co-Author*) Nothing to Disclose
Edward Ahn, MD (*Abstract Co-Author*) Nothing to Disclose
V. Michelle Silvera, MD (*Abstract Co-Author*) Nothing to Disclose
Norbert G. Campeau, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Hayden Swartz, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. The Liliequist membrane (LM) is an important landmark for both neuroradiologists and neurosurgeons to identify on preoperative and intraoperative examinations for CSF diversion, masses involving the floor of the third ventricle, and endoscopic third ventriculostomy (ETV) patency. 2. The LM is best visualized using MRI with thin-section, heavily T2-weighted imaging such as with balanced steady-state free procession (bSSFP) sequences such as FIESTA and CISS. Flow signal through ETV sites is best demonstrated using spin echo-based techniques such as T2 FSE, T2 SPACE or CUBE sequences.

### TABLE OF CONTENTS/OUTLINE

1. Defining the LM and its anatomy: Illustrate the three main components of the LM and their anatomic relationships with adjacent suprasellar and hypothalamic structures. 2. History of the LM. 3. Imaging technique: Emphasize the importance of thin-section, heavily T2-weighted imaging for anatomic visualization of the LM, and FSE-based techniques for functional assessment of flow through an ETV. 4. Review a series of cases in which the LM is visualized before and/or after endoscopic third ventriculostomy. 5. Review a series of cases in which the LM is indirectly depicted by subarachnoid contrast, subarachnoid hemorrhage, or by mass effect secondary to lesions in the suprasellar or prepontine cisterns.

## VARYING SHADES OF EPIDERMOID TUMORS - THE BLACK, THE WHITE AND EVERYTHING IN BETWEEN

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Rita G. Bhatia, MD (*Abstract Co-Author*) Nothing to Disclose
Natalya Nagornaya, MD (*Abstract Co-Author*) Nothing to Disclose
Gaurav M. Saigal, MBBS (*Abstract Co-Author*) Nothing to Disclose
Hamilton Trinh, MD (*Abstract Co-Author*) Nothing to Disclose
Denver S. Pinto, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

At the end of this exhibit, the reader should be able to:1. Identify key imaging features of epidermoid tumors and its subtypes2. Differentiate epidermoid tumors from its differential diagnoses3. Understand the clinical presentation and symptoms associated with epidermoid tumors

### TABLE OF CONTENTS/OUTLINE

Pathophysiology of epidermoids - Anatomy and patterns of growth of epidermoid cystsClinical PresentationCase discussion with imaging findings with a focus on MRI findings especiallya) Diffusion restrictionb) White Epidermoids, Dark epidermoids and varying patterns of intermediate signalc) Sites of epidermoid tumor,Sites of epidermoids:Intradural:a) Extraparenchymal: Cerebello-pontine angle, Suprasellar cistern, Middle cranial fossa, Anterior cranial fossa, Interhemispheric fissureb) Intraparenchymal: Temporal lobe, frontal lobec) Intraventricular: Fourth ventricle,Extradural: Intradiploic, Intraorbital,Extradural sites: Calvarium,,Differential diagnosis: 1. Arachnoid cyst (for the extra-axial type) 2. Dermoid cyst, Neurenteric cyst (for the midline location) 3. Cystic Schwannoma (for the cerebellopontine angle) 4. Craniopharyngioma (For the skull base location) 5. Developmental neuro-epithelial tumor (DNET) and Multi-nodular and vacuolating neuronal tumor (MVNT) --> for the intra-parenchymal location 6. Ependymoma, Subependymoma, Medulloblastoma (for the intraventricular location),,Complications: 1. Malignant degeneration 2. Chemical meningitis/ aseptic meningitis with and without hydrocephalus 3. Spontaneous hemorrhage,,Goals of treatment:

James H. Yared, MD (*Abstract Co-Author*) Nothing to Disclose
Bernardo C. Teixeira, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Standard imaging signs of CNS lymphoproliferative disorders as revealed by MRI and CT. 2. Advanced imaging techniques such as MRI spectroscopy, diffusion-weighted imaging, and perfusion imaging are indispensable for distinguishing CNS lymphoproliferative disorders from other neurological disorders and assessing tumor aggressiveness. 3. These techniques provide intricate insights into the metabolic activity, cellular density, and vascularity of lesions, facilitating differentiation from other neurological pathologies and offering crucial information regarding tumor aggressiveness. 4. Accurate imaging interpretation informs treatment decisions and aids in monitoring therapeutic outcomes. 5. The precise interpretation of imaging findings serves as a cornerstone in guiding treatment strategies and monitoring therapeutic responses, highlighting the indispensable role of neuroradiologists in the comprehensive care of patients with CNS lymphoproliferative disorders.

### TABLE OF CONTENTS/OUTLINE

1. Typical Presentation ○ Key Imaging Characteristics of CNS Lymphoma and Other Lymphoproliferative Disorders 2. Common Imaging Findings ○ Brain Manifestations of Lymphoma ○ Manifestations of Other Lymphoproliferative Disorders (*Intravascular Lymphoma, MALT Lymphoma of the Dura, Lymphomatosis Cerebri*) 3. Atypical Presentations ○ Diverse Imaging Findings Across Unusual Sites: Eyes, Spinal Cord, Leptomeninges, Cerebellum/Brainstem, and Other Locations 4. Advanced Imaging Techniques ○ Application of MR Perfusion and MR Spectroscopy in Differential Diagnosis

Fabiano Reis (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Magnetic resonance imaging (MRI) plays a fundamental role in the diagnosis of leukodystrophies.Recognition of patterns on MRI includes differentiation between hypomyelinating and demyelinating patterns of white matter,distinguishing between diffuse and multifocal abnormalities,evaluating the predominant location of abnormalities,and identifying specific characteristics such as cystic degeneration of white matter,anterior temporal cysts,megalencephaly,increased perivascular spaces or small cysts,additional gray matter lesions,contrast enhancement,calcium deposits,microhemorrhages,spinal cord involvement,cranial nerves thickening and enhancement.Some spectroscopy findings may also suggest the diagnosis:in Canavan’s disease there is an increase in the NAA peak;a peak of alpha-glutamate concentrations (at 3.75 ppm) is observed in 18q Deletion Syndrome.MRI may lead to a specific diagnosis, suggest the appropriate genetic test to confirm the diagnosis,and have contributions in monitoring disease progression,and therapeutic responses.

### TABLE OF CONTENTS/OUTLINE

IntroductionCase-based review of leukodystrophies:Metachromatic leukodystrophyKrabbe diseaseX-linked adrenoleukodystrophyCanavan diseaseAlexander diseaseL-2-hydroxyglutarig acid uriaLeukoencephalopathy involving the brainstem and spinal cord with elevated lactate.Sjogren-Larsson syndromePropionic acidemia18q Deletion SyndromePOLR3B-related Hypomyelinating Leukodystrophy Adult-Onset Leukoencephalopathy with Axonal Spheroids and Pigmented GliaMegalencephalic leukoencephalopathy with subcortical cystsFinal remarks and take home messages

Luiza A. Nahoum, MD (*Abstract Co-Author*) Nothing to Disclose
Luis A. Quevedo (*Abstract Co-Author*) Nothing to Disclose
Pedro A. Gama Carpentieri Primo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Importance of Structured Reporting- Emphasize the significance of a structured reporting format in providing comprehensive and consistent information to referring physicians and other healthcare providers. - Highlight how structured reports facilitate better understanding and interpretation of findings.2. Enhancing Communication - Encourage radiologists to use standardized terminology and formats to minimize ambiguity and misinterpretation of findings.3. Avoidance of Errors - Educate radiologists on errors in reporting pituitary macroadenomas, such as incomplete descriptions of tumor characteristics or failure to assess critical anatomical relationships.4. Clinical Decision Support - Highlight the role of structured reports in providing essential information for clinical decision-making, including tumor characteristics, proximity to critical structures, and potential treatment implications.

### TABLE OF CONTENTS/OUTLINE

1. Introduction- Overview of Pituitary Macroadenomas - Importance of Reporting and Diagnosis2. Characteristics of Pituitary Macroadenomas - Signal Intensity - Presence of Lobulation - Suprasellar Growth - Infrasellar Growth3. Relationship with Neighbor Structures - Optic Chiasm - Third Ventricle - Clivus - Sphenoid plane4. Remodeling of the Sellar Floor5. Type of Sphenoid Sinus Pneumatization6. Knosp Classification - Predicting Cavernous Sinus Invasion7. Presence and Importance of Onodi Cell8. Measure and Relevance of Intercarotid Distance9. Differential diagnosis - Red Flags that may point to other diagnosis10. Conclusion - Importance of Comprehensive and Structured Reporting - Clinical Implications

Janghoon Oh (*Abstract Co-Author*) Nothing to Disclose
Hyug-Gi Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Jeong Taek Yoon, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Deep learning has advanced AI in medical imaging, leading to significant improvements but also creating challenges like the need for extensive training data and laborious labeling. Generative Adversarial Networks (GANs) generate synthetic images for data augmentation and simplify medical image processing, enhancing efficiency and enabling unsupervised anomaly detection, thus reducing reliance on labeled datasets. Our investigation into GANs in medical imaging addresses their varied architectures, the considerations for selecting appropriate GAN models, and the nuances of model training and performance evaluation. This presentation aims to provide radiologists who are new to GAN technology with a thorough understanding, guiding them through the practical application and evaluation of GANs in brain imaging with two illustrative examples. It offers a comprehensive exploration of the transformative potential of GANs in medical imaging research. Ultimately, this paper strives to equip radiologists with the knowledge to effectively utilize GANs, encouraging further research and application within the field.

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. GAN architecture, hierarchy, and variants 3. Selecting the appropriate GAN for the research objectives 4. Input data training 5. Performance evaluation 6. Conclusion

Paula Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza Ambrozino, MD (*Abstract Co-Author*) Nothing to Disclose
Luis A. Quevedo (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This education exhibit provides an analysis of solitary fibrous tumors involving the central nervous system (SFT-CNS), which can often be misdiagnosed as meningiomas due to their rarity and similar imaging characteristics. Through the analysis of 8 consecutive cases treated in our hospital between 2014 and 2024, this exhibit aims to highlight the clinical, histopathological, and MRI characteristics of SFT-CNS. The purpose of this study are - To discuss the clinical and histopathological characteristics of SFT-CNS. - To demonstrate the main magnetic resonance imaging (MRI) findings in SFT-CNS. - To present 8 consecutive cases with histopathological confirmation treated in our hospital between 2014 and 2024. - To compare the imaging findings of differential diagnoses. - To enhance recognition of this uncommon pathology among radiologists.

### TABLE OF CONTENTS/OUTLINE

- Introduction - Clinical and Histopathological characteristics of SFT-CNS. - Main imagen features of SFT-CNS. - Compare the imaging findings of differential diagnoses, particularly with those of meningioma. - Cases of Patients with a Histopathological Diagnosis of SFT-CNS.

Yusuf Alibrahim, BMedSc, MD (*Abstract Co-Author*) Nothing to Disclose
Jiwon Oh, FRCPC,PhD (*Abstract Co-Author*) Nothing to Disclose
Timothy Reynold U. Lim, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Pathologic features of multiple sclerosis (MS) include perivenular demyelination, inflammation and neurodegeneration; active lesions predominate in relapsing-remitting, and smoldering lesions and neuroaxonal loss in progressive forms.Conventional MRI findings, while currently still the most used imaging biomarkers, lack pathologic specificity and only moderately correlate with disease activity and disability in MS.MRI biomarkers more specific to MS pathology are emerging; the two furthest along in clinical development are the central vein sign (CVS) and paramagnetic rim lesions (PRLs).CVS reflects perivenular demyelination and is highly specific and sensitive for distinguishing MS from mimics.PRLs represent lesions with chronic active inflammation along the lesion edge are also useful for diagnosis and prognosis across the entire MS spectrum.Other biomarkers such as brain and spinal cord volumetric measures, cortical lesions and leptomeningeal enhancement have also shown prognostic utility in MS.

### TABLE OF CONTENTS/OUTLINE

A. Pathologic basis of imaging biomarkers in MSa. MS involves both gray and white matterb. Perivenular inflammatory demyelinationc. Neurodegeneration in MSi. Neuroaxonal lossii. Chronic active "smoldering" lesionsB. Conventional MRI biomarkersa. T2/FLAIR lesionsi. 2017 McDonald Criteriaii. Prognostic utility of T2 lesion burdeniii. Optic nerve as 5th location for DISb. Gadolinium-enhancing lesionsc. T1 black holesC. Emerging MRI biomarkersa. CVSb. Chronic active lesionsi. PRLii. Slowly expanding lesionsc. Cortical lesionsd. Leptomeningeal enhancemente. Volumetric measuresi. Brain (global / regional) atrophyii. Spinal cord atrophy

## IMAGING INSIGHTS ON CHILDHOOD STROKE - SHEDDING LIGHT ON A CHALLENGING CONDITION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Luiz Borella (*Abstract Co-Author*) Nothing to Disclose
Fabiano Reis (*Abstract Co-Author*) Nothing to Disclose
Gustavo Yamada, MD (*Abstract Co-Author*) Nothing to Disclose
Thiago Costa Haiter, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Stroke in children raises concern to healthcare, due increasing incidence. The etiology is multifactorial, and this study emphasizes the main arterial etiologies of stroke, based on "The Childhood Arterial Ischemic Stroke Standardized Classification and Diagnostic Evaluation (CASCADE) criteria", searching for the best imaging findings, to assist accurate diagnoses. It subdivides into primary causes and secondary causes. Illustrated findings in original cases of "Moya-Moya" disease, carotid dissection in aortic/cervical arteriopathy, bacterial meningitis, viral infectious vasculitis (varicella zoster and COVID-19), occlusive vasculopathy due to Sickle Cell Disease and inflammatory vasculitis due to Behēet and Lupus are highlighted in the study, as well the main stroke mimics to keep in mind, especially hemiplegic migraine and posterior reversible encephalopathy syndrome (PRES). Ultimately, the study delves into the pitfalls, which must be considered to guarantee accurate diagnosis. The study seeks to improve diagnosis inchildren who can greatly benefit from an early diagnosis, allowing the expansion of future estudies and treatments, bringing greater quality of life to patients.

### TABLE OF CONTENTS/OUTLINE

- Introduction - Epidemiology of stroke in Children - The Childhood Arterial Ischemic Stroke Standardizes Classification and Diagnostic Evaluation(CASCADE) criteria Illustrated. - Main clinical manifestations - Diagnostic clues - Imaging investigation (cases and Imaging findings) in primary and secondary causes - Differential diagnoses and stroke mimics - Pitfalls

## EXPLORING NEURAL PATHWAYS - AI METHODS IN DIPY FOR ADVANCED NEUROANATOMICAL STUDIES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Serge Koudoro, MSc (*Abstract Co-Author*) Nothing to Disclose
Eleftherios Garyfallidis (*Presenter*) Nothing to Disclose

### TEACHING POINTS

As datasets expand and analysis methodologies evolve, the demand for sophisticated computational resources and techniques intensifies. The Diffusion Imaging in Python (DIPY) community has cultivated a robust open source software ecosystem designed for the analysis of structural and diffusion MRI data. Throughout this exhibit, we will embark attendees on a journey to: A) Explore advanced AI tools within DIPY (Diffusion Imaging in Python) for MRI data analysis. B) Highlight key methodologies addressing common research challenges. C) Showcase innovative techniques like EVAC+ for brain extraction. D) Discuss the role of generative AI in segmentation enhancement. E) Introduce Patch2Self2 for denoising and its extensions. F) Survey distortion correction methods, including style transfer. G) Present statistical analysis capabilities and tract analytics in DIPY. H) Demonstrate Tractometry with Bundle Analytics 2.0 and BundleWarp. E) Present a novel method for direct data harmonization.

### TABLE OF CONTENTS/OUTLINE

This exhibit offers a hands-on exploration of a community-driven open-source ecosystem (DIPY), vital for analyzing structural and diffusion MRI data. Attendees will deepen their understanding of MR imaging, gain insights into MR imaging and stay updated on the latest advancements. Specific topics like brain extraction techniques, distortion correction methods, and data harmonization will be covered. A focus on tractometry will demonstrate to attendees how to enable detailed group comparisons and identification of statistically significant differences in tract properties between populations. We wrap up with reflections on advancements made and future directions in MRI data analysis.

### TEACHING POINTS

This educational exhibition provides a comprehensive overview of the imaging evaluation of pediatric patients with vascular intracranial emergencies. Imaging patterns, differential diagnoses, and potential pitfalls in imaging interpretation will be addressed, as well as etiology categorization and classifications for the most common vascular emergencies, aiming at a broad review of the theme. The purpose of this exhibition is to: Provide an overview of the imaging evaluation of pediatric patients with vascular intracranial emergencies. Highlight specific imaging patterns and features that may suggest the etiology discussing differential diagnosis and potential pitfalls in imaging interpretation. Use case studies to illustrate radiological challenges and diagnostic considerations.

### TABLE OF CONTENTS/OUTLINE

1 Clinical presentation and etiologyOverview of clinical presentation of pediatric intracranial vascular emergency divided by hemorrhagic, ischemic and thrombotic etiologies. 2 Ischemic Disorders: Inflammatory Arteriopathy Focal cerebral arteriopathy, Primary or Secondary vasculitis. 3 Ischemic Disorders: Non-Inflammatory Arteriopathy Dissection, Moyamoya patterns and Genetic etiologies. 4 Hemorrhagic disorders: Coagulation disorders and Germinal Matrix Hemorrhage. Aneurysm, Vein of galen aneurysmal malformation, Arteriovenous malformations, Germinal matrix hemorrhage, Cerebral proliferative angiopathy, Cavernous angiomas, Cerebrofacial arteriovenous metameric syndrome (CAMS), Dural arteriovenous fistula and Coagulation disorders 5 Cerebrovenous Thrombosis Cerebral Venous Sinus Thrombosis, Cortical Vein Thrombosis, Medullary Vein Thrombosis

## LOST IN THE LABYRINTH: REVIEW OF THE INNER EAR AND ITS CONGENITAL MALFORMATIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Andres F. Caliz Cabrales, MD (*Abstract Co-Author*) Nothing to Disclose
Julian M. Gandur, MD (*Abstract Co-Author*) Nothing to Disclose
Oreanna Quintero, MD (*Abstract Co-Author*) Nothing to Disclose
Jesus Eduardo Barreto Fernandez (*Abstract Co-Author*) Nothing to Disclose
Sara Gomez Milanes, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This poster provides a review of the anatomy and embryology of the inner ear; this review aims to facilitate a better understanding of why congenital malformations occur and to aid in their identification. Additionally, each malformation will be reviewed, and an algorithm will be provided to assist in reaching a diagnosis easily. The poster also correlates these malformations with the most important syndromes associated with them, highlighting the importance of understanding genomics in the study of these malformations and their relationship with various genetic syndromes. The objective is to provide radiologists with a reference tool that simplifies the understanding of this topic, often considered a "labyrinth," and demystifies the inner ear by offering a clear and concise overview of its structure, embryonic development, and associated pathologies.

### TABLE OF CONTENTS/OUTLINE

Objectives; Importance of timely identification of congenital malformations of the inner ear; Embryology; Anatomy; Congenital malformations of the inner ear and their classification systems; Concise review of each congenital malformation correlating them with their respective embryonic developmental failure and imaging cases. Including: Complete labyrinthine aplasia, Rudimentary otocyst, Cochlear aplasia, Common cavity, Cochlear hypoplasia, Incomplete partition, Enlarged vestibular aqueduct, Abnormalities in the bony canal and cochlear nerve; Diagnostic algorithm; Imaging cases resolved using the diagnostic algorithm; Link between inner ear development, brain, and body: Clues for many diagnoses; Gallery of normal images of the inner ear; Bibliography

### TEACHING POINTS

Transcranial ultrasound has emerged as a valuable modality in neuroimaging due to its versatility, non-invasive nature, and low cost, offering real-time evaluation of cerebral hemodynamics and pathologies.The purpose of this exhibit is to review current applications and advancements in transcranial ultrasound techniques for adults with actual case examples, emphasizing the clinical significance of Grey Scale, Duplex Doppler, and Contrast-Enhanced modalities.

### TABLE OF CONTENTS/OUTLINE

Introduction to Transcranial Ultrasound a. Anatomy and Approaches b. Overview of ultrasound techniques: Grey Scale, Duplex Doppler, and Contrast-Enhanced UltrasoundClinical Applications of Transcranial Ultrasound in Adults a. Detection and monitoring of vasospasm in subarachnoid hemorrhage b. Evaluating cerebral stenosis with Duplex Doppler c. Management of sickle cell disease via flow velocity assessments d. Identification and implications of internal carotid artery occlusion e. Diagnosing brain death f. Real-time monitoring of emboli g. Detecting vascular lesions amenable to interventional treatment h. Assessing reperfusion post-thrombolysis i. Role in diagnosing vertebrobasilar insufficiency j. Contribution to the diagnosis of Parkinson’s disease k. Detection and follow-up of raised intracranial pressure l. Identification of right-left shunt m. Assessment of cerebrovascular reserve capacityResearch Frontiers in Transcranial Ultrasound a. Quantifying brain perfusion with contrast-enhanced ultrasoundConclusion a. Summarize the impact of transcranial ultrasound on radiological practice and its potential future applications

## DOWN THE PATH OF NEURONAL INJURY AND AXONAL DEGENERATION: PATHOLOGIC MECHANISMS AND IMAGING FINDINGS BEYOND WALLERIAN CHANGES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Cum Laude**

Nancy Margarita Gutierrez Castaneda, MD (*Abstract Co-Author*) Nothing to Disclose
Michelle Y. Gonzalez Putoy SR, MD (*Abstract Co-Author*) Nothing to Disclose
Griselda T. Romero Sanchez, MD (*Abstract Co-Author*) Nothing to Disclose
Carlos Zamora, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Angela M. Sosa, MD, MSc (*Presenter*) Nothing to Disclose

### TEACHING POINTS

After completing this exhibit, the viewer will be able to:Summarize the different types of axonal degeneration, including classic Wallerian degeneration versus non-Wallerian changes.Identify the main molecular mechanisms and pathways underlying axonal degeneration: NAD+ metabolism, mitochondrial dysfunction,and necroptosis.Describe axonal degeneration during aging and its critical role in the pathophysiology of neurodegenerative diseases,such as Alzheimer's disease,Parkinson's disease,amyotrophic lateral sclerosis.Recognize a spectrum of common and atypical imaging patterns of axonal degeneration utilizing a case-base approach.

### TABLE OF CONTENTS/OUTLINE

1.overview of neuronal and axonal structure and function. 2.Types of neuronal degeneration.3.Cellular and molecular basis of axonal degeneration.4.Axonal degeneration in aging and neurodegenerative diseases.5. Case review including:a.Classic Wallerian degeneration along corticospinal tract(acute intramyelinic edema and chronic atrophic changes).b.Pontocerebellar axonal degeneration.c.Degeneration of cranial nerves.d.Cranial and caudal axonal degeneration in the spinal cord.e.Degeneration of mammillary bodies and fornix (e.g,temporal lobe, epilepsy/mesial temporal sclerosis).f. Optic nerve degeneration(e.g.,phthisis bulbi).g.Degeneration atrophy(e.g.,tongue[CNXII],masticador muscles[CNV],shoulder muscles[brachial plexus].hHypertrophic olivary degeneration.i.Neurodegenerative disease.

## PIECING TOGETHER THE PUZZLE OF NEUROTOXOPLASMOSIS: INSIGHTS FROM NEUROIMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Fabiano Reis (*Abstract Co-Author*) Nothing to Disclose
Lazaro F. Amaral, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana T. Raeder, MD (*Abstract Co-Author*) Nothing to Disclose
Gustavo Yamada, MD (*Abstract Co-Author*) Nothing to Disclose
Lua P. Carvalho, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro Tiradentes (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Review and illustrate the imaging findings of neurotoxoplasmosis, discuss the differential diagnoses, and correlate them with pathological images. Describe, through illustrative presentations, the benefits of the multimodality imaging approach for diagnosing neurotoxoplasmosis. Present challenging cases, such as differentiating between neurotoxoplasmosis, primary CNS lymphoma, and other opportunistic infections. Highlight radiological diagnostic pearls of neurotoxoplasmosis.

### TABLE OF CONTENTS/OUTLINE

Neurotoxoplasmosis epidemiology and parasite life cycle. Imaging patterns on MR and CT. Susceptibility-weighted imaging (SWI) as an auxiliary tool for calcified lesions. Spectroscopy and perfusion as valuable tools for differential diagnosis. Imaging findings of post-treatment response. Differential diagnoses derived from a visual examination utilizing illustrative cases sourced from a database at a Tertiary University Hospital. Neurotoxoplasmosis imaging pearls. Final remarks.

## UNVEILING BRAIN METASTASIS RESPONSES TO IMMUNOTHERAPY: MRI INSIGHTS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Laura Oleaga, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nuria Bargallo, MD (*Abstract Co-Author*) Nothing to Disclose
Gary Amseian, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To illustrate the use of immune checkpoint inhibitors in treating brain metastases and the implications on MRI imaging.- To recognize both classical and novel immunotherapy-specific response patterns in brain MRI.- To highlight the importance of utilizing key radiological assessment criteria to standardize response evaluations and outline differences among them.

### TABLE OF CONTENTS/OUTLINE

1. Overview of immune checkpoint inhibitors in the management of brain metastases. 2. Imaging Patterns of Response. A. Classical response patterns: i. Complete response ii. Partial response iii. Stable disease iv. Progression of disease. B. Immunotherapy-specific patterns: i. Pseudoprogression ii. Hyperprogression iii. Durable response. 3. Assessment criteria to standardize response evaluation: A. Comparison of traditional vs Immunotherapy-specific criteria. B. The significance of timing in distinguishing pseudoprogression and durable response. C. Addressing ambiguities in response criteria. D. Impact of clinical data on MRI assessment: neurological status, systemic therapy, and local treatments. 4. Spotting immune-related intra- and extracranial adverse events on imaging. 5. Brain MRI protocols and the potential of advanced techniques. 6. Conclusion

## CRACKING THE FETAL CENTRAL NERVOUS SYSTEM MRI: THE BIG PICTURE FOR RADIOLOGIST TRAINEES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Samuel Castillo, MD (*Abstract Co-Author*) Nothing to Disclose
Aura Maria M. Gonzalez Peralta, MD, MD (*Abstract Co-Author*) Nothing to Disclose
Genier Fabian Castano Lizarazo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To assess the indications and techniques of neuro-fetal MRI in order to evaluate the main central nervous system anomalies.- To describe systematic evaluation of normal fetal central nervous system MRI. - To outline the main five fetal central nervous system pathologies as well as pearls and pitfalls that every radiologist must recognize.- To ilustrate through real-life cases assessment of fetal central nervous system pathologies at antenatal and postnatal follow-up MRI.

### TABLE OF CONTENTS/OUTLINE

1. Introduction to Central Nervous System fetal pathologies: epidemiology, indications, and MRI technique. 2. Evaluation of normal Central Nervous System fetal development at various gestational periods through MRI: A step-by-step guideline. 3. MRI assessment of the five main Central Nervous System fetal anomalies: pearls and pitfalls for radiologists trainees. 3a: Abnormal fetal Central Nervous System cortical layering, gyration, and sulcation. 3b: Fetal ventriculomegaly. 3c: Midline anomalies: holoprosencephaly, corpus callosum agenesis-dysgenesis. 3d: Posterior fossa anomalies. 3e: Spinal dysraphism. 4. Presentation of five captivating cases of cetal Central Nervous System pathologies antenatally diagnosed at a national perinatology ķnstitute with postnatal follow-up MRI. 5. Conclusions: what is the future of fetal Central Nervous System MRI?

## DIAGNOSTIC IMAGING OF PEDIATRIC SUPERFICIALLY/CORTICALLY-BASED BRAIN TUMORS: NAVIGATING COMMON AND COMPLEX CASES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Fabricio G. Goncalves, MD (*Abstract Co-Author*) Nothing to Disclose
Carmen Rosa Cerron Vela (*Abstract Co-Author*) Nothing to Disclose
Mario Mahecha, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1 Stress early and accurate diagnosis for better outcomes.2 Discuss challenges in diagnosing pediatric tumors like PXA and Ganglioglioma, focusing on their unique imaging features.3: Emphasize recognizing mimics like NCC and cortical tubers, detailing differentiation strategies with advanced MRI.4 Highlight MRI advancements for enhanced tumor visualization and diagnostic accuracy.5: Promote integrated diagnostic strategy, merging imaging, clinical assessment, and genetic profiling for precise and tailored diagnosis.

### TABLE OF CONTENTS/OUTLINE

Objective: Enhance diagnostic accuracy for pediatric brain tumors and mimics.OutlineIntroduction: Stress the importance of precise diagnosis in pediatric neuroimaging.Specific TumorsPXA Discuss MRI features to differentiate from high-grade gliomas.DNET Emphasize the "bubbly" appearance and its link to epilepsy.MVNT: Describe imaging characteristics that may appear aggressive.PLNTY Explain classification and MRI signals.DGONC Highlight difficulties in recognizing diffuse patterns.Ganglioglioma: Cover typical features including calcifications and cystic changes.DIG: Identify key diagnostic features like large cystic components and robust reaction.DLGNT: Discuss its presentation as diffuse leptomeningeal lesions, emphasizing diagnostic challenges.Cerebellar Hemangioblastomas Discuss association with VHL syndrome.Lhermitte Duclos Syndrome: Describe the "tiger-striped" MRI appearance and Cowden syndrome link.Tumor Mimics: Strategies for distinguishing mimics like neurocysticercosis and cortical tubers using advanced imaging.Cases: Present cases illustrating diagnostic challenges and typical scenarios.

## SPINAL CSF LEAKS: TYPICAL AND ATYPICAL APPEARANCES AT CT MYELOGRAPHY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Magna Cum Laude**

Daniel J. Scoffings, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
David Butteriss (*Abstract Co-Author*) Nothing to Disclose
Neha Kallam, BSc, MBBS (*Abstract Co-Author*) Nothing to Disclose
Anoma Lalani Carlton Jones, MBBS, FRCR (*Presenter*) Nothing to Disclose

### TEACHING POINTS

After viewing this exhibit the learner will be to:1. Describe the different types of spinal CSF leak that lead to spontaneous intracranial hypotension.2. Recognise the most common appearances at CT myelography that occur in each type of spinal CSF leak.3. Evaluate some of the atypical imaging manifestations of spinal CSF leaks at CT myelography.

### TABLE OF CONTENTS/OUTLINE

OUTLINE: Spinal CSF leaks have gained increased recognition over the last decade with advances in myelography and scanning techniques, imaging resolution and scanner capabilities. Our understanding of the causative pathologies are ever evolving as new techniques come to light. Dynamic CT myelography is a useful tool for detection of such leaks provided that meticulous technique is utilized. This educational exhibit will review the range of pathologies that can be encountered in the adult and paediatric population with examples of all different types of leaks from ventral and dorsal dural tears, lateral leaks, CSF venous fistulas, with typical and more atypical appearances of each, as well some lesser known and recognized entities including loculated leaks and CSF venous malformations and genetic associations. CONTENTS (1) Classification of spontaneous spinal CSF leaks. (2) Types of dynamic CT myelography and when to use them. (a) Ultrafast dynamic. (b) Modified dynamic. (c) Lateral decubitus (3) Provocation maneuvers at CT myelography. (4) Appearances of spontaneous leak types at CT myelography. (a) Ventral (type 1) leaks. (b) Lateral (type 2) leaks. (c) CSF-venous fistulas. (5) Less common forms of spinal CSF leak. (a) CSF-venous malformation fistula. (b) Arachnoid ‘blebs’. (6) Pitfalls and mimics (7) The negative or equivocal CT myelogram.

Shravan Reddy K, MBBS (*Abstract Co-Author*) Nothing to Disclose
Shreyas Reddy K, MBBS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Spontaneous intracranial hypotension (SICH) is a clinical syndrome due to diminished intracranial pressure, leading to disruptions in the homeostasis among blood, cerebrospinal fluid (CSF), and cerebral parenchyma. • SICH stems from three primary causes: (1) CSF leak originating from a nerve root sleeve diverticulum; (2) CSF leak attributed to an osteophyte spur, and (3) CSF venous fistula (CVF). • A range of modalities is employed to assess the underlying condition, including computed tomographic (CT) myelography, dynamic CT myelography, digital subtraction myelography, magnetic resonance (MR) imaging, and MR myelography with intrathecal gadolinium. Selection among these modalities is contingent upon whether the leak is characterized as high or low flow. • A targeted epidural patch using autologous blood or fibrin glue is an effective intervention.

### TABLE OF CONTENTS/OUTLINE

• Understanding the pathophysiology and clinical features of SICH. • Discuss in detail the brain and spine imaging findings of SICH, with emphasis on key findings. • Myelographic patterns of SCIH: Tips for identification. • Basics, step-by-step technical approach, and limitations of CT myelography, Dynamic CT myelography, Digital subtraction myelography and MR myelography. • Epidural blood patch: technique and limitations. • Diagnostic approach and management algorithm for SICH.

### TEACHING POINTS

Through this pictorial essay will be made a review based on cases and original drawings about the pathologies of the carotid arteries. This will be addressed by typical imaging patterns to narrow down differential diagnoses. The purpose of this exhibition is to: - Review the anatomy of the carotid arteries; - Understand the advantages and limitations of the main imaging methods used to evaluate carotid pathologies; - Recognize the main imaging patterns of the most frequent carotid artery diseases.

### TABLE OF CONTENTS/OUTLINE

ANATOMICAL CONCEPTS • Carotid arteries anatomy IMAGING ASSESSMENT METHODS • Ultrasound • Computerized Tomography • Magnetic Resonance Imaging CAROTID ARTERIES DISEASES • Imaging aspects of carotid pathologies • Teaching points to narrow down differential diagnoses INTERACTIVE CASE-BASED DIDACTICS • Sample cases to illustrate and solidify the concepts

Shadi Ebrahimian, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Accurate interpretation of post lumbar spinal surgery images is critical for radiologist. This educational exhibit focuses on the following topics:1. What are the imaging protocols used in post spinal surgery evaluation?We will explain different modalities including radiographs, CT, and MRI and the protocols used on each modality.2. How to evaluate post-operative radiographs?Different radiographic postsurgical complications will be explained including hardware fracture, loosening, et. 3. What is considered as normal postsurgical changes on CT/MRI?Expected postsurgical findings will be explained. 4. What are the early postsurgical complications on CT/MRI? Early complications including fluid collection, intraoperative vascular and neural injuries, hardware malpositioning, and possible intracranial hemorrhage will be shown. 5. What are the late complications?Late postsurgical changes such as infection, failed back surgery syndrome, pseudoarthrosis, and hardware failure will be discussed. 6. What are the challenges in evaluation of postsurgical CT and MRIs and what are the strategies to overcome those challenges?Streak artifacts related to the hardware is one of the most common limitations in evaluation of postoperative CT and MRI scans. The strategies in reducing these artifacts will be discussed.

### TABLE OF CONTENTS/OUTLINE

1. Commonly used modalities and protocols in postoperative imaging.2. Expected findings and postsurgical complications on radiographs.3. Normal post-surgical CT/MRI findings.4. Early complications on CT/MRI.5. Late complications on CT/MRI.6. Challenges in evaluation of postsurgical CT/MRI images.7. Strategies to reduce hardware related artifacts.

### TEACHING POINTS

To understand some key clinical and radiological manifestations of Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS).To provide clues for identifying imaging patterns suggestive of ICANS for prompt diagnosis and intervention.

### TABLE OF CONTENTS/OUTLINE

Chimeric antigen receptor (CAR) T cells targeting the CD19 cell surface glycoprotein have emerged as a highly effective immunologic therapy in patients with certain refractory hematologic malignancies. The engagement of these two cell receptors causes a systemic cytokine release, which can compromise the blood-brain barrier and cause an immune effector cell-associated neurotoxicity syndrome (ICANS).ICANS is a pattern of neurotoxicity observed in patients following CAR T-cell infusion with associated neurologic symptoms, such as headaches and confusion. Neuroimaging is frequently obtained in patients who present with acute neurologic changes after infusion. This pictorial review aims to summarize some of the neuroimaging findings in ICANS through illustrative cases from our institution.1. Brief overview of the fundamentals of CAR-T cell therapy and ICANS pathophysiology.2. Clinical presentation and grading severity of ICANS (ASTCT consensus).3. Neuroimaging findings. While typically yielding negative results, imaging is advised when encountering suspected ICANS cases. Such imaging is crucial for detecting brain oedema and other abnormalities including stroke, haemorrhage, leptomeningeal enhancement, and mass effect, among others. - CT and brain MRI imaging findings. - Main entities to be considered in the differential diagnosis of ICANS.- Other CNS complications following CAR-T cell therapy.

### TEACHING POINTS

Cavernous malformations (CMs) are slow flow vascular malformations most commonly found in the brain and spinal cord. The clinical significance of CMs lies in their potential to cause various neurological symptoms and complications such as bleeding, seizures, neurological deficits, and headaches. Once a CM is diagnosed, the risk of bleeding needs to be addressed, the likelihood of which depends on factors such as location and the presence of certain genetic mutations in the patient. Diagnosing a CM on imaging can be challenging if atypical imaging features are present and when CMs are very large (giant) or infiltrative. Treatment options include observation with surveillance imaging, surgical resection, stereotactic radiosurgery, and laser interstitial thermal therapy (LITT). TEACHING POINTS:1. CMs can lead to a range of neurological symptoms and complications, such as bleeding, seizures, neurological deficits, and headaches. 2. Specific genetic mutations may result in Familial Cerebral Cavernous Malformation Syndrome (FCCM), increasing the likelihood in children of developing CMs throughout their lives. 3. CMs located in critical areas such as the brainstem are at higher risk to bleed, rebleed, and cause neurological deficits. 4. Giant and infiltrative CMs are often misdiagnosed and not considered in the list of potential diagnoses before surgery.

### TABLE OF CONTENTS/OUTLINE

1. Define CMs and describe their typical imaging appearance. 2. Discuss atypical imaging features that complicate CM diagnosis. 3. Review FCCM and illustrate the three main types with case examples. 4. Review the imaging features of Giant CMs 5. Demonstrate the imaging features of Infiltrative CMs.

### TEACHING POINTS

1. Photon-counting detector (PCD-) CT offers unique advantages over traditional energy-integrating detector (EID-) CT in neuroradiology. 2. The primary inherent benefit of PCD- over EID-CT is the ultra high spatial resolution, with slice thickness on the order of 0.2mm. 3. High yield diagnostic applications in neuroradiology include temporal bone CT, CT angiography (CTA) of the head and neck, CT venography (CTV) of the head, and CT myelography (CTM). 4. Other/emerging applications include head CT and face/sinus/orbit CT.

### TABLE OF CONTENTS/OUTLINE

I. Brief review of relevant physics aspects of PCD-CT, compared to EID-CT. II. PCD-CT in temporal bone imaging a. Anatomy b. Case based pathology III. PCD-CTA a. Head CTA anatomy b. Distinguishing infundibula and aneurysms c. Evaluating aneurysms, both untreated and treated d. Assessing arterial stenoses e. Other (additional case based pathology) IV. PCD-CTV a. Anatomy b. Dural venous sinus thrombosis c. Idiopathic intracranial hypertension V. PCD-CTM a. Lateral decubitus imaging of CSF-venous fistulae b. Dynamic imaging of high-flow CSF leaks VI. Emerging applications (case based anatomy and pathology) a. Head CT b. Face/sinus/orbit CT

### TEACHING POINTS

1. To review the anatomy and embryology of the posterior fossa on fetal and postnatal MRI. 2. To describe congenital anomalies of the posterior fossa with emphasis on non-cystic anomalies, describing their distinctive imaging features and accompanying effects on the cerebellum and the brainstem. 3. To advance understanding of non-cystic posterior fossa anomalies by highlighting specific imaging phenotypes and pattern-based approaches on antenatal and postnatal MRI.

### TABLE OF CONTENTS/OUTLINE

1. Discuss various disease entities resulting in posterior fossa anomalies. 2. Identify salient imaging features of non-cystic posterior fossa disorders in the fetal and postnatal brain to reach a specific diagnosis. 3. Describe a systematic pattern-based imaging approach to help guide appropriate management and genetic evaluation.

## CAROTID PLAQUES RISK STRATIFICATION: THE APPLICABILITY AND LIMITATIONS OF THE PLAQUE-RADS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Francinne Santos, MD (*Abstract Co-Author*) Nothing to Disclose
Bruna Gontijo, MD (*Abstract Co-Author*) Nothing to Disclose
Leandro T. Lucato, MD (*Abstract Co-Author*) Nothing to Disclose
Cleiton A. Freitas, MD (*Abstract Co-Author*) Nothing to Disclose
Paula Arantes (*Abstract Co-Author*) Nothing to Disclose
Alcivan Morais Filho, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Effective reporting of carotid plaque risk is no longer limited to stenosis measurement and is essential for communication prior treatment decisions. Critical characteristics of plaque, such as ulceration or irregularity, and internal hemorrhage are revealed by axial contrast imaging techniques. These characteristics add to a complete analysis of plaque instability and the risks of the following complications. Plaque-RADS (PR) aims to standardize radiologists, clinicians, and surgeons' communication about carotid plaques. In this system, plaques are divided into: normal vessel walls (PR1); plaques with Maximum Wall Thickness (MWT) <3 mm (PR2); MWT = 3 mm without complications (PR3); thick Fibrous Cap (FC) (3a), thin or invisible FC (3b), and healed ulcers (3c); complicated plaques (PR4) with ulcerations (4a), intraplaque hemorrhage (4b), or intraluminal thrombus (4c). PR has drawbacks, even with its advantages. It may misclassify the risk associated with these plaques since it assumes that those lacking a visible FC are thin-capped. The limitations of fibrous cap visibility make it difficult to classify Categories 3c and 4b, both of which show visible ulceration. The obligation to attribute a category, even under suspicion of limited evaluation, can also be detrimental. Although the system may need to address some of these limitations in order to increase its applicability, it is worthy in order to improve communication.

### TABLE OF CONTENTS/OUTLINE

Presentation with Plaque-RADS and cases of limitations.

Thiago Jose Pinheiro Lopes, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Moyamoya is a chronic occlusive, non-inflammatory and non-atherosclerotic cerebrovascular disorder, which affects mainly the intracranial portions of the distal internal carotid artery and the proximal anterior and middle cerebral arteries. The development of compensatory collateral circulation provides the angiographic appearance of a "puff of smoke", which translates to Moyamoya in Japanese and gives the disease its name. Radiological imaging plays a central role in the diagnosis of this disease and the recognition of resulting ischemic and hemorrhagic events. Our goal is to first review the imaging features of Moyamoya and then discuss the different surgical techniques developed to treat it, how to identify them on imaging studies, and what to expect from post-treatment imaging evaluation.

### TABLE OF CONTENTS/OUTLINE

1) Introduction. 2) Pathophysiological mechanism and anatomical correlation. 3) Angiographic classification of Moyamoya disease. 4) Vascular and parenchymal findings. 5) Surgical management: revascularization techniques and postoperative image characterization. 6) Assessment of pre- and post-treatment cerebral perfusion. 7) Challenges, pearls and pitfalls in differential diagnosis. 8) Future directions. 9) Take home messages.

## STARING INTO THE BRAINS ABYSS: NAVIGATING THROUGH CORTICAL MALFORMATIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Kevin Kurt Mac Allister (*Abstract Co-Author*) Nothing to Disclose
Cristina H. Besada SR, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Federico M. Olivera Plata, MEd (*Abstract Co-Author*) Nothing to Disclose
Manuel S. Perez Akly, MD (*Abstract Co-Author*) Nothing to Disclose
Stefania Solanot, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Cortical malformations must be ruled out in essentially every pediatric patient with developmental delay or epilepsy.MRI is certainly recommended as the most important imaging method in the evaluation of MCD, thanks to its optimal delineation of grey and white matter structures.Neuroimaging plays a crucial role in the prenatal and postnatal diagnosis of malformations of cortical development, since pathological tissue is not always available except for surgeries or autopsies. Radiologically, cortical malformations exhibit distinct imaging features such as abnormal cortical lamination, dysplastic gyri, and heterotopias.CT misses the abnormality in more than 30% of cases.Radiologists should also obtain detailed information from the referring clinicians regarding the size of the head, possible syndromic clinical features, epilepsy semiology, and EEG findings (particularly, location of origin of spikes) before reporting the examination

### TABLE OF CONTENTS/OUTLINE

Role of imaging in the diagnosis of malformation of cortical development Normal cortex developmentClassification according to the affected stage of normal cortex development Description of the most important disorders and radiological findingsConclusion References

Taisa M. Guarilha, MD (*Abstract Co-Author*) Nothing to Disclose
Luis Antonio Tobaru Tibana, MD (*Abstract Co-Author*) Nothing to Disclose
Lucas G. Braga, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

In this presentation, we delve into the critical aspects of post-operative image acquisition protocols, focusing on timing and sequences essential for optimal imaging outcomes. Additionally, we explore the typical postoperative changes that occur following pituitary surgery. These changes encompass various factors, including anatomical distortions, the utilization of common surgical materials, the presence of hematic residues, gas foci, and local artifacts. Moreover, we emphasize the importance of recognizing specific imaging changes indicative of residual lesions and complications. Understanding and identifying these changes are paramount in postoperative imaging, as they provide valuable insights into the patient's recovery process and are crucial for prompt intervention and management.

### TABLE OF CONTENTS/OUTLINE

1. Contemporary Protocol for Pituitary Assessment. 2. Routes of Intervention in Pituitary Lesions: highlight transsphenoidal route particularities and other main intervention routes. 3. Primary Surgical Inclusion Materials and MRI Characteristics: describe MRI characteristics of surgical materials and common imaging artifacts. 4. Common Changes After Surgical Removal of Pituitary Adenomas. 5. Notable Complications: discuss regional hemorrhage, cerebrospinal fluid leakage, ischemia, among others. 6. Characterizing Residual Pituitary Adenoma Lesions on MRI: focus on distinct gadolinium enhancements for identifying residual lesions. 7. Current Protocol for Postoperative Pituitary Adenoma Surveillance via MRI. 8. Main Items in the Imaging Report: highlight essential components for clinical and imaging follow-up alterations.

## FROM PIXELS TO PRACTICE: IMPACTFUL NEUROIMAGING ADVANCES IN THE CLINICAL MANAGEMENT OF CEREBRAL AMYLOID ANGIOPATHY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Eduardo D. Valadares, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Clara Zanon Zotin (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Cerebral Amyloid Angiopathy (CAA) is a the second most prevalent form of cerebral small vessel disease, with devastating clinical consequences.The pattern of distribution of MRI-visible lesions aids in the distinction between CAA and other prevalent forms of sporadic cerebral small vessel diseases, such as hypertensive arteriolosclerosis.The Boston Criteria v2.0 offers high positive predictive value for the diagnosis of CAA. Edinburgh Criteria is useful in the characterization of CAA-related ICH in CT studies. Hemorrhagic markers, especially cortical superficial siderosis, more strongly predict the risk of first-ever or recurrent intracerebral hemorrhage, compared to non-hemorrhagic markers, which are more strongly associated with cognitive impairment, but are often outperformed by advanced techniques, such as diffusion-based markers.

### TABLE OF CONTENTS/OUTLINE

• Introduction: Pathophysiology, clinical spectrum, and classification of CAA.• Neuroimaging features: Hemorrhagic (cerebral microbleeds, cortical superficial siderosis, intracerebral hemorrhage, intragyral hemorrhages, convexity subarachnoid hemorrhage) and Non-hemorrhagic (perivascular spaces in the centrum semi-ovale, cortical cerebral microinfarcts, white matter hyperintensities in a multifocal subcortical pattern• Diagnostic value: Boston criteria (versions 1.0, 1.5, and 2.0) and Edinburgh criteria • Prognostic value: Risk of first-ever and recurrent intracerebral hemorrhage; Risk of transient focal neurological episodes; Risk of cognitive decline• Impact of neuroimaging markers of CAA in clinical management of patients with stroke.• CAA diagnosis in the era of anti-amyloid treatmento Risk of ARIA

## SMALL HEADS BIG TROUBLES NEONTAL CEREBRAL HYPOXIC-ISCHEMIC INJURY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Paola A. Lara Rodezno, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The assessment of the radiological signs in hypoxia in the full-term neonate are characteristic and different from older children; on the other hand, the alterations in premature neonates are different from those in full-term neonates. Assessment of signs of hypoxic damage on neonatal brain imaging requires attention to a number of specific signs. It is important for the radiologist to know the normal findings according to the gestational age of the neonate and to differentiate between severe or total hypoxia, prolonged or partial and mixed hypoxia. Brain MRI was evaluated in premature and term infants looking for 4 interrelated fundamental signs grouped under the term "1-2-3-4 sign" with findings of total severe hypoxia such as: increase in signal intensity of the basal ganglia and thalamus in T1W, posterior arm sign absent in full-term neonate, signs of diffusion hypoxia; signs of prolonged hypoxia such as hyperintensity of the cerebral cortex on T1W.

### TABLE OF CONTENTS/OUTLINE

The most frequent finding was hyperintensity of the basal nuclei, followed by hyperintensity of the gyri and lamellar cortical necrosis.

## A 360 DEGREE REVIEW OF THE POWER OF LOW INTENSITY FOCUSED ULTRASOUND (LIFUS) IN MANAGEMENT OF BRAIN TUMORS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jody L. Tanabe, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha Pisani Petrucci, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nolan Dang (*Abstract Co-Author*) Nothing to Disclose
Natalie Serkova, PhD, MBA (*Abstract Co-Author*) Nothing to Disclose
Parisa Khoshpouri, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Understanding LIFUS Mechanisms Explore the fundamental mechanisms underlying Low Intensity Focused Ultrasound (LIFUS) and its unique features in affecting the blood brain barrier. 2. Explaining the Safety Profiles: Evaluate the safety profile of LIFUS in diagnosis and management of brain tumors facilitating drug delivery, emphasizing key considerations for clinical implementation. 3. Clinical Application and Ongoing Trials: Discuss the current clinical applications of LIFUS in approaching brain lesions and highlight ongoing trials investigating its efficacy, aiming to delineate its potential role as a therapeutic modality in combination with oncologic treatments.

### TABLE OF CONTENTS/OUTLINE

• Introduction to LIFUS and its Mechanism of Action: Briefly introduce the concept of Low Intensity Focused Ultrasound (LIFUS) and the underlying mechanism of LIFUS, focusing on how it interacts with neural tissue and disrupts the BBB. its potential applications in neuroradiology and targeting brain tumors. • Safety Profile: Highlight the safety considerations associated with LIFUS, including its non-invasive nature, potential side effects, and current safety protocols. • Ongoing Clinical Trials: Provide an overview of ongoing clinical trials investigating the use of LIFUS in various neurological conditions, including the objectives, methodologies, and preliminary findings. • Conclusion: Summarize the potential of LIFUS as a promising tool in neuroradiology and neuromodulation, highlighting its role in advancing the field and addressing unmet clinical needs.

## AN EDUCATIONAL EXHIBIT OF THE DIFFERENT IMAGING CHARACTERISTICS OF HR- VWI MRI AND MRA ON PATIENTS WITH CONFIRMED INFECTIOUS VASCULITIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Javier M. Romero, MD (*Abstract Co-Author*) Stockholder, TMA Precision Medicine
Suely F. Ferraciolli, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Odette Ganem (*Presenter*) Nothing to Disclose

### TEACHING POINTS

HR- VWI has been recently utilized as an excellent sequence to detect inflammation of the intracranial circulation when vasculitis is suspected. Although imaging characteristics have been well defined in patients with primary central nervous system vasculitis, infectious or secondary vasculitis has been less well described. Many Infectious etiologies may result in vasculitis, including viral, bacterial, or fungal etiologies.In this pictorial review, we would like to highlight the local changes on the vascular wall and the predominant vascular territories compromised in infectious diseases viewed on High-resolution vessel wall imaging (HR-VWI) MRI and magnetic resonance angiography (MRA).

### TABLE OF CONTENTS/OUTLINE

- Introduction- Clinical presentation of Infectious Vasculitis: Viral, Bacterial, and Fungal - Radiographic characteristics of infectious vasculitis on MRA and HR VWI MRI - Differential Diagnosis with other causes of CNS Vasculitis (with schematic drawing)- Conclusion

## EX VIVO HIGH-RESOLUTION CAROTID PLAQUE MRI WITH EMPHASIS OF QUANTITATIVE SUSCEPTIBILITY MAPPING: IMMUNOHISTOPATHOLOGICAL CORRELATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Ryo Toya, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tomoki Nakano, MD (*Abstract Co-Author*) Nothing to Disclose
Ayano Ishiyama, MD (*Abstract Co-Author*) Nothing to Disclose
Hideki Ishimaru (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Many studies using in vivo carotid plaque MRI have highlighted its usefulness in the detection of clinically unstable plaques. However, in vivo MRI is often plagued by motion artifacts, such as carotid artery pulsation, and offers lower spatial resolution than microscopic histopathology specimens. Consequently, accurately assessing signals related to different components within carotid plaques can be difficult. Ex vivo MRI presents advantages such as eliminating motion artifacts and providing higher-resolution images that can be accurately correlated with histopathology. Quantitative susceptibility mapping (QSM), a recently developed technique for measuring tissue susceptibility, is expected to characterize the carotid plaque composition. In this presentation, we provide new insights from ex vivo high-resolution carotid plaque MRI, including QSM, and identify discrepancies with previous in vivo imaging results while also raising important issues that require further attention.

### TABLE OF CONTENTS/OUTLINE

-Immunostaining is useful for diagnosing carotid plaque components -Can intraplaque hemorrhage and lipid-containing components be distinguished? -Is it the only calcification that shows a low signal in all imaging sequences? -Is it practically possible to diagnose fibrous cap? -What signals do the fibrous component and loose matrix exhibit? -Key challenges to be solved.

## DIAGNOSTIC ACCURACY OF CONTRAST ENHANCED FLUID-ATTENUATED INVERSION RECOVERY (CE-FLAIR) MRI IN DIAGNOSIS OF INFECTIOUS MENINGITIS TAKING CSF ANALYSIS AS GOLD STANDARD”

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Urooj Kanwal, DMRD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Shaista Shoukat, MBBS (*Abstract Co-Author*) Nothing to Disclose
Sumera Shahbaz, MBBS (*Abstract Co-Author*) Nothing to Disclose
Sumaira Roohi, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Meningitis, an inflammation of the meninges, can be caused by various infectious agents. Early and accurate diagnosis is vital for effective treatment. Cerebrospinal fluid (CSF) analysis is the standard method, but Contrast Enhanced Fluid-Attenuated Inversion Recovery (CE-FLAIR) MRI shows potential for improved visualization of meningeal inflammation. However, its diagnostic accuracy compared to CSF analysis needs clarification. This study aims to address this gap.

### TABLE OF CONTENTS/OUTLINE

STUDY DESIGN Cross-Sectional Descriptive Study RESULTSThe mean age was calculated to be 35.4 + 14.7 years with 145 male participants (51.60%) and 136 female participants (48.40%).The diagnostic accuracy of CE-FLAIR MRI was further delineated in Figure No. 5. Sensitivity, specificity, positive predictive value, and negative predictive value were calculated as 96.05%, 92.23%, 94.71%, and 94.06%, respectively. The overall diagnostic accuracy of CE-FLAIR MRI was determined to be 94.51%. CONCLUSION This study provides valuable insights into the diagnostic accuracy of contrast enhanced fluid-attenuated inversion recovery (CE-FLAIR) MRI in meningitis diagnosis. The results underscore the potential of CE-FLAIR MRI as a noninvasive tool with comparable diagnostic accuracy to the gold standard cerebrospinal fluid (CSF) analysis.

Chika Somagawa, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

3DMR cisternography is a high spatial resolution image with heavy T2 contrast (cerebrospinal fluid is visualized as a high signal and the other as a low signal). Imaging methods based on fast spin echo and fast gradient echo are mainly used and are effective in the diagnosis of cerebrospinal fluid leaks, hydrocephalus, and the relationship between tumors and normal structures. This method can also be used to evaluate intracranial vascular contours and can be applied to a variety of vascular diseases. The purpose of this exhibit is to provide clinical applications of 3D MR cisternography in various intracranial vascular diseases, with an emphasis on the outer contour assessment of intracranial vessels.

### TABLE OF CONTENTS/OUTLINE

Sequence for 3D MR cisternography-Imaging parameters and image contrast-Case based presentation-A. Arterial contours (arterial course in acute arterial occlusion, evaluation of outer diameter of occluded blood vessels in moyamoya disease, aplastic/twig-like MCA)-B. Venous contours (involvement in neurovascular compression, draining veins in dural arteriovenous fistula)-C. Estimation of vascular wall pathology by comparison with TOF (atherosclerotic plaque, arterial dissection, cerebral vasospasm, etc)-D. Location of cerebral aneurysm (distal dural ring and paraclinoid aneurysm)-E. Others-F. Limitations and Pitfalls-

Ken Tatebe, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shehbaz M. Ansari, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Brian Mu, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Review imaging findings associated with intracranial metastases, with an emphasis on features that are germane to management decisions.2. Discuss the major modalities for treatment of intracranial metastases including radiation therapies, systemic treatments (chemotherapy immunotherapy), and surgical approaches with a focus on clinical issues relevant to an interpreting radiologist.3. Review post-treatment imaging of intracranial metastases and the major complications associated with each treatment modality.4. Role of advanced imaging to differentiate residual/recurrent metastasis vs treatment related changes.

### TABLE OF CONTENTS/OUTLINE

Significant advancements have been made in the diagnosis and treatment of intracranial metastases, improving outcomes but complicating their clinical landscape and evaluation on imaging. To generate cogent reporting, radiologists should understand the clinical implications of different imaging characteristics of metastatic lesions and have basic familiarity with when and how major treatment modalities are used. The exhibit focuses on the routine neuroimaging task of evaluating intracranial metastases both before and after treatment. The role of advanced imaging techniques beyond conventional MRI is discussed, particularly in the differentiation of true residual or recurrent metastastic disease from pseudoprogression or radiation necrosis. Additionally, a wide range of complications including postoperative, parenchymal and vascular post-radiation, and chemotherapy and immunotherapy related complications are also reviewed.

### TEACHING POINTS

1. Describe the clinical indications for mechanical thrombectomy and the TICI classification scale for assessing reperfusion after thrombectomy.2. Illustrate normal imaging findings and complications following mechanical thrombectomy, including a review of the clinical relevance of these findings.3. Discuss the use of different modalities to differentiate blood products from contrast staining, including dual energy CT and MRI.

### TABLE OF CONTENTS/OUTLINE

Mechanical thrombectomy is an effective intervention for ischemic stroke and relies on multimodal imaging for post-procedure follow-up. With increasing prevalence, the general radiologist should be familiar with the spectrum of post-thrombectomy imaging. In this article, we describe expected and unexpected imaging findings via a case review of patients who underwent mechanical thrombectomy for ischemic stroke.- Clinical guidelines for mechanical thrombectomy and TICI classification of reperfusion.- Review expected post-thrombectomy findings: clot resolution, contrast staining, subarachnoid hemorrhage.- Review unexpected imaging findings and their clinical relevance, including: residual clot, re-occlusion, access site dissection and pseudoaneurysm, vasospasm, hemorrhagic conversion, contrast-induced neurotoxicity.- Discuss use of dual energy CT and MRI to differentiate hemorrhage from contrast staining

## JOURNEY TO THE CENTER OF THE HEAD - IMAGING REVIEW OF CAVERNOUS SINUS TUMORAL LESIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Marta Calvo-Imirizaldu, MD (*Abstract Co-Author*) Research Grant, Siemens AG
Manuel Rafael Lopez De La Torre Carretero (*Abstract Co-Author*) Nothing to Disclose
Elida Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Pablo D. Dominguez, MD (*Abstract Co-Author*) Nothing to Disclose
Jose Miguel Escudero-Fernandez, MD (*Abstract Co-Author*) Nothing to Disclose
Reyes M. Garcia-Eulate (*Abstract Co-Author*) Nothing to Disclose
Carmen Mbongo, MD (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• To evaluate the different tumoral entities that can involve the cavernous sinuses (CS), including intrinsic and extrinsic lesions.• To describe perineural paths and anatomic relationships, such as the skull-base foramina, that are important in secondary invasion of the CS.

### TABLE OF CONTENTS/OUTLINE

Many crucial vascular and nervous structures converge in the CS, including the internal carotid artery -ICA- and the cranial nerves III, IV, V1, V2 and VI. The CS can be damaged by tumoral lesions of distinct origins.Neoplasms can primarily arise within the CS, secondarily invade it from adjacent structures, by perineural spread through skull base foramina or by metastatic disease.• Intrinsic tumors include:- Meningioma: it produces luminal narrowing of the ICA and shows homogeneous enhancement after contrast administration.- Cavernous Hemangioma: it does not produce luminal narrowing of the ICA.- Schwannoma: it shows heterogeneous enhancement, and cystic or hemorrhagic areas can be observed.- Plexiform Neurofibroma: the target sign is a typical finding of these tumors.- Other tumors: Solitary Fibrous Tumor and Melanoma.• Extrinsic tumors can be classified according to their location:- Sellar and suprasellar region: Pituitary macroadenoma invades the CS when it contacts more than 67% of the diameter of the ICA. A Craniopharyngioma can show cystic and calcified areas in children.- Oral / Maxillary region: Nasopharyngeal Carcinoma, Juvenile Nasopharyngeal Angiofibroma, Adenoid Cystic Carcinoma, Rhabdomyosarcoma, Esthesioneuroblastoma.- Bone malignancies: Chordoma, Chondrosarcoma, Osteosarcoma.- Systemic malignancies: Lymphoma, Multiple Myeloma and Metastases.

## BRIDGING THE GAP: LIFE-SIZE 3D PRINTED PEDIATRIC TO ADULT NEUROVASCULAR AND CRANIAL ANATOMY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jonathan M. Morris, MD (*Abstract Co-Author*) Consultant, Medtronic plc;Speaker, Medtronic plc;Consultant, Merit Medical Systems, Inc;Speaker, Merit Medical Systems, Inc;Consultant, Landauer Inc;Speaker, Johnson & Johnson
David F. Black, MD (*Abstract Co-Author*) Nothing to Disclose
Hayden Swartz, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Pediatric neurovascular anatomy is a series of small and complex arteries and veins overlapping critical neuroanatomic structures. Foundational knowledge begins in medical school with adult cadaveric dissections, two-dimensional (2D) medical illustrations, and progresses through cross sectional imaging and angiographic evaluation during training. 2. Current resources provide limited conceptual models of the small and complex pediatric neurovascular and neuroanatomic relationships. 3. Cadaveric dissections provide valuable understanding, however, are destructive and not widely available due to ethical factors, limited autopsy exposure, and rarity of pathology. 4. By combining coregistered computed tomography (CT), CT angiography, and gadolinium bolus magnetic resonance venogram with three-dimensional (3D) computer aided design software, 3D printing pioneers a practical solution to teach age-dependent, patient-specific, life-size neurovascular anatomy and the overlying cranial vault in normal patients ages 0-18. 5. 3D printed models offer several advantages including an ethical nondestructive means to acquire, manufacture, and teach neurovascular anatomy, including haptic perception, unattainable by current resources, critical for radiology trainees.

### TABLE OF CONTENTS/OUTLINE

1. Background of pediatric neurovascular anatomy. 2. Current state of educational tools and gap. 3. Benefits of patient and age specific 3D printed models from imaging. 4. Future directions of 3D neurovascular education.

## JOURNEY TO THE CENTER OF THE HEAD - IMAGING REVIEW OF CAVERNOUS SINUS NON-TUMORAL LESIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jose Miguel Escudero-Fernandez, MD (*Abstract Co-Author*) Nothing to Disclose
Elida Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Pablo D. Dominguez, MD (*Abstract Co-Author*) Nothing to Disclose
Marta Calvo-Imirizaldu, MD (*Abstract Co-Author*) Research Grant, Siemens AG
Reyes M. Garcia-Eulate (*Abstract Co-Author*) Nothing to Disclose
Carmen Mbongo, MD (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

; To evaluate the different non-tumoral entities that can invade the cavernous sinuses (CS).; To learn the most important imaging features of each lesion and how to make an adequate differential diagnosis with neoplastic etiologies.; To describe anatomic relationships, such as the skull-base foramina, that are important in secondary invasion of the CS.

### TABLE OF CONTENTS/OUTLINE

Unlike neoplasms, non-tumoral lesions tend to show low signal on T2-weighted imaging. They can be classified according to their etiology:; Vascular etiologies: Carotid-cavernous fistula, Internal carotid artery Aneurysm and CS thrombosis. They all produce similar clinical features; the CS syndrome (exophthalmos, ophthalmoplegia, chemosis, etc). Digital subtraction angiography plays a dual role in their diagnosis and management.; Infectious etiologies: Fungal sinusitis produces narrowing and thrombosis of the internal carotid artery and the CS, with infarction of paranasal and nasal tissues (producing the typical "black turbinate sign"). Tuberculous pachymeningitis manifests as nodular and enhancing lesions.; Inflammatory etiologies: include Granulomatosis with Polyangiitis, Tolosa-Hunt Syndrome, Sarcoidosis and IgG4 Disease. Granulomatosis with polyangiitis affects paranasal sinus, nasal cavities and orbits and may produce hypertrophic pachymeningitis with CS involvement, ICA stenosis and vasculitis. Tolosa-Hunt syndrome is a diagnosis of exclusion and involves the CS region, the superior orbital fissure and the orbital apex of the same side.; Miscellaneous: Arachnoid, Epidermoid, Dermoid Cysts and Pseudocysts. Epidermoid cysts do not enhance and show diffusion restriction.

## DEFINING THE CENTRAL ROLE OF RADIOLOGY FOR SAFE AND EFFECTIVE ANTI-AMYLOID THERAPY IN EARLY ALZHEIMER'S DISEASE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Joseph M. Mettenburg, MD (*Abstract Co-Author*) Nothing to Disclose
Riddhi Patira (*Abstract Co-Author*) Nothing to Disclose
Saurab Faruque, MPH (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Anti-amyloid (AA) monoclonal antibodies rapidly emerged as an approved treatment for Alzheimer's disease (AD) dementia. Efficacious and safe treatment requires robust clinical data to accurately classify patients at initiation and to monitor throughout treatment. Radiologists directly contribute to this process through acquisition and interpretation of baseline and serial screening MRI and careful collection of cerebrospinal fluid (CSF) samples. This educational exhibit aims to prepare radiologists for their central role in AA therapy programs.The educational objectives of this exhibit are to understand:- Factors affecting CSF AD biomarker analysis and the recommended pre-analytical protocol for mitigating variability- Conditions and imaging features that exclude patients from AA therapy, and radiographic pitfalls and mimics- The role of MRI parameters in serial amyloid-related imaging abnormality (ARIA) assessment- Imaging characteristics of ARIA-H (hemorrhage) and ARIA-E (edema)- Monitoring timelines for ARIA, and circumstances and recommendations for adjustments to monitoring and treatment

### TABLE OF CONTENTS/OUTLINE

1. AD pathophysiology therapeutic targets2. The radiologist’s role in treatment initiationa. Baseline MRI-detectable exclusionary conditions criteria, and their imaging characteristics mimicsb. Rationale recommendations for standardized CSF sample collection3. The radiologist’s role in monitoring managementa. Overview of ARIA-H ARIA-Eb. Considerations for selecting MRI sequence type field strengthc. Recommended monitoring protocol timelined. Evaluating ARIA radiographic severitye. Adjustments to monitoring therapy after detection of ARIA

## FUNCTIONAL MRI TECHNIQUES TO DETECT, UNDERSTAND, AND PROGNOSTICATE DISORDERS OF CONSCIOUSNESS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

David Fischer (*Abstract Co-Author*) Nothing to Disclose
Jeffrey Ware, MD (*Abstract Co-Author*) Nothing to Disclose
Azfar Basunia, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Disorders of consciousness (DoC) are believed to occur due to disruption of key awareness and arousal brain networks. Conventional clinical assessments have major limitations and suffer high misdiagnosis rates, posing challenges to decision making over the withdrawal of life-sustaining care. In this exhibit, we aim to:1. Highlight limitations of current clinical assessments and conventional imaging in neuroprognostication.2. Illustrate fMRI techniques to detect and differentiate between levels of consciousness and prognosticate on future recovery.3. Review current society guidelines and possible implementation strategies.

### TABLE OF CONTENTS/OUTLINE

1. Overview of disorders and levels of consciousness.2. Current clinical assessments and conventional imaging techniques (CT, MRI) a. Limitations in accurate DoC detection and neuroprognostication b. Need for novel techniques based on the neurobiology of coma.3. Functional MRI (fMRI) for understanding and prognosticating on DoC and detecting covert consciousness such as covert cortical processing and cognitive motor dissociation a. Task-based fMRI b. Stimulus-based fMRI c. Resting-state fMRI - (i) Functional network integrity for neuroprognostication (ii) Frequency domain analysis (iii) Emerging techniques such as dynamic functional connectivity.4. Practical considerations for fMRI implementation a. Acquisition and pre-processing strategies, including novel techniques to improve patient-level reliability b. Post-processing approaches and interpretation c. Considerations for scanning critically ill patients (safety, sedation, etc).5. Current society guidelines and expert consensus on DoC neuroprognostication with fMRI.

## INTRACRANIAL VESSEL WALL MRI: WHAT YOUR LUMEN IS NOT TELLING YOU

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Keena Li (*Abstract Co-Author*) Nothing to Disclose
Hediyeh Baradaran, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Bryan L. Bishop, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. We will provide an overview of what VWI entails and which patient populations are most likely to benefit from this type of advanced imaging. 2. We will provide an in-depth review of imaging techniques and protocols for high quality VWI in a timely manner which can be easily transitioned to clinical practice. 3. We will provide a clear, stepwise approach for interpreting vessel wall MR. 4. We will review specific scenarios in which VWI is a useful tool and adjunct to standard imaging.

### TABLE OF CONTENTS/OUTLINE

1. Introduction and overview of what vessel wall imaging means and who may benefit from this technique. a. Allows visualization of vessel wall rather than lumen alone. b. Differentiating etiologies of intracranial luminal stenosis. c. Identifying source of symptomatic disease which does not result in luminal stenosis and is not detected on standard imaging. 2. Imaging protocol for VWI. a. Review of various imaging techniques and protocols for VWI. b. Practical information on specific sequences and timing. 3. Stepwise approach to interpreting VWI in the clinical setting. a. Identify vessel narrowing on TOF MRA. b. Classify pattern of narrowing. c. Evaluate T2 weighted sequence. d. Evaluated for presence of and pattern of enhancement. 4. Scenarios in which VWI is a useful adjunct to standard neuro imaging. a. Non-stenosing Atherosclerotic Plaque i. Vessel wall enhancement, remodeling, plaque thickness and surface irregularity, intraplaque hemorrhage. b. CNS Vasculitis i. Concentric wall thickening and enhancement which persist over multiple examinations. c. Moyamoya i. VWI can be helpful to differentiate MMD, A-MMS, and V-MMS. d. CAA (A Beta Angiitis) i. Wall inflammation can be seen in inflammatory CAA.

### TEACHING POINTS

Since its introduction in 2012, the glymphatic system hypothesis has gained attention through animal studies showing its role in conditions like Alzheimer's disease, Parkinson's disease, stroke or head trauma. Human evaluation remains challenging due to the unavailability of fluorescent tracers and the unapproved use of intrathecal gadolinium-based contrast agents (GBCA). As an alternative, the Diffusion Tensor Image Analysis aLong the Perivascular Space (DTI-ALPS) method has gained traction for its noninvasive nature and simple interpretability through the ALPS-index. However, recent critiques question its reliability due to sensitivity to imaging conditions and issues like fiber crossing. This exhibit will introduce the concept of glymphatic system, detail the DTI-ALPS method along with its limitations, and explore additional non-invasive techniques such as choroid plexus volume, perivascular space volume assessment, and evaluations of blood-brain barrier or venous wall permeability using GBCA, offering a comprehensive overview of current methodologies for glymphatic system evaluation.

### TABLE OF CONTENTS/OUTLINE

1. Overview of the Glymphatic System- Introduction to the Glymphatic System Hypothesis- Importance of the Glymphatic System in Neurological Diseases2. Detailed Analysis of the DTI-ALPS Method-Description of the DTI-ALPS Technique and the ALPS Index-Limitations and Critiques of the DTI-ALPS Method3. Other Non-Invasive Assessment Techniques for Glymphatic System-Non-Contrast Techniques (e.g., choroid plexus volume assessment)-Contrast-Enhanced Techniques (e.g., evaluation of blood-brain barrier)

### TEACHING POINTS

- Preterm birth (PTM) continues to stand as the foremost cause of perinatal morbidity and mortality globally, with a reduced cervical length (CL) representing a clinical marker classically associated with an increased risk of preterm delivery.- Ultrasound (US) is the primary imaging method for evaluating the gravid cervix in patients at high risk for PTB (including asymptomatic women) or those exhibiting signs of preterm labor.- CL measured by US is a very useful screening test that has been associated with better prediction of PTB than previously available tests.- This pictorial review aims to illustrate key concepts in the clinical use of US as a screening tool for PTB, focusing on the evaluation of CL. Based on a step-by-step approach, we propose a systematization of this examination tailored for clinical radiologists.

### TABLE OF CONTENTS/OUTLINE

1. Background: Preterm birth- Risk factors- Screening and prevention2. Anatomy of uterine cervix and changes during pregnancy3. US-based screening strategies for preterm birth- Cervical length- Other US findings (funneling, amniotic fluid sludge, etc)4. US techniques: - Transabdominal - Translabial - Transvaginal - 3D Imaging - Elastography5. ACR Appropriateness Criteria: a step-by-step approach6. Management of short cervix: what to know and what to look for7. Summary and take-home messages

## OBEE-10 ENDOMETRIOSIS OF THE ADNEXA ON MRI: AN IN-DEPTH REVIEW BEYOND THE ENDOMETRIOMA

Anuradha S. Shenoy-Bhangle, MD (*Abstract Co-Author*) Nothing to Disclose
Haatal B. Macer, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1) A thorough understanding of adnexal anatomy is crucial to describing sites of DE for surgeons2) DE of the broad ligament manifests as T2 hypointense nodular implants contiguous with adjacent DE, in isolation or endometrioma of the broad ligament. Lateral pelvic extension may involve the pelvic nerves3) DE of the fallopian tube manifests as salpingitis, serosal/subserosal implants with tethering and hydrosalpinx, mucosal/luminal implants with hematosalpinx, or T2 hypointense thickening at a salpingectomy site4) Don't forget paratubal cysts as a potential site of endometriosis5) Ovarian endometriosis includes superficial implants, serosal disease and endometrioma6) Round ligament DE manifests as thickening, nodularity deviation and/or shortening, most commonly involving the intrapelvic portion near the uterus

### TABLE OF CONTENTS/OUTLINE

1) Adnexal Anatomy on MR: Broad Ligament, Round Ligament, Fallopian Tubes, Ovaries, Uterine Artery, Ovarian Artery, Lateral Pelvic Nerves2) Manifestations of endometriosis in the BL on MR with case examples and implications on neural involvement: Nodular implants contiguous with adjacent DE, Nodular implants in isolation, endometrioma of the broad ligament3) Manifestations of endometriosis of the FT on MR: Salpingitis, Serosal/Subserosal implants, Mucosal/Luminal Implants, Tubal Stump Implant4) Paratubal Endometriosis: Atypical site of DE, identification of cysts on MR and importance of pre-operative reporting for optimal DE excision5) Manifestations of endometriosis of the Ovaries on MR with case examples: Superficial implants, Serosal disease, Endometrioma6) Endometriosis of the RL: Normal anatomy, intra/extra pelvic involvement,7) Conclusion

## OBEE-11 ADNEXAL TORSION: DO YOU HAVE AN MRI AVAILABLE? IF YES, USE IT NO MATTER WHAT TIME IT IS

Arnaldo Scardapane (*Abstract Co-Author*) Nothing to Disclose
Luca Leo (*Abstract Co-Author*) Nothing to Disclose
Giuseppe V. Sturda (*Abstract Co-Author*) Nothing to Disclose
Roberta Montefrancesco (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To review CT and MR imaging of adnexal torsion with pathologic correlation. 2. To propose an optimized MRI protocol (as brief and diagnostic as possible) for the gynecological emergencies that are simple to perform. 3. To emphasize the validity of using DWI sequences to identify ovarian viability.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction: pathophysiology of adnexal torsion. 2. Presentation of "confusing-doubtful" clinical manifestations in Emergency Department. 3. What to do when ultrasound and CT are not enough? MRI: to whom, how and what time. 4. CT and MRI features with pathological correlations of ovarian necrosis due to delayed diagnoses. 5. Clinical cases in which the timely use of MR imaging leads to an early diagnosis preserving the ovary.

## OBEE-12 CLINICAL IMPLEMENTATION OF SOCIETY OF RADIOLOGISTS IN ULTRASOUND CONSENSUS PANEL GUIDELINES FOR DETECTING ENDOMETRIOSIS ON ROUTINE PELVIC US: CHALLENGES, OPPORTUNITIES AND STRATEGIES FOR SUCCESS

Liina Poder, MD (*Abstract Co-Author*) Nothing to Disclose
Wendaline M. VanBuren, MD (*Abstract Co-Author*) Nothing to Disclose
Scott W. Young, MD (*Abstract Co-Author*) Nothing to Disclose
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Luyao Shen, MD (*Abstract Co-Author*) Nothing to Disclose
Myra K. Feldman, MD (*Abstract Co-Author*) Nothing to Disclose
Priyanka Jha, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Endometriosis a prevalent disorder affecting approximately 10% of premenopausal patients.2. Chronic pelvic pain and infertility are the most common presenting symptoms3. Despite the high prevalence, endometriosis is frequently under recognized on imaging and patients face significant diagnostic delays of over 7-10 years4. Ultrasound is the most commonly performed imaging study for female pelvic symptoms and hence provides an opportunity for detecting endometriosis on routine pelvic imaging5. Simple maneuvers such as sliding sign and wide field of view imaging can help detect endometriosis on ultrasound6. Direct and indirect ultrasound features can be assessed, stratifying the risk for endometriosis based on the presence of these features.7. Further management and guidance for MRI can be provided based on the APU scores.

**TABLE OF CONTENTS/OUTLINE**

1. Background information on prevalence of endometriosis2. Understand reasons for diagnostic delays of 7-10 years3. Update on clinical society guidelines for endometriosis imaging4. Necessity for screening for endometriosis on routine pelvic ultrasound5. Identify screening population6. Definition of augmented ultrasound7. Learn the necessary maneuvers to adopt the protocol into clinical practice8. How to perform a sliding sign- demonstration using static and cine images9. Demonstrate wide field of view imaging on static and cine images10. Show common imaging features of endometriosis on routine pelvic ultrasound11. Imaging examples of cases detected on routine pelvic ultrasound, followed by advanced endometriosis imaging (both US or MRI) and finally surgical correlation will be presented.

## OBEE-13 ADVANCED OVARIAN NEOPLASIA: DEFINITION OF AFFECTED ANATOMICAL SITES AND THE IMPACT OF TARGETED REPORT ON SURGICAL APPROACH

Lhuanna Maria Barbosa Teixeira, MD (*Abstract Co-Author*) Nothing to Disclose

Felipe Batista Rodrigues, MD (*Abstract Co-Author*) Nothing to Disclose
Eduarda Bezerra Cirne, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Reviewing the potential anatomical sites involved in ovarian neoplasms following a standardized lexicon for radiological reporting proposed by the Society of Abdominal Radiology and the European Society of Urogenital Radiology Female Pelvic Imaging Working Group (SAR/ESUR lexicon) for CT and MRI studies. Demonstrating the particularities of each method (CT, MRI, and PET-FDG) and their main limitations in this context. Showing the importance of targeted reports in accurately defining anatomical sites for optimal surgical management.

**TABLE OF CONTENTS/OUTLINE**

Many patients with ovarian cancer present with advanced-stage disease at the time of diagnosis. In this scenario, standard treatment includes a combination of cytoreductive surgery and chemotherapy. It is unquestionable that the treatment goal should be the complete resection of all visible and palpable tumors, with imaging methods essential for determining tumor extent and guiding surgical decision-making. Targeted reports, with a systematic evaluation of 45 anatomical sites potentially involved in ovarian neoplasms, should be accurately reported and properly topographed. Additionally, recognizing radiological criteria predictive of optimal or suboptimal cytoreduction should be extensively acknowledged by radiologists to assist and guide gynecologic oncologic surgeons in decision-making.

## OBEE-15 IMAGING APPROACH FOR VULVAR DISEASES: WHAT EVERY RADIOLOGIST SHOULD KNOW

Maria N. Napoli, MD (*Abstract Co-Author*) Nothing to Disclose
Teresa A. Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Silvia E. Gimenez, MS (*Abstract Co-Author*) Nothing to Disclose
Leonela Panaccio (*Abstract Co-Author*) Nothing to Disclose
MARIA BELEN DASS CORREA (*Abstract Co-Author*) Nothing to Disclose
Felicitas Aguirre (*Abstract Co-Author*) Nothing to Disclose
Paula Hernandez Garrigo (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

; Ultrasound serves as the primary diagnostic method for the initial assessmentof vulvar lesions. Nevertheless, MRI stands out as the preeminent imaging modality for comprehensive evaluation of both the anatomical structure and pathological features of the area.; Vulvar lesions encompass a diverse array of medical conditions affecting the female lower genital tract, ranging from benign to malignant diseases.; Benign lesions usually manifest as simple cystic or solid lesions.; Malignant diseases typically manifest as sizable, compact masses infiltrating the vaginal and perineal regions.; Enhanced comprehension of the normal anatomical structures combined with refined MRI imaging techniques facilitates more precise evaluation of these conditions, mitigating the need for unwarranted interventions and facilitating surgical planning where necessary.

**TABLE OF CONTENTS/OUTLINE**

; Review of vulvar anatomy.; Assessment of the utility of magnetic resonance imaging across various vulvar pathologies and its impact on adjacent organ involvement.; Establishment of an anatomical and imaging correlation to elucidate diverse vulvar pathologies.; Comparative analysis employing algorithms to delineate the radiological features observed in magnetic resonance imaging across different pathologies.

**TEACHING POINTS**

Intrauterine devices (IUDs) exert a contraceptive effect when placed inside the uterus and represent one of the most widely used contraceptive methods worldwide. Evaluation begins before device placement to assess any factors that may impair insertion. Improper placement can result in pelvic pain, abnormal bleeding, infections, and ectopic pregnancy. Increasingly, IUD placement is guided by ultrasound to minimize complications.This presentation aims to outline radiological signs of IUD expulsion, with an emphasis on distinguishing between partial and complete expulsion. It covers the identification of radiographic evidence of IUD perforation, including visualization of the device outside the uterine cavity, displacement into adjacent organs, and migration. Associated complications are identified using imaging modalities such as ultrasound, computed tomography (CT), and magnetic resonance imaging (MRI). The discussion includes key elements of a comprehensive radiology report, including a detailed description of findings, location and extent of abnormalities, and relevant differential diagnoses, which aid in decision-making for removal and treatment.

**TABLE OF CONTENTS/OUTLINE**

Case-based didactic review of intrauterine devices complications in different imaging modalities (ultrasound, CT scan and MRI) based on our service's digital archive and correlated with a comprehensive literature review.

### OBEE-19 DUCTUS VENOSUS AGENESIS IN FETUSES: A CASE SERIES ANALYSIS OF ULTRASOUND FINDINGS AND ASSOCIATION PATTERNS

Adinaryana Makam, MD (*Abstract Co-Author*) Nothing to Disclose
Urvi Ahlawat, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

This study examines 27 fetuses diagnosed with Ductus Venosus (DV) agenesis via prenatal ultrasound, identifying association patterns with other prenatal ultrasound findings.

**TABLE OF CONTENTS/OUTLINE**

Background: This retrospective case series investigates 27 fetuses diagnosed with DV agenesis via prenatal ultrasound, analyzing maternal age, gestational age, DV agenesis types, associated anomalies, and intrahepatic portal vein system status. Results: Descriptive statistics revealed a mean maternal age of 25.96 years (range: 21-44) and a mean gestational age of 21.67 weeks. DV agenesis types included Type 1 (10 cases), Type 2 (12 cases), and Type 3A (5 cases). Association patterns indicated cardiac, genitourinary, and musculoskeletal anomalies such as Cardiomegaly, Ventricular Septal Defect, Aberrant Right Subclavian Artery, Echogenic Focus in the Left Ventricle, Renal Pelvis Dilatation, Multicystic Dysplastic Kidney, Right Crossed Fused Ectopic Kidney, Clitoromegaly, Frontal Scalloping, Spinal Dysraphism, Congenital Talipes Equinovarus, Single Umbilical Artery, Increased Nuchal Translucency, Sylvian Fissure Delayed for Gestational Age, with notable correlations between maternal age and cardiac/genitourinary anomalies ($r = 0.27$, $p < 0.05$; $r = 0.22$, $p < 0.05$, respectively). Chi-square tests revealed type-specific associations: Type 1 with cardiac anomalies ($p < 0.05$), Type 2 with genitourinary anomalies ($p < 0.05$), and Type 3A with musculoskeletal anomalies ($p < 0.05$). The study underscores the subtype-specific implications of DV agenesis on fetal development, emphasizing the importance of prenatal ultrasound in early detection and informed prenatal care.

### OBEE-2 A REVIEW OF THE MRI FEATURES OF ENDOMETRIOSIS: WHAT SHOULD BE PAID ATTENTION TO DURING THE REPORTING PROCESS?

Mehmet Simsar, MD (*Abstract Co-Author*) Nothing to Disclose
Hilal Sahin, MD (*Abstract Co-Author*) Nothing to Disclose
Yesim Y. Yuruk, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Provides a comprehensive overview of the symptoms and the possible formation mechanisms of endometriosis • Describes MRI features of endometriosis • Reviews the revised American Society for Reproductive Medicine (rASRM) classification and ENZIAN classification and their contents used in mapping of endometriosis • Demonstrates the common and rare presentations of endometriosis using case-based examples, highlighting distinctive clinical and MRI features that can aid in the best diagnosis.

**TABLE OF CONTENTS/OUTLINE**

Table of Contents 1. Terminology and etiology of endometriosis 2. A practical approach to endometriosis subtypes 3. Specific MRI features of endometriosis subtypes 4. Overview of revised American Society for Reproductive Medicine (rASRM) classification and ENZIAN classification 5. Case-based reviews of endometriosis subtypes Outlines • Knowledge of endometriosis subtypes is essential for diagnosing and localizing pathologies. • Understanding the key MRI features and common/rare locations of endometriosis is the first step in generating a diagnosis and mapping the disease for appropriate treatment. • Obtaining relevant clinical history and recognizing specific imaging appearances can help provide the best diagnosis.

### OBEE-21 ENDOMETRIOSIS: BE READY, IDENTIFY EMERGENCY, HANDLE URGENCY

Izabela P. Franco, MD (*Abstract Co-Author*) Nothing to Disclose
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Wendaline M. VanBuren, MD (*Abstract Co-Author*) Nothing to Disclose
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*) Nothing to Disclose
Lavinia Dias, MD (*Abstract Co-Author*) Nothing to Disclose
Brunna C. Oliveira, MD, MSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Endometriosis is a chronic disease characterized by the ectopic implantation of an endometrium-like tissue, containing glands and stroma, outside the uterus, and can significantly impact a woman's quality of life, manifesting in pelvic pain, infertility, and psychosocial challenges. Despite its chronicity, endometriosis can present acutely, either exacerbating an existing condition or as a primary cause, prompting patients to seek emergency medical attention, sometimes before a formal diagnosis is established.This educational exhibit aims to spotlight presentations of endometriosis commonly overlooked or misinterpreted in emergency settings, using case studies where it led to urgent situations. Emphasizing the crucial need for timely recognition, delayed diagnosis hinders prompt intervention and treatment, and may increase the likelihood of recurrent symptoms or complications.

**TABLE OF CONTENTS/OUTLINE**

Didactic cases demonstrating various emergency and urgent presentations of endometriosis using different imaging modalities such as ultrasound, computed tomography, and magnetic resonance imaging, including:Bowel obstructionUterine and vaginal vault ruptureInfection of endometriomasEctopic pregnancyHemorrhagic acute abdomenUrinary tract obstructionCatamenial pneumothorax

### OBEE-23 SERUM BIOMARKERS IN GYNECOLOGIC CONDITIONS: A RADIOLOGIST'S GUIDE TO NAVIGATE THE ALPHABET SOUP

**Awards**
**Certificate of Merit**

Sarah Taylor (*Abstract Co-Author*) Nothing to Disclose
Biatta Sholosh, MD (*Abstract Co-Author*) Nothing to Disclose
Esther Elishaev, MD (*Abstract Co-Author*) Nothing to Disclose
Alessandro Furlan, MD, MMM (*Abstract Co-Author*) Royalties, RELX;Research support, Endra, Inc;Consultant, Bracco Group
Gayathri Devi Jalluri, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Ekta Maheshwari, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. A number of malignant and benign gynecological entities are associated with elevation of serum biomarkers. The various tumor markers differ in their usefulness for screening, diagnosis, prognosis, assessing therapeutic response, and detecting recurrence. 2. Awareness of these associations and characteristic imaging patterns is integral to Radiology practice for optimal diagnosis, facilitating recommendations for ancillary imaging and work up.

**TABLE OF CONTENTS/OUTLINE**

Some important gynecologic biomarkers are: CA-125, b-HCG, Alpha-fetoprotein (AFP), Inhibin, Estradiol, Carcinoembryonic antigen, Müllerian inhibiting substance, CA 19-9, Lactate Dehydrogenase. Since pathologic diagnosis of malignancies may be difficult without laparotomy, tumor markers in addition to diagnostic imaging are useful in preoperative evaluation. An ideal marker should be highly specific and sensitive, however due to false positives and elevated indices seen in multiple benign entities, imaging plays a crucial role in guiding appropriate patient management. Multimodal approach including the evaluation of serum biomarkers combined with imaging, seems to be the best strategy for characterization, identification of recurrence, and monitoring response to treatment in female cancer patients. Tumor markers also demonstrate physiological variation with age and menopausal status as well as benign neoplasms and inflammatory conditions. This knowledge is critical to avoid overreporting of malignancy.

## OBEE-24 UNUSUAL IMAGING PRESENTATIONS OF ENDOMETRIOSIS

Rita Maria Lahoud, MD (*Abstract Co-Author*) Nothing to Disclose
Megan Kenway, MD (*Abstract Co-Author*) Nothing to Disclose
Dinushi S. Perera, MD (*Abstract Co-Author*) Nothing to Disclose
Rosaura Suazo Aguero, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Endometriosis is defined as the presence of endometrial glands in locations outside the uterus. It is a common condition that occurs in 6-10% of all reproductive woman.The most common peritoneal sites of involvement are the ovaries, uterine ligaments, cut-de-sac, and pelvic peritoneum reflected over the uterus, fallopian tubes, rectosigmoid and bladder. The most common complaints associated with endometriosis are dysmenorrhea and pelvic pain; although some patients often present without pain and only with complaints of infertility, or there is an incidental finding of an ovarian mass on imaging. However, some of these incidental findings are uncommon, prompting to a malignancy workup. While recognizing the hallmarks and typical imaging patterns of endometriosis is basic, acknowledging unusual presentations awards every radiologist the extra mile. At the end of this review we will be able to understand uncommon imaging appearances of endometriosis. To analyze the correlation between imaging features and histopathological findings. To contrast the optimal use of conventional imaging for malignancy mimickers in endometriosis.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction on Endometriosis and its manifestations 2. Description on usual and unusual imaging appearances of endometriosis 4. Case examples5. Conclusion

## OBEE-25 NOT ALL PELVIC PAIN STEMS FROM ENDOMETRIOSIS: VENOUS-ORIGIN PAIN IS ALSO A SIGNIFICANT REALITY!

**Awards**
**Certificate of Merit**

Fanilda Barros (*Abstract Co-Author*) Nothing to Disclose
Isabela Tavares (*Abstract Co-Author*) Nothing to Disclose
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Manuella Barreto Silva (*Abstract Co-Author*) Nothing to Disclose

NATHALIA CARDOSO (*Abstract Co-Author*) Nothing to Disclose
FRANCINE FREITAS FERNANDES (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Pelvic venous insufficiency is a major cause of chronic pelvic pain in women of reproductive age, accounting for 16-31% of cases.Ultrasound examination is the primary diagnostic tool, offering excellent visualization of pelvic veins. Proper identification of external and internal iliac veins, and gonadal plexuses is crucial. Transvaginal ultrasound with color Doppler provides high-resolution images of pelvic veins, facilitating detection of flow direction changes. Evaluation includes grayscale assessment for thrombus and post-thrombotic fibrocicatricial changes and color/spectral Doppler study for flow pattern and reflux detection. Transvaginal ultrasound with color Doppler plays a vital role in pelvic vein assessment across gynecological and vascular contexts.

**TABLE OF CONTENTS/OUTLINE**

1) Ultrasound assessment based on current literature for investigating pelvic varicose veins. 2) Exploring pelvic venous anatomy with transvaginal ultrasound 3) Pathophysiology of pelvic venous disorders: Why hemodynamics is so crucial? 4) Technical considerations for ultrasound examination. 5) Clinical Cases: interpretation of ultrasound findings and differential diagnoses. 6) Reporting: What information should the radiologist provide to gynecologists and vascular surgeons? 7) Future perspectives

## OBEE-26 UNVEILING ENDOMETRIOSIS INVOLVING THE LATERAL PELVIC COMPARTMENT: A RADIOLOGICAL INSIGHT

**Awards**
**Magna Cum Laude**

Ingrid Ferreira (*Abstract Co-Author*) Nothing to Disclose

Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
CICILIA F. PONTES FERNANDEZ, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Transvaginal ultrasound (TVUS) is frequently utilized for screening or monitoring gynecological pathologies throughout reproductive and postmenopausal years.Despite advancements in diagnostic accuracy for detecting small endometriosis lesions via TVUS, incomplete evaluations are still common due to technical challenges, sometimes related to patient anatomy.Discussion of techniques, adjustments, and maneuvers can mitigate technical limitations, leading to more precise diagnoses.

**TABLE OF CONTENTS/OUTLINE**

Explanation of optimal ultrasound imaging formation concepts (e.g., focus, transducer positioning, insonation angle, contrast).Review of pelvic anatomy via sonography.Overview of common technical challenges in pelvic ultrasound, including:Poor definition of contours and uterine cavity (e.g., midverted or excessively bulky uteri).Difficulty detecting/evaluating lesions too close to the transducer.Organs or lesions situated too far from the transducer (e.g., upper pelvis with a narrow field of view via vaginal route).Patients unable to undergo TVUS (e.g., virgins, individuals with vaginismus).Identification of the origin of adnexal lesions.Challenges in visualizing the ovaries.Definition of pelvic spaces.Presentation of clinical cases via ultrasound images and illustrations, accompanied by suggestions for improving image quality and resolving technical difficulties. These solutions are categorized into:Dynamic maneuvers.Technical tips and device adjustments.Optimization of transducers.Utilization of different sonographic approaches.Application of specific anatomical knowledge.Summary of key concepts in each section.

## OBEE-29 'P TO F' OF ENZIAN, AN APPROACH TO MAGNETIC RESONANCE IMAGING EVALUATION FOR ENDOMETRIOSIS: A PICTORICAL REVIEW

Araceli Yameli V. Serrato SR, PhD (*Abstract Co-Author*) Nothing to Disclose
Vanessa Hernandez Olivera, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Magnetic resonance imaging and ultrasound have been used as the staging method for endometriosis. The gold standard diagnosis for endometriosis was histopathological characterization obtained by laparoscopy, however, due to limited access to specialized surgeons and costs, laparoscopic diagnosis has been reserved for specific cases. The current role of MRI is very important, so an optimal categorization system should be able to forecast pain and fertility, describe the extent of the disease (based on anatomical features), and give patients reliable information. In this work we will exemplify the use of the #ENZIAN classification used in our workplace because it has allowed better characterization of lesions (mapping) and post-treatment surveillance imaging.

**TABLE OF CONTENTS/OUTLINE**

1. MRI protocol: Key sequences, Tips for optimization. 2. #ENZIAN classification, imaging features on MRI: evaluation of the peritoneum, ovaries, tubes, Deep endometriosis findings (recto-vaginal space, vagina, retrocervical area, sacrouterine and cardinal ligaments, rectum, adenomyosis and extragenital locations with examples from each category. 3. Differential diagnosis mimics. 4. Clinical cases and reports. 5. Post-treatment Surveillance imaging: Post-surgical appearance and local recurrence. 6. Conclusion.

## OBEE-3 EXPLORING THE CURVES OF THE UTERUS - A DETAILED LOOK AT ISTHMIC LESIONS ON MRI

Ulysses S. Torres, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Eduardo O. Pacheco, MSc, MD (*Abstract Co-Author*) Nothing to Disclose

Lucas R. Torres, MD (*Abstract Co-Author*) Nothing to Disclose
Elisa Bretas (*Abstract Co-Author*) Nothing to Disclose
Marilia A. Tavares, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Review the anatomy of the uterus, with an emphasis on the location and structure of the uterine isthmus.Explore the different lesions that can affect the uterine isthmus.Discuss the radiological findings and clinical context associated with each type of isthmic lesion.

**TABLE OF CONTENTS/OUTLINE**

The uterine isthmus, as the narrowest portion of the uterus, plays a crucial role in female reproductive health and can be the site of origin of various gynecological pathologies. Isthmic uterine lesions constitute a complex category of abnormalities affecting tissue in this region. Due to their strategic location, these lesions may manifest a variety of symptoms, presenting diagnostic challenges.Diagnosis is typically made through imaging exams such as ultrasound or magnetic resonance imaging, with appropriate management depending on accurate identification of the lesion type and assessment of factors such as size, location, and risk of malignancy.This study aims to review a wide range of isthmic lesions, including isthmoceles, fibroids, ectopic pregnancies in cesarean scars, endometriosis, adenomyosis, adenomyoma, hematomas, anomalous vessels post-curettage, intrauterine device insertion in isthmocele, implantation of trophoblastic tissue in cesarean scar, and polyps, as well as addressing imaging diagnostic methods and available treatment options.By providing a comprehensive and up-to-date overview of this topic, this work aims to contribute to a better understanding and management of isthmic uterine lesions in radiological clinical practice.

## OBEE-30 DIAGNOSING INTRACRANIAL MASSES AND THEIR MIMICS IN-UTERO

**Awards**
**Certificate of Merit**

Elka Miller, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Patrick Shannon (*Abstract Co-Author*) Nothing to Disclose
Suzanne Laughlin, MD (*Abstract Co-Author*) Nothing to Disclose
Pradeep Krishnan, MD (*Abstract Co-Author*) Nothing to Disclose
Susan I. Blaser, MD (*Abstract Co-Author*) Nothing to Disclose
Neetika Gupta, MBBS, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To explore the spectrum of antenatal identified brain tumors and their association with genetic syndromes.To describe the common and rare neuroimaging manifestations of congenital brain tumors on fetal and postnatal imaging.To discuss the significance of advanced imaging techniques and imaging protocols in diagnosing and prognosticating the congenital brain tumors.

**TABLE OF CONTENTS/OUTLINE**

1. Congenital brain tumors are typically occurring during late fetal and early postnatal stages, often incidentally through antenatal imaging or based on clinical symptoms postnatally.2. Despite their rarity, congenital brain tumors are increasingly recognized in-utero due to advancements in imaging techniques and enhanced surveillance during pregnancy and infancy.3. Understanding associated tumor predisposition syndromes and specific genetic rearrangements is crucial for elucidating tumor etiology and guiding optimal management approaches.4. Regardless of tumor type or grade, congenital brain tumors uniformly present poor prognoses, attributed to unique metabolic and genetic pathways, prevalent embryonal histology, and rapid growth rates.

## OBEE-31 LEARN BEFORE YOU SLING OFF: THE ROLE OF TRANSLABIAL ULTRASOUND IN PRE- AND POSTOPERATIVE MESH ASSESSMENT

Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
CICILIA F. PONTES FERNANDEZ, MD (*Abstract Co-Author*) Nothing to Disclose
Fernanda Pipitone, MD (*Abstract Co-Author*) Nothing to Disclose
Luciana P. Chamie, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Women commonly suffer from pelvic floor disorders such as urinary incontinence and pelvic organ prolapse, often associated with pregnancy, menopause, and obesity.Synthetic midurethral slings are a widely used surgical option for management of stress urinary incontinence, and can be transobturator or retropubic.While midurethral slings have excellent outcomes in terms of urinary continence and overall psychosocial well-being, complications like urinary retention, infection, vaginal erosion, and chronic pain may occur.Translabial ultrasound is a powerful tool for assessing synthetic slings both before and after surgery, predicting outcomes and identifying complications.This presentation aims to acquaint radiologists with the necessary skills for incorporating translabial ultrasound into routine sling evaluation.

**TABLE OF CONTENTS/OUTLINE**

Introduction to Translabial Ultrasound (TLUS), highlighting its advantages over conventional imaging modalities for evaluating pelvic floor disorders in both pre- and postoperative settings.Technical Considerations in TLUS Imaging: patient preparation and equipment setup; scanning technique and patient positioning. Role of TLUS in Sling Evaluation, including: crucial preoperative data to report; identifying sling type, quantity, position, and orientation at rest and during Valsalva maneuver; assessing sling integrity, clinical efficacy, and primary complications; most prevalent associated genital abnormalities; post-sling pelvic pain assessment; measurement and distance analysis. Illustrative case studies demonstrating TLUS's clinical effectiveness in sling assessment. Future Directions and Considerations

## OBEE-32 3D AND 4D HYSTEROSALPINGO CONTRAST SONOGRAPHY (HYCOSY): ADVANCED TUBAL PATENCY ASSESSMENT

Heron Werner JR, MD (*Abstract Co-Author*) Nothing to Disclose
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lorena Luryann Cartaxo Silva (*Abstract Co-Author*) Nothing to Disclose
Manuella Barreto Silva (*Abstract Co-Author*) Nothing to Disclose
Eduardo Schor (*Abstract Co-Author*) Nothing to Disclose
FRANCINE FREITAS FERNANDES (*Abstract Co-Author*) Nothing to Disclose
Paulo S. Cossi (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

More than 50 million women suffer from infertility worldwide, among whom 30% have pathology associated with the fallopian tubes. In this context, the assessment of tubal patency is vital. HyCoSy, utilizing second-generation microbubble contrast-enhanced ultrasound (CEUS), has emerged as a preferred initial imaging modality in Europe and Asia, offering comparable efficacy to traditional methods like hysterosalpingography (HSG). Its advantages include avoidance of ionizing radiation to the pelvis, iodine allergy concerns and reduced discomfort during the exam. The ability to assess ovarian and intrauterine lesions simultaneously, has high sensitivity and specificity to diagnose others infertility-related pathologies, being considered an important

diagnostic method for assessing fertility in the "one-stop shop". A dedicated ultrasound software facilitates its performance by showing the morphology and path of the fallopian tube, the speed and volume of contrast extravasation, and its characteristics around the ovaries.

**TABLE OF CONTENTS/OUTLINE**

1) Review of the current literature for the investigation of fallopian tubes 2) Pathophysiology of tubal dysfunctions 3) Technical considerations about HyCoSy 4) Interpretation and critical analysis of sonographic findings 5) Report: What information should the radiologist provide to gynecologists and fertility specialists? 6) Future perspective

## OBEE-34 ROLE OF MRI IN DIAGNOSING COMMON PLACENTAL PATHOLOGIES; A PICTORIAL REVIEW AND UPDATES FROM RECENT LITERATURE

Hina Arif Tiwari, MD (*Abstract Co-Author*) Nothing to Disclose
Fatima M. Al-Khafaji, MBChB (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Abnormal placentation disease has become more frequent secondary to increased rate of cesarean sections. Ultrasonography is the first imaging modality performed, but MRI remains of superior value in accurate differentiation of abnormal placentation. 2. Detailed MRI reports are of great value in describing abnormal placentation by improving the maternal outcome and involving multidisciplinary team, when needed. 3. Gradient-echo sequence provides better delineation of the placental contour and interface with the myometrium, but only the spin echo sequences provide information on signal heterogeneity and intra-placental bands. 4. The maternal surface of the placenta contains cotyledons, which are placental outpouchings surrounded by MRI T2 dark clefts and septa, these must be differentiated from placental invasion of the myometrium. 5. So far there are no reported fetal acoustic safety issues in pelvic MRI examinations performed in 30 minutes or less in magnet strength of 1.5 Tesla. 6. Although gadolinium-based MRI examination differentiates myometrium from placenta, the half-life of gadolinium in fetuses is unknown. Contrast MRI is suggested in fetal demise or in patient's willing to terminate the pregnancy.

**TABLE OF CONTENTS/OUTLINE**

1. Embryogenesis of normal placenta and pathogenesis of abnormal placentation. 2. Placental anatomy; role of MRI. 3. Abbreviated MRI protocol in placental imaging with review of recent updates. 4. Spectrum of common placental pathologies with corresponding MRI findings, including: a. Placenta accreta. b. Placenta increta. c. Placenta percreta. d. Placenta previa. e. Placental abruption. 5. Review of latest literature updates on common placental pathologies.

## OBEE-35 PELVIC ENDOMETRIOSIS: WHAT YOUR MRI REPORT CAN'T MISS

Yuri C. Neves, PhD (*Abstract Co-Author*) Nothing to Disclose
Heitor Passeri, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Carolina De Moraes Sarmento (*Abstract Co-Author*) Nothing to Disclose

Rodrigo P. Polizio, MD (*Abstract Co-Author*) Nothing to Disclose
Gabriel L. Beraldo, MD (*Abstract Co-Author*) Nothing to Disclose
Cleo F. Souza, BMedSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Endometriosis is a chronic inflammatory disease highly undiagnosed, with an incidence estimated in up to 15% of women of reproductive age. Definition: presence of endometrial tissue outside the endometrial cavity. Among the related symptoms are dyspareunia, pelvic pain, and infertility. Despite its high prevalence, the radiology signs and findings of pelvic endometriosis may not be so widespread, and the diagnosis through magnetic resonance remains a challenge for many radiologists. The purpose of this exhibit is:Review the role of MRI in the diagnosis and accurate staging of pelvic endometriosis;Propose a sequence of relevant points to analyze when examining a pelvic MRI and why they are relevant;Set a list of information the radiological report must give and how they help to module and settle the better surgical approach.

**TABLE OF CONTENTS/OUTLINE**

IntroductionEpidemiology and pathophysiology DiagnosisBlind spot endometrioid lesionsPelvic compartments - the “must have” informationAnterior compartmentMiddle compartmentPosterior compartmentCases examples with the correlation between the radiology report and the specific surgery approach;Discussion and take-home messages.

## OBEE-36 THE VISUAL JOURNEY OF ASSISTED REPRODUCTION: IMAGING INSIGHTS

Gabriela Lauar, MD (*Abstract Co-Author*) Nothing to Disclose
Cinthia C. Barbisan, MD (*Abstract Co-Author*) Nothing to Disclose
Gabriella D. Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Marcela C. Lauar, MD (*Abstract Co-Author*) Nothing to Disclose
Isabela Ribeiro (*Abstract Co-Author*) Nothing to Disclose
Paulo Silva Junior (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The increased accessibility of assisted reproduction techniques has generated a greater number of ultrasound examinations as well as a greater number of associated complications. Within this context, it is crucial for the ultrasonographer to have knowledge about normal anatomy of the female pelvis and the normal alterations related to treatment, as well as possible complications. Transvaginal ultrasound not only allows for the assessment of ovarian reserve but also strict monitoring of adnexal changes to determine the optimal time for ovarian puncture. It also provides evaluation of uterine morphology, fallopian tubes, and endometrial characteristics, which are crucial for effective treatment. The dynamic evaluation provides data on pelvic organ mobility or the presence of adhesions. Doppler not only enables vascular assessment but also ensures safer puncture procedures by detecting important vessels in the traject. Thus, when the examiner is familiar with the most common findings and the detailed patient history, ultrasound examination allows differentiation of expected alterations, such as post-puncture hemorrhagic cysts, from potentially serious complications, such as ovarian hyperstimulation syndrome, ovarian torsion, infected collections, and ectopic pregnancy. Finally, although some alterations may be rare, timely diagnosis leads to better clinical outcomes with a higher success rate of the procedure.

**TABLE OF CONTENTS/OUTLINE**

The aim of this study is to synthesize the most relevant ultrasonographic information, in correlation with other imaging methods, so that the physician can perform assisted reproduction with higher chances of success and fewer complications.

## OBEE-37 WHAT YOU MUST KNOW ABOUT THE PLACENTA AND UMBILICAL CORD

**Awards**
**Certificate of Merit**

Leonardo F. Franco, MD (*Abstract Co-Author*) Nothing to Disclose
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Ines Novis (*Abstract Co-Author*) Nothing to Disclose

Yuri C. Neves, PhD (*Abstract Co-Author*) Nothing to Disclose
Cleo F. Souza, BMedSc (*Abstract Co-Author*) Nothing to Disclose
Antonio E. Silva JR, BDS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The main clinical indications for performing an MRI of the pelvis are leiomyomatosis, endometriosis, uterine adenomyosis, ovarian cysts/lesions, pelvic pain, abnormal uterine bleeding, and postoperative evaluation; New pathological classifications for these pathologies may cause difficulties in interpreting and describing these findings to meet this new demand; The purpose of this exhibit is: Facilitate the diagnosis and description of benign uterine pathology on MRI simply and practically through flowcharts and graphic schemes, based on the most recent literature.

### TABLE OF CONTENTS/OUTLINE

A review of information and new relevant classifications for a complete radiological report on the clinical management of the main non-endometriosis benign uterine pathologies, divided into the following categories: o uterine anatomy and positioning, including measurement parameters; o myometrium: myoma, myometrial cysts, adenomyosis, ACUM, isthmocele; o endometrium: endometrial polyp, intrauterine contraceptives (types, correct position, and endoceptive migration criteria); o uterine cervix: cervical polyp, cysts and cervicitis; o parameters: pelvic varicose veins/pelvic congestion syndrome.Discussion and take-home messages.

## OBEE-39 EXPLORING UNKNOWN TERRITORIES BY SONOGRAPHY: ATYPICAL LOCATIONS OF DEEP ENDOMETRIOSIS

Karina d. Giassi, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Luciana G. Matteoni-Athayde, MD (*Abstract Co-Author*) Nothing to Disclose

Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
PENELOPE ANDRADE (*Abstract Co-Author*) Nothing to Disclose
CICILIA F. PONTES FERNANDEZ, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Deep endometriosis (DE) frequently involves the torus, posterior cul-de-sac, uterosacral ligaments, and rectum.Diagnosing DE in less common areas poses significant challenges, particularly for less experienced radiologists.Understanding the anatomy, embryology, and pathophysiology is vital for grasping DE's spread within the abdominal cavity.To review clinical presentations and ultrasonographic findings of DE, with a focus on practical tips for detecting the condition in atypical abdominal locations.Accurate recognition of uncommon sites of DE aids in complete disease mapping, leading to improved surgical planning and outcomes.

### TABLE OF CONTENTS/OUTLINE

Introduction: Provides an overview of deep endometriosis, highlighting its typical locations and the importance of recognizing atypical manifestations for effective diagnosis and management.Pelvic Anatomy: Reviews key concepts necessary to understand the anatomical distribution of DE, including peritoneal folds, the dissemination of peritoneal fluid from the pelvic cavity, and the embryology of the Nuck canal.Clinical Cases: Discusses symptoms, imaging interpretations, and detection tips through clinical cases in unusual locations such as:High Sigmoid Small IntestineCecum Terminal IleumVermiform AppendixBladder (Vesical Trigone, Peripheral Portions)Ureter (High Location in the Pelvis)Parametrium (Anterior Infiltration)Paracolic GutterHepatorenal SpaceDiaphragmAbdominal Wall (Umbilical Scar, Parietal Peritoneum)Pelvic WallDifferential Diagnoses: Explores differential diagnoses such as desmoid tumor, peritoneal implants metastasis, and carcinoid tumor.

## OBEE-4 RADIOMIC TUMOR PROFILING FOR PROGNOSTICATION AND TAILORING OF TREATMENT IN UTERINE CERVICAL CANCER - A LITERATURE REVIEW

Ingfrid H. Haldorsen, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kristine E. Fasmer, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Agnes J. Eide, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To provide an overview of published work on radiomic tumor profiling for prognostication in cervical cancer2. To highlight the potential role of radiomics for risk stratification and tailoring of treatment in cervical cancer 3. To discuss present methodological challenges in radiomic tumor profiling and future directions 4. To encourage future research and discussion on how to translate advanced radiomic profiling to better cancer care

**TABLE OF CONTENTS/OUTLINE**

1. Introduction1.1. Radiomics definition 1.2. Steps in radiomic workflow1.3. Application of radiomic profiling in cancer research2. Overview of published work on radiomics in uterine cervical cancer2.1. Methodological assessment of radiomics studies2.2. Radiomic signatures related to tumor prognostic factors2.3. Radiomic modelling for prediction of survival and recurrence 3. The potential of radiomics 3.1. Noninvasive assessment of risk profiles3.2. Personalizing treatment algorithms 3.3. Prediction of treatment response and clinical outcome4. The challenges of radiomics4.1. Sources of bias related to study design and analysis 4.2. Imaging and segmentation challenges 4.3. Need for validation4.4. Need for prospective studies and testing in clinical settings 4.5. Data sharing and open-source reporting 5. Bridging the gap between radiomics and cancer care 5.1. Proposed solutions and future directions

## OBEE-40 HYSTEROSALPINGOGRAPHY: GO BACK TO BASICS. A PICTORIAL REVIEW

Jorge Arturo Martinez Conejo, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Hysterosalpingography is a study available in most hospital centers. It is a low-cost study that, despite advances in imaging, is still useful in the diagnosis of infertility. The main uses are the evaluation of the endometrial cavity and fallopian tubes. This pictorial review This pictorial review aims to show the technique that must be performed as well as the pathologies that we can find during the studies.

**TABLE OF CONTENTS/OUTLINE**

IntroductionHow to do it? (Technique)Assesments of the uterus (Position)Fallopian tubes permeabilityTube patologyEmbriologyUterine malformationsFilling defects (Endometrial patology)Additional findings

## OBEE-41 BREAKING BAD NEWS IN OBSTETRIC ULTRASOUND: COMUNNICATION SKILLS FOR RADIOLOGISTS

Thiago Matheus Santos Rios, MD (*Abstract Co-Author*) Nothing to Disclose
MARCOS VINICIUS BROGIN (*Abstract Co-Author*) Nothing to Disclose
Sergio Kobayashi, MD (*Abstract Co-Author*) Nothing to Disclose
Jose de Arimateia B. Araujo Filho, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Matheus Tonholo Ikedo, MD (*Abstract Co-Author*) Nothing to Disclose
Enzo Calheiros, MD (*Abstract Co-Author*) Nothing to Disclose
Luciana Cerri, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Leonardo Rosolen Iunes, MD (*Abstract Co-Author*) Nothing to Disclose
Alex Dias, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. DISCUSS COMMUNICATION SKILLS IN OBSTETRIC ULTRASOUND, INCLUDING PATIENT EXPECTATIONS AND OUTCOMES 2. SUMMARIZE OBSTETRIC EMERGENCIES AND COMPLICATIONS 3. PRESENT SPIKES PROTOCOL APPLIED TO SONOGRAPHERS 4. ELABORATE ABOUT RESIDENT EDUCATION IN OBSTETRIC ULTRASOUND: 5. HIGHLIGHT CHALLENGING SCENARIOS IN OBSTETRIC ULTRASOUND WITH A CASE-REVIEW APPROACH

**TABLE OF CONTENTS/OUTLINE**

Introduction Overview of the importance of effective communication in obstetric ultrasound. Communication Skills in Obstetric Ultrasound Importance of clear and empathetic communication. Impact of poor communication on patient outcomes. Obstetric Emergencies and Complications Diagnosis and management of high-risk pregnancies. Identification of placental abnormalities and fetal anomalies. Application of SPIKES Protocol Overview of the SPIKES protocol. Adaptation of SPIKES for obstetric ultrasound scenarios. Resident Education Integration of communication skills training into the OBGYN ultrasound curriculum. Role of mentorship, simulation, and feedback in resident education. Challenging Scenarios Case studies of fetal demise, congenital malformations, ectopic pregnancies, and molar pregnancies. Strategies for effective communication and support in challenging obstetric ultrasound cases.

## OBEE-42 MULTIMODALITY IMAGING OF C-SECTION SCAR ENDOMETRIOSIS

Daniel Kowal, MD (*Abstract Co-Author*) Speaker, Samsung Electronics Co, Ltd
Camilla Ramezanzadeh, DO (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Endometriosis can spread to multiple locations through surgical intervention and iatrogenic transport, with the anterior abdominal/pelvic wall the most common location of occurrence. The incidence of C-section scar endometriosis is approximately 0.8%.• Understand that not all patients will be symptomatic, and these lesions can therefore be discovered incidentally, usually on computed tomography. Symptomatic patients can have constant or recurrent cyclical pain related to hormonal impact.• Image findings of C-section scar endometriosis on different imaging modalities can vary due to hormonal influence depending on the patient’s phase of menstrual cycle.• Mimicking lesions and differential diagnoses must be excluded, including keloids, scar granulomas, and metastases.

**TABLE OF CONTENTS/OUTLINE**

• Introduction - Review endometriosis population at risk.• Pathophysiology and clinical presentation of C-section scar endometriosis.• Sample multimodality imaging examples demonstrating the varying imaging appearance of scar endometriosis and unique location of seeding throughout the abdominal and pelvic wall.• Mimicking lesions and pitfalls to consider.• Appropriate diagnostic workup and management.

## OBEE-43 EMERGENCY DISORDERS IN PREGNANCY: STRATEGIES FOR MATERNAL CARE

Takahito Nakajima, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tsukasa Saida, MD (*Abstract Co-Author*) Nothing to Disclose
Toshitaka Ishiguro, MD (*Abstract Co-Author*) Nothing to Disclose
Sodai Hoshiai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Masafumi Sakai, MD (*Abstract Co-Author*) Nothing to Disclose
Taishi Amano, MD (*Abstract Co-Author*) Nothing to Disclose
Miki Yoshida, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Pregnant women present to the emergency department with various conditions. Radiologists collaborate with obstetricians to select appropriate imaging modalities and make accurate diagnoses based on the situation. This exhibit will discuss emergency conditions related to pregnancy as well as non-pregnancy-related emergencies common in pregnant women, covering imaging findings, examination strategies, and treatment approaches for these situations. The teaching points of this exhibition are as follows. 1. Criteria for selecting imaging tests and contrast agents based on symptoms in pregnant women presenting to the emergency department 2. Presentation of key imaging findings contributing to the diagnosis of various emergencies during pregnancy, along with subsequent treatment

**TABLE OF CONTENTS/OUTLINE**

A. Characteristics of pregnant women B. Indications for imaging modalities and contrast agent use considering pregnancy C. Imaging features, examination strategies, and treatment of emergency conditions related to pregnancy D. Imaging characteristics, examination strategies, and treatment of emergency conditions commonly observed in pregnant women but unrelated to pregnancy

## OBEE-44 AN EDUCATIONAL OVERVIEW OF THE TYPICAL AND ATYPICAL MANIFESTATIONS OF ENDOMETRIOSIS

Dalia Kazzaz, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Ioanna Papadopoulou, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Catriona L. Davies, MBBS (*Abstract Co-Author*) Nothing to Disclose
Julia C. Hillier, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Christopher Page, MBBCh, BSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Give a brief overview of the disease process. Describe classic MRI features of endometriosis from uncomplicated to deep infiltrating endometriosis (DIE) within the pelvis. Describe key review areas when assessing the pelvis for endometriosis and DIE. Suggest a structured radiology report that aims to maintain clarity and also highlight the pertinent findings to the gynaecology team. Outline some common pitfalls when assessing the female pelvis with MR for patients with endometriosis. Showcase some uncommon sites of endometriosis that should be considered when evaluating patients. Provide some correlating surgical images to help understand and consolidate the disease process.

**TABLE OF CONTENTS/OUTLINE**

Using our database we will illustrate the various spectrum of features in endometriosis. We will begin with the common MRI findings with some key tips and pitfalls in interpreting the female pelvis. We will showcase some cases of classic deep infiltrating endometriosis. Finally we will demonstrate examples of uncommon extra-pelvic depositions in cases of umbilical, diaphragmatic, neural and subcutaneous endometriosis. Throughout we will provide some real case images of the corresponding surgical findings. We will also suggest a structured report template following the ENZIAN surgical classification to ensure radiology reports are succinct and clear when dealing with the most complex cases.

## OBEE-45 A LAPAROSCOPIC LOOK AT TORSION: UNDERSTANDING ADNEXAL AND LEIOMYOMA TORSION THROUGH ANIMATION

**Awards**
**Certificate of Merit**

Toru Honda, MD (*Abstract Co-Author*) Nothing to Disclose

**TEACHING POINTS**

Adnexal torsion occurs when an adnexa becomes twisted around the tissue supporting it, leading to stromal edema, hemorrhagic infarction, and necrosis of the adnexal structures with consequent outcomes. This painful condition is a medical emergency that can result in losing an adnexa if not treated quickly. CT and MRI are valuable for diagnosing adnexal and leiomyoma torsion, and some characteristic findings have been reported. However, radiologists have limited opportunities to study adnexal and leiomyoma torsion surgery. This presentation aims to show how adnexal and leiomyoma torsion image findings appear during laparoscopic animation.

**TABLE OF CONTENTS/OUTLINE**

A) "Imaging Features of Adnexal and Leiomyoma Torsion"
- Adnexal and leiomyoma torsion can be diagnosed using CT and MRI imaging, which can reveal the following features:
- Hemorrhagic infarction
- Twisted pedicle
- Twisted vascular pedicle: flow void
- "Lack of enhancement" sign
- Deviation of uterus
- Dark fan sign
- Rim enhancement B) "Pelvic Organ Anatomy in Laparoscopic Animation"
- Laparoscopic animation can provide a detailed view of the anatomy of the organs in the pelvis, including the adnexa, uterus, fallopian tubes, and surrounding structures. C) "Relationship between Imaging Findings and Laparoscopic Animation in Adnexal Torsion"
- Adnexal torsion can occur in various structures in the pelvis, including the ovary, paraovarian cyst, and fallopian tube, as well as leiomyoma in the uterus. Laparoscopic animation can show the following conditions:
- Massive ovarian edema
- Ovarian mature cystic teratoma
- Ovarian fibroma

- Ovarian mucinous cystadenoma
- Paraovarian cyst
- Isolated fallopian tube torsion
- Fallopian tube teratoma
- Leiomyoma

## OBEE-46 IMAGING OF ENDOMETRIAL STROMAL TUMORS: KEYS TO DIAGNOSIS

**Awards**
**Certificate of Merit**

Yu Zou (*Abstract Co-Author*) Nothing to Disclose
Le Wang (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1) A well-margined T2 high-signal tumor occurring in the uterus should prompt suspicion of endometrial stromal tumor (EST). 2) The presence of a "worm-like" or "nodular" appearance, margins or internal T2 low-signal bands, and significant high signal on DWI should raise strong suspicion for ESTs. Furthermore, the tumor grows into the uterine cavity and may exhibit the “valve opening sign”, which is a key point of differentiation from cell-rich fibroids or FH-deficient fibroids. 3) EST is a rare condition with atypical clinical presentations, often leading to misdiagnosis as benign uterine tumors on imaging studies, such as uterine fibroids, adenomyomas, and endometrial polyps. According to the site of tumor occurrence and imaging manifestations, EST is summarized into five major categories: "mass-like type", " adenomyosis-type",”endometrial-type" , "external-type" and "cystic-type", in order to improve the radiologist understanding of this disease.

### TABLE OF CONTENTS/OUTLINE

1) To provide an up-to-date overview of the classification, incidence, clinical presentation, and current status of diagnostic imaging in endometrial stromal tumors (EST). 2) Elucidate the scanning equipment, sequences, and parameters utilized for magnetic resonance examination of EST. 3) Categorize the pathological and imaging manifestations of EST, with particular emphasis on the various imaging types observed in low-grade endometrial stromal sarcoma (LG-ESS), which exhibits the highest incidence rate. 4) Explore treatment options, prognosis assessment, recurrence patterns, and metastatic potential in EST. 5) Conclude with a summary encompassing key information regarding EST.

## OBEE-47 BEYOND O-RADS 4 AND 5 : A MULTIMODALITY APPROACH TO CHARACTERIZING BORDERLINE AND MALIGNANT OVARIAN NEOPLASM SUBTYPES

Daniel Kowal, MD (*Abstract Co-Author*) Speaker, Samsung Electronics Co, Ltd
Nilisha Regmi, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The Ovarian-Adnexal Reporting and Data System (O-RADS) for ultrasound (US) and magnetic resonance imaging (MRI) has significantly improved the consistency of interpretations and risk stratification for ovarian masses. The O-RADS system aids in distinguishing between benign and worrisome characteristics, guiding the need for further workup and more aggressive management strategies. Despite its effectiveness, O-RADS does not specifically characterize subtypes of borderline and malignant tumors. Identifying distinguishing imaging features of different ovarian tumoral subtypes can aid in preoperative planning, guide the radiologist’s search pattern, and potentially influence patient management.This exhibit highlights characteristic features of high-risk ovarian lesions that are typically categorized as O-RADS 4 or 5. A multimodality approach is reviewed, including computed tomography (CT), US, and MRI.We delve into the unique imaging features of various ovarian tumor types, including borderline and malignant epithelial (serous, mucinous, endometrioid, clear cell) and malignant germ cell and sex-cord stromal tumors. We discuss pitfalls to avoid such as the importance of proper CT windowing in identifying calcified peritoneal implants and address mimicking ‘chameleon lesions’ with overlapping features such as borderline mucinous tumors, endometriomas and fluid-predominant dermoid cysts.

### TABLE OF CONTENTS/OUTLINE

•Classification and characterization of different borderline and malignant lesion (from pathologically proven sample cases) •Rare Tumors (e.g., Krukenberg tumor, lymphoma, collision tumors) •Pitfalls •Summary •Reference

## OBEE-48 PEERING INTO THE PELVIS - A DEEP DIVE INTO ENDOMETRIOSIS WITH ULTRASOUND AND MRI

Madhura A. Desai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Victoria Barbee, MD (*Abstract Co-Author*) Nothing to Disclose
Kelly L. Cox, DO (*Abstract Co-Author*) Nothing to Disclose
Sadhna Nandwana, MD (*Abstract Co-Author*) Nothing to Disclose
Neema J. Patel, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Review/recognize the endometriosis phenotypes and ultrasound (US) and magnetic resonance imaging (MRI) findings, especially those of deep infiltrating endometriosis (DIE) phenotype. Review the essential endometriosis MRI pelvis protocol sequences and key sequences for detection of endometriosis and DIE. Review pelvic anatomy to understand common sites of DIE and enhance detection.

### TABLE OF CONTENTS/OUTLINE

I. Introduction A. Endometriosis phenotypes 1. Superficial Peritoneal 2. Ovarian Endometrioma 3. Deep Infiltrating Endometriosis (DIE) II. Diagnostic tools A. Imaging - Protocols and Techniques/Sequences to Diagnose Detect 1. US 2. MRI B. Laparoscopy III. Review of Pelvic Anatomy and Compartments with Endometriosis Cases A. Anterior 1. Bladder, Urethra, Ureter 2. Round Ligament 3. Spaces/planes: prevesical space, vesicouterine pouch, and vesicovaginal septum B. Middle 1. Reproductive Organs - Vagina, Uterus, Ovaries, and Fallopian Tubes 2. Spaces/planes: Broad ligament and meso-ovarium C. Posterior 1. Rectum/rectosigmoid colon 2. Uterosacral ligaments 3. Spaces/planes: rectouterine pouch, retrocervical space, and rectovaginal septum D. Additional Sites 1. Pelvic floor 2. Abdominal wall IV. Conclusions A. DIE is the most severe phenotype of endometriosis, invading the peritoneum or adjacent structures and distorting pelvic anatomy. B. US has a role in screening for endometriosis with dynamic maneuvers and better accessibility and affordability, but MRI is key to diagnose, manage, and reduce treatment delays for conservative therapies and prior to laparoscopy with high quality, multiplanar, small field-of-view, non-fat suppressed T2-weighted sequence.

## OBEE-49 A PICTURE IS WORTH THOUSAND WORDS, BUT OPTIMIZED IMAGING IS PRICELESS: EXPERT GUIDANCE ON HOW TO FINE TUNE YOUR US IMAGES FOR O-RADS US ASSESSMENT

**Awards**
**Magna Cum Laude**

Krupa K. Patel-Lippmann, MD (*Abstract Co-Author*) Nothing to Disclose
Maitray D. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Loretta M. Strachowski, MD (*Abstract Co-Author*) Royalties, RELX;Speaker, World Class CME
Myra K. Feldman, MD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth A. Sadowski, MD (*Abstract Co-Author*) Nothing to Disclose
Katherine E. Maturen, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Catherine R. Phillips, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Use the highest frequency transducer that allows adequate depth penetration to achieve optimum visualization. Adjust focal zone, gain and field-of-view settings to optimize resolution.2. Transvaginal scanning improves imaging due to closer proximity to the ovary, increasing resolution and avoiding bowel gas; but a transabdominal approach may be the best option when ovaries are anteriorly or superiorly positioned and when transvaginal is not feasible.3. Orthogonal cine clips through the entirety of a lesion are invaluable when unable to personally scan. These clips enable evaluation of the character and number of internal components which may not be captured on static images.4. For Doppler assessment, the color box should target the region of interest to improve sensitivity and minimize artifacts. Spectral Doppler can be helpful to differentiate true vascular flow from Doppler artifact.5. Special sonographic techniques can be valuable for adnexal lesion characterization. The sliding maneuver can help to clarify lesion origin; decubitus positioning enables assessment of the mobility of cyst contents.

### TABLE OF CONTENTS/OUTLINE

1. Outline of images needed for assessment of ovarian and adnexal lesions, with focus on technical parameters and methods for optimization with illustrative examples. 2. Image-rich example cases featuring proper technique and image interpretation pitfalls due to suboptimal technique.3. Review of color and spectral Doppler technique and methods for optimization including how color flow affects the O-RADS US score in certain scenarios.

## OBEE-5 MURPHY'S LAW: WHAT CAN GO WRONG IN GYNECOLOGICAL AND OBSTETRIC PROCEDURES? A PICTORIAL ESSAY ON CASES

Leandro A. Mattos Sr, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Fernando M. Coelho, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Marcus V. Nascimento, MD (*Abstract Co-Author*) Fellow, Hospital Israelita Albert Einstein
Maria Luiza Lacerda Ribeiro (*Abstract Co-Author*) Nothing to Disclose

Luciana C. Pasquini Raiza, MD (*Abstract Co-Author*) Nothing to Disclose
Matheus M. Marcelino Dias, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The purposes of this exhibit are:- Create a multimodality-based didactic review of the main topics of complications at gynecological and obstetric procedures.- Construct a practice guide with schematic figures explaining the gynecological and obstetric procedures.- Present a didactic categorization of the following topics: myomectomy, assisted reproduction, curettage, hysterectomy, and cesarean section.- Illustrate those conditions based on cases from our radiology group.

### TABLE OF CONTENTS/OUTLINE

In this exhibit, we will discuss the principles of complications during gynecological and obstetric procedures and focus on their imaging features using a multimodality approach.INTRODUCTION- Epidemiology Imaging role based on current guidelinesCASE-BASED REVIEW- MyomectomyAbscess- Assisted reproductionOvarian hyperstimulation syndrome- CurettagePerforation- HysterectomyGonadal vein thrombosis- Cesarean sectionUreteral injury with vesicouterine fistula

## OBEE-50 ENDOMETRIOSIS: A JOURNEY FROM INFERTILITY TO FERTILITY

Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Liina Poder, MD (*Abstract Co-Author*) Nothing to Disclose
Wendaline M. VanBuren, MD (*Abstract Co-Author*) Nothing to Disclose
Madison M. Breiland, MD (*Abstract Co-Author*) Nothing to Disclose
Pamela I. Causa Andrieu, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

(1) 10-15% of reproductive-age patients have endometriosis, and 30-50% are associated with infertility.Endometriosis degree may not correlate with infertility degree. Early discussion about goals of care (pain relief versus fertility) is essential.Ovarian factor: US and antimullerian hormone levels are good markers. Antral follicle count in US reflects ovarian reserve. It's best done between days 2-5 of the menstrual cycle, counting follicles between 2-10 mm in each ovary. Endometriomas can affect follicle and oocyte recovery.Tubal factor: Hysterosalpingogram evaluates tubal patency using various imaging methods and contrast agents. It's done between days 5-11 of the menstrual cycle. Both fallopian tubes and intraperitoneal spill should be visible.Uterine factor: Adenomyosis can cause infertility by affecting implantation. Mullerian malformations may coexist with endometriosis.(2) The treatment should be personalized: expectant management, surgical removal of implants, ovulation induction, or IVF.(3) Although endometriosis usually regresses during pregnancy, complications may rarely occur: spontaneous hemoperitoneum, enlargement/abscess/rupture of ovarian endometriomas, tethering/rupture of adhesions, bowel perforation, ureteral rupture, and uterine rupture. (4) The dysfunctional uterine changes could predispose to complications: preterm birth, placenta previa, stillbirth, post-partum hemorrhage, and fetal malpresentation.

### TABLE OF CONTENTS/OUTLINE

- Endometriosis and Infertility: Diagnosis
- Endometriosis and Infertility: Treatment
- Endometriosis and Fertility: Pregnancy complications
- Endometriosis and Fertility: Peripartum complications

## OBEE-51 IUD LOCATION: ARE WE SPEAKING THE SAME LANGUAGE?

Jessica J. Koster, MD (*Abstract Co-Author*) Nothing to Disclose
Meredith Gray (*Abstract Co-Author*) Nothing to Disclose
Kelli J. Andresen, MD (*Abstract Co-Author*) Nothing to Disclose
Valerie French (*Abstract Co-Author*) Nothing to Disclose
Jill A. Jones, MD, RVT (*Presenter*) Research Consultant, Corcept Therapeutics Inc

**TEACHING POINTS**

There are numerous terms used to describe variant locations of intrauterine devices (IUDs), such as displaced, low-lying, malpositioned, or partial expulsion. However, these terms are vague and frequently misinterpreted by providers, and may lead patients to infer there is risk of personal harm or that the IUD is not adequate contraception. Current consensus guidelines from the American College of Obstetricians and Gynecologists (ACOG) state the greatest risk of unwanted pregnancy may be the unnecessary removal of a nonfundal IUD. The ACOG recommends counseling patients, whether symptomatic or asymptomatic, prior to removal of the IUD. Many providers now advocate for IUDs to be left in place if located above the internal os. For this reason, radiology reports should use clear and consistent terminology to describe IUD position and avoid terms that may raise suspicion for patient injury. We support using a simple lexicon to describe the location of IUDs on ultrasound reports, which is widely understood by OB/Gyn providers and aligns with current gynecologic literature.

**TABLE OF CONTENTS/OUTLINE**

1. Provide an overview of IUD contraception, including trends in use, efficacy, and risks/side effects 2. OB/Gyn colleagues provide a clinical perspective to IUD management, including a review of current ACOG consensus guidelines for management of nonfundal IUDs 3. Introduce standard lexicon to describe IUD location, with illustrations, ultrasound cases, and sample reports

## OBEE-52 FETAL MR IMAGING OF OBSTRUCTIVE HYDROCEPHALUS: PICTORIAL REVIEW OF AETIOLOGIES

Andrea Righini (*Abstract Co-Author*) Nothing to Disclose
Giana Izzo (*Abstract Co-Author*) Nothing to Disclose

Chiara Doneda (*Abstract Co-Author*) Nothing to Disclose
Cecilia Parazzini (*Abstract Co-Author*) Nothing to Disclose
Filippo Arrigoni (*Abstract Co-Author*) Nothing to Disclose
Mario Tortora, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Fetal ventriculomegaly can be broadly classified as obstructive or non-obstructive. Several pathologies and malformations can lead to obstructive ventriculomegaly by interrupting CSF normal flow. Identifying these entities can facilitate diagnosis and clarify the mechanisms underlying ventriculomegaly as well as optimize prognostic and therapeutic management. Incorporating visual representations of etiologic pictures is beneficial for both novice and experienced radiologists specializing in fetal imaging.

**TABLE OF CONTENTS/OUTLINE**

Ventriculomegaly is the most commonly depicted abnormality of the fetal CNS at prenatal imaging. This finding is nonspecific, with a rate of associated malformations ranging from 10% to 50%. The understanding of causal factors at prenatal stage may be a challenge and is further confounded by the lack of histopathological data. Response to treatment and prognostication are not clearly defined. Early and accurate diagnosis at prenatal MRI is therefore essential, allowing improved prenatal counselling and facilitating appropriate referral. We retrospectively reviewed our Fetal MRI database (4568 exams). We included 201 cases of obstructive hydrocephalus according strict inclusion criteria: isolated aqueduct stenosis (36.3%); hemorrhagic events leading to secondary aqueduct obstruction (30.3%); rhombencephalosynapsis (7.5%); dural sinus malformation (6%); midline cysts (5.4%); diencephalic-mesencephalic junction (DMJ) dysplasia (3.5%); infective based lesions (3%); tumor/hematoma (2.5%); Chiari 1 (1.5%); Walker-Warburg disease (1%); miscellanea (3%). We discuss MR features providing clinical and postnatal MRI or histopathology correlation.

## OBEE-53 THE ROLE OF THE RADIOLOGIST IN THE EVALUATION OF UTERINE ADENOMYOSIS

Ana Belen Barba Arce, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Explain what adenomyosis consists of: etiopathogenesis, clinical manifestations, risk factors, and treatment. 2. Review normal uterine anatomy. 3. Present the diagnostic methods used to detect adenomyosis, focusing on its evaluation through magnetic resonance imaging (MRI). 4. Show the different manifestations of adenomyosis and their characteristics as seen on MRI. 5. Describe possible pitfalls and the differential diagnosis.

**TABLE OF CONTENTS/OUTLINE**

1. What is adenomyosis?. 2. Etiopathogenesis. 3. Incidence. 4. Clinical manifestations. 5. Risk factor's. 6. Diagnostic tests. 7. Treatment. 8. MRI study protocol. 8.1. Previous recommendations. 8.2. Sequences. 9. Anatomical review. 10. Classification of adenomyosis by MRI. 11. Characteristic findings of adenomyosis by MRI. 11.1. Diffuse adenomyosis. 11.2. Focal adenomyosis. 12. Pitfalls. 12.1. Physiologic changes in the uterine body during the menstrual cycle. 12.2. Uterine contractions. 12.3. Postmenopausal uteruses and in women using contraceptive drugs. 13. Differential diagnosis. 13.1. Leiomyoma. 13.2. Endometriosis. 13.3. Accessory cavitated uterine mass. 13.4. Myometrial invasion by endometrial cancer. 13.5. Low-grade endometrial stroma sarcoma. 13.6. Maligned adenomiosis. 14. Conclusions.

## OBEE-54 ULTRASOUND APPROACH TO ADENOMYOSIS, THE FIRST AND BIGGEST STEP IN DIAGNOSIS

Rodrigo Arrieta Darras, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-Identify the normal ultrasound findings of the uterus and the main characteristics and classification of adenomyosis.-Illustrate the featured ultrasound signs and imaging data in the diagnosis of adenomyosis.

**TABLE OF CONTENTS/OUTLINE**

-Normal ultrasound findings of the uterus.-Some facts of adenomyosis: -History -The introduction of ultrasound as a diagnostic modality of this disease. -Using different modalities of ultrasound-Video clips and the importance of making them.

## OBEE-55 TUMOR-LIKE CONDITIONS AND PSEUDOTUMORAL LESIONS IN THE FEMALE PELVIS: IMAGING FEATURES, DIFFERENTIAL DIAGNOSIS, AND THERAPEUTIC STRATEGY

Masafumi Harada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kenji Matsuzaki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mayumi Takeuchi, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Nonneoplastic conditions may present tumor-like manifestations in the uterus and adnexa, and normal organs may undergo dynamic changes with physiological conditions or hormonal stimulation appearing as pseudotumoral "Don't Touch" lesions. They are common in young women, occasionally with hormonal activity, and are often associated with pregnancy. Accurate diagnosis is important for the appropriate management to avoid excess surgical procedures and to preserve fertility and function. A wide spectrum of clinical and imaging features, and therapeutic strategies are reviewed. 2. To demonstrate look-alike tumors and tumor-like lesions on imaging, and to describe the clues to the differential diagnosis.

**TABLE OF CONTENTS/OUTLINE**

1. Physiological changes of normal organs: age, menstrual cycle, pregnancy, medication 2. Ovarian histological anatomy w/ hormonal synthesis 3-a. Pathogenesis of tumor-like lesions related to hormonal excess: gonadotropins, estrogen, androgen 3-b. Clinical features of functioning lesions: direct and indirect signs 4-a. Non-neoplastic ovarian cysts, 4-b. Enlarged ovaries w/ stromal proliferation or edema, 4-c. Pregnancy-related ovarian lesions 5-a. Non-neoplastic uterine lesions: Myometrial, Pregnancy-related, C-section scar-related 6. Endometriosis and related lesions 7. PID and related lesions 8. Advanced MR techniques: 3D-T2WI, DWI (computed /reduced FOV), SWI, DCE-MRI, MR Spectroscopy 9. Treatment options: Conservative, Minimal invasive, Fertility /function preserving

## OBEE-56 DIAGNOSTIC AND MANAGEMENT IMPLICATIONS OF 2023 FIGO STAGING FOR ENDOMETRIAL CANCER: A PRIMER FOR RADIOLOGISTS

**TEACHING POINTS**

Familiarize the audience with 2023 updates of the FIGO Endometrial Cancer (EC) Staging System Review new molecular classifications, pathologic advances, natural history novel therapies Describe the imaging findings adapted to updated 2023 FIGO staging system with emphasis on potential diagnostic management implications Discuss novel treatments role of imaging in assessing treatment efficacy

**TABLE OF CONTENTS/OUTLINE**

Introduction Review newly proposed 2023 FIGO Endometrial cancer staging system Pathology, genetics molecular biology Grading: Grades 1-3 Histology: Aggressive Non-aggressive; Endometrioid, Serous, clear cell, undifferentiated, carcinosarcoma mixed Lymphovascular space invasion Molecular classification: POLEmut (good prognosis), Mismatch repair deficient, No specific molecular profile p53abn (worse prognosis) Role of sentinel lymph node biopsy Imaging techniques: US, CT, MRI PET/CT MRI role in preoperative assessment: Tailor presurgical treatment, risk stratification management Effect of FIGO staging on imaging recommendations: CT vs. MRI vs. PET/CT Diagnostic and management implications MRI Role: Myometrial or cervical stromal invasion? •Uterine body, serosal, adnexal, or parametrial involvement? Pelvic, periaortic lymphadenopathy? •Distant metastases?•Treatment complications? •Recurrent disease? Role of imaging in fertility preservation strategies Novel treatments role of imaging in assessing treatment efficacy ConclusionAdvances in understanding pathology molecular classifications of EC led to 2023 FIGO staging system. MRI helps in preop assessment, risk stratification selection of most appropriate initial therapy.

## OBEE-57 THE UPDATED 2023 STAGING OF ENDOMETRIAL CANCER. TIPS FOR MRI INTERPRETATION

Alfonso Iglesias, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Learn about the current modifications in the new FIGO 2023 endometrial cancer staging Recognize the differences from the previous staging system Know the major changes in the revised FIGO 2023 endometrial cancer staging that affect MR imaging interpretation

**TABLE OF CONTENTS/OUTLINE**

Explain the new FIGO 2023 staging for endometrial cancer that includes the various histological types, tumor patterns, and molecular classification because they affect prognosis and enable a more appropriate treatment planning Description of the changes incorporated in the new FIGO 2023 with emphasis on the modifications that have occurred with respect to the FIGO 2009 staging Show MRI findings in different stages of endometrial cancer and their correlation with the updated FIGO 2023 staging and its pathological correlation and to identify those MRI findings that condition the management of patients with endometrial carcinoma

## OBEE-58 FETAL MRI: ABDOMINAL CYSTIC LESIONS

Javier Carrascoso Arranz (*Abstract Co-Author*) Nothing to Disclose
Alejandro Diaz Moreno, MD (*Abstract Co-Author*) Nothing to Disclose
Vicente Martinez de Vega, PhD (*Abstract Co-Author*) Nothing to Disclose
Lucia Sanabria, MD (*Abstract Co-Author*) Nothing to Disclose
Julia Lopez Alcolea, MD (*Abstract Co-Author*) Nothing to Disclose
David Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Manuel R. Recio Rodriguez, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

· MRI is a complementary tool to ultrasound that helps characterize lesions and assess the degree of extension.· Ovarian cysts are very common cystic lesions in female fetuses and often bleed.· Gradient echo sequences in phase and opposed phase can detect the presence of fat in teratomas.· Diffusion sequence allows us to calculate the ADC of teratomas; immature teratomas present lower ADC values than mature ones due to increased cellularity.

**TABLE OF CONTENTS/OUTLINE**

Prenatal diagnosis of abdominal cystic lesions by ultrasound is quite common. Fetal MRI, with its multiplanar capacity and greater tissue characterization, aids in diagnosing these lesions and better assessing their extension.Cystic lesions are classified into gastrointestinal (intestinal duplication cysts, meconium pseudocysts, lymphatic malformations, hepatic and biliary cystic lesions, splenic cysts, and intestinal dilatations), genitourinary (ovarian cysts, hydrometrocolpos, urogenital sinus, cloacal malformation, renal and adrenal cystic lesions), cystic teratomas, and lesions associated with the Currarino triad.Characteristic radiological findings of these lesions are described, as well as the different MRI sequences useful for diagnosis.

## OBEE-59 FETAL MRI: MIDLINE ANOMALIES AND CORTICAL DEVELOPMENT MALFORMATIONS

Paula Molina Vigara, MD (*Abstract Co-Author*) Nothing to Disclose
Vicente Martinez de Vega, PhD (*Abstract Co-Author*) Nothing to Disclose
Julia Lopez Alcolea, MD (*Abstract Co-Author*) Nothing to Disclose
Alejandro Diaz Moreno, MD (*Abstract Co-Author*) Nothing to Disclose
David Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Lucia Sanabria, MD (*Abstract Co-Author*) Nothing to Disclose
Manuel R. Recio Rodriguez, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Fetal MRI:• Has high sensitivity in detecting midline anomalies,• Detects anomalies associated with dysgenesis of the corpus callosum followed by cortical malformations and posterior fossa anomalies.• Identifies all forms of holoprosencephaly.• Is the technique of choice for cortical development malformations, lacking the limitations of ultrasound.

**TABLE OF CONTENTS/OUTLINE**

Different midline anomalies are described, including dysgenesis of the corpus callosum, alobar, semilobar, or lobar holoprosencephaly, septo-optic dysplasia, lipoma of the corpus callosum, interhemispheric cysts and absence of the cavum pellucidum. The characteristic radiological findings of each pathology and the most frequent associated genetic alterations are shown.Cerebral cortical development is divided into three processes: cell proliferation (2nd to 4th month), neuronal migration (3rd/4th month to week 24), and cortical organization (week 22 to 2 years of age). The classification proposed by Barkovich in 2012 is reviewed, showing radiological findings and the main associated genetic alterations in:• Proliferative disorders: Decreased proliferation (microlissencephaly), increased proliferation (hemimegalencephaly), and abnormal proliferation (cortical dysplasia or cortical hamartomas of tuberous sclerosis).• Migration disorders: Decreased migration (classical lissencephaly), increased migration (congenital muscular dystrophy), ectopic migration (heterotopias).• Cortical organization disorders: Polymicrogyria and schizencephaly (closed-lip type I, open-lip type II).

## OBEE-6 FROM TWISTS TO INFECTIONS: A TUBE PICTORIAL ESSAY BEYOND YOUTUBE

Matheus M. Marcelino Dias, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purposes of this exhibit are:- Create a multimodality-based didactic review of the main topics of the study of the uterine tube with multiple imaging methods.- Construct a practice guide with schematic figures explaining the main complications of the uterine tube.- Suggest a didactic categorization of the following topics: fertility study, acute emergency complication, neoplasm with tubal involvement, infectious complication, and obstetric complication.- Illustrate those conditions based on cases from our radiology group.

**TABLE OF CONTENTS/OUTLINE**

In this exhibit, we will discuss the principles of complications during gynecological and obstetric procedures and focus on their imaging features using a multimodality approach.INTRODUCTION - Review the main conditions related to uterine tube.- Describe the imaging protocols.CASE-BASED REVIEW- Fertility studyhysterosalpingographymagnetic resonance hysterosalpingography- Acute emergency complicationtubal torsion- Tumor with tubal involvementendometrioid carcinomatubal adenomatoid tumor- Infectious complicationInfectious complication- Obstetric complicationEctopic pregnancyHeterotopic pregnancy

## OBEE-60 ULTRASOUND OF THE POST PROCEDURE UTERUS: CHRONIC FINDINGS WITH CORRELATIVE IMAGING

Shuchi K. Rodgers, MD (*Abstract Co-Author*) Royalties, RELX
Mindy M. Horrow, MD (*Presenter*) Spouse, Employee, Bristol-Myers Squibb Company

**TEACHING POINTS**

1. The configuration of an anteverted and retroflexed uterus is rare other than related to adhesions from Cesarean section and may cause sub-optimal transvaginal imaging 2. Clinical complications related to the Cesarean section scar include dysfunctional bleeding, ectopic pregnancy and IUD malposition 3. Residual functional endometrial tissue after endometrial ablation can lead to cornual hematosalpinx, hematometra and adenomyosis 4. Post ablation tubal sterilization syndrome may occur after ablation in patients with prior tubal ligation when egress of blood from residual endometrium is obstructed in antegrade and retrograde directions, leading to cyclic pelvic pain despite amenorrhea

**TABLE OF CONTENTS/OUTLINE**

A. C-section- changes in uterus 1. Position 2. Scar a. Appearance of scar(s) b. Appearance of niche/isthmocele i. Measurement ii. SIS 3. Complications of the uterine scar a. Dysfunctional bleeding b. Ectopic pregnancy c. IUD malposition 4. Complications of the abdominal wall scar a. Endometrial implants b. Hernia c. Bowel obstruction B. Endometrial Ablation a. Background b. Normal appearance c. Complications i. Symptomatic obstructed menses ii. Hematometra 1. Central 2. Cornual iii. Adenomyosis iv. Post ablation tubal sterilization syndrome v. Other considerations (pregnancy, malignancy) C. Fibroid Treatments a. Myomectomy b. Uterine artery embolization D. Other a. Synechiae b. Vascular complications: AVM, PSA c. Retained devices related to uterine procedures d. Obstructed uterus

## OBEE-61 ACUTE GYNECOLOGICAL PAIN AND ITS RADIOLOGICAL FINDINGS BY TC

Pascual Adrian Gonzalvo Gomez (*Abstract Co-Author*) Nothing to Disclose
Samuel Roldan Minana (*Abstract Co-Author*) Nothing to Disclose
Elena Pascual Perez, MD (*Abstract Co-Author*) Nothing to Disclose

Elena Sierra, MD (*Abstract Co-Author*) Nothing to Disclose
Marina Rozas (*Abstract Co-Author*) Nothing to Disclose
Myriam Segarra Hernandez (*Abstract Co-Author*) Nothing to Disclose
Paloma Briceno Torralba, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Accurate evaluation of acute gynecological pathology presenting with acute pain through CT is challenging due to different gynecological conditions.- Emergency radiology in the rigorous diagnosis of urgent gynecological pathology as well as in guiding therapeutic planning is crucial due to a high morbimortality.

**TABLE OF CONTENTS/OUTLINE**

Acute gynecological pain represents a significant clinical challenge, with various forms of clinical presentation that can range from benign ailments to potentially life-threatening conditions. In this context, computed tomography (CT) has emerged as an essential tool for the fast and accurate evaluation of these conditions due to its capacity to generate detailed images rapidly. However, despite the latest advances in CT image resolution, the female pelvic region remains a tackled area to characterize and poses a challenge even for the most experienced radiologists.This review aims to explore, by different examples, the role of CT in the initial evaluation of emergent gynecological pathologies, such as ruptured ectopic pregnancy or sepsis due to pelvic inflammatory disease, often requiring immediate treatment through radiological intervention or surgery. It will also focus on other gynecological manifestations that necessitate precise differential diagnosis from other commonly occurring intra-abdominal processes due to their urgent nature.

## OBEE-62 LOOK CAREFULLY: IT'S NOT AN OVARIAN LESION!

Jorge Elias JR, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Leticia Helena Kaca Do Carmo (*Abstract Co-Author*) Nothing to Disclose
Pamela Grazielle Correa De Oliveira (*Abstract Co-Author*) Nothing to Disclose
Guilherme N. Alves, MD, MSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The adnexal and paraovarian regions can harbor various pathologies, ranging from infectious to neoplastic conditions. It's crucial for radiologists to accurately characterize and diagnose these lesions, although extraovarian findings are often overlooked due to the higher frequency of ovarian involvement. This presents a diagnostic challenge. This review aims to discuss the most common paraovarian conditions and their identification on Magnetic Resonance Imaging (MRI), Computed Tomography (CT), and Ultrasound images, with an emphasis on distinguishing them from ovarian lesions. While many findings are benign and similar to adnexal lesions, leiomyomatosis, and endometriosis affecting atypical sites like the broad ligament should be noted. Fluid-filled lesions such as hydrosalpinx, hematosalpinx, paraovarian cysts, and peritoneal inclusion cysts are also noteworthy. Malignant lesions are typically secondary, often originating from the pelvis and abdomen, although primary neoplasms can occur, posing challenges in diagnosis. Schwannomas and neurofibromas along pelvic nerves are potential findings. In fertile patients, ectopic pregnancy should be considered as a differential diagnosis for paraovarian masses. Given that accurate diagnosis can expedite treatment, recognizing and confidently reporting prevalent extraovarian lesions is paramount.

**TABLE OF CONTENTS/OUTLINE**

- Detailed anatomy of the adnexal region with imaging correlation; - The list of differentials, including the most common paraovarian lesions;- How to identify classic findings of extraovarian origin and how to confidently differentiate them from ovarian ones.

## OBEE-63 PICTORIAL REVIEW OF BILATERAL ADNEXAL LESIONS

Jean p. Akakpo Sr, MD, MD (*Abstract Co-Author*) Nothing to Disclose
Olivier Lucidarme, MD, PhD (*Abstract Co-Author*) Speaker, Bracco Group;Speaker, F. Hoffmann-La Roche Ltd;Expert Witness, Bayer AG
Natalia H. Concatto, MD (*Abstract Co-Author*) Nothing to Disclose
Yasmina Badachi, MD (*Abstract Co-Author*) Nothing to Disclose
Catherine Uzan (*Abstract Co-Author*) Nothing to Disclose
Salma Ayadi, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Explore the spectrum of bilateral adnexal lesions.• Highlight the diagnostic nuances and imaging characteristics of common and uncommon entities, also benign and malignant.• Present a selection of cases to illustrate.

**TABLE OF CONTENTS/OUTLINE**

Bilateral adnexal lesions pose a diagnostic challenge in clinical practice, necessitating a multidisciplinary approach for accurate assessment and management. These lesions, affecting structures such as the ovaries, fallopian tubes, and surrounding tissues, stem from diverse etiologies, including inflammatory, infectious, neoplastic, and functional causes.The first step when bilateral adnexal lesions are found is to exclude infection (ie: tubo-ovarian abscesses), endometriomas and functional affections such as: polycystic ovary syndrome, hyperthecosis and ovarian hyperstimulation syndrome.When organic bilateral adnexial tumors are diagnosed, the radiologist should describe and stratify the risk of malignancy of each tumor according to the Ovarian-Adnexal Reporting and Data System (O-RADS). However, the O-RADS does not include any observations when lesions are bilateral. We often encounter bilateral lesions, sometimes with divergent O-RADS categories, which may or may not be of the same etiology. Certain pathologies, such as serous carcinoma, mature teratoma, and metastasis, exhibit a propensity for bilateral involvement. Knowledge of these entities and their differential diagnoses is imperative for enriching diagnostic reports alongside O-RADS categorization.This pictorial review aims at aiding radiologists in identifying and interpreting imaging findings associated with bilateral adnexal lesions.

## OBEE-64 WORKING IN CONCERT: RADIOLOGY, PATHOLOGY, AND GYNECOLOGY ONCOLOGY APPLICATIONS OF THE 2023 FIGO UPDATES IN ENDOMETRIAL CANCER STAGING

Jamie McDowell (*Abstract Co-Author*) Nothing to Disclose
David Bass, MD (*Abstract Co-Author*) Nothing to Disclose

Denes Szekeres, BS (*Abstract Co-Author*) Nothing to Disclose
Wei Li (*Abstract Co-Author*) Nothing to Disclose
Tannaz Rajabi (*Abstract Co-Author*) Nothing to Disclose
Ashlee Smith (*Abstract Co-Author*) Nothing to Disclose
Akshya Gupta, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. The FIGO classification for endometrial cancer was recently updated, with key differences in staging that are important for radiologists to be aware of. 2. Radiologic/pathologic correlation for endometrial cancer, including different histologic subtypes and molecular classifications, will be provided. The associated clinical implications and management recommendations will be highlighted in a case-based format.

**TABLE OF CONTENTS/OUTLINE**

1. Introduce endometrial cancer demographics, clinical presentation, and initial work-up 2. Review of the updated 2023 FIGO endometrial cancer staging system with emphasis on changes from the prior system3. Case based discussion of patients with different stages of endometrial cancer, with multimodality radiologic findings and associated pathologic correlation. Specific concepts that will be addressed include: a. Non-aggressive and aggressive histologic subtypes b. Importance of myometrial and lymphovascular space invasion c. Review of molecular classification of endometrial tumors and updated prognostic and staging implications d. Key radiologic and pathologic features that impact clinical management and treatment options 4. Pitfalls of the new staging system and current gaps in the literature

## OBEE-65 BEYOND THE SURFACE: ENHANCING DIAGNOSTIC ACCURACY WITH MULTIPLANAR RECONSTRUCTION IN SALINE INFUSION SONOHYSTEROGRAPHY

**Awards**
**Certificate of Merit**

Veronica Espinosa Cruz, MD (*Abstract Co-Author*) Nothing to Disclose
Hugo A. Cervantes Flores, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela Briones, MD (*Abstract Co-Author*) Nothing to Disclose
Montserrat M. Cuadra, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Provide the learners with information about the procedure, materials, and techniques involved in sonohysterography, describing each step in a systematic manner. 2. Discover the potential of multiplanar reconstructive ultrasound images for detection of uterine pathologies, offering exceptional insights into anatomical structures and spatial relationships. 3. Explore the different imaging techniques available in uterine and endometrial pathologies, analyzing their respective advantages and limitations. 4. Describe the main abnormalities that we can diagnose with sonohysterography, identifying and interpreting these findings with precision and expertise. 5. Communicate and navigate the complexities of image interpretation in sonohysterography.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction to Sonohysterography: a. Evolution and advancements in gynecologic ultrasound techniques. b. Advantages of saline-infused sonohysterography and comparing different imaging techniques. 2. Fundamentals of Hysterosonography Technique: a. Patient preparation and positioning for hysterosonography. b. Materials. c. Imaging protocol and step-by-step instructions. 3. Normal sonographic anatomy of the uterine cavity 4. Clinical Applications and Utility of Hysterosonography a. Congenital uterine malformations b. Endometrial polyps c. Endometrial hyperplasia d. Leiomyomas e. Uterine adhesion bands 5. Diagnostic Pitfalls and Challenges in Image Interpretation

## OBEE-66 LOOKING INTO PLACENTA ACCRETA SPECTRUM WITH MRI:RADIOLOGIC-PATHOLOGIC CORRELATION

Lia A. Moulopoulos, MD (*Abstract Co-Author*) Nothing to Disclose
Anastasia Konstantinidou (*Abstract Co-Author*) Nothing to Disclose
Marianna Konidari, MD (*Abstract Co-Author*) Nothing to Disclose
Charis Bourgioti, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Placenta accreta spectrum (PAS) is considered an iatrogenic disease and it may be associated with major ante- and postpartum complications for both mother and fetus, especially if not diagnosed prenatally. • Traditionally used terminology of placenta accreta, increta, and percreta is under debate and the so-called percreta cases are attributed to uterine dehiscence and adhesions between uterine serosa and posterior bladder wall. • Standardization and update of clinical, pathologic and imaging criteria for PAS diagnosis and grading is pivotal for improvement in diagnosis and treatment of PAS. • Familiarity with the main MRI findings of PAS and deeper understanding of the clinical relevance of each sign through pathologic correlation, will help radiologists provide more accurate diagnoses, optimizing patient care.

**TABLE OF CONTENTS/OUTLINE**

• Introduction to PAS: Definitions, epidemiology, predisposing factors, common clinical findings, and appropriate diagnostic imaging modalities. • Current challenges in understanding the pathophysiology of PAS and debate on its clinical and histopathological confirmation. • Prenatal use of MRI in PAS diagnosis and management: A routine or an adjunct assessment tool? • Normal placenta pathology and correlation with MRI anatomy. • MRI protocols for PAS evaluation: Conventional protocols and implementation of advanced functional techniques • MRI description, pathophysiological and rad-path correlation of MRI signs of PAS according to SAR/ESUR joint consensus guidelines. Is it possible to discriminate between uterine dehiscence and PAS myoinvasion? • Follow-up MRI in patients with uterine sparing management for PAS. What to expect.

## OBEE-67 FINDING YOUR NICHE: IMAGING FINDINGS ALONG THE SPECTRUM OF CESAREAN SECTION SCAR COMPROMISE AND OTHER POST-CESAREAN COMPLICATIONS

Erin N. Gomez, MD (*Abstract Co-Author*) Nothing to Disclose
Ishwarya Sivakumar (*Abstract Co-Author*) Nothing to Disclose
Julia Fisher, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Cesarean Section (CS) is increasingly common. Surgical techniques vary and include classic transverse, fundal and midline vertical incisions.2. The spectrum of cesarean scar compromise includes uterine niche, uterine window, uterine dehiscence, and uterine rupture. Each entity has its own imaging features and clinical implications.3. MRI is the imaging modality of choice to evaluate cesarean scar compromise given field of view, tissue resolution and clear delineation of uterine layers.4. Key features of CS scar defects that should be reported include maximum myometrial thickness and proximity of the abnormal myometrium to the urinary bladder.5. Additional complications of CS can occur concomitantly including infection, hematoma, adhesive disease, placenta accreta spectrum and CS ectopic pregnancy.

**TABLE OF CONTENTS/OUTLINE**

1. Background including rates of Cesarean Section (CS). 2. Surgical technique: Classic, fundal and midline vertical incision3. Uterine Scar physiology, uterine anatomy, and normal appearance of the nulliparous and post-CS uterus 4. Protocol recommendations for MR evaluation of the post-CS uterus. 5. Spectrum of cesarean section scar compromise including: uterine niche. uterine window, uterine dehiscence, and uterine rupture6. What the surgeon needs to know: descriptors and features to report that may aid in operative planning7. Additional complications of CS including infection, endometritis, surgical site abscess, post operative hematoma, adhesive disease, CS ectopic, and placenta accreta spectrum. 8. Conclusion

## OBEE-68 EMPOWERING DIAGNOSIS: THE RADIOLOGIST'S KEY ROLE IN PRIMARY AMENORRHEA MANAGEMENT

Maria N. Napoli, MD (*Abstract Co-Author*) Nothing to Disclose
Carolina R. Chacon, MD (*Abstract Co-Author*) Nothing to Disclose
Martina Aineseder, MD (*Abstract Co-Author*) Nothing to Disclose
Kevin Kurt Mac Allister (*Abstract Co-Author*) Nothing to Disclose
Ayelen Leao, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Florencia Trila, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Radiology should be the first referral department as imaging plays a key role.Ultrasound is the first line investigation while Magnetic resonance imaging is important for accurate diagnosis and surgical planning.The kidneys should be assesed at all times in mullerian duct anomalies given the high frecuency of anomalies (30%)The Herlyn-Werner-Wunderlich syndrome (HWWS) usually presents as a triad: didelphys uterus, low genital obstruction and unilateral renal anomaly.Hypothalamic-pituitary axis alterations may be suspected due to findings on ultrasound such as an infantile uterus or the absence of secondary sexual characteristics.

**TABLE OF CONTENTS/OUTLINE**

Primary amenorrhea is defined as the absence of menarche at age 16 years with normal growth and development of secondary sexual characteristics, or at age 14 years in the absence of normal growth or development of secondary sexual characteristics. Its incidence is approximately 3,000 per 100,000 individuals, mainly due to hypothalamic amenorrhea. The menstrual cycle depends on the proper functioning of the hypothalamic-pituitary-ovarian axis and its target organs that constitute the outflow tract (uterus and vagina). Any alteration in these structures can trigger amenorrhea.The management of a patient with primary amenorrhea requires an interdisciplinary approach and the radiologist plays a key role since up to approximately 67% of the diagnoses are made by means of an imaging study.In order to organize the etiologies in a logical and educational way it is proposed to divide the causes into three levels. Level 1: Outlet tract. Level 2: Gonadal. Level 3: Diencephalon.

## OBEE-69 FEMALE GENITAL TRACT CONGENITAL ANOMALY SPECTRUM: THE ROLE OF IMAGING IN CLASSIFICATION, SURGICAL PLANNING, AND MULTIDISCIPLINARY CARE

**Awards**
**Cum Laude**

Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Marjan Attaran (*Abstract Co-Author*) Nothing to Disclose
Wendaline M. VanBuren, MD (*Abstract Co-Author*) Nothing to Disclose

Cara King (*Abstract Co-Author*) Nothing to Disclose
Swati V. Putcha, DO (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Female genital tract congenital anomalies (FGTCAs) impact up to 7% of those assigned female at birth and up to 25% of women with infertility or history of miscarriage. 2. FGTCAs are often associated with renal, vascular or bony anomalies due to complex embryologic interplay. 3. FGTCAs impact patients throughout their lifetime. Counseling and treatment must consider future phases of life. 4. Multidisciplinary care centers offer patients a comprehensive approach to medical management optimization and surgical correction tailored to a patient’s desires. 5. Transvaginal ultrasound is first-line imaging modality for FGTCA, but may not be possible in those with vaginal agenesis or younger patients. MRI is second-line non-invasive imaging modality for diagnosis, identification of associated anomalies, concurrent pathologies, treatment planning, and identification of innate and post-surgical complications. 6. MRI protocol tailored for FGTCA evaluation is necessary to aid in accurate classification and surgical planning.

**TABLE OF CONTENTS/OUTLINE**

1. Title 2. Disclosures 3. Learning objectives 4. Female genital tract congenital anomaly background information and embryology 5. MRI protocol and report considerations 6. Case examples with imaging and management / surgical planning information (septate spectrum longitudinal transverse; rudimentary horn spectrum including communicating, non-communicating and ACUM; agenesis cases including MRKH, cervical and vaginal agenesis, AIS; complex anomalies, associated anomalies including GU, vascular and osseous). 7. Conclusion 8. References

**TEACHING POINTS**

To discuss the diagnosis and management of early and late onset growth restriction, highlighting: The importance of early detection and understanding the distinction between small for gestational age (SGA) and fetal growth restriction (FGR) is paramount for fetal health. Ultrasound assessment that

encompasses essential parameters, timing, and frequency of surveillance, guided by ISUOG criteria for interpreting fetal growth charts. Management strategies in fetal care based on the severity of SGA/FGR and gestational age, considering optimal timing and mode of delivery. Future directions: Ongoing research in the field of SGA and FGR.

**TABLE OF CONTENTS/OUTLINE**

1. IntroductionOverview of Growth Restriction (GR) in PregnancyImportance of Early Detection and Management 2. Understanding Growth Restriction Definition and Classification of Growth Restriction Pathophysiology of Early and Late Onset Growth Restriction Risk Factors and Contributing Factors 3. Ultrasound Evaluation of Growth Restriction Role of Ultrasound in Prenatal Assessment Measurement Parameters for Fetal Growth Assessment 4. Early Onset Growth Restriction: Diagnosis and Management Clinical Features and Diagnostic Criteria Ultrasound Findings and Biometric Parameters Antenatal Surveillance Strategies Interventional Strategies and Management Approaches 5. Late Onset Growth Restriction: Diagnosis and Management Clinical Characteristics and Diagnostic Challenges Ultrasound Markers and Predictive Models Therapeutic Interventions and Management Strategies 6. Role of Advanced Ultrasound Imaging Techniques 7. Future Directions and Research Opportunities 8. Conclusion

**TEACHING POINTS**

1. Acquiring T2WI and Post-contrast T1WI with 3mm slice thickness is important to ensure visualization of small papillary projections.2. In/opposed phase images in addition to fat suppressed images are essential as dermoids may only contain microscopic fat.3. The high b value in the DWI acquisition must be at least 1000s/mm2 to ensure sufficient signal loss from fluid in cysts.4. Parallel imaging and multi band techniques can decrease acquisition time for DWI.5. Employ left/right phase encoding and anterior saturation bands on T2WI to decrease motion artifact.6. Time intensity curves can risk stratify lesions into O-RADS MRI 3, 4, and 5, while visual inspection single phase post contrast sequence can only stratify between O-RADS 4 and 5 with decreased positive predictive value.7. ROIs for time intensity curves must be placed on enhancing adnexal solid tissue and the outer myometrium for proper risk stratification.

**TABLE OF CONTENTS/OUTLINE**

1. Review the minimum requirements for MRI sequences and optimal imaging planes needed for using the O-RADS MRI risk score.2. Image rich case based review of pitfalls and importance of optimization of each sequence.3. Details on how to perform time intensity curve analysis properly.

## OBEE-9 NEXT-GENERATION DIAGNOSTICS: UNVEILING THE POWER OF $^{23}$NA-MRI IMAGING IN THE FIELD OF GYNECOLOGY

**TEACHING POINTS**

The regulation of sodium (Na+) ion influx into cells is crucially maintained by Na+ channels, Na+/H+ and Na+/Ca2+ exchangers, while Na+ ion efflux is facilitated by Na+/K+-ATPase, ensuring a significant transmembrane Na+ ion gradient. When this regulatory system is compromised, it leads to disruptions in the intracellular sodium concentration, fostering cancer metastasis by enabling cellular invasion and migration. Furthermore, Na+ ion accumulation around cancer cells, often a result of inflammation, enhances tumor immunogenicity. Consequently, alterations in Na+ ion levels could serve as vital biomarkers for the diagnosis and prognosis of tumors. 23Na-MRI stands out by providing insights into changes in Na+ ion concentration within tumors and provides biochemical information that reflects cell viability, structural integrity, and energy metabolism. This technology has proven its efficacy in detecting early molecular-level therapeutic responses before any morphological changes become apparent. In this exhibition, we delve into the basic principles of 23Na-MRI technology and explore its potential for clinical application as a non-invasive diagnostic tool, specifically in the field of gynecology.The teaching points of this exhibit are: 1. The basic principles of 23Na-MRI technology.2. The potential of 23Na-MRI for clinical application as a non-invasive diagnostic tool, specifically in the field of gynecology.

**TABLE OF CONTENTS/OUTLINE**

A. The basic principles of 23Na-MRI technology and its limitations.B. Actual 23Na-MRI images of various gynecological conditions including benign and malignant, along with interpretations of their findings.

RSNA 2024

### TEACHING POINTS

- Preterm birth (PTM) continues to stand as the foremost cause of perinatal morbidity and mortality globally, with a reduced cervical length (CL) representing a clinical marker classically associated with an increased risk of preterm delivery.- Ultrasound (US) is the primary imaging method for evaluating the gravid cervix in patients at high risk for PTB (including asymptomatic women) or those exhibiting signs of preterm labor.- CL measured by US is a very useful screening test that has been associated with better prediction of PTB than previously available tests.- This pictorial review aims to illustrate key concepts in the clinical use of US as a screening tool for PTB, focusing on the evaluation of CL. Based on a step-by-step approach, we propose a systematization of this examination tailored for clinical radiologists.

### TABLE OF CONTENTS/OUTLINE

1. Background: Preterm birth- Risk factors- Screening and prevention2. Anatomy of uterine cervix and changes during pregnancy3. US-based screening strategies for preterm birth- Cervical length- Other US findings (funneling, amniotic fluid sludge, etc)4. US techniques: - Transabdominal - Translabial - Transvaginal - 3D Imaging - Elastography5. ACR Appropriateness Criteria: a step-by-step approach6. Management of short cervix: what to know and what to look for7. Summary and take-home messages

## ENDOMETRIOSIS OF THE ADNEXA ON MRI: AN IN-DEPTH REVIEW BEYOND THE ENDOMETRIOMA

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Anuradha S. Shenoy-Bhangle, MD (*Abstract Co-Author*) Nothing to Disclose
Haatal B. Macer, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1) A thorough understanding of adnexal anatomy is crucial to describing sites of DE for surgeons2) DE of the broad ligament manifests as T2 hypointense nodular implants contiguous with adjacent DE, in isolation or endometrioma of the broad ligament. Lateral pelvic extension may involve the pelvic nerves3) DE of the fallopian tube manifests as salpingitis, serosal/subserosal implants with tethering and hydrosalpinx, mucosal/luminal implants with hematosalpinx, or T2 hypointense thickening at a salpingectomy site4) Don't forget paratubal cysts as a potential site of endometriosis5) Ovarian endometriosis includes superficial implants, serosal disease and endometrioma6) Round ligament DE manifests as thickening, nodularity deviation and/or shortening, most commonly involving the intrapelvic portion near the uterus

### TABLE OF CONTENTS/OUTLINE

1) Adnexal Anatomy on MR: Broad Ligament, Round Ligament, Fallopian Tubes, Ovaries, Uterine Artery, Ovarian Artery, Lateral Pelvic Nerves2) Manifestations of endometriosis in the BL on MR with case examples and implications on neural involvement: Nodular implants contiguous with adjacent DE, Nodular implants in isolation, endometrioma of the broad ligament3) Manifestations of endometriosis of the FT on MR: Salpingitis, Serosal/Subserosal implants, Mucosal/Luminal Implants, Tubal Stump Implant4) Paratubal Endometriosis: Atypical site of DE, identification of cysts on MR and importance of pre-operative reporting for optimal DE excision5) Manifestations of endometriosis of the Ovaries on MR with case examples: Superficial implants, Serosal disease, Endometrioma6) Endometriosis of the RL: Normal anatomy, intra/extra pelvic involvement,7) Conclusion

OBEE-11

## ADNEXAL TORSION: DO YOU HAVE AN MRI AVAILABLE? IF YES, USE IT NO MATTER WHAT TIME IT IS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Arnaldo Scardapane (*Abstract Co-Author*) Nothing to Disclose
Luca Leo (*Abstract Co-Author*) Nothing to Disclose
Giuseppe V. Sturda (*Abstract Co-Author*) Nothing to Disclose
Roberta Montefrancesco (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To review CT and MR imaging of adnexal torsion with pathologic correlation. 2. To propose an optimized MRI protocol (as brief and diagnostic as possible) for the gynecological emergencies that are simple to perform. 3. To emphasize the validity of using DWI sequences to identify ovarian viability.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: pathophysiology of adnexal torsion. 2. Presentation of “confusing-doubtful” clinical manifestations in Emergency Department. 3. What to do when ultrasound and CT are not enough? MRI: to whom, how and what time. 4. CT and MRI features with pathological correlations of ovarian necrosis due to delayed diagnoses. 5. Clinical cases in which the timely use of MR imaging leads to an early diagnosis preserving the ovary.

## CLINICAL IMPLEMENTATION OF SOCIETY OF RADIOLOGISTS IN ULTRASOUND CONSENSUS PANEL GUIDELINES FOR DETECTING ENDOMETRIOSIS ON ROUTINE PELVIC US: CHALLENGES, OPPORTUNITIES AND STRATEGIES FOR SUCCESS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Liina Poder, MD (*Abstract Co-Author*) Nothing to Disclose
Wendaline M. VanBuren, MD (*Abstract Co-Author*) Nothing to Disclose
Scott W. Young, MD (*Abstract Co-Author*) Nothing to Disclose
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Luyao Shen, MD (*Abstract Co-Author*) Nothing to Disclose
Myra K. Feldman, MD (*Abstract Co-Author*) Nothing to Disclose
Priyanka Jha, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Endometriosis a prevalent disorder affecting approximately 10% of premenopausal patients.2. Chronic pelvic pain and infertility are the most common presenting symptoms3. Despite the high prevalence, endometriosis is frequently under recognized on imaging and patients face significant diagnostic delays of over 7-10 years4. Ultrasound is the most commonly performed imaging study for female pelvic symptoms and hence provides an opportunity for detecting endometriosis on routine pelvic imaging5. Simple maneuvers such as sliding sign and wide field of view imaging can help detect endometriosis on ultrasound6. Direct and indirect ultrasound features can be assessed, stratifying the risk for endometriosis based on the presence of these features.7. Further management and guidance for MRI can be provided based on the APU scores.

### TABLE OF CONTENTS/OUTLINE

1. Background information on prevalence of endometriosis2. Understand reasons for diagnostic delays of 7-10 years3. Update on clinical society guidelines for endometriosis imaging4. Necessity for screening for endometriosis on routine pelvic ultrasound5. Identify screening population6. Definition of augmented ultrasound7. Learn the necessary maneuvers to adopt the protocol into clinical practice8. How to perform a sliding sign- demonstration using static and cine images9. Demonstrate wide field of view imaging on static and cine images10. Show common imaging features of endometriosis on routine pelvic ultrasound11. Imaging examples of cases detected on routine pelvic ultrasound, followed by advanced endometriosis imaging (both US or MRI) and finally surgical correlation will be presented.

Eduarda Bezerra Cirne, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Reviewing the potential anatomical sites involved in ovarian neoplasms following a standardized lexicon for radiological reporting proposed by the Society of Abdominal Radiology and the European Society of Urogenital Radiology Female Pelvic Imaging Working Group (SAR/ESUR lexicon) for CT and MRI studies. Demonstrating the particularities of each method (CT, MRI, and PET-FDG) and their main limitations in this context. Showing the importance of targeted reports in accurately defining anatomical sites for optimal surgical management.

### TABLE OF CONTENTS/OUTLINE

Many patients with ovarian cancer present with advanced-stage disease at the time of diagnosis. In this scenario, standard treatment includes a combination of cytoreductive surgery and chemotherapy. It is unquestionable that the treatment goal should be the complete resection of all visible and palpable tumors, with imaging methods essential for determining tumor extent and guiding surgical decision-making. Targeted reports, with a systematic evaluation of 45 anatomical sites potentially involved in ovarian neoplasms, should be accurately reported and properly topographed. Additionally, recognizing radiological criteria predictive of optimal or suboptimal cytoreduction should be extensively acknowledged by radiologists to assist and guide gynecologic oncologic surgeons in decision-making.

## IMAGING APPROACH FOR VULVAR DISEASES: WHAT EVERY RADIOLOGIST SHOULD KNOW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Maria N. Napoli, MD (*Abstract Co-Author*) Nothing to Disclose
Teresa A. Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Silvia E. Gimenez, MS (*Abstract Co-Author*) Nothing to Disclose
Leonela Panaccio (*Abstract Co-Author*) Nothing to Disclose
MARIA BELEN DASS CORREA (*Abstract Co-Author*) Nothing to Disclose
Felicitas Aguirre (*Abstract Co-Author*) Nothing to Disclose
Paula Hernandez Garrigo (*Presenter*) Nothing to Disclose

### TEACHING POINTS

; Ultrasound serves as the primary diagnostic method for the initial assessmentof vulvar lesions. Nevertheless, MRI stands out as the preeminent imaging modality for comprehensive evaluation of both the anatomical structure and pathological features of the area.; Vulvar lesions encompass a diverse array of medical conditions affecting the female lower genital tract, ranging from benign to malignant diseases.; Benign lesions usually manifest as simple cystic or solid lesions.; Malignant diseases typically manifest as sizable, compact masses infiltrating the vaginal and perineal regions.; Enhanced comprehension of the normal anatomical structures combined with refined MRI imaging techniques facilitates more precise evaluation of these conditions, mitigating the need for unwarranted interventions and facilitating surgical planning where necessary.

### TABLE OF CONTENTS/OUTLINE

; Review of vulvar anatomy.; Assessment of the utility of magnetic resonance imaging across various vulvar pathologies and its impact on adjacent organ involvement.; Establishment of an anatomical and imaging correlation to elucidate diverse vulvar pathologies.; Comparative analysis employing algorithms to delineate the radiological features observed in magnetic resonance imaging across different pathologies.

### TEACHING POINTS

Intrauterine devices (IUDs) exert a contraceptive effect when placed inside the uterus and represent one of the most widely used contraceptive methods worldwide. Evaluation begins before device placement to assess any factors that may impair insertion. Improper placement can result in pelvic pain, abnormal bleeding, infections, and ectopic pregnancy. Increasingly, IUD placement is guided by ultrasound to minimize complications.This presentation aims to outline radiological signs of IUD expulsion, with an emphasis on distinguishing between partial and complete expulsion. It covers the identification of radiographic evidence of IUD perforation, including visualization of the device outside the uterine cavity, displacement into adjacent organs, and migration. Associated complications are identified using imaging modalities such as ultrasound, computed tomography (CT), and magnetic resonance imaging (MRI). The discussion includes key elements of a comprehensive radiology report, including a detailed description of findings, location and extent of abnormalities, and relevant differential diagnoses, which aid in decision-making for removal and treatment.

### TABLE OF CONTENTS/OUTLINE

Case-based didactic review of intrauterine devices complications in different imaging modalities (ultrasound, CT scan and MRI) based on our service's digital archive and correlated with a comprehensive literature review.

OBEE-19

## DUCTUS VENOSUS AGENESIS IN FETUSES: A CASE SERIES ANALYSIS OF ULTRASOUND FINDINGS AND ASSOCIATION PATTERNS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Adinaryana Makam, MD (*Abstract Co-Author*) Nothing to Disclose
Urvi Ahlawat, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This study examines 27 fetuses diagnosed with Ductus Venosus (DV) agenesis via prenatal ultrasound, identifying association patterns with other prenatal ultrasound findings.

### TABLE OF CONTENTS/OUTLINE

Background: This retrospective case series investigates 27 fetuses diagnosed with DV agenesis via prenatal ultrasound, analyzing maternal age, gestational age, DV agenesis types, associated anomalies, and intrahepatic portal vein system status. Results: Descriptive statistics revealed a mean maternal age of 25.96 years (range: 21-44) and a mean gestational age of 21.67 weeks. DV agenesis types included Type 1 (10 cases), Type 2 (12 cases), and Type 3A (5 cases). Association patterns indicated cardiac, genitourinary, and musculoskeletal anomalies such as Cardiomegaly, Ventricular Septal Defect, Aberrant Right Subclavian Artery, Echogenic Focus in the Left Ventricle, Renal Pelvis Dilatation, Multicystic Dysplastic Kidney, Right Crossed Fused Ectopic Kidney, Clitoromegaly, Frontal Scalloping, Spinal Dysraphism, Congenital Talipes Equinovarus, Single Umbilical Artery, Increased Nuchal Translucency, Sylvian Fissure Delayed for Gestational Age, with notable correlations between maternal age and cardiac/genitourinary anomalies ($r = 0.27$, $p < 0.05$; $r = 0.22$, $p < 0.05$, respectively). Chi-square tests revealed type-specific associations: Type 1 with cardiac anomalies ($p < 0.05$), Type 2 with genitourinary anomalies ($p < 0.05$), and Type 3A with musculoskeletal anomalies ($p < 0.05$). The study underscores the subtype-specific implications of DV agenesis on fetal development, emphasizing the importance of prenatal ultrasound in early detection and informed prenatal care.

Lavinia Dias, MD (*Abstract Co-Author*) Nothing to Disclose
Brunna C. Oliveira, MD, MSc (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Endometriosis is a chronic disease characterized by the ectopic implantation of an endometrium-like tissue, containing glands and stroma, outside the uterus, and can significantly impact a woman's quality of life, manifesting in pelvic pain, infertility, and psychosocial challenges. Despite its chronicity, endometriosis can present acutely, either exacerbating an existing condition or as a primary cause, prompting patients to seek emergency medical attention, sometimes before a formal diagnosis is established.This educational exhibit aims to spotlight presentations of endometriosis commonly overlooked or misinterpreted in emergency settings, using case studies where it led to urgent situations. Emphasizing the crucial need for timely recognition, delayed diagnosis hinders prompt intervention and treatment, and may increase the likelihood of recurrent symptoms or complications.

### TABLE OF CONTENTS/OUTLINE

Didactic cases demonstrating various emergency and urgent presentations of endometriosis using different imaging modalities such as ultrasound, computed tomography, and magnetic resonance imaging, including:Bowel obstructionUterine and vaginal vault ruptureInfection of endometriomasEctopic pregnancyHemorrhagic acute abdomenUrinary tract obstructionCatamenial pneumothorax

Gayathri Devi Jalluri, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Ekta Maheshwari, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. A number of malignant and benign gynecological entities are associated with elevation of serum biomarkers. The various tumor markers differ in their usefulness for screening, diagnosis, prognosis, assessing therapeutic response, and detecting recurrence. 2. Awareness of these associations and characteristic imaging patterns is integral to Radiology practice for optimal diagnosis, facilitating recommendations for ancillary imaging and work up.

### TABLE OF CONTENTS/OUTLINE

Some important gynecologic biomarkers are: CA-125, b-HCG, Alpha-fetoprotein (AFP), Inhibin, Estradiol, Carcinoembryonic antigen, Müllerian inhibiting substance, CA 19-9, Lactate Dehydrogenase. Since pathologic diagnosis of malignancies may be difficult without laparotomy, tumor markers in addition to diagnostic imaging are useful in preoperative evaluation. An ideal marker should be highly specific and sensitive, however due to false positives and elevated indices seen in multiple benign entities, imaging plays a crucial role in guiding appropriate patient management. Multimodal approach including the evaluation of serum biomarkers combined with imaging, seems to be the best strategy for characterization, identification of recurrence, and monitoring response to treatment in female cancer patients. Tumor markers also demonstrate physiological variation with age and menopausal status as well as benign neoplasms and inflammatory conditions. This knowledge is critical to avoid overreporting of malignancy.

## UNUSUAL IMAGING PRESENTATIONS OF ENDOMETRIOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Rita Maria Lahoud, MD (*Abstract Co-Author*) Nothing to Disclose
Megan Kenway, MD (*Abstract Co-Author*) Nothing to Disclose
Dinushi S. Perera, MD (*Abstract Co-Author*) Nothing to Disclose
Rosaura Suazo Aguero, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Endometriosis is defined as the presence of endometrial glands in locations outside the uterus. It is a common condition that occurs in 6-10% of all reproductive woman.The most common peritoneal sites of involvement are the ovaries, uterine ligaments, cut-de-sac, and pelvic peritoneum reflected over the uterus, fallopian tubes, rectosigmoid and bladder. The most common complaints associated with endometriosis are dysmenorrhea and pelvic pain; although some patients often present without pain and only with complaints of infertility, or there is an incidental finding of an ovarian mass on imaging. However, some of these incidental findings are uncommon, prompting to a malignancy workup. While recognizing the hallmarks and typical imaging patterns of endometriosis is basic, acknowledging unusual presentations awards every radiologist the extra mile. At the end of this review we will be able to understand uncommon imaging appearances of endometriosis. To analyze the correlation between imaging features and histopathological findings. To contrast the optimal use of conventional imaging for malignancy mimickers in endometriosis.

### TABLE OF CONTENTS/OUTLINE

1. Introduction on Endometriosis and its manifestations 2. Description on usual and unusual imaging appearances of endometriosis 4. Case examples5. Conclusion

### TEACHING POINTS

Pelvic venous insufficiency is a major cause of chronic pelvic pain in women of reproductive age, accounting for 16-31% of cases.Ultrasound examination is the primary diagnostic tool, offering excellent visualization of pelvic veins. Proper identification of external and internal iliac veins, and gonadal plexuses is crucial. Transvaginal ultrasound with color Doppler provides high-resolution images of pelvic veins, facilitating detection of flow direction changes. Evaluation includes grayscale assessment for thrombus and post-thrombotic fibrocicatricial changes and color/spectral Doppler study for flow pattern and reflux detection. Transvaginal ultrasound with color Doppler plays a vital role in pelvic vein assessment across gynecological and vascular contexts.

### TABLE OF CONTENTS/OUTLINE

1) Ultrasound assessment based on current literature for investigating pelvic varicose veins. 2) Exploring pelvic venous anatomy with transvaginal ultrasound 3) Pathophysiology of pelvic venous disorders: Why hemodynamics is so crucial? 4) Technical considerations for ultrasound examination. 5) Clinical Cases: interpretation of ultrasound findings and differential diagnoses. 6) Reporting: What information should the radiologist provide to gynecologists and vascular surgeons? 7) Future perspectives

Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
CICILIA F. PONTES FERNANDEZ, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Transvaginal ultrasound (TVUS) is frequently utilized for screening or monitoring gynecological pathologies throughout reproductive and postmenopausal years.Despite advancements in diagnostic accuracy for detecting small endometriosis lesions via TVUS, incomplete evaluations are still common due to technical challenges, sometimes related to patient anatomy.Discussion of techniques, adjustments, and maneuvers can mitigate technical limitations, leading to more precise diagnoses.

### TABLE OF CONTENTS/OUTLINE

Explanation of optimal ultrasound imaging formation concepts (e.g., focus, transducer positioning, insonation angle, contrast).Review of pelvic anatomy via sonography.Overview of common technical challenges in pelvic ultrasound, including:Poor definition of contours and uterine cavity (e.g., midverted or excessively bulky uteri).Difficulty detecting/evaluating lesions too close to the transducer.Organs or lesions situated too far from the transducer (e.g., upper pelvis with a narrow field of view via vaginal route).Patients unable to undergo TVUS (e.g., virgins, individuals with vaginismus).Identification of the origin of adnexal lesions.Challenges in visualizing the ovaries.Definition of pelvic spaces.Presentation of clinical cases via ultrasound images and illustrations, accompanied by suggestions for improving image quality and resolving technical difficulties. These solutions are categorized into:Dynamic maneuvers.Technical tips and device adjustments.Optimization of transducers.Utilization of different sonographic approaches.Application of specific anatomical knowledge.Summary of key concepts in each section.

## 'P TO F' OF ENZIAN, AN APPROACH TO MAGNETIC RESONANCE IMAGING EVALUATION FOR ENDOMETRIOSIS: A PICTORICAL REVIEW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Araceli Yameli V. Serrato SR, PhD (*Abstract Co-Author*) Nothing to Disclose
Vanessa Hernandez Olivera, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Magnetic resonance imaging and ultrasound have been used as the staging method for endometriosis. The gold standard diagnosis for endometriosis was histopathological characterization obtained by laparoscopy, however, due to limited access to specialized surgeons and costs, laparoscopic diagnosis has been reserved for specific cases. The current role of MRI is very important, so an optimal categorization system should be able to forecast pain and fertility, describe the extent of the disease (based on anatomical features), and give patients reliable information. In this work we will exemplify the use of the #ENZIAN classification used in our workplace because it has allowed better characterization of lesions (mapping) and post-treatment surveillance imaging.

### TABLE OF CONTENTS/OUTLINE

1. MRI protocol: Key sequences, Tips for optimization. 2. #ENZIAN classification, imaging features on MRI: evaluation of the peritoneum, ovaries, tubes, Deep endometriosis findings (recto-vaginal space, vagina, retrocervical area, sacrouterine and cardinal ligaments, rectum, adenomyosis and extragenital locations with examples from each category. 3. Differential diagnosis mimics. 4. Clinical cases and reports. 5. Post-treatment Surveillance imaging: Post-surgical appearance and local recurrence. 6. Conclusion.

### TEACHING POINTS

Review the anatomy of the uterus, with an emphasis on the location and structure of the uterine isthmus.Explore the different lesions that can affect the uterine isthmus.Discuss the radiological findings and clinical context associated with each type of isthmic lesion.

### TABLE OF CONTENTS/OUTLINE

The uterine isthmus, as the narrowest portion of the uterus, plays a crucial role in female reproductive health and can be the site of origin of various gynecological pathologies. Isthmic uterine lesions constitute a complex category of abnormalities affecting tissue in this region. Due to their strategic location, these lesions may manifest a variety of symptoms, presenting diagnostic challenges.Diagnosis is typically made through imaging exams such as ultrasound or magnetic resonance imaging, with appropriate management depending on accurate identification of the lesion type and assessment of factors such as size, location, and risk of malignancy.This study aims to review a wide range of isthmic lesions, including isthmoceles, fibroids, ectopic pregnancies in cesarean scars, endometriosis, adenomyosis, adenomyoma, hematomas, anomalous vessels post-curettage, intrauterine device insertion in isthmocele, implantation of trophoblastic tissue in cesarean scar, and polyps, as well as addressing imaging diagnostic methods and available treatment options.By providing a comprehensive and up-to-date overview of this topic, this work aims to contribute to a better understanding and management of isthmic uterine lesions in radiological clinical practice.

### TEACHING POINTS

To explore the spectrum of antenatal identified brain tumors and their association with genetic syndromes.To describe the common and rare neuroimaging manifestations of congenital brain tumors on fetal and postnatal imaging.To discuss the significance of advanced imaging techniques and imaging protocols in diagnosing and prognosticating the congenital brain tumors.

### TABLE OF CONTENTS/OUTLINE

1. Congenital brain tumors are typically occurring during late fetal and early postnatal stages, often incidentally through antenatal imaging or based on clinical symptoms postnatally.2. Despite their rarity, congenital brain tumors are increasingly recognized in-utero due to advancements in imaging techniques and enhanced surveillance during pregnancy and infancy.3. Understanding associated tumor predisposition syndromes and specific genetic rearrangements is crucial for elucidating tumor etiology and guiding optimal management approaches.4. Regardless of tumor type or grade, congenital brain tumors uniformly present poor prognoses, attributed to unique metabolic and genetic pathways, prevalent embryonal histology, and rapid growth rates.

### TEACHING POINTS

Women commonly suffer from pelvic floor disorders such as urinary incontinence and pelvic organ prolapse, often associated with pregnancy, menopause, and obesity.Synthetic midurethral slings are a widely used surgical option for management of stress urinary incontinence, and can be transobturator or retropubic.While midurethral slings have excellent outcomes in terms of urinary continence and overall psychosocial well-being, complications like urinary retention, infection, vaginal erosion, and chronic pain may occur.Translabial ultrasound is a powerful tool for assessing synthetic slings both before and after surgery, predicting outcomes and identifying complications.This presentation aims to acquaint radiologists with the necessary skills for incorporating translabial ultrasound into routine sling evaluation.

### TABLE OF CONTENTS/OUTLINE

Introduction to Translabial Ultrasound (TLUS), highlighting its advantages over conventional imaging modalities for evaluating pelvic floor disorders in both pre- and postoperative settings.Technical Considerations in TLUS Imaging: patient preparation and equipment setup; scanning technique and patient positioning. Role of TLUS in Sling Evaluation, including: crucial preoperative data to report; identifying sling type, quantity, position, and orientation at rest and during Valsalva maneuver; assessing sling integrity, clinical efficacy, and primary complications; most prevalent associated genital abnormalities; post-sling pelvic pain assessment; measurement and distance analysis. Illustrative case studies demonstrating TLUS's clinical effectiveness in sling assessment. Future Directions and Considerations

Manuella Barreto Silva (*Abstract Co-Author*) Nothing to Disclose
Eduardo Schor (*Abstract Co-Author*) Nothing to Disclose
FRANCINE FREITAS FERNANDES (*Abstract Co-Author*) Nothing to Disclose
Paulo S. Cossi (*Presenter*) Nothing to Disclose

### TEACHING POINTS

More than 50 million women suffer from infertility worldwide, among whom 30% have pathology associated with the fallopian tubes. In this context, the assessment of tubal patency is vital. HyCoSy, utilizing second-generation microbubble contrast-enhanced ultrasound (CEUS), has emerged as a preferred initial imaging modality in Europe and Asia, offering comparable efficacy to traditional methods like hysterosalpingography (HSG). Its advantages include avoidance of ionizing radiation to the pelvis, iodine allergy concerns and reduced discomfort during the exam. The ability to assess ovarian and intrauterine lesions simultaneously, has high sensitivity and specificity to diagnose others infertility-related pathologies, being considered an important diagnostic method for assessing fertility in the "one-stop shop". A dedicated ultrasound software facilitates its performance by showing the morphology and path of the fallopian tube, the speed and volume of contrast extravasation, and its characteristics around the ovaries.

### TABLE OF CONTENTS/OUTLINE

1) Review of the current literature for the investigation of fallopian tubes 2) Pathophysiology of tubal dysfunctions 3) Technical considerations about HyCoSy 4) Interpretation and critical analysis of sonographic findings 5) Report: What information should the radiologist provide to gynecologists and fertility specialists? 6) Future perspective

OBEE-34

## ROLE OF MRI IN DIAGNOSING COMMON PLACENTAL PATHOLOGIES; A PICTORIAL REVIEW AND UPDATES FROM RECENT LITERATURE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Hina Arif Tiwari, MD (*Abstract Co-Author*) Nothing to Disclose
Fatima M. Al-Khafaji, MBChB (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Abnormal placentation disease has become more frequent secondary to increased rate of cesarean sections. Ultrasonography is the first imaging modality performed, but MRI remains of superior value in accurate differentiation of abnormal placentation. 2. Detailed MRI reports are of great value in describing abnormal placentation by improving the maternal outcome and involving multidisciplinary team, when needed. 3. Gradient-echo sequence provides better delineation of the placental contour and interface with the myometrium, but only the spin echo sequences provide information on signal heterogeneity and intra-placental bands. 4. The maternal surface of the placenta contains cotyledons, which are placental outpouchings surrounded by MRI T2 dark clefts and septa, these must be differentiated from placental invasion of the myometrium. 5. So far there are no reported fetal acoustic safety issues in pelvic MRI examinations performed in 30 minutes or less in magnet strength of 1.5 Tesla. 6. Although gadolinium-based MRI examination differentiates myometrium from placenta, the half-life of gadolinium in fetuses is unknown. Contrast MRI is suggested in fetal demise or in patient's willing to terminate the pregnancy.

### TABLE OF CONTENTS/OUTLINE

1. Embryogenesis of normal placenta and pathogenesis of abnormal placentation. 2. Placental anatomy; role of MRI. 3. Abbreviated MRI protocol in placental imaging with review of recent updates. 4. Spectrum of common placental pathologies with corresponding MRI findings, including: a. Placenta accreta. b. Placenta increta. c. Placenta percreta. d. Placenta previa. e. Placental abruption. 5. Review of latest literature updates on common placental pathologies.

### TEACHING POINTS

Endometriosis is a chronic inflammatory disease highly undiagnosed, with an incidence estimated in up to 15% of women of reproductive age. Definition: presence of endometrial tissue outside the endometrial cavity. Among the related symptoms are dyspareunia, pelvic pain, and infertility. Despite its high prevalence, the radiology signs and findings of pelvic endometriosis may not be so widespread, and the diagnosis through magnetic resonance remains a challenge for many radiologists. The purpose of this exhibit is:Review the role of MRI in the diagnosis and accurate staging of pelvic endometriosis;Propose a sequence of relevant points to analyze when examining a pelvic MRI and why they are relevant;Set a list of information the radiological report must give and how they help to module and settle the better surgical approach.

### TABLE OF CONTENTS/OUTLINE

## THE VISUAL JOURNEY OF ASSISTED REPRODUCTION: IMAGING INSIGHTS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Gabriela Lauar, MD (*Abstract Co-Author*) Nothing to Disclose
Cinthia C. Barbisan, MD (*Abstract Co-Author*) Nothing to Disclose
Gabriella D. Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Marcela C. Lauar, MD (*Abstract Co-Author*) Nothing to Disclose
Isabela Ribeiro (*Abstract Co-Author*) Nothing to Disclose
Paulo Silva Junior (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The increased accessibility of assisted reproduction techniques has generated a greater number of ultrasound examinations as well as a greater number of associated complications. Within this context, it is crucial for the ultrasonographer to have knowledge about normal anatomy of the female pelvis and the normal alterations related to treatment, as well as possible complications. Transvaginal ultrasound not only allows for the assessment of ovarian reserve but also strict monitoring of adnexal changes to determine the optimal time for ovarian puncture. It also provides evaluation of uterine morphology, fallopian tubes, and endometrial characteristics, which are crucial for effective treatment. The dynamic evaluation provides data on pelvic organ mobility or the presence of adhesions. Doppler not only enables vascular assessment but also ensures safer puncture procedures by detecting important vessels in the traject. Thus, when the examiner is familiar with the most common findings and the detailed patient history, ultrasound examination allows differentiation of expected alterations, such as post-puncture hemorrhagic cysts, from potentially serious complications, such as ovarian hyperstimulation syndrome, ovarian torsion, infected collections, and ectopic pregnancy. Finally, although some alterations may be rare, timely diagnosis leads to better clinical outcomes with a higher success rate of the procedure.

### TABLE OF CONTENTS/OUTLINE

The aim of this study is to synthesize the most relevant ultrasonographic information, in correlation with other imaging methods, so that the physician can perform assisted reproduction with higher chances of success and fewer complications.

Yuri C. Neves, PhD (*Abstract Co-Author*) Nothing to Disclose
Cleo F. Souza, BMedSc (*Abstract Co-Author*) Nothing to Disclose
Antonio E. Silva JR, BDS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The main clinical indications for performing an MRI of the pelvis are leiomyomatosis, endometriosis, uterine adenomyosis, ovarian cysts/lesions, pelvic pain, abnormal uterine bleeding, and postoperative evaluation; New pathological classifications for these pathologies may cause difficulties in interpreting and describing these findings to meet this new demand; The purpose of this exhibit is: Facilitate the diagnosis and description of benign uterine pathology on MRI simply and practically through flowcharts and graphic schemes, based on the most recent literature.

### TABLE OF CONTENTS/OUTLINE

A review of information and new relevant classifications for a complete radiological report on the clinical management of the main non-endometriosis benign uterine pathologies, divided into the following categories: o uterine anatomy and positioning, including measurement parameters; o myometrium: myoma, myometrial cysts, adenomyosis, ACUM, isthmocele; o endometrium: endometrial polyp, intrauterine contraceptives (types, correct position, and endoceptive migration criteria); o uterine cervix: cervical polyp, cysts and cervicitis; o parameters: pelvic varicose veins/pelvic congestion syndrome.Discussion and take-home messages.

### TEACHING POINTS

Deep endometriosis (DE) frequently involves the torus, posterior cul-de-sac, uterosacral ligaments, and rectum.Diagnosing DE in less common areas poses significant challenges, particularly for less experienced radiologists.Understanding the anatomy, embryology, and pathophysiology is vital for grasping DE's spread within the abdominal cavity.To review clinical presentations and ultrasonographic findings of DE, with a focus on practical tips for detecting the condition in atypical abdominal locations.Accurate recognition of uncommon sites of DE aids in complete disease mapping, leading to improved surgical planning and outcomes.

### TABLE OF CONTENTS/OUTLINE

Introduction: Provides an overview of deep endometriosis, highlighting its typical locations and the importance of recognizing atypical manifestations for effective diagnosis and management.Pelvic Anatomy: Reviews key concepts necessary to understand the anatomical distribution of DE, including peritoneal folds, the dissemination of peritoneal fluid from the pelvic cavity, and the embryology of the Nuck canal.Clinical Cases: Discusses symptoms, imaging interpretations, and detection tips through clinical cases in unusual locations such as:High Sigmoid Small IntestineCecum Terminal IleumVermiform AppendixBladder (Vesical Trigone, Peripheral Portions)Ureter (High Location in the Pelvis)Parametrium (Anterior Infiltration)Paracolic GutterHepatorenal SpaceDiaphragmAbdominal Wall (Umbilical Scar, Parietal Peritoneum)Pelvic WallDifferential Diagnoses: Explores differential diagnoses such as desmoid tumor, peritoneal implants metastasis, and carcinoid tumor.

## MULTIMODALITY IMAGING OF C-SECTION SCAR ENDOMETRIOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Daniel Kowal, MD (*Abstract Co-Author*) Speaker, Samsung Electronics Co, Ltd
Camilla Ramezanzadeh, DO (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Endometriosis can spread to multiple locations through surgical intervention and iatrogenic transport, with the anterior abdominal/pelvic wall the most common location of occurrence. The incidence of C-section scar endometriosis is approximately 0.8%.• Understand that not all patients will be symptomatic, and these lesions can therefore be discovered incidentally, usually on computed tomography. Symptomatic patients can have constant or recurrent cyclical pain related to hormonal impact.• Image findings of C-section scar endometriosis on different imaging modalities can vary due to hormonal influence depending on the patient's phase of menstrual cycle.• Mimicking lesions and differential diagnoses must be excluded, including keloids, scar granulomas, and metastases.

### TABLE OF CONTENTS/OUTLINE

• Introduction - Review endometriosis population at risk.• Pathophysiology and clinical presentation of C-section scar endometriosis.• Sample multimodality imaging examples demonstrating the varying imaging appearance of scar endometriosis and unique location of seeding throughout the abdominal and pelvic wall.• Mimicking lesions and pitfalls to consider.• Appropriate diagnostic workup and management.

### TEACHING POINTS

Pregnant women present to the emergency department with various conditions. Radiologists collaborate with obstetricians to select appropriate imaging modalities and make accurate diagnoses based on the situation. This exhibit will discuss emergency conditions related to pregnancy as well as non-pregnancy-related emergencies common in pregnant women, covering imaging findings, examination strategies, and treatment approaches for these situations. The teaching points of this exhibition are as follows. 1. Criteria for selecting imaging tests and contrast agents based on symptoms in pregnant women presenting to the emergency department 2. Presentation of key imaging findings contributing to the diagnosis of various emergencies during pregnancy, along with subsequent treatment

### TABLE OF CONTENTS/OUTLINE

A. Characteristics of pregnant women B. Indications for imaging modalities and contrast agent use considering pregnancy C. Imaging features, examination strategies, and treatment of emergency conditions related to pregnancy D. Imaging characteristics, examination strategies, and treatment of emergency conditions commonly observed in pregnant women but unrelated to pregnancy

Christopher Page, MBBCh, BSc (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Give a brief overview of the disease process. Describe classic MRI features of endometriosis from uncomplicated to deep infiltrating endometriosis (DIE) within the pelvis. Describe key review areas when assessing the pelvis for endometriosis and DIE. Suggest a structured radiology report that aims to maintain clarity and also highlight the pertinent findings to the gynaecology team. Outline some common pitfalls when assessing the female pelvis with MR for patients with endometriosis. Showcase some uncommon sites of endometriosis that should be considered when evaluating patients. Provide some correlating surgical images to help understand and consolidate the disease process.

### TABLE OF CONTENTS/OUTLINE

Using our database we will illustrate the various spectrum of features in endometriosis. We will begin with the common MRI findings with some key tips and pitfalls in interpreting the female pelvis. We will showcase some cases of classic deep infiltrating endometriosis. Finally we will demonstrate examples of uncommon extra-pelvic depositions in cases of umbilical, diaphragmatic, neural and subcutaneous endometriosis. Throughout we will provide some real case images of the corresponding surgical findings. We will also suggest a structured report template following the ENZIAN surgical classification to ensure radiology reports are succinct and clear when dealing with the most complex cases.

### TEACHING POINTS

Adnexal torsion occurs when an adnexa becomes twisted around the tissue supporting it, leading to stromal edema, hemorrhagic infarction, and necrosis of the adnexal structures with consequent outcomes. This painful condition is a medical emergency that can result in losing an adnexa if not treated quickly. CT and MRI are valuable for diagnosing adnexal and leiomyoma torsion, and some characteristic findings have been reported. However, radiologists have limited opportunities to study adnexal and leiomyoma torsion surgery. This presentation aims to show how adnexal and leiomyoma torsion image findings appear during laparoscopic animation.

### TABLE OF CONTENTS/OUTLINE

A) "Imaging Features of Adnexal and Leiomyoma Torsion"
- Adnexal and leiomyoma torsion can be diagnosed using CT and MRI imaging, which can reveal the following features:
- Hemorrhagic infarction
- Twisted pedicle
- Twisted vascular pedicle: flow void
- "Lack of enhancement" sign
- Deviation of uterus
- Dark fan sign
- Rim enhancement B) "Pelvic Organ Anatomy in Laparoscopic Animation"
- Laparoscopic animation can provide a detailed view of the anatomy of the organs in the pelvis, including the adnexa, uterus, fallopian tubes, and surrounding structures. C) "Relationship between Imaging Findings and Laparoscopic Animation in Adnexal Torsion"
- Adnexal torsion can occur in various structures in the pelvis, including the ovary, paraovarian cyst, and fallopian tube, as well as leiomyoma in the uterus. Laparoscopic animation can show the following conditions:
- Massive ovarian edema
- Ovarian mature cystic teratoma
- Ovarian fibroma
- Ovarian mucinous cystadenoma
- Paraovarian cyst
- Isolated fallopian tube torsion
- Fallopian tube teratoma
- Leiomyoma

Le Wang (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1) A well-margined T2 high-signal tumor occurring in the uterus should prompt suspicion of endometrial stromal tumor (EST). 2) The presence of a "worm-like" or "nodular" appearance, margins or internal T2 low-signal bands, and significant high signal on DWI should raise strong suspicion for ESTs. Furthermore, the tumor grows into the uterine cavity and may exhibit the “valve opening sign”, which is a key point of differentiation from cell-rich fibroids or FH-deficient fibroids. 3) EST is a rare condition with atypical clinical presentations, often leading to misdiagnosis as benign uterine tumors on imaging studies, such as uterine fibroids, adenomyomas, and endometrial polyps. According to the site of tumor occurrence and imaging manifestations, EST is summarized into five major categories: "mass-like type", " adenomyosis-type",”endometrial-type" , "external-type" and "cystic-type", in order to improve the radiologist understanding of this disease.

### TABLE OF CONTENTS/OUTLINE

1) To provide an up-to-date overview of the classification, incidence, clinical presentation, and current status of diagnostic imaging in endometrial stromal tumors (EST). 2) Elucidate the scanning equipment, sequences, and parameters utilized for magnetic resonance examination of EST. 3) Categorize the pathological and imaging manifestations of EST, with particular emphasis on the various imaging types observed in low-grade endometrial stromal sarcoma (LG-ESS), which exhibits the highest incidence rate. 4) Explore treatment options, prognosis assessment, recurrence patterns, and metastatic potential in EST. 5) Conclude with a summary encompassing key information regarding EST.

OBEE-47

## BEYOND O-RADS 4 AND 5 : A MULTIMODALITY APPROACH TO CHARACTERIZING BORDERLINE AND MALIGNANT OVARIAN NEOPLASM SUBTYPES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Daniel Kowal, MD (*Abstract Co-Author*) Speaker, Samsung Electronics Co, Ltd
Nilisha Regmi, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The Ovarian-Adnexal Reporting and Data System (O-RADS) for ultrasound (US) and magnetic resonance imaging (MRI) has significantly improved the consistency of interpretations and risk stratification for ovarian masses. The O-RADS system aids in distinguishing between benign and worrisome characteristics, guiding the need for further workup and more aggressive management strategies. Despite its effectiveness, O-RADS does not specifically characterize subtypes of borderline and malignant tumors. Identifying distinguishing imaging features of different ovarian tumoral subtypes can aid in preoperative planning, guide the radiologist's search pattern, and potentially influence patient management.This exhibit highlights characteristic features of high-risk ovarian lesions that are typically categorized as O-RADS 4 or 5. A multimodality approach is reviewed, including computed tomography (CT), US, and MRI.We delve into the unique imaging features of various ovarian tumor types, including borderline and malignant epithelial (serous, mucinous, endometrioid, clear cell) and malignant germ cell and sex-cord stromal tumors. We discuss pitfalls to avoid such as the importance of proper CT windowing in identifying calcified peritoneal implants and address mimicking 'chameleon lesions' with overlapping features such as borderline mucinous tumors, endometriomas and fluid-predominant dermoid cysts.

### TABLE OF CONTENTS/OUTLINE

•Classification and characterization of different borderline and malignant lesion (from pathologically proven sample cases) •Rare Tumors (e.g., Krukenberg tumor, lymphoma, collision tumors) •Pitfalls •Summary •Reference

## PEERING INTO THE PELVIS - A DEEP DIVE INTO ENDOMETRIOSIS WITH ULTRASOUND AND MRI

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Madhura A. Desai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Victoria Barbee, MD (*Abstract Co-Author*) Nothing to Disclose
Kelly L. Cox, DO (*Abstract Co-Author*) Nothing to Disclose
Sadhna Nandwana, MD (*Abstract Co-Author*) Nothing to Disclose
Neema J. Patel, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Review/recognize the endometriosis phenotypes and ultrasound (US) and magnetic resonance imaging (MRI) findings, especially those of deep infiltrating endometriosis (DIE) phenotype. Review the essential endometriosis MRI pelvis protocol sequences and key sequences for detection of endometriosis and DIE. Review pelvic anatomy to understand common sites of DIE and enhance detection.

### TABLE OF CONTENTS/OUTLINE

I. Introduction A. Endometriosis phenotypes 1. Superficial Peritoneal 2. Ovarian Endometrioma 3. Deep Infiltrating Endometriosis (DIE) II. Diagnostic tools A. Imaging - Protocols and Techniques/Sequences to Diagnose Detect 1. US 2. MRI B. Laparoscopy III. Review of Pelvic Anatomy and Compartments with Endometriosis Cases A. Anterior 1. Bladder, Urethra, Ureter 2. Round Ligament 3. Spaces/planes: prevesical space, vesicouterine pouch, and vesicovaginal septum B. Middle 1. Reproductive Organs - Vagina, Uterus, Ovaries, and Fallopian Tubes 2. Spaces/planes: Broad ligament and meso-ovarium C. Posterior 1. Rectum/rectosigmoid colon 2. Uterosacral ligaments 3. Spaces/planes: rectouterine pouch, retrocervical space, and rectovaginal septum D. Additional Sites 1. Pelvic floor 2. Abdominal wall IV. Conclusions A. DIE is the most severe phenotype of endometriosis, invading the peritoneum or adjacent structures and distorting pelvic anatomy. B. US has a role in screening for endometriosis with dynamic maneuvers and better accessibility and affordability, but MRI is key to diagnose, manage, and reduce treatment delays for conservative therapies and prior to laparoscopy with high quality, multiplanar, small field-of-view, non-fat suppressed T2-weighted sequence.

### TEACHING POINTS

1. Use the highest frequency transducer that allows adequate depth penetration to achieve optimum visualization. Adjust focal zone, gain and field-of-view settings to optimize resolution.2. Transvaginal scanning improves imaging due to closer proximity to the ovary, increasing resolution and avoiding bowel gas; but a transabdominal approach may be the best option when ovaries are anteriorly or superiorly positioned and when transvaginal is not feasible.3. Orthogonal cine clips through the entirety of a lesion are invaluable when unable to personally scan. These clips enable evaluation of the character and number of internal components which may not be captured on static images.4. For Doppler assessment, the color box should target the region of interest to improve sensitivity and minimize artifacts. Spectral Doppler can be helpful to differentiate true vascular flow from Doppler artifact.5. Special sonographic techniques can be valuable for adnexal lesion characterization. The sliding maneuver can help to clarify lesion origin; decubitus positioning enables assessment of the mobility of cyst contents.

### TABLE OF CONTENTS/OUTLINE

1. Outline of images needed for assessment of ovarian and adnexal lesions, with focus on technical parameters and methods for optimization with illustrative examples. 2. Image-rich example cases featuring proper technique and image interpretation pitfalls due to suboptimal technique.3. Review of color and spectral Doppler technique and methods for optimization including how color flow affects the O-RADS US score in certain scenarios.

## ENDOMETRIOSIS: A JOURNEY FROM INFERTILITY TO FERTILITY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Luciana P. Chamie, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Liina Poder, MD (*Abstract Co-Author*) Nothing to Disclose
Wendaline M. VanBuren, MD (*Abstract Co-Author*) Nothing to Disclose
Madison M. Breiland, MD (*Abstract Co-Author*) Nothing to Disclose
Pamela I. Causa Andrieu, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

(1) 10-15% of reproductive-age patients have endometriosis, and 30-50% are associated with infertility.Endometriosis degree may not correlate with infertility degree. Early discussion about goals of care (pain relief versus fertility) is essential.Ovarian factor: US and antimullerian hormone levels are good markers. Antral follicle count in US reflects ovarian reserve. It's best done between days 2-5 of the menstrual cycle, counting follicles between 2-10 mm in each ovary. Endometriomas can affect follicle and oocyte recovery.Tubal factor: Hysterosalpingogram evaluates tubal patency using various imaging methods and contrast agents. It's done between days 5-11 of the menstrual cycle. Both fallopian tubes and intraperitoneal spill should be visible.Uterine factor: Adenomyosis can cause infertility by affecting implantation. Mullerian malformations may coexist with endometriosis.(2) The treatment should be personalized: expectant management, surgical removal of implants, ovulation induction, or IVF.(3) Although endometriosis usually regresses during pregnancy, complications may rarely occur: spontaneous hemoperitoneum, enlargement/abscess/rupture of ovarian endometriomas, tethering/rupture of adhesions, bowel perforation, ureteral rupture, and uterine rupture. (4) The dysfunctional uterine changes could predispose to complications: preterm birth, placenta previa, stillbirth, post-partum hemorrhage, and fetal malpresentation.

### TABLE OF CONTENTS/OUTLINE

- Endometriosis and Infertility: Diagnosis
- Endometriosis and Infertility: Treatment
- Endometriosis and Fertility: Pregnancy complications

Kelli J. Andresen, MD (*Abstract Co-Author*) Nothing to Disclose
Valerie French (*Abstract Co-Author*) Nothing to Disclose
Jill A. Jones, MD, RVT (*Presenter*) Research Consultant, Corcept Therapeutics Inc

### TEACHING POINTS

There are numerous terms used to describe variant locations of intrauterine devices (IUDs), such as displaced, low-lying, malpositioned, or partial expulsion. However, these terms are vague and frequently misinterpreted by providers, and may lead patients to infer there is risk of personal harm or that the IUD is not adequate contraception. Current consensus guidelines from the American College of Obstetricians and Gynecologists (ACOG) state the greatest risk of unwanted pregnancy may be the unnecessary removal of a nonfundal IUD. The ACOG recommends counseling patients, whether symptomatic or asymptomatic, prior to removal of the IUD. Many providers now advocate for IUDs to be left in place if located above the internal os. For this reason, radiology reports should use clear and consistent terminology to describe IUD position and avoid terms that may raise suspicion for patient injury. We support using a simple lexicon to describe the location of IUDs on ultrasound reports, which is widely understood by OB/Gyn providers and aligns with current gynecologic literature.

### TABLE OF CONTENTS/OUTLINE

1. Provide an overview of IUD contraception, including trends in use, efficacy, and risks/side effects 2. OB/Gyn colleagues provide a clinical perspective to IUD management, including a review of current ACOG consensus guidelines for management of nonfundal IUDs 3. Introduce standard lexicon to describe IUD location, with illustrations, ultrasound cases, and sample reports

### TEACHING POINTS

Fetal ventriculomegaly can be broadly classified as obstructive or non-obstructive. Several pathologies and malformations can lead to obstructive ventriculomegaly by interrupting CSF normal flow. Identifying these entities can facilitate diagnosis and clarify the mechanisms underlying ventriculomegaly as well as optimize prognostic and therapeutic management. Incorporating visual representations of etiologic pictures is beneficial for both novice and experienced radiologists specializing in fetal imaging.

### TABLE OF CONTENTS/OUTLINE

Ventriculomegaly is the most commonly depicted abnormality of the fetal CNS at prenatal imaging. This finding is nonspecific, with a rate of associated malformations ranging from 10% to 50%. The understanding of causal factors at prenatal stage may be a challenge and is further confounded by the lack of histopathological data. Response to treatment and prognostication are not clearly defined. Early and accurate diagnosis at prenatal MRI is therefore essential, allowing improved prenatal counselling and facilitating appropriate referral. We retrospectively reviewed our Fetal MRI database (4568 exams). We included 201 cases of obstructive hydrocephalus according strict inclusion criteria: isolated aqueduct stenosis (36.3%); hemorrhagic events leading to secondary aqueduct obstruction (30.3%); rhombencephalosynapsis (7.5%); dural sinus malformation (6%); midline cysts (5.4%); diencephalic-mesencephalic junction (DMJ) dysplasia (3.5%); infective based lesions (3%); tumor/hematoma (2.5%); Chiari 1 (1.5%); Walker-Warburg disease (1%); miscellanea (3%). We discuss MR features providing clinical and postnatal MRI or histopathology correlation.

## THE ROLE OF THE RADIOLOGIST IN THE EVALUATION OF UTERINE ADENOMYOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Ana Belen Barba Arce, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Explain what adenomyosis consists of: etiopathogenesis, clinical manifestations, risk factors, and treatment. 2. Review normal uterine anatomy. 3. Present the diagnostic methods used to detect adenomyosis, focusing on its evaluation through magnetic resonance imaging (MRI). 4. Show the different manifestations of adenomyosis and their characteristics as seen on MRI. 5. Describe possible pitfalls and the differential diagnosis.

### TABLE OF CONTENTS/OUTLINE

1. What is adenomyosis?. 2. Etiopathogenesis. 3. Incidence. 4. Clinical manifestations. 5. Risk factor's. 6. Diagnostic tests. 7. Treatment. 8. MRI study protocol. 8.1. Previous recommendations. 8.2. Sequences. 9. Anatomical review. 10. Classification of adenomyosis by MRI. 11. Characteristic findings of adenomyosis by MRI. 11.1. Diffuse adenomyosis. 11.2. Focal adenomyosis. 12. Pitfalls. 12.1. Physiologic changes in the uterine body during the menstrual cycle. 12.2. Uterine contractions. 12.3. Postmenopausal uteruses and in women using contraceptive drugs. 13. Differential diagnosis. 13.1. Leiomyoma. 13.2. Endometriosis. 13.3. Accessory cavitated uterine mass. 13.4. Myometrial invasion by endometrial cancer. 13.5. Low-grade endometrial stroma sarcoma. 13.6. Maligned adenomiosis. 14. Conclusions.

## TUMOR-LIKE CONDITIONS AND PSEUDOTUMORAL LESIONS IN THE FEMALE PELVIS: IMAGING FEATURES, DIFFERENTIAL DIAGNOSIS, AND THERAPEUTIC STRATEGY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Masafumi Harada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kenji Matsuzaki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mayumi Takeuchi, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Nonneoplastic conditions may present tumor-like manifestations in the uterus and adnexa, and normal organs may undergo dynamic changes with physiological conditions or hormonal stimulation appearing as pseudotumoral “Don’t Touch” lesions. They are common in young women, occasionally with hormonal activity, and are often associated with pregnancy. Accurate diagnosis is important for the appropriate management to avoid excess surgical procedures and to preserve fertility and function. A wide spectrum of clinical and imaging features, and therapeutic strategies are reviewed. 2. To demonstrate look-alike tumors and tumor-like lesions on imaging, and to describe the clues to the differential diagnosis.

### TABLE OF CONTENTS/OUTLINE

1. Physiological changes of normal organs: age, menstrual cycle, pregnancy, medication 2. Ovarian histological anatomy w/ hormonal synthesis 3-a. Pathogenesis of tumor-like lesions related to hormonal excess: gonadotropins, estrogen, androgen 3-b. Clinical features of functioning lesions: direct and indirect signs 4-a. Non-neoplastic ovarian cysts, 4-b. Enlarged ovaries w/ stromal proliferation or edema, 4-c. Pregnancy-related ovarian lesions 5-a. Non-neoplastic uterine lesions: Myometrial, Pregnancy-related, C-section scar-related 6. Endometriosis and related lesions 7. PID and related lesions 8. Advanced MR techniques: 3D-T2WI, DWI (computed /reduced FOV), SWI, DCE-MRI, MR Spectroscopy 9. Treatment options: Conservative, Minimal invasive, Fertility /function preserving

Julia Lopez Alcolea, MD (*Abstract Co-Author*) Nothing to Disclose
David Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Manuel R. Recio Rodriguez, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

· MRI is a complementary tool to ultrasound that helps characterize lesions and assess the degree of extension.· Ovarian cysts are very common cystic lesions in female fetuses and often bleed.· Gradient echo sequences in phase and opposed phase can detect the presence of fat in teratomas.· Diffusion sequence allows us to calculate the ADC of teratomas; immature teratomas present lower ADC values than mature ones due to increased cellularity.

### TABLE OF CONTENTS/OUTLINE

Prenatal diagnosis of abdominal cystic lesions by ultrasound is quite common. Fetal MRI, with its multiplanar capacity and greater tissue characterization, aids in diagnosing these lesions and better assessing their extension.Cystic lesions are classified into gastrointestinal (intestinal duplication cysts, meconium pseudocysts, lymphatic malformations, hepatic and biliary cystic lesions, splenic cysts, and intestinal dilatations), genitourinary (ovarian cysts, hydrometrocolpos, urogenital sinus, cloacal malformation, renal and adrenal cystic lesions), cystic teratomas, and lesions associated with the Currarino triad.Characteristic radiological findings of these lesions are described, as well as the different MRI sequences useful for diagnosis.

### TEACHING POINTS

Fetal MRI:• Has high sensitivity in detecting midline anomalies,• Detects anomalies associated with dysgenesis of the corpus callosum followed by cortical malformations and posterior fossa anomalies.• Identifies all forms of holoprosencephaly.• Is the technique of choice for cortical development malformations, lacking the limitations of ultrasound.

### TABLE OF CONTENTS/OUTLINE

Different midline anomalies are described, including dysgenesis of the corpus callosum, alobar, semilobar, or lobar holoprosencephaly, septo-optic dysplasia, lipoma of the corpus callosum, interhemispheric cysts and absence of the cavum pellucidum. The characteristic radiological findings of each pathology and the most frequent associated genetic alterations are shown.Cerebral cortical development is divided into three processes: cell proliferation (2nd to 4th month), neuronal migration (3rd/4th month to week 24), and cortical organization (week 22 to 2 years of age). The classification proposed by Barkovich in 2012 is reviewed, showing radiological findings and the main associated genetic alterations in:• Proliferative disorders: Decreased proliferation (microlissencephaly), increased proliferation (hemimegalencephaly), and abnormal proliferation (cortical dysplasia or cortical hamartomas of tuberous sclerosis).• Migration disorders: Decreased migration (classical lissencephaly), increased migration (congenital muscular dystrophy), ectopic migration (heterotopias).• Cortical organization disorders: Polymicrogyria and schizencephaly (closed-lip type I, open-lip type II).

## ULTRASOUND OF THE POST PROCEDURE UTERUS: CHRONIC FINDINGS WITH CORRELATIVE IMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Shuchi K. Rodgers, MD (*Abstract Co-Author*) Royalties, RELX
Mindy M. Horrow, MD (*Presenter*) Spouse, Employee, Bristol-Myers Squibb Company

### TEACHING POINTS

1. The configuration of an anteverted and retroflexed uterus is rare other than related to adhesions from Cesarean section and may cause sub-optimal transvaginal imaging 2. Clinical complications related to the Cesarean section scar include dysfunctional bleeding, ectopic pregnancy and IUD malposition 3. Residual functional endometrial tissue after endometrial ablation can lead to cornual hematosalpinx, hematometra and adenomyosis 4. Post ablation tubal sterilization syndrome may occur after ablation in patients with prior tubal ligation when egress of blood from residual endometrium is obstructed in antegrade and retrograde directions, leading to cyclic pelvic pain despite amenorrhea

### TABLE OF CONTENTS/OUTLINE

A. C-section- changes in uterus 1. Position 2. Scar a. Appearance of scar(s) b. Appearance of niche/isthmocele i. Measurement ii. SIS 3. Complications of the uterine scar a. Dysfunctional bleeding b. Ectopic pregnancy c. IUD malposition 4. Complications of the abdominal wall scar a. Endometrial implants b. Hernia c. Bowel obstruction B. Endometrial Ablation a. Background b. Normal appearance c. Complications i. Symptomatic obstructed menses ii. Hematometra 1. Central 2. Cornual iii. Adenomyosis iv. Post ablation tubal sterilization syndrome v. Other considerations (pregnancy, malignancy) C. Fibroid Treatments a. Myomectomy b. Uterine artery embolization D. Other a. Synechiae b. Vascular complications: AVM, PSA c. Retained devices related to uterine procedures d. Obstructed uterus

### TEACHING POINTS

- Accurate evaluation of acute gynecological pathology presenting with acute pain through CT is challenging due to different gynecological conditions.- Emergency radiology in the rigorous diagnosis of urgent gynecological pathology as well as in guiding therapeutic planning is crucial due to a high morbimortality.

### TABLE OF CONTENTS/OUTLINE

Acute gynecological pain represents a significant clinical challenge, with various forms of clinical presentation that can range from benign ailments to potentially life-threatening conditions. In this context, computed tomography (CT) has emerged as an essential tool for the fast and accurate evaluation of these conditions due to its capacity to generate detailed images rapidly. However, despite the latest advances in CT image resolution, the female pelvic region remains a tackled area to characterize and poses a challenge even for the most experienced radiologists.This review aims to explore, by different examples, the role of CT in the initial evaluation of emergent gynecological pathologies, such as ruptured ectopic pregnancy or sepsis due to pelvic inflammatory disease, often requiring immediate treatment through radiological intervention or surgery. It will also focus on other gynecological manifestations that necessitate precise differential diagnosis from other commonly occurring intra-abdominal processes due to their urgent nature.

Guilherme N. Alves, MD, MSc (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The adnexal and paraovarian regions can harbor various pathologies, ranging from infectious to neoplastic conditions. It's crucial for radiologists to accurately characterize and diagnose these lesions, although extraovarian findings are often overlooked due to the higher frequency of ovarian involvement. This presents a diagnostic challenge. This review aims to discuss the most common paraovarian conditions and their identification on Magnetic Resonance Imaging (MRI), Computed Tomography (CT), and Ultrasound images, with an emphasis on distinguishing them from ovarian lesions. While many findings are benign and similar to adnexal lesions, leiomyomatosis, and endometriosis affecting atypical sites like the broad ligament should be noted. Fluid-filled lesions such as hydrosalpinx, hematosalpinx, paraovarian cysts, and peritoneal inclusion cysts are also noteworthy. Malignant lesions are typically secondary, often originating from the pelvis and abdomen, although primary neoplasms can occur, posing challenges in diagnosis. Schwannomas and neurofibromas along pelvic nerves are potential findings. In fertile patients, ectopic pregnancy should be considered as a differential diagnosis for paraovarian masses. Given that accurate diagnosis can expedite treatment, recognizing and confidently reporting prevalent extraovarian lesions is paramount.

### TABLE OF CONTENTS/OUTLINE

- Detailed anatomy of the adnexal region with imaging correlation; - The list of differentials, including the most common paraovarian lesions;- How to identify classic findings of extraovarian origin and how to confidently differentiate them from ovarian ones.

## PICTORIAL REVIEW OF BILATERAL ADNEXAL LESIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jean p. Akakpo Sr, MD, MD (*Abstract Co-Author*) Nothing to Disclose
Olivier Lucidarme, MD, PhD (*Abstract Co-Author*) Speaker, Bracco Group;Speaker, F. Hoffmann-La Roche Ltd;Expert Witness, Bayer AG
Natalia H. Concatto, MD (*Abstract Co-Author*) Nothing to Disclose
Yasmina Badachi, MD (*Abstract Co-Author*) Nothing to Disclose
Catherine Uzan (*Abstract Co-Author*) Nothing to Disclose
Salma Ayadi, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Explore the spectrum of bilateral adnexal lesions.• Highlight the diagnostic nuances and imaging characteristics of common and uncommon entities, also benign and malignant.• Present a selection of cases to illustrate.

### TABLE OF CONTENTS/OUTLINE

Bilateral adnexal lesions pose a diagnostic challenge in clinical practice, necessitating a multidisciplinary approach for accurate assessment and management. These lesions, affecting structures such as the ovaries, fallopian tubes, and surrounding tissues, stem from diverse etiologies, including inflammatory, infectious, neoplastic, and functional causes.The first step when bilateral adnexal lesions are found is to exclude infection (ie: tubo-ovarian abscesses), endometriomas and functional affections such as: polycystic ovary syndrome, hyperthecosis and ovarian hyperstimulation syndrome.When organic bilateral adnexial tumors are diagnosed, the radiologist should describe and stratify the risk of malignancy of each tumor according to the Ovarian-Adnexal Reporting and Data System (O-RADS). However, the O-RADS does not include any observations when lesions are bilateral. We often encounter bilateral lesions, sometimes with divergent O-RADS categories, which may or may not be of the same etiology. Certain pathologies, such as serous carcinoma, mature teratoma, and metastasis, exhibit a propensity for bilateral involvement. Knowledge of these entities and their differential diagnoses is imperative for enriching diagnostic reports alongside O-RADS categorization.This pictorial review aims at aiding radiologists in identifying and interpreting imaging findings associated with bilateral adnexal lesions.

## WORKING IN CONCERT: RADIOLOGY, PATHOLOGY, AND GYNECOLOGY ONCOLOGY APPLICATIONS OF THE 2023 FIGO UPDATES IN ENDOMETRIAL CANCER STAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jamie McDowell (*Abstract Co-Author*) Nothing to Disclose
David Bass, MD (*Abstract Co-Author*) Nothing to Disclose
Denes Szekeres, BS (*Abstract Co-Author*) Nothing to Disclose
Wei Li (*Abstract Co-Author*) Nothing to Disclose
Tannaz Rajabi (*Abstract Co-Author*) Nothing to Disclose
Ashlee Smith (*Abstract Co-Author*) Nothing to Disclose
Akshya Gupta, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. The FIGO classification for endometrial cancer was recently updated, with key differences in staging that are important for radiologists to be aware of. 2. Radiologic/pathologic correlation for endometrial cancer, including different histologic subtypes and molecular classifications, will be provided. The associated clinical implications and management recommendations will be highlighted in a case-based format.

### TABLE OF CONTENTS/OUTLINE

1. Introduce endometrial cancer demographics, clinical presentation, and initial work-up 2. Review of the updated 2023 FIGO endometrial cancer staging system with emphasis on changes from the prior system3. Case based discussion of patients with different stages of endometrial cancer, with multimodality radiologic findings and associated pathologic correlation. Specific concepts that will be addressed include: a. Non-aggressive and aggressive histologic subtypes b. Importance of myometrial and lymphovascular space invasion c. Review of molecular classification of endometrial tumors and updated prognostic and staging implications d. Key radiologic and pathologic features that impact clinical management and treatment options 4. Pitfalls of the new staging system and current gaps in the literature

## BEYOND THE SURFACE: ENHANCING DIAGNOSTIC ACCURACY WITH MULTIPLANAR RECONSTRUCTION IN SALINE INFUSION SONOHYSTEROGRAPHY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Veronica Espinosa Cruz, MD (*Abstract Co-Author*) Nothing to Disclose
Hugo A. Cervantes Flores, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela Briones, MD (*Abstract Co-Author*) Nothing to Disclose
Montserrat M. Cuadra, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Provide the learners with information about the procedure, materials, and techniques involved in sonohysterography, describing each step in a systematic manner. 2. Discover the potential of multiplanar reconstructive ultrasound images for detection of uterine pathologies, offering exceptional insights into anatomical structures and spatial relationships. 3. Explore the different imaging techniques available in uterine and endometrial pathologies, analyzing their respective advantages and limitations. 4. Describe the main abnormalities that we can diagnose with sonohysterography, identifying and interpreting these findings with precision and expertise. 5. Communicate and navigate the complexities of image interpretation in sonohysterography.

### TABLE OF CONTENTS/OUTLINE

1. Introduction to Sonohysterography: a. Evolution and advancements in gynecologic ultrasound techniques. b. Advantages of saline-infused sonohysterography and comparing different imaging techniques. 2. Fundamentals of Hysterosonography Technique: a. Patient preparation and positioning for hysterosonography. b. Materials. c. Imaging protocol and step-by-step instructions. 3. Normal sonographic anatomy of the uterine cavity 4. Clinical Applications and Utility of Hysterosonography a. Congenital uterine malformations b. Endometrial polyps c. Endometrial hyperplasia d. Leiomyomas e. Uterine adhesion bands 5. Diagnostic Pitfalls and Challenges in Image Interpretation

## LOOKING INTO PLACENTA ACCRETA SPECTRUM WITH MRI:RADIOLOGIC-PATHOLOGIC CORRELATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Lia A. Moulopoulos, MD (*Abstract Co-Author*) Nothing to Disclose
Anastasia Konstantinidou (*Abstract Co-Author*) Nothing to Disclose
Marianna Konidari, MD (*Abstract Co-Author*) Nothing to Disclose
Charis Bourgioti, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Placenta accreta spectrum (PAS) is considered an iatrogenic disease and it may be associated with major ante- and postpartum complications for both mother and fetus, especially if not diagnosed prenatally. • Traditionally used terminology of placenta accreta, increta, and percreta is under debate and the so-called percreta cases are attributed to uterine dehiscence and adhesions between uterine serosa and posterior bladder wall. • Standardization and update of clinical, pathologic and imaging criteria for PAS diagnosis and grading is pivotal for improvement in diagnosis and treatment of PAS. • Familiarity with the main MRI findings of PAS and deeper understanding of the clinical relevance of each sign through pathologic correlation, will help radiologists provide more accurate diagnoses, optimizing patient care.

### TABLE OF CONTENTS/OUTLINE

• Introduction to PAS: Definitions, epidemiology, predisposing factors, common clinical findings, and appropriate diagnostic imaging modalities. • Current challenges in understanding the pathophysiology of PAS and debate on its clinical and histopathological confirmation. • Prenatal use of MRI in PAS diagnosis and management: A routine or an adjunct assessment tool? • Normal placenta pathology and correlation with MRI anatomy. • MRI protocols for PAS evaluation: Conventional protocols and implementation of advanced functional techniques • MRI description, pathophysiological and rad-path correlation of MRI signs of PAS according to SAR/ESUR joint consensus guidelines. Is it possible to discriminate between uterine dehiscence and PAS myoinvasion? • Follow-up MRI in patients with uterine sparing management for PAS. What to expect.

OBEE-67

## FINDING YOUR NICHE: IMAGING FINDINGS ALONG THE SPECTRUM OF CESAREAN SECTION SCAR COMPROMISE AND OTHER POST-CESAREAN COMPLICATIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Erin N. Gomez, MD (*Abstract Co-Author*) Nothing to Disclose
Ishwarya Sivakumar (*Abstract Co-Author*) Nothing to Disclose
Julia Fisher, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Cesarean Section (CS) is increasingly common. Surgical techniques vary and include classic transverse, fundal and midline vertical incisions.2. The spectrum of cesarean scar compromise includes uterine niche, uterine window, uterine dehiscence, and uterine rupture. Each entity has its own imaging features and clinical implications.3. MRI is the imaging modality of choice to evaluate cesarean scar compromise given field of view, tissue resolution and clear delineation of uterine layers.4. Key features of CS scar defects that should be reported include maximum myometrial thickness and proximity of the abnormal myometrium to the urinary bladder.5. Additional complications of CS can occur concomitantly including infection, hematoma, adhesive disease, placenta accreta spectrum and CS ectopic pregnancy.

### TABLE OF CONTENTS/OUTLINE

1. Background including rates of Cesarean Section (CS). 2. Surgical technique: Classic, fundal and midline vertical incision3. Uterine Scar physiology, uterine anatomy, and normal appearance of the nulliparous and post-CS uterus 4. Protocol recommendations for MR evaluation of the post-CS uterus. 5. Spectrum of cesarean section scar compromise including: uterine niche. uterine window, uterine dehiscence, and uterine rupture6. What the surgeon needs to know: descriptors and features to report that may aid in operative planning7. Additional complications of CS including infection, endometritis, surgical site abscess, post operative hematoma, adhesive disease, CS ectopic, and placenta accreta spectrum. 8. Conclusion

OBEE-68

## EMPOWERING DIAGNOSIS: THE RADIOLOGIST'S KEY ROLE IN PRIMARY AMENORRHEA MANAGEMENT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Maria N. Napoli, MD (*Abstract Co-Author*) Nothing to Disclose
Carolina R. Chacon, MD (*Abstract Co-Author*) Nothing to Disclose
Martina Aineseder, MD (*Abstract Co-Author*) Nothing to Disclose
Kevin Kurt Mac Allister (*Abstract Co-Author*) Nothing to Disclose
Ayelen Leao, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Florencia Trila, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Radiology should be the first referral department as imaging plays a key role.Ultrasound is the first line investigation while Magnetic resonance imaging is important for accurate diagnosis and surgical planning.The kidneys should be assesed at all times in mullerian duct anomalies given the high frecuency of anomalies (30%)The Herlyn-Werner-Wunderlich syndrome (HWWS) usually presents as a triad: didelphys uterus, low genital obstruction and unilateral renal anomaly.Hypothalamic-pituitary axis alterations may be suspected due to findings on ultrasound such as an infantile uterus or the absence of secondary sexual characteristics.

### TABLE OF CONTENTS/OUTLINE

Primary amenorrhea is defined as the absence of menarche at age 16 years with normal growth and development of secondary sexual characteristics, or at age 14 years in the absence of normal growth or development of secondary sexual characteristics. Its incidence is approximately 3,000 per 100,000 individuals, mainly due to hypothalamic amenorrhea. The menstrual cycle depends on the proper functioning of the hypothalamic-pituitary-ovarian axis and its target organs that constitute the outflow tract (uterus and vagina). Any alteration in these structures can trigger amenorrhea.The management of a patient with primary amenorrhea requires an interdisciplinary approach and the radiologist plays a key role since up to approximately 67% of the diagnoses are made by means of an imaging study.In order to organize the etiologies in a logical and educational way it is proposed to divide the causes into three levels. Level 1: Outlet tract. Level 2: Gonadal. Level 3: Diencephalon.

### TEACHING POINTS

1. Female genital tract congenital anomalies (FGTCAs) impact up to 7% of those assigned female at birth and up to 25% of women with infertility or history of miscarriage. 2. FGTCAs are often associated with renal, vascular or bony anomalies due to complex embryologic interplay. 3. FGTCAs impact patients throughout their lifetime. Counseling and treatment must consider future phases of life. 4. Multidisciplinary care centers offer patients a comprehensive approach to medical management optimization and surgical correction tailored to a patient's desires. 5. Transvaginal ultrasound is first-line imaging modality for FGTCA, but may not be possible in those with vaginal agenesis or younger patients. MRI is second-line non-invasive imaging modality for diagnosis, identification of associated anomalies, concurrent pathologies, treatment planning, and identification of innate and post-surgical complications. 6. MRI protocol tailored for FGTCA evaluation is necessary to aid in accurate classification and surgical planning.

### TABLE OF CONTENTS/OUTLINE

1. Title 2. Disclosures 3. Learning objectives 4. Female genital tract congenital anomaly background information and embryology 5. MRI protocol and report considerations 6. Case examples with imaging and management / surgical planning information (septate spectrum longitudinal transverse; rudimentary horn spectrum including communicating, non-communicating and ACUM; agenesis cases including MRKH, cervical and vaginal agenesis, AIS; complex anomalies, associated anomalies including GU, vascular and osseous). 7. Conclusion 8. References

### TEACHING POINTS

1. Acquiring T2WI and Post-contrast T1WI with 3mm slice thickness is important to ensure visualization of small papillary projections.2. In/opposed phase images in addition to fat suppressed images are essential as dermoids may only contain microscopic fat.3. The high b value in the DWI acquisition must be at least 1000s/mm2 to ensure sufficient signal loss from fluid in cysts.4. Parallel imaging and multi band techniques can decrease acquisition time for DWI.5. Employ left/right phase encoding and anterior saturation bands on T2WI to decrease motion artifact.6. Time intensity curves can risk stratify lesions into O-RADS MRI 3, 4, and 5, while visual inspection single phase post contrast sequence can only stratify between O-RADS 4 and 5 with decreased positive predictive value.7. ROIs for time intensity curves must be placed on enhancing adnexal solid tissue and the outer myometrium for proper risk stratification.

### TABLE OF CONTENTS/OUTLINE

1. Review the minimum requirements for MRI sequences and optimal imaging planes needed for using the O-RADS MRI risk score.2. Image rich case based review of pitfalls and importance of optimization of each sequence.3. Details on how to perform time intensity curve analysis properly.

### TEACHING POINTS

The regulation of sodium (Na+) ion influx into cells is crucially maintained by Na+ channels, Na+/H+ and Na+/Ca2+ exchangers, while Na+ ion efflux is facilitated by Na+/K+-ATPase, ensuring a significant transmembrane Na+ ion gradient. When this regulatory system is compromised, it leads to disruptions in the intracellular sodium concentration, fostering cancer metastasis by enabling cellular invasion and migration. Furthermore, Na+ ion accumulation around cancer cells, often a result of inflammation, enhances tumor immunogenicity. Consequently, alterations in Na+ ion levels could serve as vital biomarkers for the diagnosis and prognosis of tumors. 23Na-MRI stands out by providing insights into changes in Na+ ion concentration within tumors and provides biochemical information that reflects cell viability, structural integrity, and energy metabolism. This technology has proven its efficacy in detecting early molecular-level therapeutic responses before any morphological changes become apparent. In this exhibition, we delve into the basic principles of 23Na-MRI technology and explore its potential for clinical application as a non-invasive diagnostic tool, specifically in the field of gynecology.The teaching points of this exhibit are: 1. The basic principles of 23Na-MRI technology.2. The potential of 23Na-MRI for clinical application as a non-invasive diagnostic tool, specifically in the field of gynecology.

### TABLE OF CONTENTS/OUTLINE

A. The basic principles of 23Na-MRI technology and its limitations.B. Actual 23Na-MRI images of various gynecological conditions including benign and malignant, along with interpretations of their findings.

### TEACHING POINTS

1. The 2021 WHO CNS tumor classification has undergone changes in terms of nomenclature with introduction of new tumor entities. 2. Tumors are increasingly defined by the its genetics, rather than imaging features alone. 3. Understanding the genetic landscape is essential in predicting tumor behavior, especially with the advent of improved chemotherapy.

### TABLE OF CONTENTS/OUTLINE

• Review the 2021 WHO classification of CNS tumors• Discuss genetic pathways of pediatric CNS tumors• Describe imaging features of pediatric CNS tumors with emphasis on the recently added/updated tumors, including, but not limited to:A. High Grade Gliomas: Diffuse midline glioma H3 K27-altered, diffuse hemispheric glioma H3 G34-mutant, Diffuse pediatric-type high-grade glioma H3-wildtype/ IDH-wildtype, Infant-type hemispheric glioma. B. Low-grade diffuse gliomas: Diffuse astrocytoma, MYB or MYBL1-altered, Polymorphous low-grade neuroepithelial tumor of the young, Diffuse low-grade glioma MAPK pathway altered. C. Circumscribed astrocytic gliomas: High-grade astrocytoma with piloid features, Astroblastoma MN1 -altered D. Glioneuronal and neuronal tumours: Diffuse glioneuronal tumor with oligodendroglioma-like features and nuclear clusters, Myxoid glioneuronal tumor, Multinodular and vacuolating neuronal tumor, Diffuse leptomeningeal glioneuronal tumor E. Embryonal tumours: Medulloblastoma, Atypical teratoid/ rhabdoid tumour F. Ependymal tumours: Supratentorial and posterior fossa Ependymomas

## PDEE-12 A MULTIFACETED THREAT: CNS AND SPINE MANIFESTATIONS IN PEDIATRIC LEUKEMIA

Kathleen Schenker, MD (*Abstract Co-Author*) Nothing to Disclose
Ashrith Kandula (*Presenter*) Nothing to Disclose

### TEACHING POINTS

· Pediatric leukemia can involve the central nervous system (CNS) and spine through direct infiltration, opportunistic infections, and treatment-related complications.· Recognizing the diverse CNS and spine manifestations is crucial for prompt diagnosis and effective management.· This presentation will

equip radiologists with the imaging features of these complications.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction: Epidemiology and Significance of CNS/Spine Involvement in Pediatric Leukemia2. Direct Infiltration by Leukemic Cells2.1 Chloroma (Granulocytic Sarcoma)2.2 Orbital Leukemic Infiltrate3. Infectious Complications3.1 Invasive Aspergillosis 3.2 Rhizomucor Pusillis Infection 3.3 Rothia Meningitis 3.4 Invasive Fungal Sinusitis4. Treatment-Related Toxicities4.1 Methotrexate Neurotoxicity 4.2 Posterior Reversible Encephalopathy Syndrome (PRES) 4.3 Mineralizing Vasculopathy5. Vascular Complications5.1 Blastic Hyperleukocytosis 5.2 Septic Emboli 5.3 Venous Sinus Thrombosis 5.4 Thromboembolic Strokes 5.5 Retinal Hemorrhages6. Long-Term Sequelae6.1 Radiation-Induced NeoplasmsResults: We will present a series of cases highlighting the imaging features and clinical course of each entity. The discussion will emphasize the importance of a multidisciplinary approach, including clinical presentation, laboratory findings, and neuroimaging, for accurate diagnosis and timely intervention.Conclusion: CNS and spine involvement represent a complex challenge in pediatric leukemia. Recognizing the diverse etiologies and their characteristic imaging patterns is crucial for prompt diagnosis and effective management, ultimately improving patient outcomes.

## PDEE-13 BE PREPARED: IT'S NOT BECAUSE IT'S RARE THAT IT WON'T HAPPEN! WHAT THE RADIOLOGIST NEEDS TO KNOW ABOUT SPONTANEOUS BILIARY PERFORATIONS IN CHILDREN

Lisa Suzuki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Elisa M. Carvalho, MD (*Abstract Co-Author*) Nothing to Disclose
Amanda Alves Tavares, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Spontaneous biliary perforations (SBP) are rare but an important cause of surgical jaundice in pediatrics and one of the most common causes of acute abdomen in children, most often diagnosed at the stage of biliary peritonitis. They are known to affect the extra hepatic biliary tree and occasionally, the intrahepatic ducts. This is one of the most common cause of surgical solution jaundice in neonates. And most cases present between the 2nd and 6th weeks of life, more seen under 4years of age. Preoperative diagnosis is very challenging for the radiologist and surgeon, and that is why they need to be aware of SBP as a differential diagnosis of acute abdomen in childhood, because an early diagnosis and efficient surgical management can improve the prognosis and also save the child's life. Most children who present with SBP in infancy are typically previously healthy infants with unremarkable birth and perinatal histories. The actual etiopathogenesis is unknown. Congenital weakness of the common hepatic duct, trauma, choledochal cyst, viral infection, acalculous cholecystitis are all believed to be involved, among other causes. The presenting symptoms are usually benign and non-specific, unless there is a superimposed bacterial peritonitis. However, over a period of hours, days or even weeks, the patients might gradually develop a progressively abdominal distension, jaundice, peritonitis, septicemia, and symptoms of biliary tract disease.

**TABLE OF CONTENTS/OUTLINE**

General aspects of Spontaneous Biliary Perforations- Etiology- Prognosis- Imaging Diagnosis Summary

## PDEE-14 ENDOBRONCHIAL LESIONS IN THE CHILDREN: RADIOLOGIC-BRONCHOSCOPIC-PATHOLOGIC CORRELATION

David M. Biko, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Hansel J. Otero, MD (*Abstract Co-Author*) Nothing to Disclose
Jordan B. Rapp, MD (*Abstract Co-Author*) Nothing to Disclose
Aoife Corcoran (*Abstract Co-Author*) Nothing to Disclose
Ammie M. White, MD (*Abstract Co-Author*) Nothing to Disclose
Joseph Piccione (*Abstract Co-Author*) Nothing to Disclose
Ankita Chauhan, MD, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Illustrate the imaging spectrum of endobronchial pathologic entities in children 2. Discuss benign and malignant lesions and identify imaging features that can help differentiate them 3. Understand the radiologist’s role in recognizing endobronchial pathology to aid appropriate treatment

**TABLE OF CONTENTS/OUTLINE**

Goals and objectives Background • Endobronchial lesions are sporadic in children• Endobronchial obstruction often presents with wheezing, persistent cough, recurrent fever, and hemoptysis• Obstructive symptoms occur when the mass occludes more than half the airway lumen and result in respiratory distress• Because these lesions are rare and symptoms are nonspecific, these entities are often initially misdiagnosed as asthma or pneumoniaPathologic entities • Foreign body, mucus impaction, mucoepidermoid carcinoma, inflammatory myofibroblastic tumor, carcinoid, laryngotracheal papillomatosis, mycobacterium avium-intracellulare granuloma, pyogenic granulomaImaging and Bronchoscopic Findings• Infants may present with segmental hyperinflation or persistent lobar consolidation on chest radiograph• CT findings may have specific imaging features or may need further assessment with bronchoscopy• Bronchoscopic assessment and excision/biopsy remain primary diagnostic and interventional toolsPathologic CorrelationSummary • Knowledge of characteristic imaging features aids the radiologist in making the correct diagnosis and prevents treatment delays

## PDEE-15 NONE, ONE, TWO OR THREE BALLS? SCAN, COLOR AND GO FOR IT!

Tatiana M. Fazecas, MD (*Abstract Co-Author*) Nothing to Disclose
Heron Werner JR, MD (*Abstract Co-Author*) Nothing to Disclose
Flavia M. Costa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Pedro Daltro, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

* Sonography serves as an optimal and often sole modality for imaging scrotal disorders in children. It boasts high accuracy, widespread availability in most institutions, safety, and does not necessitate sedation. * It is imperative to consider clinical symptoms during the examination, such as non-palpable testicles or the presence of one or multiple palpable nodules. * Achieving an accurate diagnosis hinges on distinguishing between painful and non-painful pathologies of the scrotum and inguinal region.

**TABLE OF CONTENTS/OUTLINE**

* Review of Sonographic Techniques: Gray-Scale and Doppler Appearance of the Pediatric Scrotum * Systematic Approach to Sonographic Imaging * Cases of Scrotal Disorders in Children: Cryptorchidism and Testicular Ectopia, Different Types of Hydrocele, Hydatid Torsion, Hyperplasia of the Rete

Testis, Splenogonadal Fusion, Polyorchidism, Meconium Peritonitis, and Testicular Neoplasms * Imaging Modalities: Gray-Scale and Doppler Ultrasound

## PDEE-16 ANOMALOUS PANCREATICOBILIARY JUNCTION ON MRCP ASSOCIATED WITH CHOLEDOCHAL CYSTS: SPECTRUM OF IMAGING FINDINGS IN CHILDREN

Abhay S. Srinivasan, MD (*Abstract Co-Author*) Nothing to Disclose
Michael R. Acord, MD (*Abstract Co-Author*) Nothing to Disclose
Rebecca Dennis, DO (*Abstract Co-Author*) Nothing to Disclose

Shyam Sunder B. Venkatakrishna, MBBS (*Abstract Co-Author*) Nothing to Disclose
Ankita Chauhan, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

In anomalous pancreaticobiliary junction (APBJ), the pancreatic and bile ducts join outside the duodenal wall to form a long common channel. APBJ is associated with raised amylase and lipase levels in the duct fluid. Obstructive cholangiopathy is a common cause of cholestatic jaundice in infants with APBJ, as it is found in patients with choledochal cysts, particularly Todani types I and IV. In older children with APBJ, the symptoms are related to cholangitis and pancreatitis. Relatively long common channel is a major risk factor for the development of cholangiocarcinoma in adulthood, so timely excision reduces morbidity and mortality. Teaching Points 1. Understand the pathophysiology behind pancreaticobiliary junction anomalies. 2. Learn the classification of junctional anomalies in children. 3. Illustrate the imaging spectrum of anomalous pancreaticobiliary junction in children with choledochal cysts. 4. Learn how to measure the length of the common channel.

### TABLE OF CONTENTS/OUTLINE

-Background information on APBJ and imaging findings on Magnetic Resonance Cholangiopancreatography (MRCP). -Normal pancreaticobiliary ductal anatomy -Pancreaticobiliary maljunction (definition, pathophysiology, demographics) -Correlation with endoscopic retrograde cholangiopancreatography (ERCP) and with surgical findings -Choledochal cyst (Todani classification) and APBJ in choledochal cysts with exemplary cases - Recommended treatment guidelines and role of surveillance imaging - Summary

## PDEE-17 IT' S A DSD! - KEEP CALM, DON'T PANIC AND FOLLOW THE TRACK

Heron Werner JR, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro Daltro, MD (*Abstract Co-Author*) Nothing to Disclose
Flavia M. Costa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Flavia P. Lopes, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tatiana M. Fazecas, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Disorders of sexual differentiation often induce anxiety among both the infant's family and the attending physicians tasked with evaluating infants presenting with genital abnormalities. It is imperative for radiologists to possess a thorough understanding of the DSD classification system. In cases involving newborns with ambiguous genitalia, pediatric radiologists are frequently consulted to conduct ultrasonography (US) examinations aimed at addressing various anatomical inquiries. Employing a systematic approach to initial sonographic imaging enables comprehensive assessment of critical genitourinary structures, pivotal for guiding diagnostic and clinical interventions. An organized ultrasonographic (US) methodology is indispensable for evaluating several structures, including those originating from the Müllerian ducts (uterus and upper vagina), discerning the type of gonad (testes, ovaries, ovotestes, or streak gonads), assessing the distal vagina, and examining the adrenal glands.

### TABLE OF CONTENTS/OUTLINE

1) DSD Classification System 2) Systematic Approach to Initial Sonographic Imaging 3) Different Cases of DSD: DDS 46 XX (CAH, testicular); DDS 46 XY (ovotestis, gonadal dysgenesis, androgen insensitivity); Ovotestis DDS 4) Imaging Modalities: Abdominal and Pelvic Ultrasound; Transperineal Ultrasound; Genitography

## PDEE-19 TINY TITANS : EYE-VENTURES IN PAEDIATRIC ULTRASOUND

Bharat Aggarwal, MD (*Abstract Co-Author*) Nothing to Disclose
Amit K. Sahu, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Ayushi Gupta, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Paediatric ocular ultrasound(US) plays a pivotal role in assessing eye health by focusing on anatomy, imaging techniques, and distinguishing between normal and abnormal conditions.US aids in differential diagnosis by assessing lesion morphology, distinguishing between solid and cystic masses, and detecting features such as calcifications, hemorrhage, retinal/choroid detachments, or foreign bodies. Color Doppler US proves useful in suspected cases of vascular, inflammatory, or neoplastic lesions.Congenital and acquired ocular conditions can be accurately diagnosed through US, spanning from irregular globe size to atypical morphological features. US reveals distinctive echoes for pathologies within the vitreous, such as hemorrhage or infection, and delineates detachment types like retinal detachment or choroid detachment with characteristic lines. It also identifies posterior wall masses, primarily retinoblastoma.Paediatric ocular US is a non-invasive adjunct to clinical assessment, especially in cases where traditional visualization methods are compromised.

### TABLE OF CONTENTS/OUTLINE

Learning normal anatomy of the paediatric globe and protocol based US to distinguish between normal and abnormal conditions.To review the congenital and acquired ocular pathology in the paediatric age group and to explain its most characteristic US findings.Distinguishing solid and cystic masses, and features such as calcifications, haemorrhage, retinal/choroid detachments, or foreign bodies.Distinguishing different kinds of haemorrhages involving eye.

## PDEE-2 THE CHALLENGING ULTRASONOGRAPHIC FINDINGS OF NEONATAL AND PEDIATRIC COW'S MILK PROTEIN ALLERGY (CMPA)

Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*) Nothing to Disclose
Fabiana Gual, MD (*Abstract Co-Author*) Nothing to Disclose
MARCIA W. MATSUOKA, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Romano, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Inflammatory and infectious intestinal diseases lead to a thickening of the intestinal wall, which can be detected using gray-scale ultrasound.- Color Doppler ultrasound can detect increases in vascular flow in the intestinal wall if there is active inflammation.- Intestinal pneumatosis is a potentially serious condition in neonatal and pediatric settings and may be associated with hepatic portal venous gas.- Although these findings are non-specific, they may be an expression of CMPA and should always be evaluated in the clinical context, particularly in the context of cow's milk protein exposure.

**TABLE OF CONTENTS/OUTLINE**

- Providing a multimodality-based didactic review of the main topics of cow's milk protein allergy (CMPA) including: pathophysiology, diagnostic evaluation, clinical presentations and ultrasonographic findings.- Preparation of a practical guide on how to perform an evaluation, in which the patterns of the structures and their clinical relevance are presented and discussed.- Correlating the findings with the differential diagnosis in the context of the emergency department.Outline: Ultrasonography can be routinely used to diagnose and monitor changes associated with CMPA. The increasing incidence of pediatric cases of CMPA in our Institution prompted us to present this work, to raise awareness of the various sonographic presentations, from the simplest to the most complex, emphasizing the systematic evaluation of the abdomen with special attention to the intestinal loops.

## PDEE-20 FROM PIROUETTES TO PATHOLOGIES: RECOGNIZING COMMON FOOT AND ANKLE INJURIES AMONG YOUNG FEMALE BALLET DANCERS

Sarah D. Bixby, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Jade Iwasaka-Neder, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Megan Kenway, MD (*Abstract Co-Author*) Nothing to Disclose
Nikhil Gupta, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Robert Freund, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

; Review relevant anatomy of the foot, ankle, and distal lower leg.; Review common imaging modalities used to assess traumatic injuries of young ballet dancers.; Demonstrate common injury patterns in the foot, ankle, and lower leg along with their mechanism of injury, including both acute and chronic conditions related to excessive turnout and dancing en pointe.; Understand the mechanism of the injury and management options that enable return to dance.

**TABLE OF CONTENTS/OUTLINE**

- Normal Anatomy
- Labeled Diagram of relevant normal foot/ankle anatomy
- Common static ballet positions and dynamic ballet movements and associated patterns of injury
- Impact of turnout and en pointe on the dancer's foot
- Imaging modalities and common imaging indications
- Plain Radiographs, Computed Tomography, Magnetic Resonance Imaging.
- Fractures
- Dancer's Fracture (5th metatarsal)
- Midfoot Fractures including the "Nutcracker" fracture
- Distal Phalanx Fractures
- Ligamentous Injuries
- Deltoid Ligament
- Anterior Talofibular Ligament
- Lisfranc Ligament
- Tibiofibular Ligament
- Impingement Syndromes
- Anterior Ankle Impingement
- Posterior Ankle Impingement "Dancer's Heel"
- Tendon Abnormalities
- Flexor Hallucis Longus Tendon Tenosynovitis "Dancer's Tendinitis"
- Posterior Tibialis/Plantaris strain/tear
- Achilles Tendon strain/tear
- Peroneus Brevis/Longus strain/tear
- Stress Reactions
- Metatarsals
- First MTP Sesamoid
- Midfoot (Cuboid, Navicular)
- Tibia/Fibula
- Other/Misc.
- Plantar Fasciitis
- Morton Neuroma
- Hallux Valgus
- "Spotty Bone Marrow" (SBM) pattern in tarsal bones

## PDEE-21 EXPLORING FETAL CERVICAL MASSES: UNDERSTANDING INTERPRETATIONS AND PROGNOSTIC INSIGHTS

Tatiana M. Fazecas, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro Daltro, MD (*Abstract Co-Author*) Nothing to Disclose
Flavia P. Lopes, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Flavia M. Costa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Heron Werner JR, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Ultrasound serves as the main screening modality for cervical masses. MRI complements ultrasound by confirming diagnosis and assessing prognosis. Virtual navigation, US and MRI reconstruction may helps in postnatal surgical planning. The primary masses encountered in the fetus include lymphatic malformation, goiter, cervical teratoma, brachial cysts and hemangioma. The main differential diagnosis are meningocele and occipital encephalocele.

**TABLE OF CONTENTS/OUTLINE**

1) Fetal Cervical Pathologies a. Benign and Malignant Masses b. Lymphatic System Malformations c. Primary Sites 2) MRI and Ultrasound Findings a. Main Features b. Differential Diagnoses c. Pitfalls 3) Application of Virtual Navigation in Diagnosis and Prognosis 4) Prognostic Indicators of the Pathologies

Flavia M. Costa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Fernanda P. Philadelpho, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Whole-Body Diffusion-Weighted Magnetic Resonance Imaging (WB-DW-MRI) represents a sensitive imaging modality devoid of ionizing radiation, capable of providing comprehensive whole-body coverage with superior soft tissue contrast and spatial resolution within a condensed timeframe. WB-DW-MRI proves invaluable in assessing various disease processes affecting the vulnerable pediatric population, encompassing cancer diagnosis and staging, disseminated infections, metabolic and idiopathic disorders, systemic rheumatologic conditions, congenital anomalies, inherited diseases, immunodeficiency disorders, and tumor predisposition syndromes. WB-DW-MRI is adept at detecting and characterizing multifocal or systemic diseases, particularly aiding in the diagnosis of challenging conditions where consensus among a multidisciplinary team of healthcare professionals may be lacking. It serves as a cost-effective diagnostic imaging method facilitating accurate diagnosis, therapeutic monitoring, and informed treatment decisions. This is particularly pertinent in the context of the vulnerable pediatric population, effectively minimizing unnecessary procedures.It is imperative to employ the optimal protocol for each disease to ensure accurate diagnosis and differential diagnosis.

**TABLE OF CONTENTS/OUTLINE**

Imaging Diagnosis in Underserved Areas of Brazil;Whole-Body Diffusion-Weighted Magnetic Resonance Imaging Technique;Diagnosis of Challenging Diseases • Inflammatory (Chronic Nonbacterial Osteomyelitis, Juvenile Idiopathic Arthritis, Polyarteritis Nodosa) • Idiopathic (Sarcoidosis, Rosai-Dorfman) • Metabolic (Hypovitaminosis - Scurvy, Alimentary Selectivity Autism)

## PDEE-24 UNDERSTANDING FACIAL CLEFTS

Eloisa M. Gebrim, MD (*Abstract Co-Author*) Nothing to Disclose
Raphael M. Reali, MD (*Abstract Co-Author*) Nothing to Disclose
Marcio Ricardo T. Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Soraia A. Souza, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Lisa Suzuki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Maira Sarpi, MD (*Abstract Co-Author*) Nothing to Disclose
Roberta C. Andrade, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The aim of this study is to revisit the classification system of craniofacial clefts proposed by Tessier in 1976. Until then, there had been a variety of nomenclatures, and some authors had attempted to standardize them. Tessier's classification is considered the main reference because of its simplicity and applicability.Although this classification system is based on clinical and surgical observation, many of the features can be explained by embryological and anatomical factors. The most accepted theory relates to disturbances in the formation or fusion of facial processes, but the molecular mechanism is partly understood.The Tessier classification involves numbering the facial clefts from 0 to 14 based on their location in two areas: the orbit/eyelid and the jaw/lips.They can also occur in combination and skeletal and soft tissue clefts do not necessarily coincide.Radiologists should be able to recognize these facial deformities and their associated findings to improve the diagnosis and surgical decision making. knowledge of this system will then allow for consistent professional communication. This manuscript outlines the Tessier classification using imaging examples to illustrate this system and to contribute to its memorability due to the rarity of some findings.

**TABLE OF CONTENTS/OUTLINE**

1. Embryological theory and anatomy 2. Tessier classification 3. CT imaging examples and main descriptors 4. Related findings

## PDEE-25 UNVEILING DEVELOPMENTAL ENIGMAS: IMAGING EMBRYOLOGIC VARIANTS AND ANOMALIES IN THE SELLAR AND SUPRASELLAR REGION

Deepali Bhalla (*Abstract Co-Author*) Nothing to Disclose
Rajan P. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Rohan Samant, MBA (*Abstract Co-Author*) Nothing to Disclose
Manav Bhalla, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The sellar and suprasellar region is a complex anatomical space harboring critical structures vital for endocrine regulation. Embryonic development plays a pivotal role in shaping the intricate anatomy of this region. Understanding the embryologic variants and anomalies of this region is paramount for accurate diagnosis and management. Variations in the development of Rathke's pouch, the infundibulum, and adjacent structures during embryogenesis can lead to a spectrum of anomalies, ranging from benign variations to clinically significant pathologies. Imaging serves as indispensable tools for the evaluation of these anomalies, in particular, detailed visualization of the pituitary gland, hypothalamus, optic chiasm, and surrounding structures, facilitating precise anatomical delineation and pathological characterization.

**TABLE OF CONTENTS/OUTLINE**

I. Importance of understanding embryologic variants and anomalies in the sellar and suprasellar region. II. Embryologic Basis of Sellar and Suprasellar Anomalies - Developmental origins of key structures: Rathke's pouch and infundibulum; Embryonic structures in the sellar and suprasellar region; Variations and anomalies arising from embryologic development III. Clinical Significance of Sellar and Suprasellar Anomalies -Effects on endocrine regulation and neurovascular function; Clinical presentation and diagnostic challenges IV. Imaging Modalities for Evaluation - Role of MRI in anatomical characterization; Utilization of CT; Advanced MRI techniques V. Diagnostic Challenges and Considerations - Pitfalls and limitations of imaging modalities; Importance of integrating clinical and radiological findings

## PDEE-27 IMAGING APPEARANCE OF CSF SHUNTS AND THEIR COMPLICATIONS

Shehanaz K. Ellika, MD (*Abstract Co-Author*) Nothing to Disclose
Matthew Koh, MD (*Abstract Co-Author*) Nothing to Disclose
Sarah Mohajeri Moghaddam, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Pranay Rao, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• A wide variety of treatment options exist for both temporary and permanent CSF diversion. • CSF shunt catheters are composed of several components including a proximal catheter, reservoir, valve, and distal catheter. • Shunt malfunction can be categorized by early and late complications. • Imaging plays an important role in assessment of shunt malfunction. • Comparison with prior imaging clinical history is key. • Ventricular shunting can result in brain calavarial changes which are also well evaluated on imaging studies.

**TABLE OF CONTENTS/OUTLINE**

• CSF Diversion o Temporary measures o Permanent measures • Shunt components • Imaging of CSF shunts • Shunt complications o Early: Tip misplacement, tip migration, infection, shunt disconnection, etc. o Late: Fracture, pseudocyst, shunt calcification, shunt erosion, over drainage, etc. • Brain calvarial changes related to ventricular shunting

## PDEE-28 ORBITAL MANIFESTATIONS OF SYNDROMIC DISEASES

Karen Moeller, MD (*Abstract Co-Author*) Nothing to Disclose
Livja Mertiri (*Abstract Co-Author*) Nothing to Disclose
Thierry Huisman, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Huy D. Tran, MD (*Abstract Co-Author*) Nothing to Disclose
Rajan P. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Oswaldo Guevara Tirado, MD, MS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- List rare syndromic disorders that may affect the orbit.- Outline a systemic approach for evaluating the orbits and surrounding structures to assist in the identification of rare syndromic diseases.- Illustrate and describe the unique optic imaging features of rare syndromic diseases.

**TABLE OF CONTENTS/OUTLINE**

Rare syndromic diseases can be particularly difficult to diagnose, especially when they present with a wide variety of symptoms and clinical findings. However, imaging of the orbit and the surrounding structures can significantly aid in narrowing down the differential diagnoses. Adopting a systematic approach when evaluating the eye involves assessing the globe, optic nerve, extraocular muscles, vascular structures, and the intracranial, maxillofacial, and temporal bone regions. Subsequent visualization of anomalies such as size discrepancies, hemorrhages, and other defects can be crucial in arriving at the correct diagnosis and improving patient care.1. Introduction Objectives2. Epidemiology3. Systemic approach for orbit evaluation among rare neurological diseases4. Case examples of syndromic diseases and their manifestations· CHARGE Syndrome· Tuberous Sclerosis· Leptin Deficient Lipodystrophy Syndrome· Norrie Disease· Septo-Optic Dysplasia· Neurofibromatosis Type 1· Kearns-Sayre Syndrome· Congenital Cranial Dysinnervation Disorders (CCDD)· Sturge-Weber Syndrome· Von-Hippel Lindau· Blue Rubber Bleb Nevus Syndrome· Terson Syndrome· PHACES Syndrome· Parry-Romberg Syndrome· Goldenhar Syndrome· Encephalocraniocutaneous Lipomatosis· Walker-Warburg Syndrome5. Conclusion

## PDEE-29 WHAT IS THIS UNEXPECTED LUMP? IMAGING EVALUATION OF LUMPS AND BUMPS IN THE PEDIATRIC PATIENT

Fabiana Gual, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia T. Lima (*Abstract Co-Author*) Nothing to Disclose
MARCIA W. MATSUOKA, MD (*Abstract Co-Author*) Nothing to Disclose
Miguel J. Neto (*Abstract Co-Author*) Nothing to Disclose
Yoshino Tamaki Sameshima, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Review common lumps and bumps in children and suggest a practical initial sonographic approach. Emphasize ultrasound (US) imaging as a safe and commonly used method for evaluating these lesions, often the first diagnostic study requested. Recommend optimal imaging techniques, such as using high-frequency linear transducers for superficial lesions and lower-frequency probes for deeper structures. Emphasize the importance of Doppler imaging for a comprehensive evaluation of soft tissue masses, confirming the vascular, cystic, or solid nature of a mass and aiding in further characterization.Recognize the limitations of ultrasound and acknowledge that in some cases, further evaluation with MRI or CT, biopsy, or surgical excision may be required for an accurate diagnosis.

**TABLE OF CONTENTS/OUTLINE**

This educational exhibit describes the sonographic imaging appearance of the most common lumps and bumps at a tertiary hospital in Sćo Paulo. We divided them into categories:CONGENITAL (branchial cleft cyst, thyroglossal duct cyst, undescended testis; VASCULAR ANOMALIES (vascular tumors (e.g. hemangioma); Vascular malformations (e.g. lymphatic malformations); INFECTION (abscess, retained foreign body; myiasis; TRAUMATIC INJURY (hematoma and muscle injury; subgaleal hematoma; fibromatosis colli; fracture; subcutaneous fat necrosis of the newborn; LYMPH NODES (reactive lymphadenopathy; Bacille Calmette-Guérin (BCG) lymphadenitis; Malignant lymphadenopathy (lymphoma); BREAST LUMP (physiologic neonatal breast enlargement; Gynecomastia; SKIN AND SOFT TISSUE (epidermoid Cyst; Lipoma; Baker's Cyst; HERNIAS (Hernia of the Nuck Canal; Umbilical Hernia; Inguinal Hernia).

## PDEE-3 PEDIATRIC RHABDOMYOSARCOMA FROM HEAD TO TOE: A COMPREHENSIVE ANALYSIS OF IMAGING FINDINGS

Fabiana Gual, MD (*Abstract Co-Author*) Nothing to Disclose
Suheyla P. Ribeiro, MD (*Abstract Co-Author*) Nothing to Disclose
Carolina R. Soares, MD (*Abstract Co-Author*) Nothing to Disclose
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*) Nothing to Disclose
Adham A. Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Romano, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Rhabdomyosarcoma is a malignant tumor with morphology resembling skeletal muscle cells.- Imaging findings are nonspecific and indistinguishable from other sarcomas. The tumor’s anatomic location and demographic data of the patient are more useful for narrowing the differential diagnosis.- Up to 20% of patients with rhabdomyosarcomas present with metastases at the time of diagnosis (typically in the lungs and bone marrow).

**TABLE OF CONTENTS/OUTLINE**

Table of contents:- Establishing the importance and effectiveness of accurate evaluation of rhabdomyosarcoma.- Review imaging findings across various examination modalities (MRI, CT, US, PET-CT) for different anatomical systems (head and neck, abdomen and musculoskeletal).- Creation of a practical guide for conducting an evaluation, including the necessary variables for follow-up.- Illustrating these conditions based on cases from our radiology group.Outline: Imaging modalities have played a decisive role in the localization of rhabdomyosarcomas. Assessing the local extent of the tumor is an essential aspect of radiological evaluation and has a direct impact on treatment. Detecting invasion of adjacent structures, considering the involvement of critical anatomical structures, and metastatic spread are fundamental to staging the disease and determining appropriate treatment strategies, be it surgical resection, radiotherapy, or a combination of these procedures.The correlation between radiological findings and histopathological characteristics is a noteworthy aspect of our discussion. Understanding how imaging features align with underlying pathology can help refine diagnostic criteria and predict tumor behavior.

## PDEE-30 FOLLOW THE PATH: A SYSTEMATIC APPROACH TO THE LINEAR AND RETICULAR PATTERN ON CHEST COMPUTED TOMOGRAPHY IN PEDIATRIC PATIENTS

Luisa L. Faria, MD (*Abstract Co-Author*) Nothing to Disclose
Deborah Y. Otto (*Abstract Co-Author*) Nothing to Disclose
Lisa Suzuki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Rodolfo Lourenco (*Abstract Co-Author*) Nothing to Disclose
Amanda Alves Tavares, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Linear and reticular opacities constitute a radiological pattern of lung involvement that represents thickening of the pulmonary interstitium by fluid, fibrosis or infiltration by cells or other material, presenting a broad differential diagnosis. The objective of this work is to present a systematic approach for interpreting the linear and reticular pattern in chest computed tomography specifically in pediatric patients, bringing to light important, and often not well-known, differential diagnoses in this age group. The approach to learning through radiological patterns brings advantages to learning, improving diagnostic skills and expanding knowledge.This presentation aims to:(1) review the linear and reticular patterns of abnormality on chest computed tomography;(2) present a case-based and systematic approach to the linear and reticular pattern on chest computed tomography in pediatric patients.

**TABLE OF CONTENTS/OUTLINE**

- Introduction- Anatomy of the secondary lobule.- Basic chest computed tomography patterns.- Case-based and systematic approach to the linear and reticular pattern (interlobular septal thickening, centrilobular peribronchovascular interstitial thickening, peribronchovascular interstitial thickening, intralobular interstitial thickening, fissure thickening, subpleural lines)

## PDEE-31 METÁSTASIS DE RETINOBLASTOMA: MÁS ALLÁ DE LO CONVENCIONAL

Diana N. Nunez Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Vilma J. Varela George SR, MEd (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1.- Pediatric intraocular malignancies have retinoblastoma as the most common cause. The cause is loss of function of the RB1 tumor suppressor gene, although some tumors result from amplification of the MYCN oncogene with normal RB1 genes.2.- 1 in every 16,000 births has retinoblastoma. There are no known geographic, racial or sexual preferences. Heritable retinoblastoma is diagnosed at midlife at 12 months and non-heritable disease at 24 months. 3.-Preoperative evaluation of retinoblastoma relies on magnetic resonance imaging. In addition to evaluate of tumor invasion of the ON, choroid, and sclera, all of which are high-risk features for systemic dissemination.4.- Trilateral retinoblastoma refers to the presence of intracranial tumor histologically similar to retinoblastoma in the pineal gland or suprasellar cistern in addition to bilateral ocular involvement.5.-Extraocular extension of retinoblastoma is an important risk factor for the development of distant metastases in the non-central nervous system, as it allows the tumor to access vascular and lymphatic channels .

**TABLE OF CONTENTS/OUTLINE**

1.Radiological anatomy2.Retinoblastoma generalities3.Retinoblastoma disemination pathwaysa) Intracraneal spaceb)Trilateral retinoblastomac)Tetralateral retinoblastomad)lymphatic routese)Hematogenous via4.Factors that increase the risk of progression5.Unusual Cancer Spread6.Estadification system

**TEACHING POINTS**

This article aims to: 1 - Review the definition of precocious puberty, its clinical and laboratory findings, as well as aspects related to the treatment and follow-up of patients. 2 - Demonstrate the role of radiological exams such as hand and wrist x-ray, pelvic ultrasound and pituitary MRI in the diagnosis and follow-up of the disease, showing several cases of precocious puberty, correlating the different imaging methods used for diagnosis.

**TABLE OF CONTENTS/OUTLINE**

1 - To provide a complete review o precocious puberty, starting with its definition, its clinical and laboratory findings, showing the way to correctly identify and diagnose the disease and its subtypes, as well as the hormonal profiles that can be identified in its various spectrums and the main types of treatment currently available. 2 - Discuss the main radiological exams used for diagnosis and follow-up, including hand and wrist x-ray for estimating bone age, showing how the exam is performed and interpreted, what should be assessed for the calculation, as well as the main classification methods (Greulich-Pyle and Tanner-Whitehouse) and also show new techniques. 3 - Demonstrate the importance of pelvic ultrasound in the assessment of patients with suspected precocious puberty, reviewing the main changes related to hormonal stimulation and how this affects the female sex organs and pituitary MRI in the evaluation of central origin precocious puberty.

## PDEE-33 3D IMAGING IN MüLLERIAN DUCT ANOMALIES: WHAT THE SURGEON WANTS TO KNOW

Sunit Davda, MBBS, MRCP (*Abstract Co-Author*) Nothing to Disclose
Amanda R. Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Kantheera Leesmidt, MD (*Abstract Co-Author*) Nothing to Disclose
Jesse L. Courtier, MD (*Abstract Co-Author*) Founder, Sira Medical, Inc;Consultant, Sira Medical, Inc
Sloane Berger-Chen (*Abstract Co-Author*) Nothing to Disclose
Jocelyn Cheng, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Müllerian duct anomalies (MDA) have important implications on the reproductive health of female children. MDAs are frequently associated with other congenital anomalies of the cervix, vagina, or urinary tract, and are a common cause of infertility and pregnancy loss after adolescence. The purpose of this educational exhibit is to: (1) Review the embryology, classification, imaging features of Müllerian duct anomalies (2) Review the indications and techniques for surgical management of Müllerian duct anomalies in pediatric patients (3) Provide specific cases and clinical courses of patients with specific Müllerian duct anomalies (4) Allow learners to test their knowledge with a quiz.

**TABLE OF CONTENTS/OUTLINE**

Using original images and figures from our institution, this exhibit will review the role of MRI in detecting, classifying and guiding surgical management of Müllerian duct anomalies in children. (1) Introduction: Review the embryology, classification, imaging features and treatment options of Müllerian duct anomalies (2) Indications/contraindications to surgical management of Müllerian duct anomalies (3) Procedure and techniques for surgical management of Müllerian duct anomalies (4) Case review of patients with specific Müllerian duct anomalies (5) Allow learners to test their knowledge with a quiz.

## PDEE-34 IMAGING OF THE NEONATAL BRAIN: HYPOXIC ISCHEMIC ENCEPHALOPATHY AND BEYOND

Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Vivek B. Pai, MBBS, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. MRI is a key step in the evaluation of neonatal encephalopathy 2. MR imaging of the neonatal brain relies on optimized protocols and neonate-specific MR hardware 3. A myriad of etiologies cause bilateral brain injury in neonates, clinically and radiologically mimicking Hypoxic Ischemic Encephalopathy (HIE) 4. Having a pattern-based approach is crucial in narrowing down a diagnosis

**TABLE OF CONTENTS/OUTLINE**

1. Review imaging protocols for assessment of the neonatal brain 2. Discuss the pathophysiology and imaging patterns of neonatal HIE 3. Detailed review of other causes of neonatal encephalopathy: A. Metabolic etiologies: • Molybdenum Cofactor, Sulphite Oxidase Deficiency • Urea Cycle disorder: OTC deficiency, Citrullinemia • Organic Acidopathies: Maple Syrup Urine Disease, Non-ketotic hyperglycinemia, Isovaleric aciduria, Methylmalonic acidemia • Hypernatremia • Hypoglycemia • Mitochondrial Encephalopathy: Leigh's Disease, MELAS• Peroxisomal disorders: Zellweger's Syndrome B. Infections: • TORCH • Viral: Herpes Simplex Virus Encephalitis, Parechoviral infection • Bacterial: Group B streptococcal Septicemia, Bacillus cereus. E. Coli meningitis • Fungal: Candidiasis C. Arterial and Venous Ischemia D. Malformations: Hemimegalencephaly E. Others: Abusive Head Injury

## PDEE-35 LUNG TRANSPLANT IN CHILDREN: OUR RADIOLOGICAL EXPERIENCE AND APPROACH

German Ramos Rubio, MD (*Abstract Co-Author*) Nothing to Disclose
Sandra Lopez Coello, MD (*Abstract Co-Author*) Nothing to Disclose

Juan Fernando Casanova Barba, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Generalities in children lung transplantation Principal causes and epidemiologyMethodsFollow-upHow CT results can substantially impact the patient's management and treatment.Normal findings in CT scanDescribe main radiological findings of short and long-term complications

**TABLE OF CONTENTS/OUTLINE**

Introductions in pediatric lung transplantation, overview, materials and methods and importance of study.Our results: Normal findings that include those related to the bronchial and vascular anastomoses. The most frequent parenchymal complications following lung transplantation including differents types of infections and acute or chronic rejection (bronchiolitis obliterans). Postoperative vascular complication that required CT angiography for diagnosis (Bleeding from the surgical bed).The most frequent posttransplantation airway complications include dehiscence as an early complication and stenosis as a long term problem. CT is useful when bronchopleural fistula is suspected.The protocol/checklist we use in our center and propose to optimal evaluate after a lung transplant in childrenConclusions:Importance of CT scan examination after lung transplantation in children for follow-up and the assessment of airway and parenchymal complications. To know the most common findings after lung transplantation and to recognize signs of complications, especially in their early stages.Importance of the role that the radiologists play to preserve the graft and ensure accurate assessment.

## PDEE-36 UNDERSTANDING PEDIATRIC NEUROINFLAMMATION: WHAT SPARKS THE FIRE?

Manohar M. Shroff, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Vivek B. Pai, MBBS, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Pediatric neuroinflammation (PN) is an expanding group of disorders presenting with symptoms ranging from mild to severe neuropsychiatric manifestations with variable levels of consciousness. 2. PN has gained traction in recent literature because of the improved understanding of pathologic / genetic triggers and ensuring inflammatory cascades, thereby enhancing therapeutic options. 3. Knowledge of the pathophysiology of these disorders forms the fundamental basis of understanding the pattern of brain injury detected on imaging. 4. Imaging findings may often be non-specific, to begin with, however, lesions may evolve within a few hours to days. A high index of suspicion, in an appropriate clinical setting is imperative to initiate prompt institution of anti-inflammatory and neuroprotective treatment measures.

**TABLE OF CONTENTS/OUTLINE**

1. Revisit key concepts of adaptive and innate immunity 2. Discuss the role of Microglia 3. Review the physiology of the blood barrier and demystify the concept of its immune privilege 4. Discuss the pathophysiology and imaging appearances of specific neuroinflammatory entities in pediatric patients: • Multiple Sclerosis • Neuromyelitis optica spectrum disorder (NMOSD) • Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) • Rasmussen's encephalitis • Anti-NMDAR encephalitis • Opsoclonus-myoclonus ataxia syndrome (OMAS) • Acute necrotizing encephalopathy • Hemophagocytic Lymphohistiocytosis (HLH) • Langerhans cell histiocytosis • Interferonopathies / Aicardi- Goutičres syndrome

## PDEE-37 NEUROIMAGING OF PEDIATRIC CNS TUMORS IN TUMOR PREDISPOSITION SYNDROMES

Karuna V. Shekdar, MD (*Abstract Co-Author*) Nothing to Disclose
Aashim Bhatia, MS (*Abstract Co-Author*) Consultant, Guerbet SA
Mariam S. Aboian, MD, PhD (*Abstract Co-Author*) Researcher, Blue Earth Diagnostics Ltd;Researcher, Fusion Pharmaceuticals;Research collaboration, Pro Medicus Limited
Austin Moats, MD (*Abstract Co-Author*) Nothing to Disclose
Raisa Amiruddin, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Several tumor predisposition syndromes (TPS) have been described in association with common childhood CNS tumors such as medulloblastoma, Atypical Teratoid Rhabdoid Tumor, retinoblastoma, choroid plexus carcinoma etc., It is important to recognize TPS as they directly impact treatment and outcome in affected patients, and surveillance imaging in unaffected patients. We aim to illustrate neuroimaging findings in common as well as some newly described TPS presenting in childhood and the common genes/genetic pathways affected. The educational exhibit will provide trainees and practicing radiologists information on CNS tumors and TPS needed to participate in brain tumor board discussions.

**TABLE OF CONTENTS/OUTLINE**

The vast array of TPS can be an intimidating topic. Although there is overlap with TPS of CNS tumors in adults, we will describe neuroimaging entities associated with common pediatric CNS tumors. (A) Common TPS: - NF1 - NF2 - Tuberous sclerosis - Li Fraumeni - Gorlin syndrome - Rhabdoid tumor predisposition syndrome - Von Hippel Lindau - Ataxia Telangiectasia - Cowden/PTEN hamartoma tumor syndrome - DICER1 syndrome - Brain tumor polyposis syndrome 2 - RB1 - Lynch syndrome - Noonan syndrome - Constitutional Mismatch Repair Deficiency - Hereditary paraganglioma-pheochromocytoma syndrome (B) Other TPS: - Shelterin complex gene POT1 - MEN1 - Familial melanoma astrocytoma syndrome - BAP1 tumor predisposition syndrome - SMARCE1

## PDEE-38 PEDIATRIC ABDOMINAL RADIOGRAPHS -- WHEN TO WORRY

Akosua Sintim-Damoa, MD (*Abstract Co-Author*) Nothing to Disclose
Edward Harpstead (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Common exam in pediatric setting- Indications include abdominal distention, abdominal pain, nausea, and vomiting· Findings are frequently normal or nonspecific, however certain findings should cause concern and warrant further evaluation

**TABLE OF CONTENTS/OUTLINE**

Abnormal Findings on Abdominal Radiographs Misplaced Air - Pneumoperitoneum, common signs- Pneumatosis Intestinalis, primary and secondary- Pneumobilia- Portal Venous Gas- Gas in Foreign Body Dilated Bowel- Proximal bowel obstruction- Distal bowel obstruction- Paucity of bowel gas- Centralized bowel loops Calcifications- Meconium Peritonitis- Intraluminal- Neonatal Ovarian Torsion- Teratoma- Malignancy Mass Effect- Intussusception- Malignancy- Pseudocyst Osseous Abnormalities

## PDEE-39 PEDIATRIC PANCREATIC IMAGING: NAVIGATING COMPLEX LANDSCAPES

**Awards**
**Cum Laude**

Emilio Inarejos Clemente, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha K. Gerrie, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Maria Navallas, MD (*Abstract Co-Author*) Nothing to Disclose
Eman E. Marie, MD, MSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Describe the conventional and novel imaging modalities used in the diagnosis and management of pancreatic lesions in children. Illustrate the imaging features of the most common pancreatic diseases in children including congenital, inflammatory, traumatic and neoplastic lesions. Discuss pattern-based approach for diagnosing pediatric pancreatic diseases.

**TABLE OF CONTENTS/OUTLINE**

Pancreatic embryology, normal anatomy and anatomical variants. Imaging modalities: Conventional (US-CT-MRI-MRCP-Nuclear medicine-Interventional radiology- Endoscopic US) Novel (Contrast enhanced US-Elastography (US and MR)-Dual energy CT-Photon counting CT-New radiotracers-radiomics, radiogenomics, artificial intelligence and machine learning. Special consideration about children with pancreatic diseases: Patients with pancreatic endocrine and exocrine insufficiencies (fasting duration- renal function)-Radiation and contrast precautions. Pancreatic diseases in children: Congenital (e.g. pancreatic divsium and annular pancreas), hereditary (e.g. cystic fibrosis and hemochromatosis), pancreatitis (acute-recurrent acute-chronic-others: autoimmune, drug-induced- dialysis related), traumatic and neoplastic (PRIMARY: SPEN, Pancreatoblastoma, Adenocarcinoma, NET and Lymphoma/ METASTASIS: Local extension from retroperitoneal rhabdomyosarcoma and neuroblastoma or Distant metastases). Pattern-based approach for pancreatic diseases in children. Diagnostic pitfalls and mimics of different pancreatic lesions Post-surgical imaging of the pancreas: Types of pancreatic surgeries and techniques- Expected post-operative findings- Post-operative complications imaging features.

## PDEE-4 IMAGING EVALUATION OF PEDIATRIC POSTERIOR FOSSA TUMORS - PEARLS AND PITFALLS

Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Maria Navallas, MD (*Abstract Co-Author*) Nothing to Disclose
Eman E. Marie, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Emilio Inarejos Clemente, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha K. Gerrie, MD, FRCPC (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Knowledge of the updated WHO classification of tumors of the central nervous system facilitates pathologic and radiologic categorization of posterior fossa tumors 2. A fundamental understanding of key tumorigenesis pathways aids in multidisciplinary patient management discussion 3. Appropriate use and understanding of available MRI sequences in tumor work-up can narrow the differential diagnosis of posterior fossa tumors

**TABLE OF CONTENTS/OUTLINE**

1. Introduction a. Overview of WHO classification of tumors of CNSb. MRI protocolc. Tumors - classic features, differential diagnosis, tumor genetics, pearls, pitfallsi. Pilocytic astrocytomaii. Ependymomaiii. Medulloblastomaiv. Diffuse midline gliomav. Atypical teratoid rhabdoid tumor vi. Embryonal tumor with multilayered rosettesvii. High-grade glioma - including diffuse pediatric-type, infant-typeviii. Choroid plexus tumord. Other less common posterior fossa tumors to recognize i. Pilomyxoid astrocytoma ii. Rosette-forming glioneuronal tumor iii. Lhermitte-Duclos iv. Diffuse leptomeningeal glioneuronal tumor v. Ganglioglioma vi. Hemangioblastoma vii. Schwannoma e. Cheat sheets - differentiating tumors based on T2 appearance, presence of restricted diffusion, calcification, hemorrhage, growth pattern, enhancement pattern 2. Conclusion

## PDEE-40 PEDIATRIC MENISCAL RETEARS: WHAT WE MISS AND WHAT THE SURGEON NEEDS TO KNOW FROM THE MRI

Pritish Bawa, MD (*Abstract Co-Author*) Nothing to Disclose
Indranil V. Kushare, MD (*Abstract Co-Author*) Nothing to Disclose
Lorece A. Harris (*Abstract Co-Author*) Nothing to Disclose
Megan May, MD (*Abstract Co-Author*) Nothing to Disclose
Livja Mertiri (*Abstract Co-Author*) Nothing to Disclose
Jason Amaral (*Abstract Co-Author*) Nothing to Disclose
J. H. Kan, MD (*Abstract Co-Author*) Nothing to Disclose
Oladipupo Fagbongbe (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Understand unique pediatric meniscal pathology after primary repair, and the surgeon’s approach to treatment when there is a retear. This includes but is not limited to retears of a treated lateral discoid meniscus and retears that occur in the setting of multi-ligamentous injury in children. 2. Learn how to use arthroscopic report and MRI findings to differentiate normal post-operative meniscal change from meniscal retears

**TABLE OF CONTENTS/OUTLINE**

1. Surgical approaches to meniscal repaira. Primary repair, including coverage of meniscal root repairs and menisco-capsular repairsb. Saucerization technique for discoid meniscus 2. Diagnostic search pattern for identification of a meniscal retear. A step-by-step approach a. How to read arthroscopic report: a radiologist’s perspective b. Primary repairs: how to interpret fluid or contrast interposition at primary repair site - is this a retear or normal post-op meniscus? c. Saucerization/reshaping: knowing surgeon’s objectives to help identify superimposed tearing after saucerization d. Radiologist search pattern approach to meniscus characterization of retears when there are changes related to both meniscal primary repair and saucerization 3. MR imaging gallery after meniscal repair with emphasis on great calls and humble retear misses with arthroscopic correlation with pediatric orthopaedic surgeon’s perspectives. How we can do better as radiologists? a. Complete discoid meniscus with meniscal retear after saucerization and primary repair (Case 1) b. Incomplete discoid meniscus with meniscal retear after saucerization and primary repair (Case 2) c. Meniscal retears with displacement d. Meniscal retears in setting of multi-ligamentous injury

## PDEE-41 IMAGING ASSESSMENT OF THE POST-SURGICAL TETHERED CORD, RELEVANT FINDINGS ON MRI

Valeria Morales, MD (*Abstract Co-Author*) Nothing to Disclose
Yady V. Hurtado Burbano, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Identify the general characteristics and types of dysraphisms and post-surgical tethered cord. • Illustrate the featured imaging data of the post-surgical tethered cord and the additional related and unrelated findings.

**TABLE OF CONTENTS/OUTLINE**

• An overview of dysraphisms. • Myelomeningocele, an open spinal dysraphism.• Post-surgical tethered cord. o Imaging clues to aid the diagnosis. o Classification. • Additional related and unrelated findings.

## PDEE-42 BUILDING BRIDGES: RADIOLOGICAL PERSPECTIVES ON COMMISSURAL PLAQUE

**TEACHING POINTS**

Understand the Anatomy and Embryology of Commisural Plaque Show a protocol for evaluating commisural malformationsReview the malformations and syndromes related to Commisural PlaqueTips for evaluating fetal MRI in cases of commisural malformations

**TABLE OF CONTENTS/OUTLINE**

Anatomy and EmbryologyMRI protocol to access commissural anomaliesSpectrum of commissural abnormalitiesComplete Agenesis, Partial Agenesis, Dysgenesis, Hypoplasia, Abnormal ThickeningAnterior commissure developmental anomaly and related structuresCorpus callosum developmental anomaly and related structuresPosterior comissure developmental anomaly and related structuresDevelopment of other important related structuresAssociated intracranial anomalies in corpus callosum agenesisInterhemispheric cystNeuronal migration disordersAgenesis of inferior vermisEncephaloceleLipoma of interhemispheric fissureSyndromes Commonly Associated With Commissural AnomaliesAicardi syndromeChiari II malformationDandy Walker ContinuumShapiro SyndromePallister-KillianWalker-Warburg syndromeSepto-optic syndromeTurner syndromeNoonanMoebius syndromeJoubert syndrome HoloprosencephalyOthers SyndromesFetal MRIClinical implications of commissural anomaliesTakehome messages

## PDEE-43 LOST AND FOUND: US REVELATIONS IN THE EMPTY SCROTUM AND GROIN LUMPS. A GUIDE FOR THE RESIDENT

Manuela Laguna Kirof, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia B. Pugliese SR (*Abstract Co-Author*) Nothing to Disclose
Diana M. Rodriguez, MD (*Abstract Co-Author*) Nothing to Disclose
Juan Bautista Rolla, MD (*Abstract Co-Author*) Nothing to Disclose
Juan Pablo Tobon, MD (*Abstract Co-Author*) Nothing to Disclose
Maria E. Orozco, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The widespread use of ultrasound (US) has led to increased detection of scrotal pathology, primarily involving extratesticular alterations originating in the tunica vaginalis. The tunica vaginalis should close during embryonic development. Anomalous closure is associated with persistent processus vaginalis, hydrocele of the spermatic cord, and inguinoscrotal hernia.US facilitates the diagnosis of persistence, associated alterations, and complications. Additionally, it plays a crucial role in conservative management (follow-up) and aids in determining the need for urgent surgery.Teaching Points:Understand the anatomy of the inguinal canal and its embryology, particularly in relation to the process of testicular descent.Recognize some of the most common pathologies that can occur in the inguinal canal in pediatrics.Review practical aspects of performing ultrasound of the inguinal canal.Summarize the different ultrasound patterns observed in testicles located within the inguinal canal and those that remain undescended.Identify the different types of hydrocele in pediatrics.

**TABLE OF CONTENTS/OUTLINE**

Anatomy and embryology.Imaging description of different cases of common pathologies in the inguinal region in pediatrics.Tips and differential diagnoses.Conclusions.

## PDEE-44 SEE IT, KNOW IT, TREAT IT: IMAGING SPECTRUM OF ADNEXAL PATHOLOGIES IN THE PEDIATRIC AGE GROUP

Anand Dorai Raju, MD (*Abstract Co-Author*) Nothing to Disclose
Asif Jamal, MBBS (*Abstract Co-Author*) Nothing to Disclose
Preet K. Sandhu, MD (*Abstract Co-Author*) Nothing to Disclose
Chinky Patel, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Adnexal pathology is frequently encountered in the pediatric age group.2. The diagnosis can be delayed or missed as younger patients often present with non-specific symptoms of abdominal pain mimicking other acute abdominal processes or due to a low index of suspicion.3. Various adnexal masses can be encountered including cysts, neoplasms, surgical emergencies, and pelvic infections.4. Ultrasound is the primary imaging modality with CT or MRI indicated for further characterization in some clinical scenarios.5. Clinical correlation with the imaging findings directs diagnosis and subsequent management of these patients.6. The radiologist should know the spectrum of adnexal disease processes that can affect the pediatric age group and their imaging appearance.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction: prevalence of adnexal pathologies in the pediatric age group, spectrum of adnexal disease, and the importance of imaging.2. Imaging modalities utilized for diagnosing adnexal pathologies.3. Importance of correlating imaging findings with the clinical presentation.4. Examples of various adnexal pathologies at our institution.

## PDEE-45 CRANIAL ULTRASOUND IN PAEDIATRIC EMERGENCIES: EXPLORING THE BRAIN IN REAL TIME

Marta Pelaz Esteban (*Abstract Co-Author*) Nothing to Disclose
Sofia Bretos Azcona, MD (*Abstract Co-Author*) Nothing to Disclose
Marta Barrios Lopez, MD (*Abstract Co-Author*) Nothing to Disclose
Rodrigo Sutil (*Abstract Co-Author*) Nothing to Disclose
Maria J. Galante I, MD (*Abstract Co-Author*) Nothing to Disclose

Marina Arroyo Olmedo, MD (*Abstract Co-Author*) Nothing to Disclose
Ana Berasategui Criado, MD (*Abstract Co-Author*) Nothing to Disclose
Celia Cantolla, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- To review the indications for transfontanelar ultrasound, especially in the emergency setting.- To review the CUS technique (including technical parameters, standardized planes?)- To know the main pathologic findings that are relevant for emergency management.

**TABLE OF CONTENTS/OUTLINE**

Transfontanelar ultrasound is a fast, readily available test lack of ionizing radiation. It is suitable for the neonatal period and very useful as long as the anterior fontanel remains open. However, it is a test with some limitations, such as being highly operator-dependent. This may give rise to doubts in the radiologist inexperienced in the technique. A) CUS indications in the emergency settingB) CUS techinque- Technical parameters (probes, frecuency, depth, focus?)- Standard coronal and sagittal planes- Other accesses (mastoid, sphenoid fontanelle?)- Doppler ultrasoundC) Normal variants of the brain ultrasound appearanceD) Main pathologic findings- Hemorraghe (germinal matrix hemorraghe, intra and extraaxial hemorrage)- Hypoxic ischemic events (periventricular leukomalacia, hypoxic-ischaemic encephalopathy of the term neonate, arterial infarction, sinus thrombosis)- Hydrocephalus- Neonatal brain infections

## PDEE-46 THINK OUTSIDE THE GRAY: THE COMMON, THE UNCOMMON AND THE RARE PEDIATRIC EXTRA-AXIAL TUMORS OF BRAIN

Manish Bajaj, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Adam Goldman-Yassen, MD, MS (*Abstract Co-Author*) Nothing to Disclose
John V. Dennison, MD (*Abstract Co-Author*) Nothing to Disclose
Vidya Sankar Viswanathan, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Discuss the different types of extra-axial brain tumors in pediatric patients and its classification, highlight the histological characteristics and typical locations of each tumor type2. Describe the imaging characteristics of each tumor type on various modalities such as MRI, CT, and sometimes PET scans.3. Identify common tumors or lesions that may mimic the appearance of atypical extra-axial brain tumors in pediatric patients4. Explore the role of advanced imaging techniques such as diffusion-weighted imaging (DWI), perfusion-weighted imaging (PWI) in characterizing these tumors.5. Discuss the management approach for various types of tumors

**TABLE OF CONTENTS/OUTLINE**

1. Introduction to Atypical Extra-Axial Brain Tumors in Pediatrics. -Typical locations and demographics. -Classification based on histological features. -Current challenges in Diagnosis.2Advanced Imaging Techniques. -DWI and its applications. -PWI for assessing tumor vascularity. 3.Imaging Characteristics. -Solitary Fibrous Tumor. -Occipital Schwannoma. -Intracranial Chondroma. -Atypical Teratoid/Rhabdoid Tumor. -Posterior fossa medulloblastoma. 4.Differential Diagnosis and Classic Mimics. -Common differential diagnoses. -Imaging features that help differentiate tumors from mimics. 5.Management Strategies. -Surgical considerations. -Adjuvant therapies. -Long-term follow-up recommendations. 6.Solve the case. -Example case to solve. -Discussion of diagnosis and management

## PDEE-47 SPECTRUM OF PEDIATRIC ABNORMALITIES OF THE BILIARY TRACT

Pallavi Sagar, MBBS (*Abstract Co-Author*) Nothing to Disclose
Katherine Nimkin, MD (*Abstract Co-Author*) Nothing to Disclose
Neha Udayakumar, MD (*Abstract Co-Author*) Nothing to Disclose
Teresa Victoria, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hajer Jarraya (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Pediatric biliary tract abnormalities include congenital anomalies such as anatomic anomalies, various cholestatic processes, congenital cystic and non-cystic anomalies and non-congenital anomalies such as neoplastic, inflammatory or infectious disorders. 2. Differential diagnoses of cystic congenital anomalies include cystic biliary atresia, fibrocystic liver diseases which designate a group of disorders affecting biliary tree and encompasses congenital hepatic fibrosis, Caroli disease and choledochal cysts. 3. The differential diagnoses of non-cystic congenital anomalies include biliary atresia and Alagille syndrome. 4. Spectrum of biliary atresia depends on the anatomic level of obstruction, four different types are described. Most common cases are perinatal. 5. Most common cases of biliary atresia are non-syndromic. Syndromic biliary atresia which occurs in 10%, can be associated with various congenital anomalies such as polysplenia, asplenia, heterotaxy syndrome, intestinal malrotation and interrupted IVC. 6. Congenital abnormalities of the gallbladder include agenesis and hypoplasia but also variations in position of the gallbladder, its shape, number and structure.

**TABLE OF CONTENTS/OUTLINE**

1) Epidemiology and classification of congenital and non-congenital biliary anomalies 2) Imaging Findings a) Biliary anomalies in the prenatal period b) Cystic biliary anomalies in neonates, infants, children and adolescentsc) Non cystic biliary anomalies in neonates, infants, children and adolescents3) Associated abnormalities in syndromic biliary tract congenital abnormalities 4) Algorithm of differential diagnosis based on level of biliary tree involvement

## PDEE-48 SONOGRAPHIC DEPICTION OF A DEFECT IN THE WALL OF THE INTESTINE IN NEONATES AND YOUNG CHILDREN WITH INTESTINAL PERFORATION

Alan Daneman, MD (*Abstract Co-Author*) Nothing to Disclose
Ricardo Faingold, MD (*Abstract Co-Author*) Nothing to Disclose
Caroline Rutten, MD (*Abstract Co-Author*) Nothing to Disclose
Benjamin Traubici, BSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To illustrate a group of neonates and young children with a variety of causes of intestinal perforation in whom the defect in the intestinal wall was correctly recognized preoperatively on sonography (US) as this has not been previously recognized in this age group.To emphasize that intestinal perforation in neonates and young children does not always lead to the presence of free gas on plain radiographs or US.To emphasize other US features, such as echogenic ascites and focal fluid collections, as important US signs of perforation in this age group.

**TABLE OF CONTENTS/OUTLINE**

We illustrate four neonates or young children in whom the intestinal defect due to perforation was depicted on US and correctly recognized on preoperative US.Plain abdominal X-Rays (AXR) showed abdominal distension, a paucity of bowel gas, and absence of free gas in three.In the fourth, the AXR, showed diffuse distension of bowel with a large amount of gas and a moderate amount of free gas.On US, there was no evidence of free gas in one, a tiny amount of free gas in two, and a moderate amount of free gas in one.On US, there were moderate to large amounts of echogenic ascites in all four.On US, a focal defect at the site of intestinal perforation was depicted and was recognized by the fellow or US technologist performing the examination in all four.The intestinal defect was proven at surgery in all four.These four cases illustrate the ability of US to depict the defect in the intestinal wall in neonates and young children with intestinal perforation. It is essential for US technologists and radiologists to search for such defects on US, especially in those cases with no evidence of free gas on AXR or US, and in the presence of echogenic ascites.

## PDEE-49 FETAL STROKE PRECEDES CORTICAL DYSPLASIA: MRI DEMONSTRATION

Ignacio Delgado, MD (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Nerea Maiz (*Abstract Co-Author*) Nothing to Disclose
Angel Sanchez-Montanez, MD (*Abstract Co-Author*) Nothing to Disclose
Carlota Rodo (*Abstract Co-Author*) Nothing to Disclose
Elida Vazquez (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To understand that fetal brain hypoxia-ischemia can cause more classically recognized patterns of abnormal neuronal migration and organization2. To recognize the evolving appearance of fetal cerebral hypoxic-ischemic lesions, which also can lead to lesions such as polymicrogyria, schizencephaly or focal cortical dysplasia3. To show in an educational format demonstrative selected cases seen in our tertiary center with evidence that hypoxia in the developing fetal brain may also lead to anomalies that suggest a more classic teratogenic effect.

**TABLE OF CONTENTS/OUTLINE**

Fetal stroke usually leads to loss of brain tissue or atrophy (porencephaly, encephalomalacia). Schizencephaly, distinguished from porencephaly by the presence of gray matter heterotopias lining the cleft, is assumed to result from an early vascular-disruptive process before migration. Both conditions can be caused by COL4A1-COL4A2 mutations. Most authors also suggest that many cases of polymicrogyria result from ischemia, cases related to carbon monoxide inhalation or twins with fetal demise have been reported.Authors show here several relevant cases with evidence that hypoxia occurring early in the developing fetal brain has the potential to lead not only to the more commonly accepted disruptive-type defects but also to patterns of anomalies that suggest a more classic teratogenic effect, such as schizencephaly, polymicrogyria or both together. Moreover, these cases also show by fetal MR imaging the follow-up demonstration intrauterus about the evolving nature of cerebral infarction or germinal matrix hemorrhage leading to cortical gyration anomalies. In most of these cases, we will show the postnatal MR imaging correlation.

## PDEE-5 IMAGING EVALUATION OF PEDIATRIC PINEAL REGION LESIONS - PEARLS AND PITFALLS

Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Maria Navallas, MD (*Abstract Co-Author*) Nothing to Disclose
Eman E. Marie, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Emilio Inarejos Clemente, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha K. Gerrie, MD, FRCPC (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Knowledge of the updated WHO classification of tumors of the central nervous system facilitates pathologic and radiologic categorization of pineal region tumors 2. A fundamental understanding of key tumorigenesis pathways aids in multidisciplinary patient management discussion 3. Appropriate use and understanding of available MRI sequences in tumor work-up can narrow the differential diagnosis of pineal region tumors

**TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Overview of the WHO classification of tumors of the central nervous system 3. MRI protocol for tumor work-up 4. Non-neoplastic lesions a. Pineal cyst b. Calcification c. Cavum velum interpositum 4. Arachnoid cyst 5. Vein of Galen malformation 5. Pineal region tumors a. Pineocytoma b. Pineal parenchymal tumor of intermediate differentiation c. Pineoblastoma d. Papillary tumor of pineal region e. Germinoma - bifocal, trifocal f. Low-grade glioma 6 Cheat sheets - differentiating tumors based on T2 appearance, presence of restricted diffusion, calcification, hemorrhage, growth pattern, enhancement pattern 7. Conclusion

## PDEE-50 CEREBELLAR HYPOPLASIA: A ROAD MAP TO FETAL MRI EVALUATION AND DIFFERENTIAL DIAGNOSIS

Anna Silva (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Learn the correct protocol for proper measurement and evaluation of the cerebellum using screening ultrasound. Identify the morphological aspects of the cerebellum in fetal magnetic resonance imaging, as well as the principal associated congenital anomalies. Understand the stages of cerebellar development and common anomalies that can occur. Acknowledge the importance of fetal MRI in diagnosing cerebellar hypoplasias.

**TABLE OF CONTENTS/OUTLINE**

The purpose of this presentation is to demonstrate the main congenital anomalies associated with cerebellar hypoplasia using fetal MRI. We will start by briefly discussing the epidemiology, causes, prognosis, and screening ultrasonography findings. Furthermore, we will review the available literature on the normal aspects of the brainstem and cerebellum. Then, we will provide examples of each case with the MRI findings that helped in the diagnosis and correlate them with genetic markers. Finally, we will propose a flowchart of the main cerebellar hypoplasias.

## PDEE-51 PEDIATRIC NECK ULTRASOUND: A PRACTICAL GUIDANCE FOR RADIOLOGY RESIDENTS BASED ON CLINICAL CASES

Laura Alonso, MD (*Abstract Co-Author*) Nothing to Disclose
Mabel Garcia-Hidalgo Alonso, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Alberto Ramirez Garcia-Mina, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-To provide a practical guide on how to do a proper pediatric neck ultrasound.-To review the most frequent pediatric neck pathology in an organized way.-To demonstrate a pertinent differential diagnosis according to the age of the patient, and location of the lesion.-To emphasize the ultrasound characteristics of the different pathology and its correlation with MR imaging through a series of representative cases within our hospital setting.-To highlight warning signs that require further evaluation of proper management.

**TABLE OF CONTENTS/OUTLINE**

1) Background. Radiologic evaluation with high-frequency ultrasonography (US) is essential for the diagnosis of neck lumps in the pediatric population.2) Ultrasound anatomy and systematic.3) Thyroidal pathology. Thyroid nodules, from benign (adenomatoid/colloid nodule, hemorrhagic thyroid cyst) to malignant (thyroid papillary carcinoma). Autoimmune pathology.4) Cystic lesions. Thyroglossal duct cyst, branchial cleft cyst (cranial fasciitis as a first branchial cleft cyst mimicker), dermoid and epidermoid cyst.5) Lymphadenopathies. Cervical adenitis and complicated adenitis (non-tuberculous mycobacteria adenitis, complicated lymphadenopathy with abscess formation).6) Hemangioma and vascular malformations (venous, lymphatic, and arteriovenous malformations).7) Ectopic thymus.8) Fibromatosis colli.9) Leukemia and lymphoma.10) Rhabdomyosarcoma.11) Salivary glands. Obstructive sialadenitis. Neonatal suppurative sialadenitis. Acute parotitis. Ranula. Pleomorphic adenoma.12) Conclusion.

## PDEE-52 PLAYGROUND INJURIES: WHEN IT'S NOT ALL FUN AND GAMES

**Awards**
**Magna Cum Laude**

Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Jennifer Stimec, MD (*Abstract Co-Author*) Nothing to Disclose
Manuela Perez Matta, MD (*Abstract Co-Author*) Nothing to Disclose
Ryan K. Campbell, MD (*Abstract Co-Author*) Nothing to Disclose
Trent Mizzi (*Abstract Co-Author*) Nothing to Disclose
Mary-Louise C. Greer, MBBS (*Abstract Co-Author*) Research Grant, AbbVie Inc
Caroline Rutten, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Raise awareness and increase recognition of playground-related injury patterns in children, with particular emphasis on those associated with different types of playground equipment - Describe the timing, frequency and age distribution of imaged playground injuries - Discuss the distribution of fractures across body parts with different playground equipment - Illustrate common and less common injury patterns

**TABLE OF CONTENTS/OUTLINE**

- Background - Learning objectives - When do playground injuries occur? - What playground equipment? - What location of injuries? - Normal bone development and healing patterns - Differing fracture patterns based on location and mechanism:
- Salter-Harris classification
- Elbow fractures
- Forearm fractures
- Clavicle and shoulder fractures
- Trampoline fractures
- Toddler fractures
- Ankle and feet fractures
- Rib and sternum fractures - Head and spine trauma - Abdominal trauma - Would you fall for these pitfalls?

## PDEE-53 PEDIATRIC TRANSTHORACIC ECHOCARDIOGRAPHY (TTE): A PRIMER FOR THE CONGENITAL CARDIAC RADIOLOGIST

Haytham Ibrahim (*Abstract Co-Author*) Nothing to Disclose
Saad Saeed (*Abstract Co-Author*) Nothing to Disclose

Diana Bernal Quintero (*Abstract Co-Author*) Nothing to Disclose
Mehak Un Nisa P. Raja, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Decipher comprehensive anatomic data acquired by TTE?Understand the qualitative and quantitative evaluation of cardiovascular physiology and function by TTE through standard modalities such as M-mode, Color mapping, Pulsed wave and Continuous wave Doppler interrogation?Interpret standard quantification tools in TTE (i.e distances, areas, volumes, mass, blood flow velocities, tissue velocities, time intervals, peak gradients and mean gradients)?Familiarize with TTE appearances of valvular heart diseases and pre and post-op TTE assessment of the commonest pediatric CHD lesions ?

**TABLE OF CONTENTS/OUTLINE**

Anatomy: The standard echocardiographic views (tips and tricks)?Physics Principles of US and Doppler?TTE modalities (made-easy):?Motion mode, ?Color mapping, ?Pulsed wave (PW), Doppler ?Continuous Wave (CW) Doppler ?Standard quantification tools ?Pathology- Valvular heart diseases ?Pathology- Congenital heart diseases (pre and post-op imaging): ?ASD, VSD?, TOF, TGA

## PDEE-54 A NEW PERSPECTIVE OF PEDIATRIC RHEUMATOLOGIC DISORDERS: AUTOINFLAMMATORY-AUTOIMMUNE CONTINUUM

Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*) Support, Canon Medical Systems Corporation;Support, General Electric Company
Gen Nishimura (*Abstract Co-Author*) Nothing to Disclose
Taiki Nozaki, MD (*Abstract Co-Author*) Nothing to Disclose
Yoshitake Yamada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsuhiko Handa, MD (*Abstract Co-Author*) Nothing to Disclose
Orito Ikeda (*Abstract Co-Author*) Nothing to Disclose
Tatsuo Kono, MD (*Abstract Co-Author*) Nothing to Disclose
Yuko Tsujioka, MD,PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Autoimmune diseases are a diverse group of disorders caused by dysregulation of acquired immunity with loss of immune tolerance to self-tissues and autoantibodies, which commonly manifest as a multisystem disorder and has been a major issue in rheumatology. Autoinflammatory diseases are caused by dysregulation of innate immunity with pathogen-independent cytokine-induced inflammation and absence of autoantibodies, which were initially thought to be a group of rare hereditary periodic fever syndromes, e.g., cryopyrin-associated periodic syndrome. However, the concept of autoinflammatory diseases has recently expanded to a broader group of disorders with chronic inflammation, e.g., systemic juvenile idiopathic arthritis. Studies of cytokine signature have revealed the importance of innate immunity in autoimmune diseases, and thus anti-cytokine therapy is used for affected individuals. Given these advancements, it is proposed that autoinflammatory and autoimmune diseases are not separate conditions but autoinflammatory-autoimmune continuum. Based on the new perspective, we show the imaging spectrum of pediatric multisystem disorders, mainly focusing on rheumatological disorders. We highlight imaging similarities between autoimmune and autoinflammatory disorders, which support the hypothesis of autoinflammatory-autoimmune continuum.

**TABLE OF CONTENTS/OUTLINE**

Introduction (the perspective of autoinflammatory-autoimmune continuum) - Monogenic autoinflammatory diseases - Polygenic autoinflammatory diseases - Intermediate diseases - Polygenic autoimmune diseases - Pathology bridging the autoimmune and autoinflammatory diseases including interferonopathy

## PDEE-55 BEYOND MILK FOR HEALTHY BONES: PEDIATRIC METABOLIC BONE DISEASES

Jorge Delgado, MD (*Abstract Co-Author*) Nothing to Disclose
Mohammad Jalloul, MD (*Abstract Co-Author*) Nothing to Disclose
John D. Karp, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Hamza Alizai, MD (*Abstract Co-Author*) Nothing to Disclose
Mostafa Alnoury, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Recognize Common Culprits Identify prevalent pediatric metabolic bone diseases like rickets, hypophosphatasia, osteogenesis imperfecta, and Ehlers-Danlos syndrome.
- Image Interpretation for Differentiation Understand characteristic imaging findings on radiographs, CT scans, and MRI scans to differentiate these diseases.
- Modality Selection Made Easy Grasp the strengths and applications of radiography, CT, MRI, and bone scintigraphy for optimal evaluation of each condition.

**TABLE OF CONTENTS/OUTLINE**

Pediatric Metabolic Bone Diseases (PMBDs) disrupt the processes for building and maintaining strong functional bones. Early diagnosis and proper management of PMBDs are crucial to prevent complications like fractures, bone deformities, and growth impairment. Specific Diseases and their Imaging Signatures A. Rickets and Osteomalacia B. Mineralization Disorders: • Hypophosphatemic Rickets • Hereditary Hyperphosphatasia (juvenile Paget disease) C. Bone Density Abnormalities: • Osteoporosis • Osteopetrosis D. Collagen Disorders Affecting Bone: • Osteogenesis Imperfecta • Ehlers-Danlos Syndrome • Marfan syndrome E. Other PMBDs • McCune-Albright Syndrome • Renal Osteodystrophy

## PDEE-56 GUT CHECK ON PEDIATRIC ENTERIC CONTRAST: ARE YOU POSITIVE, NEGATIVE, OR NEUTRAL?

**Awards**
**Certificate of Merit**

Mitchell A. Chess, MD (*Abstract Co-Author*) Nothing to Disclose
Apeksha Chaturvedi, MD (*Abstract Co-Author*) Nothing to Disclose
Nina B. Klionsky, MD (*Abstract Co-Author*) Nothing to Disclose
Steve Stephen, BS, MBA (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Enteric contrast agents may enhance the visibility and diagnostic certainty of intestinal and peritoneal findings in pediatric CT imaging. Despite these advantages, their need is debated. Key considerations for using enteric contrast in pediatric body imaging include: • Caution with using positive enteric contrast in patients with gastrointestinal (GI) mucosal or intramural bleeds, as it may obscure the source of bleeding and vascular malformations • Enteric contrast can enhance distinction between serosal tumors and gut lumen when the source of GI bleed is extraluminal • Neutral enteric contrast can improve bowel wall enhancement • Improved scanner technology with ability to perform multiplanar reconstructions reduce reliance on enteric contrast for diagnostic clarity • Emergency department patient throughput and safety considerations (e.g., extended exposure to transmissible diseases including COVID and RSV)

**TABLE OF CONTENTS/OUTLINE**

• Review common enteric contrast agents, emphasizing indications, risks, and other considerations unique to children • Summarize arguments for and against the use of enteric contrast, including perceived benefits, risks to patients, increased radiation dose, and logistical challenges • Discuss weight-based enteric contrast dose and administration protocols in children • Present pediatric imaging findings on a case-based template alongside a discussion of whether enteric contrast would be appropriate in similar cases • Highlight the potential for novel enteric contrast agents still in development, including dark enteric contrast agents and high-Z contrast agents

## PDEE-57 CATHETERS, TUBES AND OTHER MEDICAL DEVICES IN PEDIATRICS: MALPOSITION AND COMPLICATIONS ARISING FROM THEIR USE

Pablo Castanon Remy (*Abstract Co-Author*) Nothing to Disclose
Beatriz Espejo Garcia (*Abstract Co-Author*) Nothing to Disclose
Maria I. Martinez-Leon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Alejandro Jose Garcia Munoz (*Abstract Co-Author*) Nothing to Disclose
Andrea Gallego Gomez (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Assessment through various imaging tests, primarily utilize simple radiography to assess the status and placement of different medical devices in pediatric patients.• Understand the importance of early detection by the radiologist of potential complications that may arise from their use, primarily mechanical complications, caused by improper placement of these devices.• Interpret different clinical cases of pediatric patients.

**TABLE OF CONTENTS/OUTLINE**

In this presentation, we will conduct a systematic review of the types of medical devices used in pediatrics, considering that they are more common in patients admitted to pediatric ICU and neonatology. These devices are essential for managing pediatric patients in intensive care; therefore, understanding them in pediatric patients and learning to assess their correct localization is fundamental in the work of a radiologist. Early detection of possible complications secondary to their use is also crucial.It is often challenging to interpret. Therefore, it is essential to know which devices to look for in each case, their appropriate location, and how to interpret data suggestive of possible complications.Subsequently, we will present a series of tables explaining the appropriate indications, route, and location of devices in imaging tests suitable for their study, followed by a series of cases of pediatric patients with these complications. The devices that can be evaluated with images in this presentation include: Nasogastric tube, endotracheal tube, chest drainage tube, umbilical venous catheter, umbilical arterial catheter, epicutaneous catheter, central venous catheter, ventriculoperitoneal shunt and others less commonly used devices.

## PDEE-58 WHAT THE RADIOLOGY RESIDENT NEEDS TO KNOW ABOUT PEDIATRIC MODIFIED BARIUM SWALLOW

**Awards**
**Certificate of Merit**

Bindu Setty, MD (*Abstract Co-Author*) Nothing to Disclose
Kerry Pearl (*Abstract Co-Author*) Nothing to Disclose
Jessica Pisegna (*Abstract Co-Author*) Nothing to Disclose
Ilse Castro-Aragon, MD (*Abstract Co-Author*) Nothing to Disclose
Ali A. Elzieny (*Abstract Co-Author*) Nothing to Disclose
Pooja Sikka, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Provide an overview on the speech language pathologist (SLP) assessment of the indications, preparation, and terminology for a pediatric modified barium swallow (pMBS) study.2. Highlight imaging abnormalities detected on a pMBS study.3. Correlate pMBS radiologic findings with their etiologies and management.4. Discuss how a pediatric swallow evaluation differs from that of adults.

**TABLE OF CONTENTS/OUTLINE**

1. SLP clinical feeding evaluation and indications for a pMBS study.2. Brief overview of the normal peripheral and central mechanisms of swallowing, including the sequential phases, supportive anatomy, and pediatric neuroanatomic correlates.3. SLP pMBS examination with a description of the setup and rationale for utilizing different types of positioning, equipment, bolus consistencies (thicker vs. thinner), delivery methods, and timed fatigue testing to assess form and function.4. Definitions of specific SLP pMBS terminology, such as oral aversion, pharyngeal residue, swallowing delay, and reduced esophageal clearance.5. Imaging findings in pMBS penetration, aspiration, nasopharyngeal reflux, laryngomalacia, etc.6. Causes and pathophysiology of abnormalities detected on a pMBS study.7. Findings on brain MRI in patients who would need a pMBS study.8. Management options for a failed pMBS study.9. How a pediatric MBS study differs from an adult MBS study in terms of clinical evaluation, grading of findings, and intervention.10. Summary highlighting the applications of a pMBS study for radiology residents.

## PDEE-59 PEARLS AND PITFALLS IN PEDIATRIC NEUROVASCULAR RADIOLOGY: A TRAINEE'S AFTER-HOURS GUIDE

Kathleen Schenker, MD (*Abstract Co-Author*) Nothing to Disclose
Ashrith Kandula (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Master the Fundamentals: Grasp the cerebrovascular anatomy of the brain and spinal cord in children to understand blood flow patterns and interpret neuroimaging.
- Recognize Early Signs: Identify the classic presentation of congestive heart failure in neonates with Vein of Galen Malformation (VGAM) and its characteristic imaging findings.
- Sharpen Stroke Diagnosis: Broaden your understanding of pediatric stroke symptoms in septic embolism. Utilize CTA and MRA to identify characteristic features and differentiate from other etiologies.
- Unveil Behēet's Disease: Recognize the multifocal vascular involvement (venous thrombosis and arterial stenoses) seen on angiography in Behēet's disease.
- Think Collateral Flow: Suspect moyamoya syndrome in children with progressive ischemic symptoms or headaches,
- MRI Venography is Key: Importance of MRV for accurate and timely diagnosis of Venous Sinus Thrombosis (VST) in children, which can mimic other stroke etiologies.
- Thunderclap Headache: Consider RCVS in adolescents with normal initial MRI.

**TABLE OF CONTENTS/OUTLINE**

Pearls for Initial Assessment:
- Key historical details and presenting signs/symptoms specific to pediatric patients.
- Tailoring imaging protocols to minimize radiation exposure.
- Pitfalls to Avoid:
- Misinterpreting normal variants for pathology.
- Missing subtle findings due to limited experience.
- Ordering unnecessary imaging studies.
- Case-Based Learning:
- Common pediatric neurovascular emergencies will be presented in a concise case format.
- Each case will highlight key imaging findings, differential diagnoses, and pearls for interpretation.
- Pitfalls specific to each case will be emphasized to guide trainees in avoiding misdiagnosis.

## PDEE-6 IMAGING EVALUATION OF PEDIATRIC SELLA/SUPRASELLAR LESIONS: PEARLS AND PITFALLS

Emilio Inarejos Clemente, MD (*Abstract Co-Author*) Nothing to Disclose
Eman E. Marie, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Maria Navallas, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha K. Gerrie, MD, FRCPC (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Knowledge of the updated WHO classification of tumors of the central nervous system facilitates pathologic and radiologic categorization of sella/suprasellar region tumors 2. A fundamental understanding of key tumorigenesis pathways aids in multidisciplinary patient management discussion 3. Appropriate use and understanding of available MRI sequences in tumor work-up can narrow the differential diagnosis of sella/suprasellar tumors

**TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Overview of the WHO classification of tumors of the central nervous system 3. MRI protocol for tumor work-up 4. Pseudotumors - classic features, differential diagnosis, pearls, pitfalls a. Pars intermedius cyst b. Rathke cleft cyst c. Arachnoid cyst d. Epidermoid cyst e. Dermoid cyst f. Suprasellar lipoma 5. Sella/suprasellar tumors - classic features, differential diagnosis, pearls, pitfalls a. Pilocytic astrocytoma b. Pilomyxoid astrocytoma c. Craniopharyngioma d. Hypothalamic hamartoma e. Germinoma f. Pituitary macroadenoma 6. Cheat sheets - differentiating tumors based on T2 appearance, presence of restricted diffusion, calcification, hemorrhage, growth pattern, enhancement pattern 7. Conclusion

## PDEE-60 ROLE OF INTERVENTIONAL RADIOLOGY IN DIAGNOSIS OF EXTRA HEPATIC BILIARY ATRESIA (EHBA)

Kushaljit S. Sodhi, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Anmol Bhatia, MD (*Abstract Co-Author*) Nothing to Disclose
Ravi Kanojia, MBBS (*Abstract Co-Author*) Nothing to Disclose
Sadhna Lal (*Abstract Co-Author*) Nothing to Disclose
Akshay K. Saxena, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Importance of early diagnosis of EHBA, Classification of EHBA, Technique of ultrasound guided Percutaneous Transhepatic Cholecysto Cholangiography (PTCC), Review of published literature regarding advantages and safety of the PTCC, Technique of ultrasound guided liver biopsy, Benefit of combined ultrasound guided PTCC and liver biopsy

**TABLE OF CONTENTS/OUTLINE**

Definition and types of EHBA, Clinical presentation, differential diagnosis and urgency in clinching early diagnosis of EHBA, Brief summary of diagnostic ultrasonography features of EHBA, Emphasizing status of intra operative cholangiography (IOC) as the gold standard and highlighting the risk of negative laparotomy, Technique of ultrasound guided PTCC, Illustrative cases comparing PTCC and IOC from the authors' institute, Advantages, pitfalls and complications of PTCC, Use of combined ultrasound guided PTCC and liver biopsy for establishing the diagnosis of EHBA

## PDEE-61 FETAL MRI PICKING UP THE TORCH AGAIN! - UPDATE ON PRENATAL INFECTIONS OF THE CENTRAL NERVOUS SYSTEM

**Awards**
**Certificate of Merit**

Ignacio Delgado, MD (*Abstract Co-Author*) Nothing to Disclose
Elida Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Angel Sanchez-Montanez, MD (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

; Prenatal central nervous system (CNS) infections remain an important cause of acute and long-term neurological morbidity.; Fetal MRI is the best modality for demonstrating the expressions of the inflammatory response to infection in the brain in fetuses and neonates.; Prompt brain imaging diagnosis facilitates immediate therapy and early recognition of complications.

**TABLE OF CONTENTS/OUTLINE**

Early diagnosis of CNS infections in fetuses is best performed with US, whereas MRI is the best diagnostic study for determining areas of involvement in the brain and spine and for improving the ability to narrow the differential diagnosis. Diffusion-weighted imaging identifies cytotoxic edema and abscesses.Prenatal CNS infections are included in the STORCH acronym (syphilis, toxoplasmosis, rubella, CMV, HIV and herpes simplex), also Zika virus or Parvovirus B19. Early infections affect organogenesis, while later infections lead to brain destruction.; CMV is the most common agent. Early infections may result in malformations within the lissencephaly-pachygyria spectrum, and cerebellar hypoplasia and periventricular calcifications, while infections acquired later produce diffuse polymicrogyria, or white matter injury.; Herpes simplex virus (type 2) is a major cause of neonatal encephalitis. Neuroimaging reflects leptomeningeal inflammation and diffuse parenchymal involvement, ranging from vasogenic to cytotoxic edema, with diffusion restriction and necrosis, evolving to cystic encephalomalacia or dystrophic calcification.; Zika virus prenatal infection can lead to microcephaly, cerebral calcification, cortical malformation, ventriculomegaly and corpus callosum hypoplasia.

## PDEE-62 PEDIATRIC EWING SARCOMA: THE RADIOLOGIST'S GUIDE TO UPDATES IN TUMOR CLASSIFICATION, STAGING, PROGNOSTICATION AND SURVEILLANCE

**Awards**
**Certificate of Merit**

Apeksha Chaturvedi, MD (*Abstract Co-Author*) Nothing to Disclose
Sheela B. Garudaiyengar, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Philip J. Katzman, MD (*Abstract Co-Author*) Nothing to Disclose
Hunter R. Carlock, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. WHO 2020 has introduced a new category of "undifferentiated round cell sarcomas of the bone and soft tissue" including Ewing sarcoma and Ewing-like sarcoma entities.2. Clinical, epidemiologic, immunohistochemical, genetic, and imaging characteristics help distinguish individual tumor subtypes within this broad category.3. With advances in FDG-PET CT/MR, bone marrow biopsy is no longer universally recommended for tumor staging.4. Whole Body MR is increasingly used for tumor staging and surveillance.5. Tumor prognostication is hinged on both pretreatment factors and response to therapy, with presence of metastases at diagnosis the most important prognostic factor.6. Key imaging findings impact clinical decision making and surgical approach.

**TABLE OF CONTENTS/OUTLINE**

1. Background information2. New WHO 2020 classification of Ewing sarcoma and its relevance to radiologists3. Clinical, epidemiologic, immunohistochemical, and molecular genetic features of Ewing sarcoma relative to Ewing-like sarcoma entities4. Multimodal imaging appearances of

Ewing sarcoma and Ewing-like sarcoma entities5. Updated MR imaging protocols, with a focus on diffusion-weighted and whole-body MR6. Evolving staging/surveillance recommendations7. Revised report templates incorporating prognostic variables (localized versus metastatic disease; proximal/distal tumors; extraskeletal/skeletal Ewing sarcoma; tumor size; pathologic fracture+/-; residual viable tumor after chemotherapy or local control surgery+/-)8. Conclusions

## PDEE-63 IF A PICTURE IS WORTH A THOUSAND WORDS THEN WHAT ABOUT A NUMBER? PEDIATRIC IBD IMAGING-BASED INDICES IN CLINICAL PRACTICE

**Awards**
**Certificate of Merit**

Ruth Cytter-Kuint, MD (*Abstract Co-Author*) Nothing to Disclose
Denise A. Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Li-Tal Pratt, MD (*Abstract Co-Author*) Nothing to Disclose
Ailish Coblentz, MD (*Abstract Co-Author*) Nothing to Disclose
Ronit Precel, MD (*Abstract Co-Author*) Nothing to Disclose
Gili Focht, MSc, MBA (*Abstract Co-Author*) Nothing to Disclose
Mary-Louise C. Greer, MBBS (*Presenter*) Research Grant, AbbVie Inc

### TEACHING POINTS

1. To understand the role of imaging biomarkers in inflammatory bowel disease (IBD); 2. To be familiar with pediatric and adult-derived MRI and ultrasound-based indices; 3. To calculate pediatric MRI- and ultrasound- based indices for inclusion in diagnostic imaging reports; and 4. To consider future applications of imaging-based indices in pediatric IBD.

### TABLE OF CONTENTS/OUTLINE

1. Background Explain the evolution of biomarkers in IBD from clinical and endoscopic scores to imaging-based indices, gauging disease activity, severity and treatment response, guiding drug development, with potential for prognostication. 2. Imaging-based Indices: Describe specific indices using MR enterography (MRE), pelvic MRI (PMR) and bowel ultrasound, quantifying disease activity, severity and treatment response, highlighting new MRI-based indices developed in pediatric cohorts. 3. Pediatric Imaging-based Indices (a) Pediatric Inflammatory Crohn's MRE Index - PICMI, (b) Pediatric MRI-Based Perianal Crohn Disease index - PEMPAC and (c) Pediatric ultrasound-based scores - SPAUSS and PCD-US Define index components, methodology for score calculation and cut-off values for remission, active inflammation and response as relevant. Provide examples illustrating scores and reporting templates. 4. Future Directions: Consider current and emerging roles of imaging biomarkers including use of Artificial Intelligence/Deep Learning, integration with texture analysis, and exploration of unmet needs such as quantification of intestinal fibrosis. 5. Practice Cases: Interactive exercise trialing score calculations on MRE, PMR and ultrasound.

## PDEE-64 ALTERNATIVE ACCESS SITES FOR PEDIATRIC ARTERIAL INTERVENTIONS - THINK BEYOND THE FEMORAL

**Awards**
**Cum Laude**

Joao G. Amaral, MD (*Abstract Co-Author*) Nothing to Disclose
Elaine Y. Kan, MBChB (*Abstract Co-Author*) Nothing to Disclose
Moritz Wildgruber, MD, PhD (*Abstract Co-Author*) Consultant, Sirtex Medical Ltd;Consultant, iThera Medical GmbH;Consultant, Bayer AG

Jonathan Chen (*Abstract Co-Author*) Nothing to Disclose
Dimitri A. Parra, MD, MMEd (*Abstract Co-Author*) Nothing to Disclose
Kin Fen Kevin Fung, MBBS, FRCR (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Obtaining arterial access is the one of the most challenging aspects for pediatric arterial interventions, especially in neonates and young infants.- Due to larger sheath-to-vessel ratio, the risk of thrombo-occlusive complication is higher in young children. Strategies to prevent complications include limb warming, ultrasound guided access, low-profile hydrophilic sheath and heparinization.- Common femoral artery access remains the standard for interventions in children. Alternative access sites include axillary, brachial, radial, carotid, and umbilical arteries and umbilical vein in neonates.- Upper extremity access sites should be considered in children with significant aorta caliber differences such as in hepatic hemangioma, and aortoiliac occlusive conditions such as mid-aortic syndrome. Other advantages include ease of catheterisation and passage of interventional devices into visceral arteries with acute downward angulation- Carotid access is not commonly used but can be an alternative in infants requiring complex cardiac or neurovascular interventions.- Umbilical artery can be used in neonates up to 1 week of age. Umbilical vein is an alternative if there is a patent ductus arteriosus or foramen ovale, which can act as a conduit between the arterial and venous systems. Advantages include ability to use larger sheaths and prevention of access-related complications in the extremities.

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Technique for arterial access in children 3. Strategies to prevent access-related complications 4. Standard and alternative arterial access sites: Advantages and potential issues 5. Illustrative cases 6. Management of complications 7. Conclusions

## PDEE-65 PEDIATRIC GENITOURINARY RADIONUCLIDE SCINTIGRAPHY WITH INTERESTING ANATOMIC CASE CORRELATION

Michael A. Steiner, MD (*Abstract Co-Author*) Nothing to Disclose
John Hollis Tackett, BS (*Abstract Co-Author*) Nothing to Disclose

Johnny Yang, BS, BA (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Review anatomy and physiology of MAG3 renal scans - Correlate with other imaging for common and uncommon pediatric genitourinary pathology.- Discuss complementary role of MAG3 renal scans for diagnostic purposes

### TABLE OF CONTENTS/OUTLINE

Technetium-99m (Tc-99m) scintigraphy, using tracers such as mercaptoacetyltriglycine (MAG3), dimercaptosuccinic acid (DMSA), and diethylenetriaminepentaacetic acid (DTPA) offers excellent anatomical and physiological details. Tc-99m MAG3 is considered one of the best methods for

assessing renal function owing to favorable qualities in energy and dosimetry. DTPA adds glomerular filtration rate assessment, and DMSA provides information for differentiating pyelonephritis versus scarring in the presence of vesicoureteral reflux and multiple episodes of urinary tract infection. Thus, pediatric genitourinary imaging commonly utilizes technetium scintigraphy. Through a case series, this exhibit will include cases of collecting system dilatation and other GU pathology due to various obstructive and nonobstructive pathology where MAG3 imaging proved useful in diagnosis and/or clinical management. Illustrative cases are reviewed with ultrasound and CT correlation.

## PDEE-66 INNER EAR ANOMALIES IN CONGENITAL HEARING LOSS, STEP BY STEP APPROACH FOR NOVICE

**Awards**
**Certificate of Merit**

Moegamad A. Ederies, MBBCh, FRCR (*Abstract Co-Author*) Nothing to Disclose
Jehan Al-Rayahi, MD (*Abstract Co-Author*) Nothing to Disclose
Alaa O. Koko, MD, BMBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

General objective Step by step approach to identify inner ear abnormalities in congenital hearing loss.Detailed Objectives: 1- To define the concept of congenital hearing loss and the variable classification approach 2-To determine the optimum CT MRI planes (and MRI sequences ) 3-To review the inner ear components imaged in CT MRI 4-To clarify in detail the abnormal morphology of cochlea, vestibule , semicircular canals, and IAM in congenital hearing loss.5- To review images of real cases.

### TABLE OF CONTENTS/OUTLINE

Definition and classification of Congenital hearing loss.The applied CT MRI protocols.The anatomy of inner ear structure's. Simple approach to identify inner ear abnormality.Detailed abnormal morphology of cochlea ,vestibule ,semicircular canals and IAM.

## PDEE-67 BENIGN AND MALIGNANT PEDIATRIC LIVER MASSES: RADIOLOGIC-PATHOLOGIC UPDATE FROM THE PEDIATRIC LIRADS WORKING GROUP

Michael R. Acord, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Many classification schemes and management recommendations for benign and malignant liver masses in children have evolved over the last 15 years.2. There are characteristic pathologic findings that may affect the imaging appearance of these tumors in children.3. Contrast enhanced ultrasound and use of hepatobiliary contrast agents are becoming standard of care for imaging liver masses in children.

### TABLE OF CONTENTS/OUTLINE

• Introduction: General discussion of updates in the imaging of benign and malignant pediatric liver tumors. Review of the Los Angeles liver tumor symposium consensus classification of tumor histopathology • Specific Pathologies: Each section will discuss clinical, imaging, and pathologic features, differential diagnoses, and management recommendations. o Infantile and congenital hemangiomas. Updates: ISSVA nomenclature and classification. o Mesenchymal hamartoma. o Focal nodular hyperplasia. Updates: FNH-like lesions o Hepatocellular adenoma. Updates: Subtypes and associations o Hepatoblastoma. Updates: LIRADS imaging recommendations, PRETEXT staging for risk stratification, treatment strategies, and prognosis. Discussion of hepatocellular neoplasm NOS. o Hepatocellular carcinoma. Updates: LIRADS, imaging recommendations, predisposition, available screening recommendations, and prognosis. o Fibrolamellar hepatocellular carcinoma. o Undifferentiated embryonal sarcoma.

## PDEE-68 IMAGING OF HEARING LOSS IN PEDIATRIC POPULATION

Vijay S. Pande, MD (*Abstract Co-Author*) Nothing to Disclose
Pratit Pokharel, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Approximate prevalence of hearing loss is between 2 to 3 per 1000 babies, while by the age of 12 years approximately 20% of children have detectable hearing loss either in one or both ears. Congenital hearing loss is often sensorineural and associated with genetic conditions or isolated inner ear malformations. While in older children conductive hearing loss is common. Early detection and treatment are important to prevent significant language disability. High resolution CT and MR imaging plays crucial role in demonstrating the inner ear anatomy and pathologies. Imaging has also established pivotal role in selecting patients for cochlear implantation.We wish to make the residents and radiologist in practice aware of the imaging anatomy of temporal bone and imaging features in commonly encountered conditions.

### TABLE OF CONTENTS/OUTLINE

Technical considerations in CT, MRI, for imaging in pediatric hearing loss. Pertinent imaging anatomy in evaluation of hearing loss. Imaging features of congenital and acquired external and middle ear pathologies. Imaging features of congenital and acquired inner ear pathologies.

## PDEE-69 UNPEELING SUBPIAL HEMORRHAGES IN NEONATES: ANATOMY, IMAGING AND CLINICAL INSIGHTS

Saul Rodriguez (*Abstract Co-Author*) Nothing to Disclose
Natally AlArab, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Yutaka Sato, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lillian M. Lai, MD (*Abstract Co-Author*) Nothing to Disclose
T. Shawn Sato, MD (*Presenter*) Research Grant, Bracco Group

### TEACHING POINTS

Subpial hemorrhages (SPH) are an often under-recognized and misdiagnosed type of intracranial hemorrhage, most commonly seen in neonates and young infants. Although the etiology remains elusive, SPH are known to be associated with various conditions including but not limited to the birth trauma, neonatal hypoxic brain injury, abusive head trauma and hydrocephalus shunting. SPH are located superficial to the cortex, in the potential space between the glia limitans and the pia matter. On MR imaging, SPH are localized to the brain surface and the subjacent cortex can show diffusion restriction. Accurate diagnosis holds significant clinical implications given the potential parenchymal damage associated with SPH. We present the pertinent anatomy, proposed pathophysiology and imaging features crucial for accurate diagnosis of SPH.

### TABLE OF CONTENTS/OUTLINE

- Review pertinent anatomy and pathophysiology and understand the unique imaging features and clinical significance of SPH.- Become familiar with the typical imaging features of SPH and learn to differentiate it from subarachnoid and subdural hemorrhages.- Review cases of subpial hemorrhage to familiarize and aid in recognizing this frequently misdiagnosed entity.

## PDEE-7 IMAGING EVALUATION OF PEDIATRIC SUPRATENTORIAL TUMORS: PEARLS AND PITFALLS

Emilio Inarejos Clemente, MD (*Abstract Co-Author*) Nothing to Disclose
Eman E. Marie, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Samantha K. Gerrie, MD, FRCPC (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Knowledge of the updated WHO classification of tumors of the central nervous system facilitates pathologic and radiologic categorization of supratentorial tumors 2. A fundamental understanding of key tumorigenesis pathways aids in multidisciplinary patient management discussion 3. Appropriate use and understanding of available MRI sequences in tumor work-up can narrow the differential diagnosis of supratentorial tumors

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Overview of the WHO classification of tumors of the central nervous system 3. MRI protocol for tumor work-up 4. Tumors - classic features, differential diagnosis, tumor genetics, pearls, pitfalls a. High-grade glioma: i. Diffuse hemispheric glioma: H3 G34 mutant ii. Diffuse pediatric-type glioma: H3 WT, IDH WT iii.Diffuse infant-type hemispheric glioma: NTRK, ROS1, ALK, MET b. Pilocytic astrocytoma c. Subependymal giant cell astrocytoma d. Ependymoma: ZFTA fusion positive, YAP1 fusion positive e. Choroid plexus tumor: Choroid plexus papilloma, atypical choroid plexus papilloma, choroid plexus carcinoma f. Embryonal tumor with multilayered rosettes g. Atypical teratoid rhabdoid tumor h. Seizure-related tumors: i. Pilomyxoid xanthoastrocytoma ii. Ganglioglioma iii. Dysembryoplastic neuroepithelial tumor i. Other less common supratentorial tumors to recognize i. Desmoplastic infantile astrocytoma/Desmoplastic infantile ganglioglioma ii. Multinodular and vacuolating neuronal tumor iii. Meningioma iv. Solitary fibrous tumor of dura v. Metastasis 5. Cheat sheets - differentiating tumors based on T2 appearance, presence of restricted diffusion, calcification, hemorrhage, growth pattern, enhancement pattern 6. Conclusion

## PDEE-70 WHAT DO I DO WITH IT? UPDATE ON PEDIATRIC THYROID NODULE ASSESSMENT AND MANAGEMENT

Jesse L. Courtier, MD (*Abstract Co-Author*) Founder, Sira Medical, Inc;Consultant, Sira Medical, Inc
Sunit Davda, MBBS, MRCP (*Abstract Co-Author*) Nothing to Disclose
Amanda R. Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Kalpana Manral, MD (*Abstract Co-Author*) Nothing to Disclose
Rachelle Durand, DO (*Abstract Co-Author*) Nothing to Disclose
Kantheera Leesmidt, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Thyroid nodules in the pediatric population exhibit a lower incidence rate of 0.5% to 1.6%, yet the malignancy rate is 25% to 30% which is higher compared to adults.2. Pediatric thyroid cancer has a greater risk of metastasis to lungs and lymph nodes with more likely extrathyroidal growth and recurrence. However, their prognosis is favorable.3. ATA and ACR-TIRADS are the two most common ultrasound-based risk stratification systems for description of thyroid nodules and stratify the risk characteristics in adults, however, the diagnostic performance when applying to the pediatric population has been less reported.4. Utilizing thyroid ultrasound reference standards tailored for adults in pediatric populations may offer advantages, although they may not always be accurate. ATA, ACR-TIRADS, and EU-TIRADS have moderate diagnostic performance in pediatric thyroid nodule patients.5. US features of microcalcifications, ill-defined margins, size > 3.5 cm, and abnormal lymph nodes increase sensitivity and specificity for malignancy in pediatric population.6. Performing biopsies on nodules categorized as the highest risk and smaller than 1 cm could improve diagnostic accuracy.

### TABLE OF CONTENTS/OUTLINE

1. Review features of common pediatric benign and malignant thyroid lesions.2. Illustrate potential pitfalls and mimics of thyroid masses.3. Evaluate the strengths and weaknesses of various adult thyroid nodule scoring criteria as they apply to pediatrics.4. Review management of pediatric thyroid nodules.5. Test understanding with a short quiz.

## PDEE-71 VARIOUS ASPECTS AND MIMICKERS OF IMAGING FINDINGS OF ACUTE ENCEPHALOPATHY WITH BIPHASIC SEIZURES AND LATE REDUCED DIFFUSION (AESD)

Harushi Mori, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akihiro Nakamata, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

AESD is one of the most common acute encephalopathies in infants and young children in East Asia. Clinically, it develops as febrile status epilepticus and often shows no abnormal findings on diffusion-weighted image(DWI) or T2-weighted images taken on the first or second day of onset; therefore, distinguishing it from febrile seizures in the early stages of the disease is challenging. However, magnetic resonance spectroscopy (MRS) and arterial spin labeling (ASL) may exhibit characteristic abnormalities, even in the early stages of the disease. Unlike febrile seizures, AESD has a high rate of sequelae, exceeding 60%, and early therapeutic intervention improves neurological prognosis; thus, early diagnosis is important. Therefore, radiologists should be

familiar with the typical patterns, variants, and mimickers of AESD. The purpose of this exhibit is:1. To explain the disease concept and pathogenesis of AESD2. To discuss the clinical course and imaging findings of AESD3. To discuss the excitotoxity encephalopathy spectrum4. To discuss the mimickers of AESD

**TABLE OF CONTENTS/OUTLINE**

•Disease concept and pathogenesis of AESD.•Clinical aspects of AESD•Typical imaging findings ?DWI ?ASL ?MRS •Other imaging findings •Spectrum of encephalopathy with excitotoxicity (e.g. hemiconvulsion-hemiplegia/hemiconvulsion-hemiplegia-epilepsy syndrome, clinically mild infantile encephalopathy associated with excitotoxicity, infantile traumatic brain injury with a biphasic clinical course and late reduced diffusion) •Imaging mimickers (e.g. hemorrhagic shock and encephalopathy syndrome, meningitis, posterior reversible encephalopathy syndrome)

## PDEE-72 DECODING THE PUZZLE: A MULTIMODAL APPROACH TO PEDIATRIC NON-TRAUMATIC HEAD AND NECK EMERGENCIES

Kathleen Schenker, MD (*Abstract Co-Author*) Nothing to Disclose
Ashrith Kandula (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Unravel the diverse causes of pediatric non-traumatic head and neck emergencies.• Master the art of differential diagnosis using a multimodal imaging approach.• Gain insight into the unique imaging characteristics of frequently encountered emergencies.

**TABLE OF CONTENTS/OUTLINE**

- Introduction:
- Challenges in diagnosing pediatric non-traumatic head and neck emergencies.
- Unveiling the Culprit:
- Plain radiography: Unveiling the bony clues.
- Ultrasound: A bedside warrior for rapid evaluation.
- CT: Delineating intricate anatomy and complications.
- MRI: Unveiling soft tissue involvement.
- Decoding the Images:
- Infectious emergencies:
- Lemierre syndrome: Painting the jugular vein red.
- Gradenigo syndrome: Facial pain whispers of a cranial nerve dilemma.
- Cavernous sinus thrombosis: When the crossroads of blood flow become inflamed.
- Epiglottitis: The cherry red flag of a life-threatening airway obstruction.
- Branchial cleft cyst and lymphangioma: When remnants of development turn troublesome.
- Atypical mycobacterial infection: The sly infectious invader.
- Mastoiditis with intracranial complications: Balancing hearing with brain health.
- Sinusitis with intracranial complications (Pott's puffy tumor): When a sinus infection breaches its boundaries.
- Skull base osteomyelitis: A bone infection with a cranial address.
- Non-infectious emergencies:
- Labyrinthitis: The inner ear's dance gone wrong.
- Orbital pseudotumor: Inflammation masquerading as a mass.
- Juvenile angiofibroma: An aggressive vascular anomaly.
- Orbital varix: Bulging eye caused by a dilated vein.
- Mimics:
- Langerhans cell histiocytosis (LCH) vs. infectious processes.
- Discitis/osteomyelitis vs. infectious complications.

## PDEE-73 UNVEILING IMAGING INSIGHTS INTO CHILDHOOD INTERSTITIAL LUNG DISEASES (CHILDS): A COMPREHENSIVE REVIEW OF CLINICAL AND RADIOLOGICAL PROFILES

**Awards**
**Certificate of Merit**

Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*) Support, Canon Medical Systems Corporation;Support, General Electric Company
Tatsuo Kono, MD (*Abstract Co-Author*) Nothing to Disclose
Gen Nishimura (*Abstract Co-Author*) Nothing to Disclose
Yuko Tsujioka, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Eugene Nishi, MD (*Abstract Co-Author*) Nothing to Disclose

Taiki Nozaki, MD (*Abstract Co-Author*) Nothing to Disclose
Yoshitake Yamada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Orito Ikeda (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Childhood interstitial lung diseases (chILDs) are individually rare, but overall, many affected children seek medical services. Since chILDs, particularly of the infantile-onset, were poorly understood for a long time, many cases remained undiagnosed as "unexplained" ILDs. However, the new chILD classification (2007) for children under 2 years, and the expanded classification (2015) for children ages 2-18 years provided a more comprehensive picture of chILDs. The genetic and histological background of chILDs has been revealed as well. Radiologists should be aware of the disease classification, pathophysiology, and relevant imaging findings of chILDs. Accurate diagnosis will lead to further elucidation and development of efficient medical interventions for this group of disorders. TEACHING POINTS 1. Based on the current classification of chILDs, their pathophysiology and imaging findings will be presented, highlighting imaging findings that may enable us to make definitive diagnoses. 2. The spectrum of chILDs overlaps with that of adult ILDs; however, we should be aware of distinctive clinical and imaging characteristics in chILDs and the presence of infant-specific chILDs.

**TABLE OF CONTENTS/OUTLINE**

1) Introduction2) Disorders of infancy (diffuse developmental abnormalities/alveolar growth abnormalities/surfactant dysfunction and related abnormalities/specific conditions of poorly defined etiology/miscellaneous monogenic chILDs)3) Disorders not specific to infancy and childhood (disorders of normal host/disorders related to systemic diseases/disorders of the immunocompromised host/disorders masquerading as interstitial lung disease)4) Discussion

## PDEE-74 UPDATE ON US SCREENING FOR DEVELOPMENTAL DYSPLASIA OF THE HIP (DDH): WHY, HOW AND WHEN?

Placzek (*Abstract Co-Author*) Nothing to Disclose
Hakan Omeroglu (*Abstract Co-Author*) Nothing to Disclose
Ustun Aydingoz, MD (*Abstract Co-Author*) Nothing to Disclose
Carolina Casini (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Chlapoutakis, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• To demonstrate why and how hip ultrasound has largely replaced clinical examination and radiography, as the screening method of choice for the early detection of developmental dysplasia of the hip in neonates and infants. • To justify the selection of Graf's technique over the other sonographic techniques, as the "one-stop-shop" for the diagnosis and monitoring of treatment of developmental dysplasia of the hip. • To present the evidence which proves that universal sonographic screening is preferred over selective screening. • To present Graf's technique main examination steps, including baby positioning, quality evaluation, morphological classification, and final typing. • To demonstrate the main treatment principles according to the Graf's hip type. • To comment on the main reasons for underperformance and practically demonstrate the main sources of erroneous practice and confusion. • To emphasize the importance of structured training as a requisite for the "lege artis" performance of the technique.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Screening methods for developmental dysplasia of the hip 3. Sonographic techniques 4. Why Graf's technique 5. Universal vs. selective screening with Graf's technique 6. Presentation of Graf's technique examination steps 7. Common errors and how to avoid them. 8. Treatment guidance / monitoring of treatment 9. Structured training 10. Conclusions

## PDEE-75 UNRAVELING CHALLENGES: IMAGING DIAGNOSIS OF PEDIATRIC SOLID PERITONEAL TUMORS

Salma Moalla, MD (*Abstract Co-Author*) Nothing to Disclose
Manel Mestiri, MD (*Abstract Co-Author*) Nothing to Disclose
Corinne Balleyguier, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Remy Barbe, MD (*Abstract Co-Author*) Nothing to Disclose
Yassamin Benhayoun Sadafyine (*Abstract Co-Author*) Nothing to Disclose
El Mehdi Mniai, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Peritoneal neoplasms are a group of tumors that arise within the peritoneum space but outside the major organs. Diagnosis of these tumors is often challenging for radiologists and consists of several steps, including determining the tumor's location within the peritoneum, often by excluding involvement of adjacent abdominal structures, and identifying distinctive imaging features. The diagnostic spectrum for rare solid peritoneal masses in children is broad, and includes rhabdomyosarcomas, desmoid tumors, teratomas, and inflammatory myofibroblastic tumors... Ultrasound serves as the frontline imaging modality for initial assessment thanks to its accessibility and lack of ionizing radiation. Computed Tomography (CT) offers superior visualization and aids in lesion detection, localization, and distant staging, especially when malignancy is suspected. Magnetic Resonance Imaging (MRI) provides excellent soft tissue contrast and is valuable for diagnosis and surveillance, particularly with diffusion-weighted sequences for detecting subtle peritoneal lesions. A methodical approach to diagnosing solid peritoneal masses in pediatric patients is essential. This approach involves integrating clinical data with imaging findings while taking into account age-related differences and the rarity of such tumors in children. Despite the major contribution of imaging, biopsy is still often warranted for histological confirmation.

**TABLE OF CONTENTS/OUTLINE**

1) Introduction and Objectives 2) Imaging signs of localization 3) Contribution of imaging modalities 4) Illustration of some rare solid peritoneal tumors in pediatrics 5) Take home messages 6) References

## PDEE-76 IMAGING OF MYXOID-CONTAINING TUMORS IN CHILDREN AND ADOLESCENTS

Oscar M. Navarro, MD (*Abstract Co-Author*) Nothing to Disclose
Andrea S. Doria, MD, PhD (*Abstract Co-Author*) Baxalta-Shire (Research Grant), Novo Nordisk (Research Grant), Terry Fox Foundation (Research Grant), PSI Foundation (Research Grant), Society of Pediatric Radiology (Research Grant), Garron Family Cancer Centre (Research Grant)
Afsaneh Amirabadi, PhD (*Abstract Co-Author*) Nothing to Disclose
Magdalena P. Reyes Recasens, MD (*Abstract Co-Author*) Nothing to Disclose
Jesus A. Arenos-Abril, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. List the most common myxoid-containing tumors involving the pediatric and adolescent age group. 2. Discuss the role of different imaging modalities used in the work-up of these lesions and describe the main imaging findings, emphasizing MRI features. 3. Recognize the characteristic MRI signal of the myxoid matrix to facilitate the differential diagnosis of soft tissue tumors.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. MRI characteristics including diffusion weighted-imaging features of myxoid-containing lesions. 3. Histological types involving the pediatric and adolescent age group: a. Myxoid liposarcoma b. Primitive myxoid mesenchymal tumor of infancy (PMMTI) c. Low-grade myxoid fibrosarcoma d. Chondromyxoid fibroma e. NTRK-rearranged spindle cell neoplasm f. Extraskeletal myxoid chondrosarcoma 4. Take home points 5. References

## PDEE-77 TUBE FOR THOUGHT: IMAGING OF COMPLICATIONS ASSOCIATED WITH GASTROSTOMY AND GASTROJEJUNOSTOMY TUBES

Eugene G. Sheffield, MD (*Abstract Co-Author*) Nothing to Disclose
Asif Jamal, MBBS (*Abstract Co-Author*) Nothing to Disclose
Preet K. Sandhu, MD (*Abstract Co-Author*) Nothing to Disclose
Chinky Patel, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Percutaneous feeding tubes such as gastrostomy and gastrojejunostomy tubes are widely used in the pediatric age group requiring long-term nutritional support. 2. Several complications are associated with the feeding tube apparatus such as abnormal placement, malpositioning, malfunction, and other uncommon complications. 3. Fluoroscopy is the initial modality of choice to evaluate for feeding tube complications using water soluble, non-ionic iodinated contrast agents. Ultrasound and CT are complementary in some cases. 4. A scout radiograph of the abdomen is often obtained prior to fluoroscopic evaluation to look for obvious malpositioning of the percutaneous feeding apparatus followed by fluoroscopy in the posteroanterior and right

lateral positions to look for contrast opacifying the stomach and jejunum depending on the type of feeding tube, and to assess the position of the apparatus. 6. It is often challenging to identify feeding tube related complications on fluoroscopy and a high index of suspicion is required based on the clinical scenario. 7. The role of the radiologist is to be aware of percutaneous feeding tube related complications and to identify them in a timely manner for optimal patient care.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction: use and importance of percutaneous gastrostomy and gastrojejunostomy tubes in the pediatric age group.2. Highlight various types of complications associated with feeding tube placement.3. Approach to evaluating these complications with an emphasis on imaging findings on fluoroscopy.4. Examples of feeding tube-related complications at our facility.

## PDEE-78 THE CHALLENGE OF UNDERSTANDING THE AIRWAY OBSTRUCTION IN FETUS: AN APPROACH TO EMBRIOLOGY, IMAGING ASPECTS AND PATOLOGY

Antonio S. Souza, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro Daltro, MD (*Abstract Co-Author*) Nothing to Disclose
Fernanda D. Braojos Braga, MD (*Abstract Co-Author*) Nothing to Disclose
Heron Werner JR, MD (*Abstract Co-Author*) Nothing to Disclose
Marcus Otavio Silva de Campos Meneses, MD (*Abstract Co-Author*) Nothing to Disclose
Tatiana M. Fazecas, MD (*Abstract Co-Author*) Nothing to Disclose
Luiz Rodrigues Santos, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Fetal magnetic resonance imaging (MRI) is the modality of choice for evaluation of congenital airway pathologies, which present a diagnostic challenge when assessed by ultrasound. The radiologist should be also accustomed with the embryology and normal anatomy of the airway and have a checklist to identify all structures every time is reading a fetal MRI. Identification of congenital airway anomalies become a crucial topic, as managing these pathologies may require interventions at the time of delivery or even during intrauterine life, posing a significant challenge for the perinatal care team due to the complexities of these pathologies and the risk of fetal demise.This pictorial essay will provide a detailed review of normal airway imaging findings in fetal MRI and their correlation with pathological findings, including some postnatal correlation cases.The objectives of this pictorial essay are:1 - To demonstrate the normal anatomy of the airway on fetal MRI; 2 - To present the primary congenital diseases involving the larynx and trachea; 3 - To identify the key radiological features of tracheal atresia, tracheal agenesis, and bronchial atresia;

**TABLE OF CONTENTS/OUTLINE**

1-Normal embryology of the airway; 2-Anatomy and anatomical relationships of the fetal airway; 3-Tracheal agenesis; 4-Tracheal atresia, stenosis or web; 5- Laryngeal stenosis, atresia or web; 6- Bronchial Atresia 7- Correlation between fetal MRI findings and postnatal outcomes;

## PDEE-79 IMAGING OF PEDIATRIC THYROID REVISITED

Oscar M. Navarro, MD (*Abstract Co-Author*) Nothing to Disclose
Emilio Inarejos Clemente, MD (*Abstract Co-Author*) Nothing to Disclose
Eman E. Marie, MD, MSc (*Abstract Co-Author*) Nothing to Disclose

Lucia Riaza Martin, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Navallas, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To describe key imaging features and discuss practical tips that can help the radiologist narrow the differential diagnosis of pediatric thyroid disorders2. To explain the use of new imaging technologies in pediatric thyroid evaluation3. To discuss the utility of Kwak TI-RADS, ACR-TIRADS, ATA and structured report system in the evaluation of pediatric thyroid disorders

**TABLE OF CONTENTS/OUTLINE**

1. US technique2. Normal anatomy, normal variants and pitfalls (cricoid cartilage, pyramidal lobe, intrathyroid thymus)3. Congenital thyroid abnormalities3.1. Congenital hypothyroidysm- Thyroid dysgenesis (agenesis, hemiagenesis, ectopia, hypoplasia)- Thyroid dyshormonogenesis3.2. Thyroglossal duct cyst4. Diffuse thyroid diseases4.1. Chronic lymphocytic thyroiditis (Hashimoto disease)4.2. Diffuse hyperplasia (Graves disease)4.3. Nodular hyperplasia4.5. Non-autoimmune thyroiditis (suppurative, granulomatous, subacute non-suppurative thyroiditis (De Quervain)4.6. Diffuse sclerosing variant of papillary carcinoma5. Focal thyroid lesions5.1. Benign lesions (colloid follicles/cysts, true epithelial-lined cysts, hyperplastic nodules with cystic degeneration, follicular adenoma)5.2. Thyroid cancer (papillary, follicular and medullary carcinoma)5.3. Predisposing factors for pediatric thyroid cancer including genetic disorders such as RET, DICER1 or PTEN gene mutations6. Utility and reproducibility of Kwak TI-RADS, ACR-TIRADS, ATA and structured report in the evaluation of pediatric thyroid lesions7. Evaluation of lymphadenopathy8. Newer techniques (elastography, superb microvascular imaging, contrast-enhanced US, radiomics/radiogenomics, AI)9. Conclusions

## PDEE-8 FLUOROSCOPIC IMAGING IN TRACHEOESOPHAGEAL FISTULA REPAIR: MASTERING THE TECHNIQUE TO MINIMIZE COMPLICATIONS

Kari L. Hayes (*Abstract Co-Author*) Nothing to Disclose
Chelsea S. Life, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Understand the pathology and subtypes of tracheoesophageal fistula (TEF)- Recognize imaging appearance of TEF, so as to not delay diagnosis- Review the potential complications of surgical correction of TEF and how would they be recognized on imaging- A model protocol for a pediatric post-operative esophagram will be provided- Pearls and pitfalls of pediatric esophagrams

**TABLE OF CONTENTS/OUTLINE**

- Title slide- TEF: Pathology- TEF: Subtypes- Diagnosing TEF: Pathway and Typical Imaging Appearance- Management of TEF- Potential Complications of Surgical Correction of TEF- Fluoroscopic Post-operative Evaluation: Appropriate Technique and Protocol- Pearls and Pitfalls of Fluoroscopic Esophagrams- Cases/Examples illustrating the aforementioned teaching points

## PDEE-80 SUSTAINING THE FUTURE OF PEDIATRIC RADIOLOGY

Hansel J. Otero, MD (*Abstract Co-Author*) Nothing to Disclose
Sweta Parmar (*Abstract Co-Author*) Nothing to Disclose
Johnny McLaughlin (*Abstract Co-Author*) Nothing to Disclose
Alexandra Sharashidze (*Abstract Co-Author*) Nothing to Disclose
Karen I. Ramirez Suarez, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Understand the environmental implications of radiology practices, including waste generation and energy consumption, prompting a commitment to sustainability.
- Provide specific examples of interventions that are cost-saving and friendlier to the environment adapted to pediatric radiology practices.
- Examine the cost and environmental impact of changes in equipment energy efficiency, reduction of single use items, and the adoption of multipatient contrast vials.

### TABLE OF CONTENTS/OUTLINE

- Introduction:
- Radiology environmental impact
- Environmental responsibility and vulnerability
- Principles for radiology sustainability and decarbonization
- First steps towards a more sustainable pediatric radiology department:
- Assembling the team
- Focus on cost-saving strategies
- Improving equipment energy efficiency and decreasing energy use
- Workstation power consumption
- Getting rid of single-use supplies and items
- Iodinated contrast vials
- Additional Projects
- Future directions
- Evaluation of climate-aware metrics tools for radiology departments
- Sustainability action plan

## PDEE-81 IMAGING SPECTRUM OF PEDIATRIC PANCREATIC ABNORMALITIES

Luis F. Goncalves, MD, MSc (*Abstract Co-Author*) Speaker, Koninklijke Philips NV;;
Susan M. Hamman, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Zulfiqar, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Asmaa Aamir, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The pancreas can be involved in a wide array of congenital and acquired conditions in the pediatric population. The purpose of this exhibit is: 1. To become familiar with the spectrum of pancreatic disorders in children. 2. Review a multimodality approach and technical considerations for the diagnosis of pancreatic pathology. 3. To illustrate the imaging features of common and uncommon pancreatic disorders in pediatric patients.

### TABLE OF CONTENTS/OUTLINE

Imaging approach to pancreatic lesions. Normal appearance of the pancreas on different imaging modalities. Congenital pancreatic anomalies: pancreas divisum, annular pancreas, ectopic pancreas, pancreatic hypoplasia, abnormal pancreaticobiliary junction. Congenital disorders with pancreatic insufficiency: cystic fibrosis, Schwachman- Diamond syndrome, hereditary pancreatitis, other genetic risk factors. Pancreatitis: acute, chronic, autoimmune. Pancreatic trauma: blunt trauma, penetrating trauma, nonaccidental trauma. Pancreatic infection. Cystic lesions of pancreas: congenital cyst, pseudocyst, von Hippel- Lindau syndrome, autosomal dominant polycystic kidney disease, cystic pancreatic neoplasms. Solid pancreatic tumors: Pancreatoblastoma, solid pseudopapillary neoplasm, neuroendocrine tumor, acinar cell carcinoma, adenocarcinoma, non-epithelial tumors including lymphoma, inflammatory myofibroblastic tumor, invading tumors, metastatic disease. Other pancreatic lesions: intrapancreatic accessory spleen, vascular lesions. Summary.

## PDEE-82 DON'T STICK YOUR NECK OUT: DISSECTING THE SPECTRUM OF PEDIATRIC NECK EMERGENCIES

Ajay Malhotra, MD, MMM (*Abstract Co-Author*) Nothing to Disclose
Shadi Ebrahimian, MD (*Abstract Co-Author*) Nothing to Disclose
Dheeman Futela, MBBS (*Abstract Co-Author*) Nothing to Disclose
Mihir Khunte (*Abstract Co-Author*) Nothing to Disclose
Rahul Jayaram, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Accurate imaging is crucial for diagnosing and managing non-traumatic pediatric head and neck emergencies. The appropriate imaging modality, such as ultrasound, CT, or MRI, varies depending on the particular condition. These conditions include orbital and sinus emergencies, deep neck emergencies, ear emergencies, or airway emergencies. Choosing the proper imaging is critical for determining the most suitable treatment approach and distinguishing between cases requiring immediate intervention and those that can be addressed with medical therapy. Familiarity with the clinical features of pediatric emergencies and collaboration with clinicians can ultimately improve diagnostic precision and treatment effectiveness.

### TABLE OF CONTENTS/OUTLINE

1. Introduction-Importance of imaging in pediatric emergencies-Overview of common head and neck emergencies2. Choosing the Appropriate Imaging Modality-Ultrasound: Safe, cost-effective, but limited depth and operator dependent.-CT: Rapid, detailed bone imaging, but radiation exposure and contrast risks.-MRI: Radiation-free, superior soft tissue contrast, but longer scan times.3. Specific Conditions and Imaging Guidelines-Orbital Emergencies: Identifying cellulitis and abscesses· Sinus / Nasal Emergencies: Complications of sinusitis-Ear Emergencies: Diagnosing otitis and mastoiditis-Airway Emergencies: Recognizing epiglottitis and croup-Neck Emergencies: Recognizing infection, foreign body, vascular emergencies, congenital anomalies4. Case Studies-Application of skills discussed toward patient cases5. Conclusion-Summary of key points-Importance of clinical picture and collaboration when interpreting imaging

## PDEE-83 "TUMMIES" FOR "DUMMIES": NAVIGATING PEDIATRIC ABDOMINAL X-RAYS

Thierry Huisman, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nadia F. Mahmood, MD (*Abstract Co-Author*) Nothing to Disclose

Ricardo Torres, BS (*Abstract Co-Author*) Nothing to Disclose
Karla Santiago-Soltero, BS (*Abstract Co-Author*) Nothing to Disclose
Danet Lugo (*Abstract Co-Author*) Nothing to Disclose
Laura Santiago Caobi, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Explore the prevalence and significance of pediatric abdominal pain and the diagnostic role of abdominal x-rays.- Outline a systematic approach to interpreting pediatric abdominal X-rays to improve diagnostic precision and patient outcomes.- Illustrate common pathologies identified in pediatric abdominal x-rays with case examples and address their diagnostic challenges.- Discuss common pitfalls and limitations of pediatric abdominal x-rays.

### TABLE OF CONTENTS/OUTLINE

Pediatric abdominal pain is one of the most common encounters in medical practice, often requiring prompt and accurate evaluation. Optimal use of abdominal x-rays in the pediatric population requires a proper technical assessment, recognition of pathological signs, and knowledge of common pitfalls and limitations. Adopting a systematic approach when reviewing abdominal x-rays entails a careful evaluation of gas patterns, extraluminal air, abdominal masses, calcifications, the peritoneal cavity, and surrounding osseous structures. Maintaining such a structure is key to enhancing diagnostic accuracy and improving patient outcomes.1. Introduction Objectives. 2. Epidemiology 3. How to approach a Pediatric Abdominal X-Rays 4. Common Encounters Stratified 5. Common Pitfalls Limitations 6. Case Examples 7. Conclusion

## PDEE-84 CHILDHOOD ILD (CHILD) PART II: LUNG DISEASE NOT SPECIFIC TO INFANCY - IMAGING FINDINGS AND HISTOPATHOLOGIC CORRELATION

**Awards**

Jordan B. Rapp, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Overview the current understanding of pediatric interstitial lung diseases, from early childhood to adolescent years 2. Describe the distinctive imaging features and patterns associated with these conditions, emphasizing key CT findings 3. Correlate imaging findings with corresponding pathologic characteristics, highlighting the relationship between radiologic appearance and underlying pathophysiologic processes

### TABLE OF CONTENTS/OUTLINE

- Introduction: The role of imaging in the evaluation and management of chILD in children and adolescents Importance of a multidisciplinary approach- Diagnostic approach depending on clinical presentation and background- Imaging modalities and protocols- Describe characteristic imaging findings of pediatric diffuse lung disease related to:- Connective tissue disease or immune mediated e.g. sJIA, Systemic Sclerosis, SLE, MCTD, Sarcoidosis- Alveolar Hemorrhage e.g. Capillaritis, GPA, BMPR2 - Enviromental or drug related e.g. Hypersensitivity Pneumonitis, Eosinophilic PNA, Pleuroparenchymal fibroelastosis- Bronchiolitis Obliterans e.g. post-infection, post-transplant- Pulmonary Alveolar Proteinosis- Unclassified conditions e.g. Other cystic and fibrotic lung diseases- Differential Diagnosis: Considerations and potential mimics- Conclusion: Take-home points and future directions in imaging and management of pediatric diffuse lung disease

## PDEE-9 BRAIN MALFORMATION IN THE GENOMIC ERA, WHAT THE RADIOLOGIST NEED TO KNOW

Osamah A. Alwalid, MMed (*Abstract Co-Author*) Nothing to Disclose
Marwa Al-Subhi, MD (*Abstract Co-Author*) Nothing to Disclose
Jehan Al-Rayahi, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To understand the role of radiology in the evaluation of brain malformation.- To understand basic genetic principles and lingo related to CNS malformation.- To learn the different genetic techniques utilized in the evaluation of patient with brain malformation. - To understand the genetic landscape of common brain malformation and the radiology phenpotype correlation.

### TABLE OF CONTENTS/OUTLINE

Introduction Genetic Principles and Techniques: - - Cytogenetic testing - - Narrow gene testing - - Next generation sequencing Brain malformation and their genetic landscape: - - Holoprosencephaly - - Malformation of cortical development - -Tubulopathies - - Ciliopathies o Joubert o Others related disorders Conclusion

PDEE-1

## RAPID MRI FOR PEDIATRIC ACUTE ABDOMINOPELVIC PAIN IN THE EMERGENCY DEPARTMENT: A REVIEW OF IMAGING TECHNIQUE, IMPLEMENTATION, AND DIAGNOSES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Rama S. Ayyala, MD (*Abstract Co-Author*) Nothing to Disclose
Gary R. Schooler, MD (*Abstract Co-Author*) Nothing to Disclose
Cara E. Morin, PhD (*Abstract Co-Author*) Nothing to Disclose
Justine M. Kemp, MD (*Abstract Co-Author*) Nothing to Disclose
Katherine N. Epstein, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

After reviewing this education exhibit, the learner will have an improved understanding of:1- How to implement a rapid MRI protocol for acute abdominopelvic pain in pediatric patients2- Benefits and limitations of rapid MRI in comparison to other imaging modalities in the emergent setting3- Most common etiologies of pediatric abdominopelvic pain encountered in the emergency department

### TABLE OF CONTENTS/OUTLINE

1- Background, including indications and protocol for emergent rapid MRI:a. Review of MRI sequence options, suggested protocol, and strategies for successful service line implementationb. Review advantages and limitations of rapid MRI, including scenarios where other modalities such as ultrasound and CT provide necessary alternative or supplemental informationc.c. Presentation of clinical and imaging algorithms for acute abdominopelvic pain in pediatric patients incorporating rapid MRI2- Case based approach of emergent pediatric diagnoses, including:a. Acute appendicitis (uncomplicated and complicated), ovarian torsion, tubo-ovarian abscess, pyelonephritis, omental infarction, pancreatitis, colitis, and abdominopelvic massesb. Imaging mimics and potential pitfalls3- Summary: Take home points

PDEE-10

## PEDIATRIC BRAIN TUMORS: A GENETIC AND IMAGING SYNOPSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Vivek B. Pai, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Matthias W. Wagner, MD (*Abstract Co-Author*) Nothing to Disclose
Manohar M. Shroff, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Aaditeya Jhaveri, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. The 2021 WHO CNS tumor classification has undergone changes in terms of nomenclature with introduction of new tumor entities. 2. Tumors are increasingly defined by the its genetics, rather than imaging features alone. 3. Understanding the genetic landscape is essential in predicting tumor behavior, especially with the advent of improved chemotherapy.

### TABLE OF CONTENTS/OUTLINE

• Review the 2021 WHO classification of CNS tumors• Discuss genetic pathways of pediatric CNS tumors• Describe imaging features of pediatric CNS tumors with emphasis on the recently added/updated tumors, including, but not limited to:A. High Grade Gliomas: Diffuse midline glioma H3 K27-altered, diffuse hemispheric glioma H3 G34-mutant, Diffuse pediatric-type high-grade glioma H3-wildtype/ IDH-wildtype, Infant-type hemispheric glioma. B. Low-grade diffuse gliomas: Diffuse astrocytoma, MYB or MYBL1-altered, Polymorphous low-grade neuroepithelial tumor of the young, Diffuse low-grade glioma MAPK pathway altered. C. Circumscribed astrocytic gliomas: High-grade astrocytoma with piloid features, Astroblastoma MN1 -altered D. Glioneuronal and neuronal tumours: Diffuse glioneuronal tumor with oligodendroglioma-like features and nuclear clusters, Myxoid glioneuronal tumor, Multinodular and vacuolating neuronal tumor, Diffuse leptomeningeal glioneuronal tumor E. Embryonal tumours: Medulloblastoma, Atypical teratoid/ rhabdoid tumour F. Ependymal tumours: Supratentorial and posterior fossa Ependymomas

PDEE-12

## A MULTIFACETED THREAT: CNS AND SPINE MANIFESTATIONS IN PEDIATRIC LEUKEMIA

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Kathleen Schenker, MD (*Abstract Co-Author*) Nothing to Disclose
Ashrith Kandula (*Presenter*) Nothing to Disclose

### TEACHING POINTS

· Pediatric leukemia can involve the central nervous system (CNS) and spine through direct infiltration, opportunistic infections, and treatment-related complications.· Recognizing the diverse CNS and spine manifestations is crucial for prompt diagnosis and effective management.· This presentation will equip radiologists with the imaging features of these complications.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: Epidemiology and Significance of CNS/Spine Involvement in Pediatric Leukemia2. Direct Infiltration by Leukemic Cells2.1 Chloroma (Granulocytic Sarcoma)2.2 Orbital Leukemic Infiltrate3. Infectious Complications3.1 Invasive Aspergillosis 3.2 Rhizomucor Pusillis Infection 3.3 Rothia Meningitis 3.4 Invasive Fungal Sinusitis4. Treatment-Related Toxicities4.1 Methotrexate Neurotoxicity 4.2 Posterior Reversible Encephalopathy Syndrome (PRES) 4.3 Mineralizing Vasculopathy5. Vascular Complications5.1 Blastic Hyperleukocytosis 5.2 Septic Emboli 5.3 Venous Sinus Thrombosis 5.4 Thromboembolic Strokes 5.5 Retinal Hemorrhages6. Long-Term Sequelae6.1 Radiation-Induced NeoplasmsResults: We will present a series of cases highlighting the imaging features and clinical course of each entity. The discussion will emphasize the importance of a multidisciplinary approach, including clinical presentation, laboratory findings, and neuroimaging, for accurate diagnosis and timely intervention.Conclusion: CNS and spine involvement represent a complex challenge in pediatric leukemia. Recognizing the diverse etiologies and their characteristic imaging patterns is crucial for prompt diagnosis and effective management, ultimately improving patient outcomes.

PDEE-13

## BE PREPARED: IT'S NOT BECAUSE IT'S RARE THAT IT WON'T HAPPEN! WHAT THE RADIOLOGIST NEEDS TO KNOW ABOUT SPONTANEOUS BILIARY PERFORATIONS IN CHILDREN

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Lisa Suzuki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Silvia Maria S. Rocha (*Abstract Co-Author*) Nothing to Disclose
Jorge Mesquita, MD (*Abstract Co-Author*) Nothing to Disclose
Luisa L. Faria, MD (*Abstract Co-Author*) Nothing to Disclose
Livia Alves (*Abstract Co-Author*) Nothing to Disclose
Elisa M. Carvalho, MD (*Abstract Co-Author*) Nothing to Disclose
Amanda Alves Tavares, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Spontaneous biliary perforations (SBP) are rare but an important cause of surgical jaundice in pediatrics and one of the most common causes of acute abdomen in children, most often diagnosed at the stage of biliary peritonitis. They are known to affect the extra hepatic biliary tree and occasionally, the intrahepatic ducts. This is one of the most common cause of surgical solution jaundice in neonates. And most cases present between the 2nd and 6th weeks of life, more seen under 4years of age. Preoperative diagnosis is very challenging for the radiologist and surgeon, and that is why they need to be aware of SBP as a differential diagnosis of acute abdomen in childhood, because an early diagnosis and efficient surgical management can improve the prognosis and also save the child's life. Most children who present with SBP in infancy are typically previously healthy infants with unremarkable birth and perinatal histories. The actual etiopathogenesis is unknown. Congenital weakness of the common hepatic duct, trauma, choledochal cyst, viral infection, acalculous cholecystitis are all believed to be involved, among other causes. The presenting symptoms are usually benign and non-specific, unless there is a superimposed bacterial peritonitis. However, over a period of hours, days or even weeks, the patients might gradually develop a progressively abdominal distension, jaundice, peritonitis, septicemia, and symptoms of biliary tract disease.

### TABLE OF CONTENTS/OUTLINE

General aspects of Spontaneous Biliary Perforations- Etiology- Prognosis- Imaging Diagnosis Summary

Ammie M. White, MD (*Abstract Co-Author*) Nothing to Disclose
Joseph Piccione (*Abstract Co-Author*) Nothing to Disclose
Ankita Chauhan, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Illustrate the imaging spectrum of endobronchial pathologic entities in children 2. Discuss benign and malignant lesions and identify imaging features that can help differentiate them 3. Understand the radiologist’s role in recognizing endobronchial pathology to aid appropriate treatment

### TABLE OF CONTENTS/OUTLINE

Goals and objectives Background • Endobronchial lesions are sporadic in children• Endobronchial obstruction often presents with wheezing, persistent cough, recurrent fever, and hemoptysis• Obstructive symptoms occur when the mass occludes more than half the airway lumen and result in respiratory distress• Because these lesions are rare and symptoms are nonspecific, these entities are often initially misdiagnosed as asthma or pneumoniaPathologic entities • Foreign body, mucus impaction, mucoepidermoid carcinoma, inflammatory myofibroblastic tumor, carcinoid, laryngotracheal papillomatosis, mycobacterium avium-intracellulare granuloma, pyogenic granulomaImaging and Bronchoscopic Findings• Infants may present with segmental hyperinflation or persistent lobar consolidation on chest radiograph• CT findings may have specific imaging features or may need further assessment with bronchoscopy• Bronchoscopic assessment and excision/biopsy remain primary diagnostic and interventional toolsPathologic CorrelationSummary • Knowledge of characteristic imaging features aids the radiologist in making the correct diagnosis and prevents treatment delays

### TEACHING POINTS

* Sonography serves as an optimal and often sole modality for imaging scrotal disorders in children. It boasts high accuracy, widespread availability in most institutions, safety, and does not necessitate sedation. * It is imperative to consider clinical symptoms during the examination, such as non-palpable testicles or the presence of one or multiple palpable nodules. * Achieving an accurate diagnosis hinges on distinguishing between painful and non-painful pathologies of the scrotum and inguinal region.

### TABLE OF CONTENTS/OUTLINE

* Review of Sonographic Techniques: Gray-Scale and Doppler Appearance of the Pediatric Scrotum * Systematic Approach to Sonographic Imaging * Cases of Scrotal Disorders in Children: Cryptorchidism and Testicular Ectopia, Different Types of Hydrocele, Hydatid Torsion, Hyperplasia of the Rete Testis, Splenogonadal Fusion, Polyorchidism, Meconium Peritonitis, and Testicular Neoplasms * Imaging Modalities: Gray-Scale and Doppler Ultrasound

Ankita Chauhan, MD, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

In anomalous pancreaticobiliary junction (APBJ), the pancreatic and bile ducts join outside the duodenal wall to form a long common channel. APBJ is associated with raised amylase and lipase levels in the duct fluid. Obstructive cholangiopathy is a common cause of cholestatic jaundice in infants with APBJ, as it is found in patients with choledochal cysts, particularly Todani types I and IV. In older children with APBJ, the symptoms are related to cholangitis and pancreatitis. Relatively long common channel is a major risk factor for the development of cholangiocarcinoma in adulthood, so timely excision reduces morbidity and mortality. Teaching Points 1. Understand the pathophysiology behind pancreaticobiliary junction anomalies. 2. Learn the classification of junctional anomalies in children. 3. Illustrate the imaging spectrum of anomalous pancreaticobiliary junction in children with choledochal cysts. 4. Learn how to measure the length of the common channel.

### TABLE OF CONTENTS/OUTLINE

-Background information on APBJ and imaging findings on Magnetic Resonance Cholangiopancreatography (MRCP). -Normal pancreaticobiliary ductal anatomy -Pancreaticobiliary maljunction (definition, pathophysiology, demographics) -Correlation with endoscopic retrograde cholangiopancreatography (ERCP) and with surgical findings -Choledochal cyst (Todani classification) and APBJ in choledochal cysts with exemplary cases - Recommended treatment guidelines and role of surveillance imaging - Summary

## IT’ S A DSD! - KEEP CALM, DON’T PANIC AND FOLLOW THE TRACK

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Heron Werner JR, MD (*Abstract Co-Author*) Nothing to Disclose
Pedro Daltro, MD (*Abstract Co-Author*) Nothing to Disclose
Flavia M. Costa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Flavia P. Lopes, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tatiana M. Fazecas, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Disorders of sexual differentiation often induce anxiety among both the infant’s family and the attending physicians tasked with evaluating infants presenting with genital abnormalities. It is imperative for radiologists to possess a thorough understanding of the DSD classification system. In cases involving newborns with ambiguous genitalia, pediatric radiologists are frequently consulted to conduct ultrasonography (US) examinations aimed at addressing various anatomical inquiries. Employing a systematic approach to initial sonographic imaging enables comprehensive assessment of critical genitourinary structures, pivotal for guiding diagnostic and clinical interventions. An organized ultrasonographic (US) methodology is indispensable for evaluating several structures, including those originating from the Müllerian ducts (uterus and upper vagina), discerning the type of gonad (testes, ovaries, ovotestes, or streak gonads), assessing the distal vagina, and examining the adrenal glands.

### TABLE OF CONTENTS/OUTLINE

1) DSD Classification System 2) Systematic Approach to Initial Sonographic Imaging 3) Different Cases of DSD: DDS 46 XX (CAH, testicular); DDS 46 XY (ovotestis, gonadal dysgenesis, androgen insensitivity); Ovotestis DDS 4) Imaging Modalities: Abdominal and Pelvic Ultrasound; Transperineal Ultrasound; Genitography

## TINY TITANS : EYE-VENTURES IN PAEDIATRIC ULTRASOUND

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Bharat Aggarwal, MD (*Abstract Co-Author*) Nothing to Disclose
Amit K. Sahu, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Ayushi Gupta, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Paediatric ocular ultrasound(US) plays a pivotal role in assessing eye health by focusing on anatomy, imaging techniques, and distinguishing between normal and abnormal conditions.US aids in differential diagnosis by assessing lesion morphology, distinguishing between solid and cystic masses, and detecting features such as calcifications, hemorrhage, retinal/choroid detachments, or foreign bodies. Color Doppler US proves useful in suspected cases of vascular, inflammatory, or neoplastic lesions.Congenital and acquired ocular conditions can be accurately diagnosed through US, spanning from irregular globe size to atypical morphological features. US reveals distinctive echoes for pathologies within the vitreous, such as hemorrhage or infection, and delineates detachment types like retinal detachment or choroid detachment with characteristic lines. It also identifies posterior wall masses, primarily retinoblastoma.Paediatric ocular US is a non-invasive adjunct to clinical assessment, especially in cases where traditional visualization methods are compromised.

### TABLE OF CONTENTS/OUTLINE

Learning normal anatomy of the paediatric globe and protocol based US to distinguish between normal and abnormal conditions.To review the congenital and acquired ocular pathology in the paediatric age group and to explain its most characteristic US findings.Distinguishing solid and cystic masses, and features such as calcifications, haemorrhage, retinal/choroid detachments, or foreign bodies.Distinguishing different kinds of haemorrhages involving eye.

## THE CHALLENGING ULTRASONOGRAPHIC FINDINGS OF NEONATAL AND PEDIATRIC COW'S MILK PROTEIN ALLERGY (CMPA)

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*) Nothing to Disclose
Fabiana Gual, MD (*Abstract Co-Author*) Nothing to Disclose
MARCIA W. MATSUOKA, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Romano, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Inflammatory and infectious intestinal diseases lead to a thickening of the intestinal wall, which can be detected using gray-scale ultrasound.- Color Doppler ultrasound can detect increases in vascular flow in the intestinal wall if there is active inflammation.- Intestinal pneumatosis is a potentially serious condition in neonatal and pediatric settings and may be associated with hepatic portal venous gas.- Although these findings are non-specific, they may be an expression of CMPA and should always be evaluated in the clinical context, particularly in the context of cow’s milk protein exposure.

### TABLE OF CONTENTS/OUTLINE

- Providing a multimodality-based didactic review of the main topics of cow’s milk protein allergy (CMPA) including: pathophysiology, diagnostic evaluation, clinical presentations and ultrasonographic findings.- Preparation of a practical guide on how to perform an evaluation, in which the patterns of the structures and their clinical relevance are presented and discussed.- Correlating the findings with the differential diagnosis in the context of the emergency department.Outline: Ultrasonography can be routinely used to diagnose and monitor changes associated with CMPA. The increasing incidence of pediatric cases of CMPA in our Institution prompted us to present this work, to raise awareness of the various sonographic presentations, from the simplest to the most complex, emphasizing the systematic evaluation of the abdomen with special attention to the intestinal loops.

### TEACHING POINTS

; Review relevant anatomy of the foot, ankle, and distal lower leg.; Review common imaging modalities used to assess traumatic injuries of young ballet dancers.; Demonstrate common injury patterns in the foot, ankle, and lower leg along with their mechanism of injury, including both acute and chronic conditions related to excessive turnout and dancing en pointe.; Understand the mechanism of the injury and management options that enable return to dance.

### TABLE OF CONTENTS/OUTLINE

- Normal Anatomy
- Labeled Diagram of relevant normal foot/ankle anatomy
- Common static ballet positions and dynamic ballet movements and associated patterns of injury
- Impact of turnout and en pointe on the dancer's foot
- Imaging modalities and common imaging indications
- Plain Radiographs, Computed Tomography, Magnetic Resonance Imaging.
- Fractures
- Dancer's Fracture (5th metatarsal)
- Midfoot Fractures including the "Nutcracker" fracture
- Distal Phalanx Fractures
- Ligamentous Injuries
- Deltoid Ligament
- Anterior Talofibular Ligament
- Lisfranc Ligament
- Tibiofibular Ligament
- Impingement Syndromes
- Anterior Ankle Impingement
- Posterior Ankle Impingement "Dancer's Heel"
- Tendon Abnormalities
- Flexor Hallucis Longus Tendon Tenosynovitis "Dancer's Tendinitis"
- Posterior Tibialis/Plantaris strain/tear
- Achilles Tendon strain/tear
- Peroneus Brevis/Longus strain/tear
- Stress Reactions
- Metatarsals
- First MTP Sesamoid
- Midfoot (Cuboid, Navicular)
- Tibia/Fibula
- Other/Misc.
- Plantar Fasciitis
- Morton Neuroma
- Hallux Valgus
- "Spotty Bone Marrow" (SBM) pattern in tarsal bones

### TEACHING POINTS

Whole-Body Diffusion-Weighted Magnetic Resonance Imaging (WB-DW-MRI) represents a sensitive imaging modality devoid of ionizing radiation, capable of providing comprehensive whole-body coverage with superior soft tissue contrast and spatial resolution within a condensed timeframe. WB-DW-MRI proves invaluable in assessing various disease processes affecting the vulnerable pediatric population, encompassing cancer diagnosis and staging, disseminated infections, metabolic and idiopathic disorders, systemic rheumatologic conditions, congenital anomalies, inherited diseases, immunodeficiency disorders, and tumor predisposition syndromes. WB-DW-MRI is adept at detecting and characterizing multifocal or systemic diseases, particularly aiding in the diagnosis of challenging conditions where consensus among a multidisciplinary team of healthcare professionals may be lacking. It serves as a cost-effective diagnostic imaging method facilitating accurate diagnosis, therapeutic monitoring, and informed treatment decisions. This is particularly pertinent in the context of the vulnerable pediatric population, effectively minimizing unnecessary procedures.It is imperative to employ the optimal protocol for each disease to ensure accurate diagnosis and differential diagnosis.

### TABLE OF CONTENTS/OUTLINE

Imaging Diagnosis in Underserved Areas of Brazil;Whole-Body Diffusion-Weighted Magnetic Resonance Imaging Technique;Diagnosis of Challenging Diseases • Inflammatory (Chronic Nonbacterial Osteomyelitis, Juvenile Idiopathic Arthritis, Polyarteritis Nodosa) • Idiopathic (Sarcoidosis, Rosai-Dorfman) • Metabolic (Hypovitaminosis - Scurvy, Alimentary Selectivity Autism)

Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Maira Sarpi, MD (*Abstract Co-Author*) Nothing to Disclose
Roberta C. Andrade, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The aim of this study is to revisit the classification system of craniofacial clefts proposed by Tessier in 1976. Until then, there had been a variety of nomenclatures, and some authors had attempted to standardize them. Tessier's classification is considered the main reference because of its simplicity and applicability.Although this classification system is based on clinical and surgical observation, many of the features can be explained by embryological and anatomical factors. The most accepted theory relates to disturbances in the formation or fusion of facial processes, but the molecular mechanism is partly understood.The Tessier classification involves numbering the facial clefts from 0 to 14 based on their location in two areas: the orbit/eyelid and the jaw/lips.They can also occur in combination and skeletal and soft tissue clefts do not necessarily coincide.Radiologists should be able to recognize these facial deformities and their associated findings to improve the diagnosis and surgical decision making. knowledge of this system will then allow for consistent professional communication. This manuscript outlines the Tessier classification using imaging examples to illustrate this system and to contribute to its memorability due to the rarity of some findings.

### TABLE OF CONTENTS/OUTLINE

1. Embryological theory and anatomy 2. Tessier classification 3. CT imaging examples and main descriptors 4. Related findings

## UNVEILING DEVELOPMENTAL ENIGMAS: IMAGING EMBRYOLOGIC VARIANTS AND ANOMALIES IN THE SELLAR AND SUPRASELLAR REGION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Deepali Bhalla (*Abstract Co-Author*) Nothing to Disclose
Rajan P. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Rohan Samant, MBA (*Abstract Co-Author*) Nothing to Disclose
Manav Bhalla, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The sellar and suprasellar region is a complex anatomical space harboring critical structures vital for endocrine regulation. Embryonic development plays a pivotal role in shaping the intricate anatomy of this region. Understanding the embryologic variants and anomalies of this region is paramount for accurate diagnosis and management. Variations in the development of Rathke's pouch, the infundibulum, and adjacent structures during embryogenesis can lead to a spectrum of anomalies, ranging from benign variations to clinically significant pathologies. Imaging serves as indispensable tools for the evaluation of these anomalies, in particular, detailed visualization of the pituitary gland, hypothalamus, optic chiasm, and surrounding structures, facilitating precise anatomical delineation and pathological characterization.

### TABLE OF CONTENTS/OUTLINE

I. Importance of understanding embryologic variants and anomalies in the sellar and suprasellar region. II. Embryologic Basis of Sellar and Suprasellar Anomalies - Developmental origins of key structures: Rathke's pouch and infundibulum; Embryonic structures in the sellar and suprasellar region; Variations and anomalies arising from embryologic development III. Clinical Significance of Sellar and Suprasellar Anomalies -Effects on endocrine regulation and neurovascular function; Clinical presentation and diagnostic challenges IV. Imaging Modalities for Evaluation - Role of MRI in anatomical characterization; Utilization of CT; Advanced MRI techniques V. Diagnostic Challenges and Considerations - Pitfalls and limitations of imaging modalities; Importance of integrating clinical and radiological findings

## IMAGING APPEARANCE OF CSF SHUNTS AND THEIR COMPLICATIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Shehanaz K. Ellika, MD (*Abstract Co-Author*) Nothing to Disclose
Matthew Koh, MD (*Abstract Co-Author*) Nothing to Disclose
Sarah Mohajeri Moghaddam, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Pranay Rao, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• A wide variety of treatment options exist for both temporary and permanent CSF diversion. • CSF shunt catheters are composed of several components including a proximal catheter, reservoir, valve, and distal catheter. • Shunt malfunction can be categorized by early and late complications. • Imaging plays an important role in assessment of shunt malfunction. • Comparison with prior imaging clinical history is key. • Ventricular shunting can result in brain calavarial changes which are also well evaluated on imaging studies.

### TABLE OF CONTENTS/OUTLINE

• CSF Diversion o Temporary measures o Permanent measures • Shunt components • Imaging of CSF shunts • Shunt complications o Early: Tip misplacement, tip migration, infection, shunt disconnection, etc. o Late: Fracture, pseudocyst, shunt calcification, shunt erosion, over drainage, etc. • Brain calvarial changes related to ventricular shunting

## ORBITAL MANIFESTATIONS OF SYNDROMIC DISEASES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Karen Moeller, MD (*Abstract Co-Author*) Nothing to Disclose
Livja Mertiri (*Abstract Co-Author*) Nothing to Disclose
Thierry Huisman, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Huy D. Tran, MD (*Abstract Co-Author*) Nothing to Disclose
Rajan P. Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Oswaldo Guevara Tirado, MD, MS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- List rare syndromic disorders that may affect the orbit.- Outline a systemic approach for evaluating the orbits and surrounding structures to assist in the identification of rare syndromic diseases.- Illustrate and describe the unique optic imaging features of rare syndromic diseases.

### TABLE OF CONTENTS/OUTLINE

Rare syndromic diseases can be particularly difficult to diagnose, especially when they present with a wide variety of symptoms and clinical findings. However, imaging of the orbit and the surrounding structures can significantly aid in narrowing down the differential diagnoses. Adopting a systematic approach when evaluating the eye involves assessing the globe, optic nerve, extraocular muscles, vascular structures, and the intracranial, maxillofacial, and temporal bone regions. Subsequent visualization of anomalies such as size discrepancies, hemorrhages, and other defects can be crucial in arriving at the correct diagnosis and improving patient care.1. Introduction Objectives2. Epidemiology3. Systemic approach for orbit evaluation among rare neurological diseases4. Case examples of syndromic diseases and their manifestations· CHARGE Syndrome· Tuberous Sclerosis· Leptin Deficient Lipodystrophy Syndrome· Norrie Disease· Septo-Optic Dysplasia· Neurofibromatosis Type 1· Kearns-Sayre Syndrome· Congenital Cranial Dysinnervation Disorders (CCDD)· Sturge-Weber Syndrome· Von-Hippel Lindau· Blue Rubber Bleb Nevus Syndrome· Terson Syndrome· PHACES Syndrome· Parry-Romberg Syndrome· Goldenhar Syndrome· Encephalocraniocutaneous Lipomatosis· Walker-Warburg Syndrome5. Conclusion

## WHAT IS THIS UNEXPECTED LUMP? IMAGING EVALUATION OF LUMPS AND BUMPS IN THE PEDIATRIC PATIENT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Fabiana Gual, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia T. Lima (*Abstract Co-Author*) Nothing to Disclose
MARCIA W. MATSUOKA, MD (*Abstract Co-Author*) Nothing to Disclose
Miguel J. Neto (*Abstract Co-Author*) Nothing to Disclose
Yoshino Tamaki Sameshima, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Review common lumps and bumps in children and suggest a practical initial sonographic approach. Emphasize ultrasound (US) imaging as a safe and commonly used method for evaluating these lesions, often the first diagnostic study requested. Recommend optimal imaging techniques, such as using high-frequency linear transducers for superficial lesions and lower-frequency probes for deeper structures. Emphasize the importance of Doppler imaging for a comprehensive evaluation of soft tissue masses, confirming the vascular, cystic, or solid nature of a mass and aiding in further characterization.Recognize the limitations of ultrasound and acknowledge that in some cases, further evaluation with MRI or CT, biopsy, or surgical excision may be required for an accurate diagnosis.

### TABLE OF CONTENTS/OUTLINE

This educational exhibit describes the sonographic imaging appearance of the most common lumps and bumps at a tertiary hospital in Sćo Paulo. We divided them into categories:CONGENITAL (branchial cleft cyst, thyroglossal duct cyst, undescended testis; VASCULAR ANOMALIES (vascular tumors (e.g. hemangioma); Vascular malformations (e.g. lymphatic malformations); INFECTION (abscess, retained foreign body; myiasis; TRAUMATIC INJURY (hematoma and muscle injury; subgaleal hematoma; fibromatosis colli; fracture; subcutaneous fat necrosis of the newborn; LYMPH NODES (reactive lymphadenopathy; Bacille Calmette-Guérin (BCG) lymphadenitis; Malignant lymphadenopathy (lymphoma); BREAST LUMP (physiologic neonatal breast enlargement; Gynecomastia; SKIN AND SOFT TISSUE (epidermoid Cyst; Lipoma; Baker's Cyst; HERNIAS (Hernia of the Nuck Canal; Umbilical Hernia; Inguinal Hernia).

## PEDIATRIC RHABDOMYOSARCOMA FROM HEAD TO TOE: A COMPREHENSIVE ANALYSIS OF IMAGING FINDINGS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Fabiana Gual, MD (*Abstract Co-Author*) Nothing to Disclose
Suheyla P. Ribeiro, MD (*Abstract Co-Author*) Nothing to Disclose
Carolina R. Soares, MD (*Abstract Co-Author*) Nothing to Disclose
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*) Nothing to Disclose
Adham A. Castro, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor C. Romano, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Rhabdomyosarcoma is a malignant tumor with morphology resembling skeletal muscle cells.- Imaging findings are nonspecific and indistinguishable from other sarcomas. The tumor’s anatomic location and demographic data of the patient are more useful for narrowing the differential diagnosis.- Up to 20% of patients with rhabdomyosarcomas present with metastases at the time of diagnosis (typically in the lungs and bone marrow).

### TABLE OF CONTENTS/OUTLINE

Table of contents:- Establishing the importance and effectiveness of accurate evaluation of rhabdomyosarcoma.- Review imaging findings across various examination modalities (MRI, CT, US, PET-CT) for different anatomical systems (head and neck, abdomen and musculoskeletal).- Creation of a practical guide for conducting an evaluation, including the necessary variables for follow-up.- Illustrating these conditions based on cases from our radiology group.Outline: Imaging modalities have played a decisive role in the localization of rhabdomyosarcomas. Assessing the local extent of the tumor is an essential aspect of radiological evaluation and has a direct impact on treatment. Detecting invasion of adjacent structures, considering the involvement of critical anatomical structures, and metastatic spread are fundamental to staging the disease and determining appropriate treatment strategies, be it surgical resection, radiotherapy, or a combination of these procedures.The correlation between radiological findings and histopathological characteristics is a noteworthy aspect of our discussion. Understanding how imaging features align with underlying pathology can help refine diagnostic criteria and predict tumor behavior.

## FOLLOW THE PATH: A SYSTEMATIC APPROACH TO THE LINEAR AND RETICULAR PATTERN ON CHEST COMPUTED TOMOGRAPHY IN PEDIATRIC PATIENTS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Luisa L. Faria, MD (*Abstract Co-Author*) Nothing to Disclose
Deborah Y. Otto (*Abstract Co-Author*) Nothing to Disclose
Lisa Suzuki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Rodolfo Lourenco (*Abstract Co-Author*) Nothing to Disclose
Amanda Alves Tavares, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Linear and reticular opacities constitute a radiological pattern of lung involvement that represents thickening of the pulmonary interstitium by fluid, fibrosis or infiltration by cells or other material, presenting a broad differential diagnosis. The objective of this work is to present a systematic approach for interpreting the linear and reticular pattern in chest computed tomography specifically in pediatric patients, bringing to light important, and often not well-known, differential diagnoses in this age group. The approach to learning through radiological patterns brings advantages to learning, improving diagnostic skills and expanding knowledge.This presentation aims to:(1) review the linear and reticular patterns of abnormality on chest computed tomography;(2) present a case-based and systematic approach to the linear and reticular pattern on chest computed tomography in pediatric patients.

### TABLE OF CONTENTS/OUTLINE

- Introduction- Anatomy of the secondary lobule.- Basic chest computed tomography patterns.- Case-based and systematic approach to the linear and reticular pattern (interlobular septal thickening, centrilobular peribronchovascular interstitial thickening, peribronchovascular interstitial thickening, intralobular interstitial thickening, fissure thickening, subpleural lines)

### TEACHING POINTS

1.- Pediatric intraocular malignancies have retinoblastoma as the most common cause. The cause is loss of function of the RB1 tumor suppressor gene, although some tumors result from amplification of the MYCN oncogene with normal RB1 genes.2.- 1 in every 16,000 births has retinoblastoma. There are no known geographic, racial or sexual preferences. Heritable retinoblastoma is diagnosed at midlife at 12 months and non-heritable disease at 24 months. 3.-Preoperative evaluation of retinoblastoma relies on magnetic resonance imaging. In addition to evaluate of tumor invasion of the ON, choroid, and sclera, all of which are high-risk features for systemic dissemination.4.- Trilateral retinoblastoma refers to the presence of intracranial tumor histologically similar to retinoblastoma in the pineal gland or suprasellar cistern in addition to bilateral ocular involvement.5.-Extraocular extension of retinoblastoma is an important risk factor for the development of distant metastases in the non-central nervous system, as it allows the tumor to access vascular and lymphatic channels .

### TABLE OF CONTENTS/OUTLINE

1.Radiological anatomy2.Retinoblastoma generalities3.Retinoblastoma disemination pathwaysa) Intracraneal spaceb)Trilateral retinoblastomac)Tetralateral retinoblastomad)lymphatic routese)Hematogenous via4.Factors that increase the risk of progression5.Unusual Cancer Spread6.Estadification system

### TEACHING POINTS

This article aims to: 1 - Review the definition of precocious puberty, its clinical and laboratory findings, as well as aspects related to the treatment and follow-up of patients. 2 - Demonstrate the role of radiological exams such as hand and wrist x-ray, pelvic ultrasound and pituitary MRI in the diagnosis and follow-up of the disease, showing several cases of precocious puberty, correlating the different imaging methods used for diagnosis.

### TABLE OF CONTENTS/OUTLINE

1 - To provide a complete review o precocious puberty, starting with its definition, its clinical and laboratory findings, showing the way to correctly identify and diagnose the disease and its subtypes, as well as the hormonal profiles that can be identified in its various spectrums and the main types of treatment currently available. 2 - Discuss the main radiological exams used for diagnosis and follow-up, including hand and wrist x-ray for estimating bone age, showing how the exam is performed and interpreted, what should be assessed for the calculation, as well as the main classification methods (Greulich-Pyle and Tanner-Whitehouse) and also show new techniques. 3 - Demonstrate the importance of pelvic ultrasound in the assessment of patients with suspected precocious puberty, reviewing the main changes related to hormonal stimulation and how this affects the female sex organs and pituitary MRI in the evaluation of central origin precocious puberty.

Jocelyn Cheng, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Müllerian duct anomalies (MDA) have important implications on the reproductive health of female children. MDAs are frequently associated with other congenital anomalies of the cervix, vagina, or urinary tract, and are a common cause of infertility and pregnancy loss after adolescence. The purpose of this educational exhibit is to: (1) Review the embryology, classification, imaging features of Müllerian duct anomalies (2) Review the indications and techniques for surgical management of Müllerian duct anomalies in pediatric patients (3) Provide specific cases and clinical courses of patients with specific Müllerian duct anomalies (4) Allow learners to test their knowledge with a quiz.

### TABLE OF CONTENTS/OUTLINE

Using original images and figures from our institution, this exhibit will review the role of MRI in detecting, classifying and guiding surgical management of Müllerian duct anomalies in children. (1) Introduction: Review the embryology, classification, imaging features and treatment options of Müllerian duct anomalies (2) Indications/contraindications to surgical management of Müllerian duct anomalies (3) Procedure and techniques for surgical management of Müllerian duct anomalies (4) Case review of patients with specific Müllerian duct anomalies (5) Allow learners to test their knowledge with a quiz.

## IMAGING OF THE NEONATAL BRAIN: HYPOXIC ISCHEMIC ENCEPHALOPATHY AND BEYOND

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Vivek B. Pai, MBBS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. MRI is a key step in the evaluation of neonatal encephalopathy 2. MR imaging of the neonatal brain relies on optimized protocols and neonate-specific MR hardware 3. A myriad of etiologies cause bilateral brain injury in neonates, clinically and radiologically mimicking Hypoxic Ischemic Encephalopathy (HIE) 4. Having a pattern-based approach is crucial in narrowing down a diagnosis

### TABLE OF CONTENTS/OUTLINE

1. Review imaging protocols for assessment of the neonatal brain 2. Discuss the pathophysiology and imaging patterns of neonatal HIE 3. Detailed review of other causes of neonatal encephalopathy: A. Metabolic etiologies: • Molybdenum Cofactor, Sulphite Oxidase Deficiency • Urea Cycle disorder: OTC deficiency, Citrullinemia • Organic Acidopathies: Maple Syrup Urine Disease, Non-ketotic hyperglycinemia, Isovaleric aciduria, Methylmalonic acidemia • Hypernatremia • Hypoglycemia • Mitochondrial Encephalopathy: Leigh's Disease, MELAS• Peroxisomal disorders: Zellweger's Syndrome B. Infections: • TORCH • Viral: Herpes Simplex Virus Encephalitis, Parechoviral infection • Bacterial: Group B streptococcal Septicemia, Bacillus cereus. E. Coli meningitis • Fungal: Candidiasis C. Arterial and Venous Ischemia D. Malformations: Hemimegalencephaly E. Others: Abusive Head Injury

### TEACHING POINTS

Generalities in children lung transplantation Principal causes and epidemiologyMethodsFollow-upHow CT results can substantially impact the patient's management and treatment.Normal findings in CT scanDescribe main radiological findings of short and long-term complications

### TABLE OF CONTENTS/OUTLINE

Introductions in pediatric lung transplantation, overview, materials and methods and importance of study.Our results: Normal findings that include those related to the bronchial and vascular anastomoses. The most frequent parenchymal complications following lung transplantation including differents types of infections and acute or chronic rejection (bronchiolitis obliterans). Postoperative vascular complication that required CT angiography for diagnosis (Bleeding from the surgical bed).The most frequent posttransplantation airway complications include dehiscence as an early complication and stenosis as a long term problem. CT is useful when bronchopleural fistula is suspected.The protocol/checklist we use in our center and propose to optimal evaluate after a lung transplant in childrenConclusions:Importance of CT scan examination after lung transplantation in children for follow-up and the assessment of airway and parenchymal complications. To know the most common findings after lung transplantation and to recognize signs of complications, especially in their early stages.Importance of the role that the radiologists play to preserve the graft and ensure accurate assessment.

## UNDERSTANDING PEDIATRIC NEUROINFLAMMATION: WHAT SPARKS THE FIRE?

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Manohar M. Shroff, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Vivek B. Pai, MBBS, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Pediatric neuroinflammation (PN) is an expanding group of disorders presenting with symptoms ranging from mild to severe neuropsychiatric manifestations with variable levels of consciousness. 2. PN has gained traction in recent literature because of the improved understanding of pathologic / genetic triggers and ensuring inflammatory cascades, thereby enhancing therapeutic options. 3. Knowledge of the pathophysiology of these disorders forms the fundamental basis of understanding the pattern of brain injury detected on imaging. 4. Imaging findings may often be non-specific, to begin with, however, lesions may evolve within a few hours to days. A high index of suspicion, in an appropriate clinical setting is imperative to initiate prompt institution of anti-inflammatory and neuroprotective treatment measures.

### TABLE OF CONTENTS/OUTLINE

1. Revisit key concepts of adaptive and innate immunity 2. Discuss the role of Microglia 3. Review the physiology of the blood barrier and demystify the concept of its immune privilege 4. Discuss the pathophysiology and imaging appearances of specific neuroinflammatory entities in pediatric patients: • Multiple Sclerosis • Neuromyelitis optica spectrum disorder (NMOSD) • Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) • Rasmussen's encephalitis • Anti-NMDAR encephalitis • Opsoclonus-myoclonus ataxia syndrome (OMAS) • Acute necrotizing encephalopathy • Hemophagocytic Lymphohistiocytosis (HLH) • Langerhans cell histiocytosis • Interferonopathies / Aicardi- Goutičres syndrome

Raisa Amiruddin, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Several tumor predisposition syndromes (TPS) have been described in association with common childhood CNS tumors such as medulloblastoma, Atypical Teratoid Rhabdoid Tumor, retinoblastoma, choroid plexus carcinoma etc., It is important to recognize TPS as they directly impact treatment and outcome in affected patients, and surveillance imaging in unaffected patients. We aim to illustrate neuroimaging findings in common as well as some newly described TPS presenting in childhood and the common genes/genetic pathways affected. The educational exhibit will provide trainees and practicing radiologists information on CNS tumors and TPS needed to participate in brain tumor board discussions.

### TABLE OF CONTENTS/OUTLINE

The vast array of TPS can be an intimidating topic. Although there is overlap with TPS of CNS tumors in adults, we will describe neuroimaging entities associated with common pediatric CNS tumors. (A) Common TPS: - NF1 - NF2 - Tuberous sclerosis - Li Fraumeni - Gorlin syndrome - Rhabdoid tumor predisposition syndrome - Von Hippel Lindau - Ataxia Telangiectasia - Cowden/PTEN hamartoma tumor syndrome - DICER1 syndrome - Brain tumor polyposis syndrome 2 - RB1 - Lynch syndrome - Noonan syndrome - Constitutional Mismatch Repair Deficiency - Hereditary paraganglioma-pheochromocytoma syndrome (B) Other TPS: - Shelterin complex gene POT1 - MEN1 - Familial melanoma astrocytoma syndrome - BAP1 tumor predisposition syndrome - SMARCE1

### TEACHING POINTS

Describe the conventional and novel imaging modalities used in the diagnosis and management of pancreatic lesions in children. Illustrate the imaging features of the most common pancreatic diseases in children including congenital, inflammatory, traumatic and neoplastic lesions. Discuss pattern-based approach for diagnosing pediatric pancreatic diseases.

### TABLE OF CONTENTS/OUTLINE

Pancreatic embryology, normal anatomy and anatomical variants. Imaging modalities: Conventional (US-CT-MRI-MRCP-Nuclear medicine-Interventional radiology- Endoscopic US) Novel (Contrast enhanced US-Elastography (US and MR)-Dual energy CT-Photon counting CT-New radiotracers-radiomics, radiogenomics, artificial intelligence and machine learning. Special consideration about children with pancreatic diseases: Patients with pancreatic endocrine and exocrine insufficiencies (fasting duration- renal function)-Radiation and contrast precautions. Pancreatic diseases in children: Congenital (e.g. pancreatic divsium and annular pancreas), hereditary (e.g. cystic fibrosis and hemochromatosis), pancreatitis (acute-recurrent acute-chronic-others: autoimmune, drug-induced- dialysis related), traumatic and neoplastic (PRIMARY: SPEN, Pancreatoblastoma, Adenocarcinoma, NET and Lymphoma/ METASTASIS: Local extension from retroperitoneal rhabdomyosarcoma and neuroblastoma or Distant metastases). Pattern-based approach for pancreatic diseases in children. Diagnostic pitfalls and mimics of different pancreatic lesions Post-surgical imaging of the pancreas: Types of pancreatic surgeries and techniques- Expected post-operative findings- Post-operative complications imaging features.

Oladipupo Fagbongbe (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Understand unique pediatric meniscal pathology after primary repair, and the surgeon’s approach to treatment when there is a retear. This includes but is not limited to retears of a treated lateral discoid meniscus and retears that occur in the setting of multi-ligamentous injury in children. 2. Learn how to use arthroscopic report and MRI findings to differentiate normal post-operative meniscal change from meniscal retears

### TABLE OF CONTENTS/OUTLINE

1. Surgical approaches to meniscal repaira. Primary repair, including coverage of meniscal root repairs and menisco-capsular repairsb. Saucerization technique for discoid meniscus 2. Diagnostic search pattern for identification of a meniscal retear. A step-by-step approach a. How to read arthroscopic report: a radiologist’s perspective b. Primary repairs: how to interpret fluid or contrast interposition at primary repair site - is this a retear or normal post-op meniscus? c. Saucerization/reshaping: knowing surgeon’s objectives to help identify superimposed tearing after saucerization d. Radiologist search pattern approach to meniscus characterization of retears when there are changes related to both meniscal primary repair and saucerization 3. MR imaging gallery after meniscal repair with emphasis on great calls and humble retear misses with arthroscopic correlation with pediatric orthopaedic surgeon’s perspectives. How we can do better as radiologists? a. Complete discoid meniscus with meniscal retear after saucerization and primary repair (Case 1) b. Incomplete discoid meniscus with meniscal retear after saucerization and primary repair (Case 2) c. Meniscal retears with displacement d. Meniscal retears in setting of multi-ligamentous injury

## LOST AND FOUND: US REVELATIONS IN THE EMPTY SCROTUM AND GROIN LUMPS. A GUIDE FOR THE RESIDENT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Manuela Laguna Kirof, MD (*Abstract Co-Author*) Nothing to Disclose
Natalia B. Pugliese SR (*Abstract Co-Author*) Nothing to Disclose
Diana M. Rodriguez, MD (*Abstract Co-Author*) Nothing to Disclose
Juan Bautista Rolla, MD (*Abstract Co-Author*) Nothing to Disclose
Juan Pablo Tobon, MD (*Abstract Co-Author*) Nothing to Disclose
Maria E. Orozco, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The widespread use of ultrasound (US) has led to increased detection of scrotal pathology, primarily involving extratesticular alterations originating in the tunica vaginalis. The tunica vaginalis should close during embryonic development. Anomalous closure is associated with persistent processus vaginalis, hydrocele of the spermatic cord, and inguinoscrotal hernia.US facilitates the diagnosis of persistence, associated alterations, and complications. Additionally, it plays a crucial role in conservative management (follow-up) and aids in determining the need for urgent surgery.Teaching Points:Understand the anatomy of the inguinal canal and its embryology, particularly in relation to the process of testicular descent.Recognize some of the most common pathologies that can occur in the inguinal canal in pediatrics.Review practical aspects of performing ultrasound of the inguinal canal.Summarize the different ultrasound patterns observed in testicles located within the inguinal canal and those that remain undescended.Identify the different types of hydrocele in pediatrics.

### TABLE OF CONTENTS/OUTLINE

Anatomy and embryology.Imaging description of different cases of common pathologies in the inguinal region in pediatrics.Tips and differential diagnoses.Conclusions.

## SEE IT, KNOW IT, TREAT IT: IMAGING SPECTRUM OF ADNEXAL PATHOLOGIES IN THE PEDIATRIC AGE GROUP

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Anand Dorai Raju, MD (*Abstract Co-Author*) Nothing to Disclose
Asif Jamal, MBBS (*Abstract Co-Author*) Nothing to Disclose
Preet K. Sandhu, MD (*Abstract Co-Author*) Nothing to Disclose
Chinky Patel, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Adnexal pathology is frequently encountered in the pediatric age group.2. The diagnosis can be delayed or missed as younger patients often present with non-specific symptoms of abdominal pain mimicking other acute abdominal processes or due to a low index of suspicion.3. Various adnexal masses can be encountered including cysts, neoplasms, surgical emergencies, and pelvic infections.4. Ultrasound is the primary imaging modality with CT or MRI indicated for further characterization in some clinical scenarios.5. Clinical correlation with the imaging findings directs diagnosis and subsequent management of these patients.6. The radiologist should know the spectrum of adnexal disease processes that can affect the pediatric age group and their imaging appearance.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: prevalence of adnexal pathologies in the pediatric age group, spectrum of adnexal disease, and the importance of imaging.2. Imaging modalities utilized for diagnosing adnexal pathologies.3. Importance of correlating imaging findings with the clinical presentation.4. Examples of various adnexal pathologies at our institution.

Celia Cantolla, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- To review the indications for transfontanelar ultrasound, especially in the emergency setting.- To review the CUS technique (including technical parameters, standardized planes?)- To know the main pathologic findings that are relevant for emergency management.

### TABLE OF CONTENTS/OUTLINE

Transfontanelar ultrasound is a fast, readily available test lack of ionizing radiation. It is suitable for the neonatal period and very useful as long as the anterior fontanel remains open. However, it is a test with some limitations, such as being highly operator-dependent. This may give rise to doubts in the radiologist inexperienced in the technique. A) CUS indications in the emergency settingB) CUS techinque- Technical parameters (probes, frecuency, depth, focus?)- Standard coronal and sagittal planes- Other accesses (mastoid, sphenoid fontanelle?)- Doppler ultrasoundC) Normal variants of the brain ultrasound appearanceD) Main pathologic findings- Hemorraghe (germinal matrix hemorraghe, intra and extraaxial hemorrage)- Hypoxic ischemic events (periventricular leukomalacia, hypoxic-ischaemic encephalopathy of the term neonate, arterial infarction, sinus thrombosis)- Hydrocephalus- Neonatal brain infections

## THINK OUTSIDE THE GRAY: THE COMMON, THE UNCOMMON AND THE RARE PEDIATRIC EXTRA-AXIAL TUMORS OF BRAIN

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Manish Bajaj, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Adam Goldman-Yassen, MD, MS (*Abstract Co-Author*) Nothing to Disclose
John V. Dennison, MD (*Abstract Co-Author*) Nothing to Disclose
Vidya Sankar Viswanathan, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Discuss the different types of extra-axial brain tumors in pediatric patients and its classification, highlight the histological characteristics and typical locations of each tumor type2. Describe the imaging characteristics of each tumor type on various modalities such as MRI, CT, and sometimes PET scans.3. Identify common tumors or lesions that may mimic the appearance of atypical extra-axial brain tumors in pediatric patients4. Explore the role of advanced imaging techniques such as diffusion-weighted imaging (DWI), perfusion-weighted imaging (PWI) in characterizing these tumors.5. Discuss the management approach for various types of tumors

### TABLE OF CONTENTS/OUTLINE

1. Introduction to Atypical Extra-Axial Brain Tumors in Pediatrics. -Typical locations and demographics. -Classification based on histological features. -Current challenges in Diagnosis.2Advanced Imaging Techniques. -DWI and its applications. -PWI for assessing tumor vascularity. 3.Imaging Characteristics. -Solitary Fibrous Tumor. -Occipital Schwannoma. -Intracranial Chondroma. -Atypical Teratoid/Rhabdoid Tumor. -Posterior fossa medulloblastoma. 4.Differential Diagnosis and Classic Mimics. -Common differential diagnoses. -Imaging features that help differentiate tumors from mimics. 5.Management Strategies. -Surgical considerations. -Adjuvant therapies. -Long-term follow-up recommendations. 6.Solve the case. -Example case to solve. -Discussion of diagnosis and management

## SPECTRUM OF PEDIATRIC ABNORMALITIES OF THE BILIARY TRACT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Pallavi Sagar, MBBS (*Abstract Co-Author*) Nothing to Disclose
Katherine Nimkin, MD (*Abstract Co-Author*) Nothing to Disclose
Neha Udayakumar, MD (*Abstract Co-Author*) Nothing to Disclose
Teresa Victoria, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hajer Jarraya (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Pediatric biliary tract abnormalities include congenital anomalies such as anatomic anomalies, various cholestatic processes, congenital cystic and non-cystic anomalies and non-congenital anomalies such as neoplastic, inflammatory or infectious disorders. 2. Differential diagnoses of cystic congenital anomalies include cystic biliary atresia, fibrocystic liver diseases which designate a group of disorders affecting biliary tree and encompasses congenital hepatic fibrosis, Caroli disease and choledochal cysts. 3. The differential diagnoses of non-cystic congenital anomalies include biliary atresia and Alagille syndrome. 4. Spectrum of biliary atresia depends on the anatomic level of obstruction, four different types are described. Most common cases are perinatal. 5. Most common cases of biliary atresia are non-syndromic. Syndromic biliary atresia which occurs in 10%, can be associated with various congenital anomalies such as polysplenia, asplenia, heterotaxy syndrome, intestinal malrotation and interrupted IVC. 6. Congenital abnormalities of the gallbladder include agenesis and hypoplasia but also variations in position of the gallbladder, its shape, number and structure.

### TABLE OF CONTENTS/OUTLINE

1) Epidemiology and classification of congenital and non-congenital biliary anomalies 2) Imaging Findings a) Biliary anomalies in the prenatal period b) Cystic biliary anomalies in neonates, infants, children and adolescentsc) Non cystic biliary anomalies in neonates, infants, children and adolescents3) Associated abnormalities in syndromic biliary tract congenital abnormalities 4) Algorithm of differential diagnosis based on level of biliary tree involvement

PDEE-48

## SONOGRAPHIC DEPICTION OF A DEFECT IN THE WALL OF THE INTESTINE IN NEONATES AND YOUNG CHILDREN WITH INTESTINAL PERFORATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Alan Daneman, MD (*Abstract Co-Author*) Nothing to Disclose
Ricardo Faingold, MD (*Abstract Co-Author*) Nothing to Disclose
Caroline Rutten, MD (*Abstract Co-Author*) Nothing to Disclose
Benjamin Traubici, BSc (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To illustrate a group of neonates and young children with a variety of causes of intestinal perforation in whom the defect in the intestinal wall was correctly recognized preoperatively on sonography (US) as this has not been previously recognized in this age group.To emphasize that intestinal perforation in neonates and young children does not always lead to the presence of free gas on plain radiographs or US.To emphasize other US features, such as echogenic ascites and focal fluid collections, as important US signs of perforation in this age group.

### TABLE OF CONTENTS/OUTLINE

We illustrate four neonates or young children in whom the intestinal defect due to perforation was depicted on US and correctly recognized on preoperative US.Plain abdominal X-Rays (AXR) showed abdominal distension, a paucity of bowel gas, and absence of free gas in three.In the fourth, the AXR, showed diffuse distension of bowel with a large amount of gas and a moderate amount of free gas.On US, there was no evidence of free gas in one, a tiny amount of free gas in two, and a moderate amount of free gas in one.On US, there were moderate to large amounts of echogenic ascites in all four.On US, a focal defect at the site of intestinal perforation was depicted and was recognized by the fellow or US technologist performing the examination in all four.The intestinal defect was proven at surgery in all four.These four cases illustrate the ability of US to depict the defect in the intestinal wall in neonates and young children with intestinal perforation. It is essential for US technologists and radiologists to search for such defects on US, especially in those cases with no evidence of free gas on AXR or US, and in the presence of echogenic ascites.

Nerea Maiz (*Abstract Co-Author*) Nothing to Disclose
Angel Sanchez-Montanez, MD (*Abstract Co-Author*) Nothing to Disclose
Carlota Rodo (*Abstract Co-Author*) Nothing to Disclose
Elida Vazquez (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To understand that fetal brain hypoxia-ischemia can cause more classically recognized patterns of abnormal neuronal migration and organization2. To recognize the evolving appearance of fetal cerebral hypoxic-ischemic lesions, which also can lead to lesions such as polymicrogyria, schizencephaly or focal cortical dysplasia3. To show in an educational format demonstrative selected cases seen in our tertiary center with evidence that hypoxia in the developing fetal brain may also lead to anomalies that suggest a more classic teratogenic effect.

### TABLE OF CONTENTS/OUTLINE

Fetal stroke usually leads to loss of brain tissue or atrophy (porencephaly, encephalomalacia). Schizencephaly, distinguished from porencephaly by the presence of gray matter heterotopias lining the cleft, is assumed to result from an early vascular-disruptive process before migration. Both conditions can be caused by COL4A1-COL4A2 mutations. Most authors also suggest that many cases of polymicrogyria result from ischemia, cases related to carbon monoxide inhalation or twins with fetal demise have been reported.Authors show here several relevant cases with evidence that hypoxia occurring early in the developing fetal brain has the potential to lead not only to the more commonly accepted disruptive-type defects but also to patterns of anomalies that suggest a more classic teratogenic effect, such as schizencephaly, polymicrogyria or both together. Moreover, these cases also show by fetal MR imaging the follow-up demonstration intrauterus about the evolving nature of cerebral infarction or germinal matrix hemorrhage leading to cortical gyration anomalies. In most of these cases, we will show the postnatal MR imaging correlation.

## IMAGING EVALUATION OF PEDIATRIC PINEAL REGION LESIONS - PEARLS AND PITFALLS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Maria Navallas, MD (*Abstract Co-Author*) Nothing to Disclose
Eman E. Marie, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Emilio Inarejos Clemente, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha K. Gerrie, MD, FRCPC (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Knowledge of the updated WHO classification of tumors of the central nervous system facilitates pathologic and radiologic categorization of pineal region tumors 2. A fundamental understanding of key tumorigenesis pathways aids in multidisciplinary patient management discussion 3. Appropriate use and understanding of available MRI sequences in tumor work-up can narrow the differential diagnosis of pineal region tumors

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Overview of the WHO classification of tumors of the central nervous system 3. MRI protocol for tumor work-up 4. Non-neoplastic lesions a. Pineal cyst b. Calcification c. Cavum velum interpositum 4. Arachnoid cyst 5. Vein of Galen malformation 5. Pineal region tumors a. Pineocytoma b. Pineal parenchymal tumor of intermediate differentiation c. Pineoblastoma d. Papillary tumor of pineal region e. Germinoma - bifocal, trifocal f. Low-grade glioma 6 Cheat sheets - differentiating tumors based on T2 appearance, presence of restricted diffusion, calcification, hemorrhage, growth pattern, enhancement pattern 7. Conclusion

## CEREBELLAR HYPOPLASIA: A ROAD MAP TO FETAL MRI EVALUATION AND DIFFERENTIAL DIAGNOSIS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Roberto Bastos, MD (*Abstract Co-Author*) Nothing to Disclose
Thiago De Gaultier Paulo, MD (*Abstract Co-Author*) Nothing to Disclose
Mariana Cerdeira Machado, MD (*Abstract Co-Author*) Nothing to Disclose
Patricia Oliveira-Szejnfeld, MD (*Abstract Co-Author*) Nothing to Disclose
Anna Silva (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Learn the correct protocol for proper measurement and evaluation of the cerebellum using screening ultrasound. Identify the morphological aspects of the cerebellum in fetal magnetic resonance imaging, as well as the principal associated congenital anomalies. Understand the stages of cerebellar development and common anomalies that can occur. Acknowledge the importance of fetal MRI in diagnosing cerebellar hypoplasias.

### TABLE OF CONTENTS/OUTLINE

The purpose of this presentation is to demonstrate the main congenital anomalies associated with cerebellar hypoplasia using fetal MRI. We will start by briefly discussing the epidemiology, causes, prognosis, and screening ultrasonography findings. Furthermore, we will review the available literature on the normal aspects of the brainstem and cerebellum. Then, we will provide examples of each case with the MRI findings that helped in the diagnosis and correlate them with genetic markers. Finally, we will propose a flowchart of the main cerebellar hypoplasias.

## PEDIATRIC NECK ULTRASOUND: A PRACTICAL GUIDANCE FOR RADIOLOGY RESIDENTS BASED ON CLINICAL CASES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Laura Alonso, MD (*Abstract Co-Author*) Nothing to Disclose
Mabel Garcia-Hidalgo Alonso, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Alberto Ramirez Garcia-Mina, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

-To provide a practical guide on how to do a proper pediatric neck ultrasound.-To review the most frequent pediatric neck pathology in an organized way.-To demonstrate a pertinent differential diagnosis according to the age of the patient, and location of the lesion.-To emphasize the ultrasound characteristics of the different pathology and its correlation with MR imaging through a series of representative cases within our hospital setting.-To highlight warning signs that require further evaluation of proper management.

### TABLE OF CONTENTS/OUTLINE

1) Background. Radiologic evaluation with high-frequency ultrasonography (US) is essential for the diagnosis of neck lumps in the pediatric population.2) Ultrasound anatomy and systematic.3) Thyroidal pathology. Thyroid nodules, from benign (adenomatoid/colloid nodule, hemorrhagic thyroid cyst) to malignant (thyroid papillary carcinoma). Autoimmune pathology.4) Cystic lesions. Thyroglossal duct cyst, branchial cleft cyst (cranial fasciitis as a first branchial cleft cyst mimicker), dermoid and epidermoid cyst.5) Lymphadenopathies. Cervical adenitis and complicated adenitis (non-tuberculous mycobacteria adenitis, complicated lymphadenopathy with abscess formation).6) Hemangioma and vascular malformations (venous, lymphatic, and arteriovenous malformations).7) Ectopic thymus.8) Fibromatosis colli.9) Leukemia and lymphoma.10) Rhabdomyosarcoma.11) Salivary glands. Obstructive sialadenitis. Neonatal suppurative sialadenitis. Acute parotitis. Ranula. Pleomorphic adenoma.12) Conclusion.

Yuko Tsujioka, MD,PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Autoimmune diseases are a diverse group of disorders caused by dysregulation of acquired immunity with loss of immune tolerance to self-tissues and autoantibodies, which commonly manifest as a multisystem disorder and has been a major issue in rheumatology. Autoinflammatory diseases are caused by dysregulation of innate immunity with pathogen-independent cytokine-induced inflammation and absence of autoantibodies, which were initially thought to be a group of rare hereditary periodic fever syndromes, e.g., cryopyrin-associated periodic syndrome. However, the concept of autoinflammatory diseases has recently expanded to a broader group of disorders with chronic inflammation, e.g., systemic juvenile idiopathic arthritis. Studies of cytokine signature have revealed the importance of innate immunity in autoimmune diseases, and thus anti-cytokine therapy is used for affected individuals. Given these advancements, it is proposed that autoinflammatory and autoimmune diseases are not separate conditions but autoinflammatory-autoimmune continuum. Based on the new perspective, we show the imaging spectrum of pediatric multisystem disorders, mainly focusing on rheumatological disorders. We highlight imaging similarities between autoimmune and autoinflammatory disorders, which support the hypothesis of autoinflammatory-autoimmune continuum.

### TABLE OF CONTENTS/OUTLINE

Introduction (the perspective of autoinflammatory-autoimmune continuum) - Monogenic autoinflammatory diseases - Polygenic autoinflammatory diseases - Intermediate diseases - Polygenic autoimmune diseases - Pathology bridging the autoimmune and autoinflammatory diseases including interferonopathy

John D. Karp, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Hamza Alizai, MD (*Abstract Co-Author*) Nothing to Disclose
Mostafa Alnoury, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Recognize Common Culprits Identify prevalent pediatric metabolic bone diseases like rickets, hypophosphatasia, osteogenesis imperfecta, and Ehlers-Danlos syndrome.
- Image Interpretation for Differentiation Understand characteristic imaging findings on radiographs, CT scans, and MRI scans to differentiate these diseases.
- Modality Selection Made Easy Grasp the strengths and applications of radiography, CT, MRI, and bone scintigraphy for optimal evaluation of each condition.

### TABLE OF CONTENTS/OUTLINE

Pediatric Metabolic Bone Diseases (PMBDs) disrupt the processes for building and maintaining strong functional bones. Early diagnosis and proper management of PMBDs are crucial to prevent complications like fractures, bone deformities, and growth impairment. Specific Diseases and their Imaging Signatures A. Rickets and Osteomalacia B. Mineralization Disorders: • Hypophosphatemic Rickets • Hereditary Hyperphosphatasia (juvenile Paget disease) C. Bone Density Abnormalities: • Osteoporosis • Osteopetrosis D. Collagen Disorders Affecting Bone: • Osteogenesis Imperfecta • Ehlers-Danlos Syndrome • Marfan syndrome E. Other PMBDs • McCune-Albright Syndrome • Renal Osteodystrophy

## GUT CHECK ON PEDIATRIC ENTERIC CONTRAST: ARE YOU POSITIVE, NEGATIVE, OR NEUTRAL?

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Mitchell A. Chess, MD (*Abstract Co-Author*) Nothing to Disclose
Apeksha Chaturvedi, MD (*Abstract Co-Author*) Nothing to Disclose
Nina B. Klionsky, MD (*Abstract Co-Author*) Nothing to Disclose
Steve Stephen, BS, MBA (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Enteric contrast agents may enhance the visibility and diagnostic certainty of intestinal and peritoneal findings in pediatric CT imaging. Despite these advantages, their need is debated. Key considerations for using enteric contrast in pediatric body imaging include: • Caution with using positive enteric contrast in patients with gastrointestinal (GI) mucosal or intramural bleeds, as it may obscure the source of bleeding and vascular malformations • Enteric contrast can enhance distinction between serosal tumors and gut lumen when the source of GI bleed is extraluminal • Neutral enteric contrast can improve bowel wall enhancement • Improved scanner technology with ability to perform multiplanar reconstructions reduce reliance on enteric contrast for diagnostic clarity • Emergency department patient throughput and safety considerations (e.g., extended exposure to transmissible diseases including COVID and RSV)

### TABLE OF CONTENTS/OUTLINE

• Review common enteric contrast agents, emphasizing indications, risks, and other considerations unique to children • Summarize arguments for and against the use of enteric contrast, including perceived benefits, risks to patients, increased radiation dose, and logistical challenges • Discuss weight-based enteric contrast dose and administration protocols in children • Present pediatric imaging findings on a case-based template alongside a discussion of whether enteric contrast would be appropriate in similar cases • Highlight the potential for novel enteric contrast agents still in development, including dark enteric contrast agents and high-Z contrast agents

## CATHETERS, TUBES AND OTHER MEDICAL DEVICES IN PEDIATRICS: MALPOSITION AND COMPLICATIONS ARISING FROM THEIR USE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Pablo Castanon Remy (*Abstract Co-Author*) Nothing to Disclose
Beatriz Espejo Garcia (*Abstract Co-Author*) Nothing to Disclose
Maria I. Martinez-Leon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Alejandro Jose Garcia Munoz (*Abstract Co-Author*) Nothing to Disclose
Andrea Gallego Gomez (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Assessment through various imaging tests, primarily utilize simple radiography to assess the status and placement of different medical devices in pediatric patients.• Understand the importance of early detection by the radiologist of potential complications that may arise from their use, primarily mechanical complications, caused by improper placement of these devices.• Interpret different clinical cases of pediatric patients.

### TABLE OF CONTENTS/OUTLINE

In this presentation, we will conduct a systematic review of the types of medical devices used in pediatrics, considering that they are more common in patients admitted to pediatric ICU and neonatology. These devices are essential for managing pediatric patients in intensive care; therefore, understanding them in pediatric patients and learning to assess their correct localization is fundamental in the work of a radiologist. Early detection of possible complications secondary to their use is also crucial.It is often challenging to interpret. Therefore, it is essential to know which devices to look for in each case, their appropriate location, and how to interpret data suggestive of possible complications.Subsequently, we will present a series of tables explaining the appropriate indications, route, and location of devices in imaging tests suitable for their study, followed by a series of cases of pediatric patients with these complications. The devices that can be evaluated with images in this presentation include: Nasogastric tube, endotracheal tube, chest drainage tube, umbilical venous catheter, umbilical arterial catheter, epicutaneous catheter, central venous catheter, ventriculoperitoneal shunt and others less commonly used devices.

### TEACHING POINTS

1. Provide an overview on the speech language pathologist (SLP) assessment of the indications, preparation, and terminology for a pediatric modified barium swallow (pMBS) study.2. Highlight imaging abnormalities detected on a pMBS study.3. Correlate pMBS radiologic findings with their etiologies and management.4. Discuss how a pediatric swallow evaluation differs from that of adults.

### TABLE OF CONTENTS/OUTLINE

1. SLP clinical feeding evaluation and indications for a pMBS study.2. Brief overview of the normal peripheral and central mechanisms of swallowing, including the sequential phases, supportive anatomy, and pediatric neuroanatomic correlates.3. SLP pMBS examination with a description of the setup and rationale for utilizing different types of positioning, equipment, bolus consistencies (thicker vs. thinner), delivery methods, and timed fatigue testing to assess form and function.4. Definitions of specific SLP pMBS terminology, such as oral aversion, pharyngeal residue, swallowing delay, and reduced esophageal clearance.5. Imaging findings in pMBS penetration, aspiration, nasopharyngeal reflux, laryngomalacia, etc.6. Causes and pathophysiology of abnormalities detected on a pMBS study.7. Findings on brain MRI in patients who would need a pMBS study.8. Management options for a failed pMBS study.9. How a pediatric MBS study differs from an adult MBS study in terms of clinical evaluation, grading of findings, and intervention.10. Summary highlighting the applications of a pMBS study for radiology residents.

## PEARLS AND PITFALLS IN PEDIATRIC NEUROVASCULAR RADIOLOGY: A TRAINEE'S AFTER-HOURS GUIDE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Kathleen Schenker, MD (*Abstract Co-Author*) Nothing to Disclose
Ashrith Kandula (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Master the Fundamentals: Grasp the cerebrovascular anatomy of the brain and spinal cord in children to understand blood flow patterns and interpret neuroimaging.
- Recognize Early Signs: Identify the classic presentation of congestive heart failure in neonates with Vein of Galen Malformation (VGAM) and its characteristic imaging findings.
- Sharpen Stroke Diagnosis: Broaden your understanding of pediatric stroke symptoms in septic embolism. Utilize CTA and MRA to identify characteristic features and differentiate from other etiologies.
- Unveil Behēet's Disease: Recognize the multifocal vascular involvement (venous thrombosis and arterial stenoses) seen on angiography in Behēet's disease.
- Think Collateral Flow: Suspect moyamoya syndrome in children with progressive ischemic symptoms or headaches,
- MRI Venography is Key: Importance of MRV for accurate and timely diagnosis of Venous Sinus Thrombosis (VST) in children, which can mimic other stroke etiologies.
- Thunderclap Headache: Consider RCVS in adolescents with normal initial MRI.

### TABLE OF CONTENTS/OUTLINE

Pearls for Initial Assessment:
- Key historical details and presenting signs/symptoms specific to pediatric patients.
- Tailoring imaging protocols to minimize radiation exposure.
- Pitfalls to Avoid:
- Misinterpreting normal variants for pathology.
- Missing subtle findings due to limited experience.
- Ordering unnecessary imaging studies.
- Case-Based Learning:
- Common pediatric neurovascular emergencies will be presented in a concise case format.
- Each case will highlight key imaging findings, differential diagnoses, and pearls for interpretation.
- Pitfalls specific to each case will be emphasized to guide trainees in avoiding misdiagnosis.

Maria Navallas, MD (*Abstract Co-Author*) Nothing to Disclose
Samantha K. Gerrie, MD, FRCPC (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Knowledge of the updated WHO classification of tumors of the central nervous system facilitates pathologic and radiologic categorization of sella/suprasellar region tumors 2. A fundamental understanding of key tumorigenesis pathways aids in multidisciplinary patient management discussion 3. Appropriate use and understanding of available MRI sequences in tumor work-up can narrow the differential diagnosis of sella/suprasellar tumors

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Overview of the WHO classification of tumors of the central nervous system 3. MRI protocol for tumor work-up 4. Pseudotumors - classic features, differential diagnosis, pearls, pitfalls a. Pars intermedius cyst b. Rathke cleft cyst c. Arachnoid cyst d. Epidermoid cyst e. Dermoid cyst f. Suprasellar lipoma 5. Sella/suprasellar tumors - classic features, differential diagnosis, pearls, pitfalls a. Pilocytic astrocytoma b. Pilomyxoid astrocytoma c. Craniopharyngioma d. Hypothalamic hamartoma e. Germinoma f. Pituitary macroadenoma 6. Cheat sheets - differentiating tumors based on T2 appearance, presence of restricted diffusion, calcification, hemorrhage, growth pattern, enhancement pattern 7. Conclusion

Elida Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Angel Sanchez-Montanez, MD (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

; Prenatal central nervous system (CNS) infections remain an important cause of acute and long-term neurological morbidity.; Fetal MRI is the best modality for demonstrating the expressions of the inflammatory response to infection in the brain in fetuses and neonates.; Prompt brain imaging diagnosis facilitates immediate therapy and early recognition of complications.

### TABLE OF CONTENTS/OUTLINE

Early diagnosis of CNS infections in fetuses is best performed with US, whereas MRI is the best diagnostic study for determining areas of involvement in the brain and spine and for improving the ability to narrow the differential diagnosis. Diffusion-weighted imaging identifies cytotoxic edema and abscesses.Prenatal CNS infections are included in the STORCH acronym (syphilis, toxoplasmosis, rubella, CMV, HIV and herpes simplex), also Zika virus or Parvovirus B19. Early infections affect organogenesis, while later infections lead to brain destruction.; CMV is the most common agent. Early infections may result in malformations within the lissencephaly-pachygyria spectrum, and cerebellar hypoplasia and periventricular calcifications, while infections acquired later produce diffuse polymicrogyria, or white matter injury.; Herpes simplex virus (type 2) is a major cause of neonatal encephalitis. Neuroimaging reflects leptomeningeal inflammation and diffuse parenchymal involvement, ranging from vasogenic to cytotoxic edema, with diffusion restriction and necrosis, evolving to cystic encephalomalacia or dystrophic calcification.; Zika virus prenatal infection can lead to microcephaly, cerebral calcification, cortical malformation, ventriculomegaly and corpus callosum hypoplasia.

## PEDIATRIC EWING SARCOMA: THE RADIOLOGIST'S GUIDE TO UPDATES IN TUMOR CLASSIFICATION, STAGING, PROGNOSTICATION AND SURVEILLANCE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Apeksha Chaturvedi, MD (*Abstract Co-Author*) Nothing to Disclose
Sheela B. Garudaiyengar, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Philip J. Katzman, MD (*Abstract Co-Author*) Nothing to Disclose
Hunter R. Carlock, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. WHO 2020 has introduced a new category of "undifferentiated round cell sarcomas of the bone and soft tissue" including Ewing sarcoma and Ewing-like sarcoma entities.2. Clinical, epidemiologic, immunohistochemical, genetic, and imaging characteristics help distinguish individual tumor subtypes within this broad category.3. With advances in FDG-PET CT/MR, bone marrow biopsy is no longer universally recommended for tumor staging.4. Whole Body MR is increasingly used for tumor staging and surveillance.5. Tumor prognostication is hinged on both pretreatment factors and response to therapy, with presence of metastases at diagnosis the most important prognostic factor.6. Key imaging findings impact clinical decision making and surgical approach.

### TABLE OF CONTENTS/OUTLINE

1. Background information2. New WHO 2020 classification of Ewing sarcoma and its relevance to radiologists3. Clinical, epidemiologic, immunohistochemical, and molecular genetic features of Ewing sarcoma relative to Ewing-like sarcoma entities4. Multimodal imaging appearances of Ewing sarcoma and Ewing-like sarcoma entities5. Updated MR imaging protocols, with a focus on diffusion-weighted and whole-body MR6. Evolving staging/surveillance recommendations7. Revised report templates incorporating prognostic variables (localized versus metastatic disease; proximal/distal tumors; extraskeletal/skeletal Ewing sarcoma; tumor size; pathologic fracture+/-; residual viable tumor after chemotherapy or local control surgery+/-)8. Conclusions

Ronit Precel, MD (*Abstract Co-Author*) Nothing to Disclose
Gili Focht, MSc, MBA (*Abstract Co-Author*) Nothing to Disclose
Mary-Louise C. Greer, MBBS (*Presenter*) Research Grant, AbbVie Inc

### TEACHING POINTS

1. To understand the role of imaging biomarkers in inflammatory bowel disease (IBD); 2. To be familiar with pediatric and adult-derived MRI and ultrasound-based indices; 3. To calculate pediatric MRI- and ultrasound- based indices for inclusion in diagnostic imaging reports; and 4. To consider future applications of imaging-based indices in pediatric IBD.

### TABLE OF CONTENTS/OUTLINE

1. Background Explain the evolution of biomarkers in IBD from clinical and endoscopic scores to imaging-based indices, gauging disease activity, severity and treatment response, guiding drug development, with potential for prognostication. 2. Imaging-based Indices: Describe specific indices using MR enterography (MRE), pelvic MRI (PMR) and bowel ultrasound, quantifying disease activity, severity and treatment response, highlighting new MRI-based indices developed in pediatric cohorts. 3. Pediatric Imaging-based Indices (a) Pediatric Inflammatory Crohn's MRE Index - PICMI, (b) Pediatric MRI-Based Perianal Crohn Disease index - PEMPAC and (c) Pediatric ultrasound-based scores - SPAUSS and PCD-US Define index components, methodology for score calculation and cut-off values for remission, active inflammation and response as relevant. Provide examples illustrating scores and reporting templates. 4. Future Directions: Consider current and emerging roles of imaging biomarkers including use of Artificial Intelligence/Deep Learning, integration with texture analysis, and exploration of unmet needs such as quantification of intestinal fibrosis. 5. Practice Cases: Interactive exercise trialing score calculations on MRE, PMR and ultrasound.

Jonathan Chen (*Abstract Co-Author*) Nothing to Disclose
Dimitri A. Parra, MD, MMEd (*Abstract Co-Author*) Nothing to Disclose
Kin Fen Kevin Fung, MBBS, FRCR (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Obtaining arterial access is the one of the most challenging aspects for pediatric arterial interventions, especially in neonates and young infants.- Due to larger sheath-to-vessel ratio, the risk of thrombo-occlusive complication is higher in young children. Strategies to prevent complications include limb warming, ultrasound guided access, low-profile hydrophilic sheath and heparinization.- Common femoral artery access remains the standard for interventions in children. Alternative access sites include axillary, brachial, radial, carotid, and umbilical arteries and umbilical vein in neonates.- Upper extremity access sites should be considered in children with significant aorta caliber differences such as in hepatic hemangioma, and aortoiliac occlusive conditions such as mid-aortic syndrome. Other advantages include ease of catheterisation and passage of interventional devices into visceral arteries with acute downward angulation- Carotid access is not commonly used but can be an alternative in infants requiring complex cardiac or neurovascular interventions.- Umbilical artery can be used in neonates up to 1 week of age. Umbilical vein is an alternative if there is a patent ductus arteriosus or foramen ovale, which can act as a conduit between the arterial and venous systems. Advantages include ability to use larger sheaths and prevention of access-related complications in the extremities.

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Technique for arterial access in children 3. Strategies to prevent access-related complications 4. Standard and alternative arterial access sites: Advantages and potential issues 5. Illustrative cases 6. Management of complications 7. Conclusions

### TEACHING POINTS

- Review anatomy and physiology of MAG3 renal scans - Correlate with other imaging for common and uncommon pediatric genitourinary pathology.- Discuss complementary role of MAG3 renal scans for diagnostic purposes

### TABLE OF CONTENTS/OUTLINE

Technetium-99m (Tc-99m) scintigraphy, using tracers such as mercaptoacetyltriglycine (MAG3), dimercaptosuccinic acid (DMSA), and diethylenetriaminepentaacetic acid (DTPA) offers excellent anatomical and physiological details. Tc-99m MAG3 is considered one of the best methods for assessing renal function owing to favorable qualities in energy and dosimetry. DTPA adds glomerular filtration rate assessment, and DMSA provides information for differentiating pyelonephritis versus scarring in the presence of vesicoureteral reflux and multiple episodes of urinary tract infection. Thus, pediatric genitourinary imaging commonly utilizes technetium scintigraphy. Through a case series, this exhibit will include cases of collecting system dilatation and other GU pathology due to various obstructive and nonobstructive pathology where MAG3 imaging proved useful in diagnosis and/or clinical management. Illustrative cases are reviewed with ultrasound and CT correlation.

### TEACHING POINTS

1. Many classification schemes and management recommendations for benign and malignant liver masses in children have evolved over the last 15 years.2. There are characteristic pathologic findings that may affect the imaging appearance of these tumors in children.3. Contrast enhanced ultrasound and use of hepatobiliary contrast agents are becoming standard of care for imaging liver masses in children.

### TABLE OF CONTENTS/OUTLINE

• Introduction: General discussion of updates in the imaging of benign and malignant pediatric liver tumors. Review of the Los Angeles liver tumor symposium consensus classification of tumor histopathology • Specific Pathologies: Each section will discuss clinical, imaging, and pathologic features, differential diagnoses, and management recommendations. o Infantile and congenital hemangiomas. Updates: ISSVA nomenclature and classification. o Mesenchymal hamartoma. o Focal nodular hyperplasia. Updates: FNH-like lesions o Hepatocellular adenoma. Updates: Subtypes and associations o Hepatoblastoma. Updates: LIRADS imaging recommendations, PRETEXT staging for risk stratification, treatment strategies, and prognosis. Discussion of hepatocellular neoplasm NOS. o Hepatocellular carcinoma. Updates: LIRADS, imaging recommendations, predisposition, available screening recommendations, and prognosis. o Fibrolamellar hepatocellular carcinoma. o Undifferentiated embryonal sarcoma.

PDEE-68

## IMAGING OF HEARING LOSS IN PEDIATRIC POPULATION

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Vijay S. Pande, MD (*Abstract Co-Author*) Nothing to Disclose
Pratit Pokharel, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Approximate prevalence of hearing loss is between 2 to 3 per 1000 babies, while by the age of 12 years approximately 20% of children have detectable hearing loss either in one or both ears. Congenital hearing loss is often sensorineural and associated with genetic conditions or isolated inner ear malformations. While in older children conductive hearing loss is common. Early detection and treatment are important to prevent significant language disability. High resolution CT and MR imaging plays crucial role in demonstrating the inner ear anatomy and pathologies. Imaging has also established pivotal role in selecting patients for cochlear implantation.We wish to make the residents and radiologist in practice aware of the imaging anatomy of temporal bone and imaging features in commonly encountered conditions.

### TABLE OF CONTENTS/OUTLINE

Technical considerations in CT, MRI, for imaging in pediatric hearing loss. Pertinent imaging anatomy in evaluation of hearing loss. Imaging features of congenital and acquired external and middle ear pathologies. Imaging features of congenital and acquired inner ear pathologies.

## UNPEELING SUBPIAL HEMORRHAGES IN NEONATES: ANATOMY, IMAGING AND CLINICAL INSIGHTS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Saul Rodriguez (*Abstract Co-Author*) Nothing to Disclose
Natally AlArab, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Yutaka Sato, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lillian M. Lai, MD (*Abstract Co-Author*) Nothing to Disclose
T. Shawn Sato, MD (*Presenter*) Research Grant, Bracco Group

### TEACHING POINTS

Subpial hemorrhages (SPH) are an often under-recognized and misdiagnosed type of intracranial hemorrhage, most commonly seen in neonates and young infants. Although the etiology remains elusive, SPH are known to be associated with various conditions including but not limited to the birth trauma, neonatal hypoxic brain injury, abusive head trauma and hydrocephalus shunting. SPH are located superficial to the cortex, in the potential space between the glia limitans and the pia matter. On MR imaging, SPH are localized to the brain surface and the subjacent cortex can show diffusion restriction. Accurate diagnosis holds significant clinical implications given the potential parenchymal damage associated with SPH. We present the pertinent anatomy, proposed pathophysiology and imaging features crucial for accurate diagnosis of SPH.

### TABLE OF CONTENTS/OUTLINE

- Review pertinent anatomy and pathophysiology and understand the unique imaging features and clinical significance of SPH.- Become familiar with the typical imaging features of SPH and learn to differentiate it from subarachnoid and subdural hemorrhages.- Review cases of subpial hemorrhage to familiarize and aid in recognizing this frequently misdiagnosed entity.

## WHAT DO I DO WITH IT? UPDATE ON PEDIATRIC THYROID NODULE ASSESSMENT AND MANAGEMENT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Jesse L. Courtier, MD (*Abstract Co-Author*) Founder, Sira Medical, Inc;Consultant, Sira Medical, Inc
Sunit Davda, MBBS, MRCP (*Abstract Co-Author*) Nothing to Disclose
Amanda R. Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Kalpana Manral, MD (*Abstract Co-Author*) Nothing to Disclose
Rachelle Durand, DO (*Abstract Co-Author*) Nothing to Disclose
Kantheera Leesmidt, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Thyroid nodules in the pediatric population exhibit a lower incidence rate of 0.5% to 1.6%, yet the malignancy rate is 25% to 30% which is higher compared to adults.2. Pediatric thyroid cancer has a greater risk of metastasis to lungs and lymph nodes with more likely extrathyroidal growth and recurrence. However, their prognosis is favorable.3. ATA and ACR-TIRADS are the two most common ultrasound-based risk stratification systems for description of thyroid nodules and stratify the risk characteristics in adults, however, the diagnostic performance when applying to the pediatric population has been less reported.4. Utilizing thyroid ultrasound reference standards tailored for adults in pediatric populations may offer advantages, although they may not always be accurate. ATA, ACR-TIRADS, and EU-TIRADS have moderate diagnostic performance in pediatric thyroid nodule patients.5. US features of microcalcifications, ill-defined margins, size > 3.5 cm, and abnormal lymph nodes increase sensitivity and specificity for malignancy in pediatric population.6. Performing biopsies on nodules categorized as the highest risk and smaller than 1 cm could improve diagnostic accuracy.

### TABLE OF CONTENTS/OUTLINE

1. Review features of common pediatric benign and malignant thyroid lesions.2. Illustrate potential pitfalls and mimics of thyroid masses.3. Evaluate the strengths and weaknesses of various adult thyroid nodule scoring criteria as they apply to pediatrics.4. Review management of pediatric thyroid nodules.5. Test understanding with a short quiz.

PDEE-71

## VARIOUS ASPECTS AND MIMICKERS OF IMAGING FINDINGS OF ACUTE ENCEPHALOPATHY WITH BIPHASIC SEIZURES AND LATE REDUCED DIFFUSION (AESD)

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Harushi Mori, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akihiro Nakamata, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

AESD is one of the most common acute encephalopathies in infants and young children in East Asia. Clinically, it develops as febrile status epilepticus and often shows no abnormal findings on diffusion-weighted image(DWI) or T2-weighted images taken on the first or second day of onset; therefore, distinguishing it from febrile seizures in the early stages of the disease is challenging. However, magnetic resonance spectroscopy (MRS) and arterial spin labeling (ASL) may exhibit characteristic abnormalities, even in the early stages of the disease. Unlike febrile seizures, AESD has a high rate of sequelae, exceeding 60%, and early therapeutic intervention improves neurological prognosis; thus, early diagnosis is important. Therefore, radiologists should be familiar with the typical patterns, variants, and mimickers of AESD. The purpose of this exhibit is:1. To explain the disease concept and pathogenesis of AESD2. To discuss the clinical course and imaging findings of AESD3. To discuss the excitotoxity encephalopathy spectrum4. To discuss the mimickers of AESD

### TABLE OF CONTENTS/OUTLINE

•Disease concept and pathogenesis of AESD.•Clinical aspects of AESD•Typical imaging findings ?DWI ?ASL ?MRS •Other imaging findings •Spectrum of encephalopathy with excitotoxicity (e.g. hemiconvulsion-hemiplegia/hemiconvulsion-hemiplegia-epilepsy syndrome, clinically mild infantile encephalopathy associated with excitotoxicity, infantile traumatic brain injury with a biphasic clinical course and late reduced diffusion) •Imaging mimickers (e.g. hemorrhagic shock and encephalopathy syndrome, meningitis, posterior reversible encephalopathy syndrome)

## DECODING THE PUZZLE: A MULTIMODAL APPROACH TO PEDIATRIC NON-TRAUMATIC HEAD AND NECK EMERGENCIES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Kathleen Schenker, MD (*Abstract Co-Author*) Nothing to Disclose
Ashrith Kandula (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Unravel the diverse causes of pediatric non-traumatic head and neck emergencies.• Master the art of differential diagnosis using a multimodal imaging approach.• Gain insight into the unique imaging characteristics of frequently encountered emergencies.

### TABLE OF CONTENTS/OUTLINE

- Introduction:
- Challenges in diagnosing pediatric non-traumatic head and neck emergencies.
- Unveiling the Culprit:
- Plain radiography: Unveiling the bony clues.
- Ultrasound: A bedside warrior for rapid evaluation.
- CT: Delineating intricate anatomy and complications.
- MRI: Unveiling soft tissue involvement.
- Decoding the Images:
- Infectious emergencies:
- Lemierre syndrome: Painting the jugular vein red.
- Gradenigo syndrome: Facial pain whispers of a cranial nerve dilemma.
- Cavernous sinus thrombosis: When the crossroads of blood flow become inflamed.
- Epiglottitis: The cherry red flag of a life-threatening airway obstruction.
- Branchial cleft cyst and lymphangioma: When remnants of development turn troublesome.
- Atypical mycobacterial infection: The sly infectious invader.
- Mastoiditis with intracranial complications: Balancing hearing with brain health.
- Sinusitis with intracranial complications (Pott's puffy tumor): When a sinus infection breaches its boundaries.
- Skull base osteomyelitis: A bone infection with a cranial address.
- Non-infectious emergencies:
- Labyrinthitis: The inner ear's dance gone wrong.
- Orbital pseudotumor: Inflammation masquerading as a mass.
- Juvenile angiofibroma: An aggressive vascular anomaly.
- Orbital varix: Bulging eye caused by a dilated vein.
- Mimics:
- Langerhans cell histiocytosis (LCH) vs. infectious processes.
- Discitis/osteomyelitis vs. infectious complications.

### TEACHING POINTS

Childhood interstitial lung diseases (chILDs) are individually rare, but overall, many affected children seek medical services. Since chILDs, particularly of the infantile-onset, were poorly understood for a long time, many cases remained undiagnosed as "unexplained" ILDs. However, the new chILD classification (2007) for children under 2 years, and the expanded classification (2015) for children ages 2-18 years provided a more comprehensive picture of chILDs. The genetic and histological background of chILDs has been revealed as well. Radiologists should be aware of the disease classification, pathophysiology, and relevant imaging findings of chILDs. Accurate diagnosis will lead to further elucidation and development of efficient medical interventions for this group of disorders. TEACHING POINTS 1. Based on the current classification of chILDs, their pathophysiology and imaging findings will be presented, highlighting imaging findings that may enable us to make definitive diagnoses. 2. The spectrum of chILDs overlaps with that of adult ILDs; however, we should be aware of distinctive clinical and imaging characteristics in chILDs and the presence of infant-specific chILDs.

### TABLE OF CONTENTS/OUTLINE

1) Introduction2) Disorders of infancy (diffuse developmental abnormalities/alveolar growth abnormalities/surfactant dysfunction and related abnormalities/specific conditions of poorly defined etiology/miscellaneous monogenic chILDs)3) Disorders not specific to infancy and childhood (disorders of normal host/disorders related to systemic diseases/disorders of the immunocompromised host/disorders masquerading as interstitial lung disease)4) Discussion

## UPDATE ON US SCREENING FOR DEVELOPMENTAL DYSPLASIA OF THE HIP (DDH): WHY, HOW AND WHEN?

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Richard Placzek (*Abstract Co-Author*) Nothing to Disclose
Hakan Omeroglu (*Abstract Co-Author*) Nothing to Disclose
Ustun Aydingoz, MD (*Abstract Co-Author*) Nothing to Disclose
Carolina Casini (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Chlapoutakis, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• To demonstrate why and how hip ultrasound has largely replaced clinical examination and radiography, as the screening method of choice for the early detection of developmental dysplasia of the hip in neonates and infants. • To justify the selection of Graf's technique over the other sonographic techniques, as the "one-stop-shop" for the diagnosis and monitoring of treatment of developmental dysplasia of the hip. • To present the evidence which proves that universal sonographic screening is preferred over selective screening. • To present Graf's technique main examination steps, including baby positioning, quality evaluation, morphological classification, and final typing. • To demonstrate the main treatment principles according to the Graf's hip type. • To comment on the main reasons for underperformance and practically demonstrate the main sources of erroneous practice and confusion. • To emphasize the importance of structured training as a requisite for the "lege artis" performance of the technique.

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Screening methods for developmental dysplasia of the hip 3. Sonographic techniques 4. Why Graf's technique 5. Universal vs. selective screening with Graf's technique 6. Presentation of Graf's technique examination steps 7. Common errors and how to avoid them. 8. Treatment guidance / monitoring of treatment 9. Structured training 10. Conclusions

El Mehdi Mniai, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Peritoneal neoplasms are a group of tumors that arise within the peritoneum space but outside the major organs. Diagnosis of these tumors is often challenging for radiologists and consists of several steps, including determining the tumor's location within the peritoneum, often by excluding involvement of adjacent abdominal structures, and identifying distinctive imaging features. The diagnostic spectrum for rare solid peritoneal masses in children is broad, and includes rhabdomyosarcomas, desmoid tumors, teratomas, and inflammatory myofibroblastic tumors... Ultrasound serves as the frontline imaging modality for initial assessment thanks to its accessibility and lack of ionizing radiation. Computed Tomography (CT) offers superior visualization and aids in lesion detection, localization, and distant staging, especially when malignancy is suspected. Magnetic Resonance Imaging (MRI) provides excellent soft tissue contrast and is valuable for diagnosis and surveillance, particularly with diffusion-weighted sequences for detecting subtle peritoneal lesions. A methodical approach to diagnosing solid peritoneal masses in pediatric patients is essential. This approach involves integrating clinical data with imaging findings while taking into account age-related differences and the rarity of such tumors in children. Despite the major contribution of imaging, biopsy is still often warranted for histological confirmation.

### TABLE OF CONTENTS/OUTLINE

1) Introduction and Objectives 2) Imaging signs of localization 3) Contribution of imaging modalities 4) Illustration of some rare solid peritoneal tumors in pediatrics 5) Take home messages 6) References

Magdalena P. Reyes Recasens, MD (*Abstract Co-Author*) Nothing to Disclose
Jesus A. Arenos-Abril, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. List the most common myxoid-containing tumors involving the pediatric and adolescent age group. 2. Discuss the role of different imaging modalities used in the work-up of these lesions and describe the main imaging findings, emphasizing MRI features. 3. Recognize the characteristic MRI signal of the myxoid matrix to facilitate the differential diagnosis of soft tissue tumors.

### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. MRI characteristics including diffusion weighted-imaging features of myxoid-containing lesions. 3. Histological types involving the pediatric and adolescent age group: a. Myxoid liposarcoma b. Primitive myxoid mesenchymal tumor of infancy (PMMTI) c. Low-grade myxoid fibrosarcoma d. Chondromyxoid fibroma e. NTRK-rearranged spindle cell neoplasm f. Extraskeletal myxoid chondrosarcoma 4. Take home points 5. References

## TUBE FOR THOUGHT: IMAGING OF COMPLICATIONS ASSOCIATED WITH GASTROSTOMY AND GASTROJEJUNOSTOMY TUBES

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Eugene G. Sheffield, MD (*Abstract Co-Author*) Nothing to Disclose
Asif Jamal, MBBS (*Abstract Co-Author*) Nothing to Disclose
Preet K. Sandhu, MD (*Abstract Co-Author*) Nothing to Disclose
Chinky Patel, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Percutaneous feeding tubes such as gastrostomy and gastrojejunostomy tubes are widely used in the pediatric age group requiring long-term nutritional support. 2. Several complications are associated with the feeding tube apparatus such as abnormal placement, malpositioning, malfunction, and other uncommon complications. 3. Fluoroscopy is the initial modality of choice to evaluate for feeding tube complications using water soluble, non-ionic iodinated contrast agents. Ultrasound and CT are complementary in some cases. 4. A scout radiograph of the abdomen is often obtained prior to fluoroscopic evaluation to look for obvious malpositioning of the percutaneous feeding apparatus followed by fluoroscopy in the posteroanterior and right lateral positions to look for contrast opacifying the stomach and jejunum depending on the type of feeding tube, and to assess the position of the apparatus. 6. It is often challenging to identify feeding tube related complications on fluoroscopy and a high index of suspicion is required based on the clinical scenario. 7. The role of the radiologist is to be aware of percutaneous feeding tube related complications and to identify them in a timely manner for optimal patient care.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: use and importance of percutaneous gastrostomy and gastrojejunostomy tubes in the pediatric age group.2. Highlight various types of complications associated with feeding tube placement.3. Approach to evaluating these complications with an emphasis on imaging findings on fluoroscopy.4. Examples of feeding tube-related complications at our facility.

### TEACHING POINTS

Fetal magnetic resonance imaging (MRI) is the modality of choice for evaluation of congenital airway pathologies, which present a diagnostic challenge when assessed by ultrasound. The radiologist should be also accustomed with the embryology and normal anatomy of the airway and have a checklist to identify all structures every time is reading a fetal MRI. Identification of congenital airway anomalies become a crucial topic, as managing these pathologies may require interventions at the time of delivery or even during intrauterine life, posing a significant challenge for the perinatal care team due to the complexities of these pathologies and the risk of fetal demise.This pictorial essay will provide a detailed review of normal airway imaging findings in fetal MRI and their correlation with pathological findings, including some postnatal correlation cases.The objectives of this pictorial essay are:1 - To demonstrate the normal anatomy of the airway on fetal MRI; 2 - To present the primary congenital diseases involving the larynx and trachea; 3 - To identify the key radiological features of tracheal atresia, tracheal agenesis, and bronchial atresia;

### TABLE OF CONTENTS/OUTLINE

1-Normal embryology of the airway; 2-Anatomy and anatomical relationships of the fetal airway; 3-Tracheal agenesis; 4-Tracheal atresia, stenosis or web; 5- Laryngeal stenosis, atresia or web; 6- Bronchial Atresia 7- Correlation between fetal MRI findings and postnatal outcomes;

Samantha K. Gerrie, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Lucia Riaza Martin, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Navallas, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To describe key imaging features and discuss practical tips that can help the radiologist narrow the differential diagnosis of pediatric thyroid disorders2. To explain the use of new imaging technologies in pediatric thyroid evaluation3. To discuss the utility of Kwak TI-RADS, ACR-TIRADS, ATA and structured report system in the evaluation of pediatric thyroid disorders

### TABLE OF CONTENTS/OUTLINE

1. US technique2. Normal anatomy, normal variants and pitfalls (cricoid cartilage, pyramidal lobe, intrathyroid thymus)3. Congenital thyroid abnormalities3.1. Congenital hypothyroidysm- Thyroid dysgenesis (agenesis, hemiagenesis, ectopia, hypoplasia)- Thyroid dyshormonogenesis3.2. Thyroglossal duct cyst4. Diffuse thyroid diseases4.1. Chronic lymphocytic thyroiditis (Hashimoto disease)4.2. Diffuse hyperplasia (Graves disease)4.3. Nodular hyperplasia4.5. Non-autoimmune thyroiditis (suppurative, granulomatous, subacute non-suppurative thyroiditis (De Quervain)4.6. Diffuse sclerosing variant of papillary carcinoma5. Focal thyroid lesions5.1. Benign lesions (colloid follicles/cysts, true epithelial-lined cysts, hyperplastic nodules with cystic degeneration, follicular adenoma)5.2. Thyroid cancer (papillary, follicular and medullary carcinoma)5.3. Predisposing factors for pediatric thyroid cancer including genetic disorders such as RET, DICER1 or PTEN gene mutations6. Utility and reproducibility of Kwak TI-RADS, ACR-TIRADS, ATA and structured report in the evaluation of pediatric thyroid lesions7. Evaluation of lymphadenopathy8. Newer techniques (elastography, superb microvascular imaging, contrast-enhanced US, radiomics/radiogenomics, AI)9. Conclusions

### TEACHING POINTS

The pancreas can be involved in a wide array of congenital and acquired conditions in the pediatric population. The purpose of this exhibit is: 1. To become familiar with the spectrum of pancreatic disorders in children. 2. Review a multimodality approach and technical considerations for the diagnosis of pancreatic pathology. 3. To illustrate the imaging features of common and uncommon pancreatic disorders in pediatric patients.

### TABLE OF CONTENTS/OUTLINE

Imaging approach to pancreatic lesions. Normal appearance of the pancreas on different imaging modalities. Congenital pancreatic anomalies: pancreas divisum, annular pancreas, ectopic pancreas, pancreatic hypoplasia, abnormal pancreaticobiliary junction. Congenital disorders with pancreatic insufficiency: cystic fibrosis, Schwachman- Diamond syndrome, hereditary pancreatitis, other genetic risk factors. Pancreatitis: acute, chronic, autoimmune. Pancreatic trauma: blunt trauma, penetrating trauma, nonaccidental trauma. Pancreatic infection. Cystic lesions of pancreas: congenital cyst, pseudocyst, von Hippel- Lindau syndrome, autosomal dominant polycystic kidney disease, cystic pancreatic neoplasms. Solid pancreatic tumors: Pancreatoblastoma, solid pseudopapillary neoplasm, neuroendocrine tumor, acinar cell carcinoma, adenocarcinoma, non-epithelial tumors including lymphoma, inflammatory myofibroblastic tumor, invading tumors, metastatic disease. Other pancreatic lesions: intrapancreatic accessory spleen, vascular lesions. Summary.

Dheeman Futela, MBBS (*Abstract Co-Author*) Nothing to Disclose
Mihir Khunte (*Abstract Co-Author*) Nothing to Disclose
Rahul Jayaram, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Accurate imaging is crucial for diagnosing and managing non-traumatic pediatric head and neck emergencies. The appropriate imaging modality, such as ultrasound, CT, or MRI, varies depending on the particular condition. These conditions include orbital and sinus emergencies, deep neck emergencies, ear emergencies, or airway emergencies. Choosing the proper imaging is critical for determining the most suitable treatment approach and distinguishing between cases requiring immediate intervention and those that can be addressed with medical therapy. Familiarity with the clinical features of pediatric emergencies and collaboration with clinicians can ultimately improve diagnostic precision and treatment effectiveness.

### TABLE OF CONTENTS/OUTLINE

1. Introduction-Importance of imaging in pediatric emergencies-Overview of common head and neck emergencies2. Choosing the Appropriate Imaging Modality-Ultrasound: Safe, cost-effective, but limited depth and operator dependent.-CT: Rapid, detailed bone imaging, but radiation exposure and contrast risks.-MRI: Radiation-free, superior soft tissue contrast, but longer scan times.3. Specific Conditions and Imaging Guidelines-Orbital Emergencies: Identifying cellulitis and abscesses· Sinus / Nasal Emergencies: Complications of sinusitis-Ear Emergencies: Diagnosing otitis and mastoiditis-Airway Emergencies: Recognizing epiglottitis and croup-Neck Emergencies: Recognizing infection, foreign body, vascular emergencies, congenital anomalies4. Case Studies-Application of skills discussed toward patient cases5. Conclusion-Summary of key points-Importance of clinical picture and collaboration when interpreting imaging

Danet Lugo (*Abstract Co-Author*) Nothing to Disclose
Laura Santiago Caobi, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Explore the prevalence and significance of pediatric abdominal pain and the diagnostic role of abdominal x-rays.- Outline a systematic approach to interpreting pediatric abdominal X-rays to improve diagnostic precision and patient outcomes.- Illustrate common pathologies identified in pediatric abdominal x-rays with case examples and address their diagnostic challenges.- Discuss common pitfalls and limitations of pediatric abdominal x-rays.

### TABLE OF CONTENTS/OUTLINE

Pediatric abdominal pain is one of the most common encounters in medical practice, often requiring prompt and accurate evaluation. Optimal use of abdominal x-rays in the pediatric population requires a proper technical assessment, recognition of pathological signs, and knowledge of common pitfalls and limitations. Adopting a systematic approach when reviewing abdominal x-rays entails a careful evaluation of gas patterns, extraluminal air, abdominal masses, calcifications, the peritoneal cavity, and surrounding osseous structures. Maintaining such a structure is key to enhancing diagnostic accuracy and improving patient outcomes.1. Introduction Objectives. 2. Epidemiology 3. How to approach a Pediatric Abdominal X-Rays 4. Common Encounters Stratified 5. Common Pitfalls Limitations 6. Case Examples 7. Conclusion

Hideharu Nakao (*Abstract Co-Author*) Nothing to Disclose
MASAYA NISHIWAKI (*Abstract Co-Author*) Nothing to Disclose
Hiroaki Kobayashi (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To understand the issues with noise evaluation using Noise Standard Deviation (Noise SD) and Noise Power Spectrum (NPS). To explore apparent noise, a novel approach that addresses the shortcomings of conventional noise evaluation methods. To recognize the advantages of evaluating noise in clinical imaging. To identify the limitations of apparent noise and strategies to overcome them.

### TABLE OF CONTENTS/OUTLINE

A. Limitations of Noise Standard Deviation (SD) : A Simple Measurement Method that Does Not Account for Frequency Information B. Challenges of Noise Power Spectrum (NPS) : Complicated Analysis and Difficulties in Clinical Imaging Applications C. Advantages of Apparent Noise Evaluation D. Application of Apparent Noise Evaluation in Clinical Imaging E. Overcoming the Limitations of Noise SD and NPS with Apparent Noise Evaluation

## PHEE-10 GENERAL RADIOGRAPHY ARTIFACTS: A VISUAL REVIEW

Beth A. Schueler, PhD (*Abstract Co-Author*) Nothing to Disclose
Jill M. Lucas, ARRT, BS (*Abstract Co-Author*) Nothing to Disclose
Zaiyang Long, PhD (*Abstract Co-Author*) Nothing to Disclose
Lindsay Ranschau, BS, ARRT (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Identify radiographic image artifacts participants will learn how to recognize the appearance of image artifacts that may obscure pathology. Investigate the cause of artifacts learners will study potential sources of common artifacts. Implement artifact resolution methods participants will be equipped with practical techniques to minimize artifact occurrence, prompting the production of high-quality radiographic images.

### TABLE OF CONTENTS/OUTLINE

Radiographic artifacts can cause obscured or undiagnostic images, possibly requiring repeat imaging and radiographic room downtime. Our team has gathered image artifacts in many different types of equipment configurations and clinical scenarios. We will describe the investigation and diagnosis of artifact causes as well as resolution methods. Sharing this information with imaging technologists and radiologists will empower them to be able to minimize artifact occurrence and optimize image quality, facilitating accurate diagnosis and clinical decision-making. The following types of artifacts will be reviewed:system hardware-related, system software-related, patient-related, technologist-related, environment-related.

## PHEE-11 BEYOND THE BASICS. MRI GADOLINIUM BASED CONTRASTS AGENTS: UPDATES AND GUIDELINES REVIEW

### TEACHING POINTS

• To describe the classification of contrast agents in Magnetic resonance imaging based on the type and biodistribution.• To explain the main characteristics of Gadolinium.• To review Gadolinium-based contrast agents (GBCAs), describing their generalities and classifications.• To list the early and late adverse reactions GBCAs and explain Gadolinium deposition disease/symptoms associated with Gadolinium exposure, based on the different

guidelines of the American College of Radiology (ACR) and European Society of Radiology (ESUR).• To define nephrogenic systemic fibrosis.• To review current recommendations according to ACR and ESUR guidelines on risk assessment, pregnancy, breastfeeding and waiting time between examinations.• To summarize information about the development of new GBCAs.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction.2. Contrast agents in Magnetic Resonance Imaging.3. Gadolinium features.4. Gadolinium-Based Contrast Agents (GBCAs): Generalities, classifications, adverse reactions and risk factors, Gadolinium deposition disease (GDD)/symptoms associated with Gadolinium exposure (SAGE), Nephrogenyc systemic fibrosis (NSF), pregnancy and lactation, update and guidelines: risk assessment recommendations, waiting times between examinations recommendations.5. What's new? Contrast agents in development.6. Conclusions.7. References.

## PHEE-12 DOSE REDUCTION IN INTERVENTIONAL CT PROCEDURES BY OPTIMIZING HELICAL SCAN PARAMETERS

**Awards**
**Cum Laude**

Keith B. Quencer, MD (*Abstract Co-Author*) Nothing to Disclose
Matthew B. O'Brien, MD (*Abstract Co-Author*) Nothing to Disclose
Bryan R. Foster, MD (*Abstract Co-Author*) Royalties, RELX;Consultant, RELX
Lindsay S. DeWeese, PHD (*Abstract Co-Author*) Nothing to Disclose
Lindsay N. Douglas, PhD (*Abstract Co-Author*) Nothing to Disclose
Isaac J. Bailey, MS (*Abstract Co-Author*) Nothing to Disclose
Rachel Malinowski (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Define common CT procedures, workflow, and different scan mode options for procedures. 2) Discuss image quality requirements for diagnostic versus CT procedures. 3) Review protocol parameters relevant to dose optimization including automatic tube current and iterative reconstruction settings. 4) Identify strategies for CT dose optimization in CT procedures. 5) Understand that adjustments can be made to the helical portion of the procedure to significantly reduce patient dose.

**TABLE OF CONTENTS/OUTLINE**

1) CT Procedures a) Common types of CT procedures 2) Scan mode options a) Workflow of procedures b) Helical versus CT scanner interventional scan modes Takeaway 1-2: Knowledge of scan mode options and parameters for common CT procedures is imperative for knowing where optimization is viable. 3) Protocol parameters to be adjusted to optimize the helical scan used in procedures a) Image quality requirements for diagnostic versus CT procedures b) Automatic tube current modulation image quality reference setting c) Iterative reconstruction Takeaway: Parameter adjustments are used to optimize procedure protocols based on image quality requirements. 4) Prior studies that have had success in CT dose optimization 5) Targeting the helical scan success at a single institution and future work a) Adjusting DRI and iDose4 resulted in 30-40% dose reduction b) Utilize what was learned to optimize pediatric procedures Takeaway: Results from a single institution demonstrate the feasibility of optimizing CT procedures.

## PHEE-14 DIXON METHOD AND IN-PHASE/OPPOSED-PHASE IMAGING: CLINICAL UTILITY AND PITFALLS

Aoi Uchida, MD (*Abstract Co-Author*) Nothing to Disclose
Masako Tokuhashi, MD (*Abstract Co-Author*) Nothing to Disclose
Juri Miyaji, MD (*Abstract Co-Author*) Nothing to Disclose
Takashi Katayama, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

In this presentation, our aim is to review the clinical utility and pitfalls of the different types of Dixon methods and in-phase (IP) and opposed-phase (OP) imaging in MRI. The Dixon method and IP/OP MR imaging are routinely used in various fields. Currently, several techniques with different characteristics are used, and there is no one perfect method that is suitable for all purposes. It is important for radiologists to be aware of the characteristics of the different types of Dixon methods, as improper interpretation of the Dixon method can lead to misdiagnosis. However, many radiologists find it difficult to understand the principles of MRI and also to understand how the principles of different techniques affect clinical practice. Simplified explanations or explanations for commercial purposes are provided to doctors, but they may not be sufficient to solve clinical problems. We have made efforts to provide explanations that are easy to understand for radiologists, without sacrificing accuracy, by referring to many clinical cases.

**TABLE OF CONTENTS/OUTLINE**

Introduction/ About chemical shift/ IP/OP imaging/ Minimal basics of the Dixon method/ Advantages of the Dixon method 1. Uniform and selective fat suppression 2. Four (+ 1) kinds of images obtained from one scan 3. Quantification of fat and R2* values / Pitfalls 1. Underestimation of both fat and iron deposition (IP/OP imaging) 2. Swapping artifact (Dixon method) 3. Effect of an incomplete signal model (GRE conventional Dixon method) 4. Reversed echo time order (IP/OP imaging) 5. OP signal drop in the TSE Dixon method (TSE Dixon method using acquired data for OP image) 6. IP/OP images in the modified Dixon method / Conclusions

## PHEE-15 FLUOROSCOPIC COLPOCYSTODEFECOGRAPHY: TIPS FOR SUCCESSFUL TECHNIQUE AND RELEVANT INTERPRETATION

EMNA YOUNSI (*Abstract Co-Author*) Nothing to Disclose
Marc Zins, MD (*Abstract Co-Author*) Nothing to Disclose
Boulay-Coletta Isabelle, MD (*Abstract Co-Author*) Nothing to Disclose
Sophie Anglaret, MD (*Abstract Co-Author*) Nothing to Disclose
Mohamed A. Haouari I, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Pelvic floor dysfunction constitutes a major public health issue. - Fluoroscopic defecography is considered as the best imaging study to explore obstructed defecation. When rectal opacification is combined with vaginal, bladder and small bowel opacification, the examination is called colpocystodefecography (CCD). - Like dynamic pelvic MR, CCD is very useful for identifying different pelvic floor disorders (rectal and pelvic organ prolapses, anismus, descending perineum syndrome?) and the interplay of the different compartments. - Although CCD does not allow pelvic floor muscles study, it provides optimal functional evaluation during defecation reproducing natural conditions for normal defecation (sitting position, soft stool consistency?). For this reason, dynamic pelvic MR and CCD should be considered as complementary examinations, particularly when MR is not conclusive (no rectal emptying obtained). - Good technique is necessary to unmask all the abnormalities presented by the patient, and methodical interpretation in line with the latest recommendations is mandatory to communicate the result of the examination to the prescribing physician in the right terminology and with the right anomalies quantification.

**TABLE OF CONTENTS/OUTLINE**

- Describe the appropriate technique for the realization of the CCD according to the latest recommendations., with tips on how to overcome technical limitations and reduce radiation exposure. - Define the various pelvic floor disorders using pathological CCD exams examples. - Propose a synthetic reporting template using the consensual terminology.

## PHEE-16 EXPLORING UNCHARTED FRONTIERS: ADVANCING BEYOND DIFFUSION TENSOR IMAGING

Robert C. McKinstry III, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Joshua S. Shimony, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tammie S. Benzinger, MD, PhD (*Abstract Co-Author*) Research Grant, Eli Lilly and Company;Investigator, Eli Lilly and Company;Investigator, F. Hoffmann-La Roche Ltd;Consultant, Siemens AG;Research Grant, Siemens AG;Consultant, ADM Diagnostics, LLC;Speakers Bureau, Biogen Idec Inc;Advisory Board, Biogen Idec Inc
Ali Y. Mian, MD (*Abstract Co-Author*) Nothing to Disclose
Zhongwei Zhang, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Diffusion tensor imaging (DTI) has firmly established as a cornerstone in clinic, offering unparalleled insights into brain microstructure. Traditionally employed for acute infarction assessment, it now finds common use in brain tumor treatment planning (tractography), evaluating transient metabolic failure during seizures, and assessing perivascular spaces and glymphatic clearance. The purposes of this Education Exhibit are 1. To offer a comprehensive and visually engaging overview of DTI, enabling readers to develop an intuitive understanding of DTI physics and to recognize its strengths and limitations. 2. Discuss the DTI fundamentals and recent advances towards bolstering the quality, speed, and reliability of data acquisition. 3. Graphically illustrate the underlying principles behind the transformation from directional diffusion data to the tensor matrix. 4. Discuss both qualitative and quantitative DTI measures, along with underlying biophysical mechanisms. 5. Review recent advances beyond traditional DTI, such as DTI-ALPS, FWE-DTI, IVIM-DTI, TBSS, and NODDI, etc.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction; 2. Why is a tensor needed in DTI? 3. DTI Data Acquisition: Echo Planar Imaging and its variants; 4. DTI Data Acquisition: Practical considerations; 5. Diffusion modeling and diffusion tensor Processing; 6. From directional diffusion data to tensor matrix; 7. Understanding the eigenvalues and the eigenvectors; 8. Diffusion Tensor Ellipsoid; 9. The basis of anisotropic water diffusion in the nervous system; 10. Qualitative Measures; 11. Quantitative DTI Measures; 12. Tensor Shape Classification; 13. Principal Diffusion Direction Map; 14. Fiber Tracking; 15. Beyond traditional DTI.

## PHEE-17 HOW CAN WE USE EFFECTIVE ATOMIC NUMBER INFORMATION GENERATED BY PHOTON-COUNTING COMPUTED TOMOGRAPHY? - A PROPOSAL FOR APPLICATION TO DENTAL FORENSICS -

Hiroaki Hayashi, PhD (*Abstract Co-Author*) Research collaboration, Meditec Japan Co., Ltd;Research collaboration, JOB Corporation

Takashi Asahara (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Effective atomic number (Zeff) images can be calculated using photon-counting CT and dual-energy CT.2. The Zeff value of artificial dental materials can be used for dental forensics, because the value is a consistent physical indicator for dental materials and can be obtained with various imaging systems such as photon-counting CT, dual-energy CT and scanogram systems using a photon-counting detector.

**TABLE OF CONTENTS/OUTLINE**

1. Forensic dentistry often confirms the identities of unidentified persons by comparing postmortem dental information with the antemortem treatment history. Zeff values of artificial dental materials provided by photon-counting CT (PC-CT) can improve identification accuracy. 2. Explanation of our algorithm for deriving Zeff images using PC-CT. 3. Accuracy evaluation of Zeff images from a multi-energy CT phantom consisting of known atomic number materials. 4. Phantom experiments using artificial dental materials. The atomic number for each artificial dental material was the same value regardless of the imaging systems, and even when the material was embedded in the dental head phantom, it indicated a consistent value. 5. We proposed a procedure for identifying unidentified persons using dental information for dental forensics. By combining quantitative analysis and qualitative analysis using PC-CT, the identification accuracy of undefined persons can be improved.

## PHEE-18 PHOTON-COUNTING-DETECTOR (STANDARD- AND ULTRA-HIGH-RESOLUTION) VS. ENERGY-INTEGRATING-DETECTOR CT: A PRACTICAL GUIDE TO SELECTING THE RIGHT TECHNOLOGY

Joel G. Fletcher, MD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Pfizer Inc;Research Grant, Takeda Pharmaceutical Company Limited;Consultant, Takeda Pharmaceutical Company Limited;Research Grant, Nextrast, Inc;Consultant, Medtronic plc
Nikkole Weber, ARRT, RT (*Abstract Co-Author*) Nothing to Disclose

Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Joseph R. Swicklik, RT, BS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Photon-counting-detector (PCD) CT offers many advantages over energy-integrating-detector (EID) CT. However, access to PCD-CT is typically limited. Many CT practices face challenges in determining which exams should be performed using PCD-CT. Priority should be given to exams that would benefit patients the most. 2. PCD-CT provides clear benefits for exams requiring high spatial resolution, ultra-low radiation doses, or simultaneous high-resolution/high speed/spectral imaging 3. PCD-CT has not shown clear benefits in exams that only require smooth kernel reconstruction for soft tissue (e.g., routine abdomen and brain) and quantitative spectral imaging. 4. In PCD-CT, the ultra-high-resolution (UHR) mode is usually preferred, but it has limitations in tube capacity and scan speed compared to the standard-resolution (SR) mode.

**TABLE OF CONTENTS/OUTLINE**

1. Background: PCD-CT vs. EID-CT 2. Describe the challenges in choosing between scanners and techniques on PCD-CT: a. UHR vs. SR b. Threshold vs. spectral images c. With or without Sn filter d. Flash mode vs. regular mode e. Metal artifact reduction (MAR) software vs. virtual monochromatic images (VMI) 3. Provide a practical guide on how to choose the right scanner and techniques: a. Compare image quality of PCD-CT (SR and UHR) and EID-CT in phantom scans b. List exam types and provide examples where PCD-CT has or hasn't shown clear benefits over EID-CT c. Describe pros and cons of SR and UHR modes on PCD-CT d. Compare options for MAR: high-energy VMI vs. MAR software vs. threshold high images

## PHEE-19 THE IMPORTANCE OF ACQUIRED RESOLUTION IN THE AGE OF AI RECONSTRUCTIONS

Scott Robertson, PhD (*Abstract Co-Author*) Nothing to Disclose
Dorothy A. Lowell, MD (*Abstract Co-Author*) Nothing to Disclose
Alex K. Smith, PhD, MS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Novel Artificial Intelligence (AI)-assisted reconstructions are becoming more prevalent in all areas of radiology. While these reconstruction algorithms offer several major advantages compared with conventional reconstructions, such as improved image sharpness, higher signal-to-noise ratio (SNR), and overall better image quality, the connection between the acquired resolution and the resulting image resolution has become less apparent. In particular, the improved SNR provided by these AI reconstructions can be leveraged to reduce acquisition time (through reduced averages, increased readout bandwidth, etc.), while still delivering improved image quality. This may lead a naḭve observer to reduce the acquisition resolution in an attempt to further reduce acquisition time. In this exhibit, we will review the connection between acquired, and final (interpolated) image resolution, focusing on how the DL reconstruction enhances the acquired resolution, as well as how reducing the acquisition resolution will negatively impact the final images. Potential pitfalls of reducing acquisition resolution will be demonstrated, and we will show an example of how reducing the acquisition resolution can acquire a BI-RADS non-compliant exam.

**TABLE OF CONTENTS/OUTLINE**

1. Key components of a DL-based reconstruction algorithm, 2. How DL can enhance a conventional acquisition, 3. Comparison of conventional reconstruction to DL-based reconstruction, 4. The effect of reducing acquisition resolution on conventional and DL-based reconstructions, 5. Alternative methods to reduce acquisition time in the age of DL-based reconstructions, 6. Summary

## PHEE-2 DEEP LEARNING FOR SUPER-RESOLUTION IN SCENARIOS WITH INSUFFICIENT PAIRED DATA IN MEDICAL IMAGING

Yuichiro Hayashi, PhD (*Abstract Co-Author*) Nothing to Disclose
Kensaku Mori, PhD (*Abstract Co-Author*) Research Grant, Cybernet Systems Co, Ltd;Intellectual Property, Cybernet Systems Co, Ltd;Research Grant, J Morita Corporation;Intellectual Property, J Morita Corporation;Developer, J Morita Corporation
Masahiro Oda, PhD (*Abstract Co-Author*) Nothing to Disclose
YUNHENG WU (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purposes of our exhibit are:1. To understand the concept of super-resolution (SR).2. To realize generative adversarial network which is a common deep learning model for SR.3. To recognize the challenges of insufficient paired data in performing SR on medical images.4. To learn about some deep-learning methods that overcome the challenge in medical image SR.5. To discuss the potential for future advancements in medical image SR with insufficient paired data.

**TABLE OF CONTENTS/OUTLINE**

Deep Learning-Based Super-Resolution (SR) and Its Applications in Medical Imaging- Introduce what deep learning-based super-Resolution is.- Explain how SR technology is applied to medical images.Deep Learning Model for SR- Introduce what GAN is.- Explain why GAN can be used in SR.Challenge of Insufficient Paired Data- Explain why sufficient paired data is lacking in medical imaging.- Describe the impact of insufficient paired data on deep learning models.Methods for Overcoming Insufficient Paired Data in Medical Image- Data augmentation and paired data creation method through downsampling for SR model training.• Increasing sample diversity through methods such as rotation and flipping.• Creating training data pairs by downsampling HR (High Resolution) images to obtain LR (Low Resolution) images.- Precise registration and coarse-to-fine cascade training method for SR model training.• Improving the quality of training data by improving HR-LR image registration.• Coars-to-fine Cascade training method to gradually enhancing image details while reducing artifacts.Future Prospects and Discussion- Discuss artifacts generated by GAN in medical images.- Explore potential methods to minimize the generation of artifacts.

## PHEE-20 RE-EXPLAINING SOFT TISSUE CONTRAST ON MRI: TISSUE PROPERTY FILTERS

**Awards**
**Certificate of Merit**

Daniel Cornfeld, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The Bloch equations are useful for plotting tissue signal as a function of time for a given pulse sequence but are limited for comparing the signal between tissues. Consequently, many radiologists have limited knowledge of how contrast is generated and disease is detected by the standard pulse sequences used in clinical practice. Through interactive plots and didactic text the exhibit will introduce the concept of tissue property filters as a way understanding what makes tissues and disease bright or dark on images. We explain T1, T2, and PD weighting both quantitatively and qualitatively. The filters are then used to explain how sequence parameters are chosen to optimise contrast between normal tissues and also between normal tissues and disease. Finally, we explain how these concepts are used to design sequences highly sensitive to disease and to understand the limitations of these sequences.

**TABLE OF CONTENTS/OUTLINE**

A. Introduction to tissue property filters B. Explanation of Fast Spin Echo T1, T2, and PD C. Grey matter vs White matter - Contrast in Brain imaging D. Ligaments, Tendons, Fat, and Muscle - Contrast in MSK Imaging E. Quantification of T1, T2, and PD weighting F. Inversion Recovery: Why T2-STIR and T2-FLAIR work G. Inversion Recovery T1: Why T1-FLAIR and MP-RAGE work H. Future applications: Imaging white matter and fascia

## PHEE-21 ULTRASOUND SPATIAL COMPOUNDING AND HARMONIC IMAGING: WHAT ARE THEY AND HOW DO THEY CHANGE THE IMAGE?

Mark D. Sugi, MD (*Abstract Co-Author*) Consultant, Nextrast, Inc;Author with royalties, RELX
Cameron Adler, MD (*Abstract Co-Author*) Nothing to Disclose
Samuel J. Fahrenholtz, PhD (*Abstract Co-Author*) Stockholder, Nano X Imaging
Cole P. Thompson, MD (*Abstract Co-Author*) Nothing to Disclose
Khushnood Hamdani (*Abstract Co-Author*) Nothing to Disclose
William F. Sensakovic, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Understand how harmonic and spatial compound imaging work 2. Learn how harmonic and spatial compound imaging impact image quality3. Determine where harmonic and spatial compound imaging can improve clinical imaging

**TABLE OF CONTENTS/OUTLINE**

1. How does harmonic imaging work?1a. Physics and knobology for harmonic imaging1b. What are the advantages/disadvantages of harmonic imaging?2. How does spatial compound imaging work? 2a. Physics and knobology for harmonic imaging 2b. What are the advantages/disadvantages of compound imaging?3. Can we combine spatial compound imaging and harmonic imaging?3a. What are the advantages/disadvantages of combining? 4. Guidance on clinical usage of harmonic and compound imaging

## PHEE-22 THE USE OF DIAGNOSTIC CT AND MR IN TREATMENT PLANNING FOR TRANS-ARTERIAL RADIOEMBOLIZATION OF HEPATOCELLULAR CARCINOMA--WHAT MEDICAL PHYSICISTS SHOULD KNOW

Huimin Wu, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhihua Qi, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To understand the roles of diagnostic CT and MR in the dosimetry guided treatment planning process for trans-arterial radioembolization of hepatocellular carcinoma (HCC); 2. To recognize the constituent series or sequences of a diagnostic CT and MR liver study based on their purposes and appearance; 3. To properly select the series or sequence to fuse with the non-diagnostic CT (as part of MAA mapping SPECT-CT) in the subsequent treatment planning process

**TABLE OF CONTENTS/OUTLINE**

1. Brief overview of trans-arterial radioembolization of HCC; 2. The value of diagnostic images in treatment planning for trans-arterial radioembolization of HCC; 3. Brief overview of liver's segmental anatomy; 4. Brief overview of liver's vascular anatomy including hepatic arteries, portal veins, and hepatic veins; 5. Typical diagnostic CT liver protocols (a). Different phases of CT scans (b). Key anatomy identified on CT images (c). Appearance and possible artifacts; 6. Typical diagnostic MR liver protocols (focusing on purpose, appearance and possible artifacts for each type of sequences) (a). T2 weighted sequence (b). T1 weighted sequence (c). DIXON sequence (d). Diffusion weighted imaging sequence (e). Other advanced sequences; 7. Rationale for choosing the best series for treatment planning (a). Clinical consideration (b). Image CNR consideration (c). Artifact consideration (d). Image registration consideration.

## PHEE-23 FACTORS AFFECTING CONTRAST ENHANCEMENT IN COMPUTED TOMOGRAPHY IMAGING

**Awards**
**Certificate of Merit**

Giuseppe V. Toia, MD, MS (*Abstract Co-Author*) Research Consultant, General Electric Company;Research Grant, General Electric Company
Sean Rose, PhD (*Abstract Co-Author*) Research Grant, medInt Holdings, LLC;
Kelsey Schluter, BS (*Abstract Co-Author*) Nothing to Disclose
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*) Consultant, Aidoc Medical Ltd;Consultant, Flowhow.ai;Consultant, medInt Holdings, LLC;Consultant, Alara, Inc;Consultant, AstoCT, Inc;Research Grant, General Electric Company;Research Grant, Canon Medical Systems Corporation
Carrie Bartels, RT (*Abstract Co-Author*) Nothing to Disclose
Rachel Bladorn, BS, RT (*Abstract Co-Author*) Nothing to Disclose
Zahra Alyani Nezhad, BSc, MSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

(1) Improper contrast enhancement is a leading motivator for repeated CT examinations. (2) Many interacting factors influence contrast enhancement including physics-based, patient-related and contrast protocol-related. (3) Three physics (beam energy, beam hardening, scan duration), two patient (blood volume, cardiac output), and five contrast prescriptions (contrast volume, injection rate, iodine concentration, scan delay, saline flush) related factors will be quantitatively described giving the reader the ability to quantify the change in contrast enhancement when performing CT protocol optimization to achieve optimal contrast enhancement.

**TABLE OF CONTENTS/OUTLINE**

This education exhibit will provide a survey of how iodinated contrast agent is required for specific CT indications. Then, ten different factors affecting CT enhancement will be described and placed into categories of: physics, patient, or contrast prescription. We will then present a categorization which places each factor into a scalar category (i.e., the factor scales CT number enhancement but doesn't change the form of the enhancement curve in time) and a temporal category (i.e., the factor changes the temporal dynamics of the contrast enhancement curve). When possible, we will present a quantitative model explaining the impact of the factor on CT number enhancement. The interaction between factors will also be described. Lastly, we will present case examples demonstrating the factors described in this exhibit.

## PHEE-24 EXPLANATION OF NON-PHYSICAL VALUES ON SPECTRAL MATERIAL DENSITY MAPS IN CT

**Awards**
**Cum Laude**

Giuseppe V. Toia, MD, MS (*Abstract Co-Author*) Research Consultant, General Electric Company;Research Grant, General Electric Company
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*) Consultant, Aidoc Medical Ltd;Consultant, Flowhow.ai;Consultant, medInt Holdings, LLC;Consultant, Alara, Inc;Consultant, AstoCT, Inc;Research Grant, General Electric Company;Research Grant, Canon Medical Systems Corporation
Aria Salyapongse, BS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Readers of this exhibit will come away understanding: (1) why non-iodine containing tissues (e.g., bone) may have positive iodine (water) material density map values, (2) why a radiologist may see negative material density values, (3) how the choice of bases affects the predicted iodine density in an iodine (water) map for an iodine-containing tissue, and (4) the conditions for material basis choices yielding accurate iodine density values.

**TABLE OF CONTENTS/OUTLINE**

We will begin with a review of basic physics of material decomposition based on Alvarez and Macovski's 1976 work describing how any tissue can be described as a photoelectric and Compton scattering basis. We will then describe how the photoelectric and Compton basis can be extended to material basis pairs to characterize tissue in terms of material basis (i.e., iodine and water). Then we will explain the well-known problem of calcium in iodine (water) images. Then, we will present an explanation of why a radiologist might observe a negative value on a material density map. Next, we will describe how basis pair choice affects the measured iodine in an iodine-containing voxel with different background materials. Finally, we will conclude with a description of the conditions necessary for accurate iodine density based on the choice of basis materials.

## PHEE-25 HOW CAN WE MEASURE BIOLOGICAL VISCOSITY NON-INVASIVELY USING MRI?

Yuki Kanazawa, PhD (*Abstract Co-Author*) Nothing to Disclose
Akihiro Haga, PhD (*Abstract Co-Author*) Nothing to Disclose
Mitsuharu Miyoshi (*Abstract Co-Author*) Employee, General Electric Company
Hiroaki Hayashi, PhD (*Abstract Co-Author*) Research collaboration, Meditec Japan Co., Ltd;Research collaboration, JOB Corporation
Masafumi Harada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tosiaki Miyati, PhD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mayuka Seguchi (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. The viscosity measurement in vivo should be quantitively derived using DWI.2. The higher the viscosity according to material density, the lower the ADC.3. The viscosity depends on both concentration and temperature.4. Conversion of the ADC of biological tissue into viscosity using the DWI-viscosity function, utilizing the linear relationship between ADC and viscosity corresponding to the Stokes-Einstein equation.5. The DWI-viscosity measurement method we developed could be applied to patients with atherosclerotic plaque non-invasively, e.g., undergoing preoperative evaluation for carotid endarterectomy (CEA) or carotid artery stenting (CAS).

**TABLE OF CONTENTS/OUTLINE**

• The Stokes-Einstein equation shows the linear relationship between the diffusion coefficient and viscosity. However, experimentally measuring the viscosity of living cells non-invasively is challenging.• Polymers with viscosity that mimic substances that make up living cells, for example, glycerin solutions.• The DWI viscosity function was determined from the two phantom experiments using glycerin solutions.• The slopes of the linear regression curves in the relationship between ADC and viscosity, that is, the DWI-viscosity function, decreased at elevated temperatures with a significant correlation (All, $R2 > 0.98$).• When comparing DWI viscosity with pathological findings for atherosclerotic plaques, a significant difference was observed between patients with and without symptoms ($P < 0.001$) and hemorrhage findings ($P < 0.05$).

## PHEE-26 ARTIFICIAL INTELLIGENCE: WHAT EVERY RADIOLOGIST SHOULD KNOW

Abhishek Mishra, DO (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Understand the intersection of artificial intelligence and radiology, exploring what exactly defines "artificial intelligence".2) Explore the foundational principles behind the integration of AI in radiology.3) Survey the diverse applications of AI in radiology, from image interpretation and diagnosis, to workflow optimization and more.4) Examine the AI techniques utilized in radiology, such as deep learning, convolutional neural networks, and natural language processing, elucidating their roles in medical images and reports.

**TABLE OF CONTENTS/OUTLINE**

- Introduction to AI in Radiology:
- Define artificial intelligence and its relevance in the field of radiology.
- Discuss the technological advancements that have facilitated the integration of AI into radiology, such as improvements in computational power, availability of large datasets, and development of advanced algorithms.
- Overview of Different Application of AI in Radiology
- Image Interpretation: (1) Computer-Aided Detection (2) Automated Detection (3) Image Segmentation (4) Quantitative Analysis
- Decision Support: (1) Diagnostic Assistance (2) Treatment Planning (3) Risk Stratification
- Workflow Optimization: (1) Prioritization (2) Resource Allocation (3) Automation of Repetitive Tasks (4) Integration with clinical data
- Dictation: (1) Natural Language Processing (2) Contextual Assistance (3) Quality Assurance (4) Automated Reporting
- Review of Key AI Techniques (and examples in current practice)
- Machine learning
- Convolutional neural networks
- Deep Learning
- Natural Language Processing
- Computer Vision
- Knowledge Representation and Reasoning

## PHEE-27 INSIGHTS INTO MSK DECT: ILLUMINATING THE SHADOWS

Elena Canales Lachen (*Abstract Co-Author*) Nothing to Disclose
Jose Acosta Batlle, MD (*Abstract Co-Author*) Nothing to Disclose
Carlos Suevos, MD (*Abstract Co-Author*) Nothing to Disclose
Lucia Martinez De Vega, MD (*Abstract Co-Author*) Nothing to Disclose

Ana M. Vera-Carmona, MD (*Abstract Co-Author*) Nothing to Disclose
Miguel Angel Gomez Bermejo, MD (*Abstract Co-Author*) Nothing to Disclose
Alba Fernandez-Rodriguez, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Develop the potential Spectral CT imaging has in both traumatic and non-traumatic musculoskeletal diseases through a case-based approach.- Explore different Spectral CT maps applied to a varied spectrum of musculoskeletal disorders with a special focus on Virtual Non-Calcium reconstructions correlated with conventional X-rays and MRI scans.- Propose a practical step-by-step post-processing method to display Spectral CT data and optimize color-coded reconstruction maps.- Standardize a basic lexicon to describe findings and avoid pitfalls when reading musculoskeletal Spectral CT scans.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction. 1.1 DECT Imaging Principles. 1.2 DECT Reconstructions Workflow.2. MSK Spectral CT Case-based Approach Learning. 2.1 Traumatic Pathology: 2.1.1. Vertebral fractures. 2.1.2. Scaphoid fractures. 2.1.3. Trochanteric BME. 2.2 Non-traumatic Pathology: 2.2.1. Arthropathies: Gout, CPPD, HAAD. 2.2.2. Bone infection: osteomyelitis. 2.2.3. Bone Metastasis. 2.2.4. Vanishing bone metastasis. 2.2.5. Foreign modeling agent reactions (FMAR).3. Conclusion

## PHEE-28 PHOTON COUNTING CT - WHAT DO WE KNOW AND WHAT CAN WE EXPECT?

Srujana Ganti, MBChB, FRCR (*Abstract Co-Author*) Nothing to Disclose
Bimal Mayur Kumar Vora (*Abstract Co-Author*) Nothing to Disclose
Parag R. Salkade, FRCR,MMed (*Abstract Co-Author*) Nothing to Disclose
Steven B. Wong, MD, MBChB (*Abstract Co-Author*) Nothing to Disclose
Stefanie Lee, MBBS (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1.Explain the technology underpinning Photon Counting CT and discuss the differences between Photon Counting CT and current available CT technology. 2. Discuss the advantages and clinical applications of Photon Counting CT 3.Discuss the potential challenges and considerations that Radiology departments need to take into account before obtaining a Photon Counting CT scanner.

**TABLE OF CONTENTS/OUTLINE**

Photon counting CT is one of the latest developments in CT scanner technology and holds significant promise, in areas of superior image quality and radiation dose reduction. This poster will aim to give an overview of this novel technology and what can be expected, in terms of clinical applications, benefits and potential challenges. The timeline of CT scanner technology development, culminating in the creation of the latest, photon counting CT scanner will be discussed.The poster will also elucidate the fundamental differences between photon counting CT and existing CT technology, such as dual energy CT. Clinical applications and advantages over conventional CT scanning technology will be presented. The poster also aims to discuss some of the potential problems and challenges that Radiology departments may face if they were to obtain this scanner, such as cost and infrastructure considerations.

## PHEE-29 REGULATORY SCIENCE CHALLENGES AND GAPS AT THE FDA FOR RADIOLOGY AI DEVICES

Frank W. Samuelson, PhD (*Abstract Co-Author*) Nothing to Disclose
Nicholas Petrick, PhD (*Abstract Co-Author*) Nothing to Disclose
Aldo Badano, PhD (*Abstract Co-Author*) Research Grant, Barco nv
Kenny H. Cha, PhD (*Abstract Co-Author*) Nothing to Disclose
Alexej Gossmann (*Abstract Co-Author*) Nothing to Disclose
Ravi K. Samala, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Regulatory science is the science of developing tools, methods, and data, including computational approaches, to stimulate innovation and facilitate the scientific regulatory evaluation of medical products. Increased attention and investment in radiology artificial intelligence (AI) enabled software as medical devices (AI-SaMDs) over the last decade has recently led to an exponential increase in AI-enabled devices authorized by the FDA. However, there are inconsistencies between performance results reported in the academic literature and the number and type of devices authorized for clinical use in the US. In this exhibit, we discuss issues related to regulatory science, in (a) data, (b) AI development and (c) AI performance assessment. We provide a comprehensive view of these regulatory science challenges and gaps and describe related Regulatory Science Tools (RSTs) made publicly available to reduce risk of AI development and facilitate consistent and rigorous evaluation.

**TABLE OF CONTENTS/OUTLINE**

Challenges in radiology AI regulatory science are key factors limiting the advancement, development, and deployment of AI-SaMDs. The outline of this presentation is as follows: (1) Addressing patient data access, augmentation approaches using synthetic data, generative AI, and other in silico approaches. (2) Assessing the limitations in AI development including bias, subgroup analysis, continual learning, and post-market monitoring. (3) Developing evaluation methods for novel devices including metric selection, LLM-based devices, and triage, notification and rule-out devices. (4) Deliver resources to support device innovation and patient access to new technologies by use of FDA's RSTs.

## PHEE-3 VISUALIZATION AND PROTECTION OF RADIATION FOR EYE LENS EXPOSED BY SINGLE WEARABLE DOSIMETER

Masaki Fujisawa (*Abstract Co-Author*) Nothing to Disclose
Ryota Shindo (*Abstract Co-Author*) Nothing to Disclose
Koichi Chida, PhD (*Abstract Co-Author*) Nothing to Disclose
Yohei Inaba, PhD, RT (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-To understand the importance of visualizing and monitoring the radiation dose for eye lenses by wearable radio-photoluminescence (RPL) glass dosimeter. -To understand the need for managing the occupational dose to reduce radiation exposure for eye lenses in radiology exams. -To understand the importance of protecting medical staffs or caregivers attending to patients from radiation.

**TABLE OF CONTENTS/OUTLINE**

TABLE OF CONTENTS In this study, we utilized radio-photoluminescence (RPL) silver-activated phosphate glasses as the lens body of over-glass eyewear. The wearable RPL dosimeter developed successfully exhibited RPL emission in proportion to the X-ray irradiation dose. Moreover, we demonstrated the feasibility of the developed dosimeter for visualization and protection at the same time. OUTLINE Growing interest is being paid for local radiation exposure on the human eye triggered by the recommendation given by International Commission on Radiological Protection (ICRP). The risk of cataracts

should be more strictly controlled and managed under the new regulation, effective in Japan in April 2021. Optical observation of the phosphate-glass lens for the wearable device successfully exhibited RPL emission after X-ray irradiation in different schemes, including clinical conditions. To evaluate the radiation shielding functions of the developed wearable RPL dosimeter, commercially available RPL dosimeters were placed in front and backward of the RPL lens during the irradiation. Results suggested that the developed wearable device has the potential to accomplish convenient dosimetry for local radiation exposure for human eyes as well as radiation protection functions in a single wearable device.

## PHEE-4 HOW IMAGE GENERATION AI AND MULTIMODAL AI WORK AND THEIR APPLICATIONS IN CAD

Hirotsugu Takabatake, MD,PhD (*Abstract Co-Author*) Nothing to Disclose

Masahiro Oda, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The purposes of our exhibit are:1. To confirm what are the differences between previous and recent image generation AIs (VAE, GAN vs Diffusion Model (DM))2. To learn applications of DM-based image generation AI in CAD3. To learn what is multimodal AI4. To learn applications of multimodal AI in CAD

### TABLE OF CONTENTS/OUTLINE

Image generation AI- What is image generation AI- Introductions of image generation models: VAE, GAN, Diffusion Model (DM)- Advantages and drawbacks of models- How DM generates imagesApplications of DM-based image generation AIs in CAD- Image generation: Generate variations of tumor images to improve the performance of CAD systems- Segmentation: Segmentation of organ and tumor regions from various medical images- Image translation: Convert image modalities from CT to MR, MR to CT, between MR images of different weighting conditionsMultimodal AI- What is Multimodal AI- Multimodal AIs and their mechanisms: DALL-E 2, Stable Diffusion- How do large multimodal datasets contribute to building multimodal AIApplication of Multimodal AI in CAD- Image explanation generation: Generate texts explaining findings in medical images- Anonymization: Automatically anonymize medical image and text

## PHEE-5 DREAMS AND REALITY IN PHOTON COUNTING CT: CURRENT CAPABILITY OF THE PHOTON COUNTING CT AND FUTURE PROSPECTS

### TEACHING POINTS

Photon counting detector CT (PCD CT) is becoming popular worldwide, and CT vendors other than Siemens Healthineers, which was the first to launch a commercial scanner, are also developing PCDCT. PCDCT is superior to conventional CT in spatial- and low-contrast resolution and is expected to reduce radiation dose. However, there is a limit to the improvement of spatial- and low contrast resolution, and radiation dose cannot be reduced without limitation. Spectral imaging also has various limitations at present. This educational exhibit will outline the current technical capabilities of PCD CT and discuss how we might utilize PCD CT in clinical practice.

### TABLE OF CONTENTS/OUTLINE

1. Current technical issues of PCD CT 1) Charge sharing, 2) K-escape, 3) Compton scatter, 4) Pulse pile-up2. To what extent can PCD CT improve spatial resolution? - limitation factors for spatial resolution3. To what extent can low contrast resolution be improved by PCD CT?4. Current radiation dose reduction in PCD CT5. When will the K-edge imaging be realized?6. Do the detector materials affect the diagnostic capability of PCD CT?7. Which areas of clinical practice will be advanced by introduction of the PCD CT?

## PHEE-6 HOW DO WE DETERMINE THE WATER VOLUME IN THE CENTRAL NERVOUS SYSTEM?

Masafumi Harada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuki Kanazawa, PhD (*Abstract Co-Author*) Nothing to Disclose
Akihiro Haga, PhD (*Abstract Co-Author*) Nothing to Disclose
Ryuji Oshiro (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. T2 signal decay multi-component model: the amplitude of each structural water needs to be determined using a curve fitting.2. The electronic microscope image of myelinated axons can be divided into three water pools: myelin sheath (My), axon (Ax), and intra/extracellular fluid (IE).3. T2 values of each component: My < Ax < IE.4. T2 distribution with different peaks for myelin water and other water components.5. Myelin water fraction (MWF) values have some variations in response to B0 inhomogeneity and multi-echo dataset.

### TABLE OF CONTENTS/OUTLINE

• MWF is calculated using some MR signal models for the central nervous system (CNS), which consists of three structural water pools (myelin sheath, axon, and IE).• Convert process of multi-component water phantom derived from electron microscopic analysis: Machine learning is instrumental.• The data acquisition using MR simulator: Setting pulse sequence and imaging parameters.• The fitting algorithm for the T2 signal decay multi-component model: Each amplitude is derived from the fraction of the divided regions.• Applying numerical MWF phantom for multicomponent CNS relaxometry: Comparison of MWF derived from different imaging parameters and B0 inhomogeneity datasets.

## PHEE-7 THE RADIOLOGY RESIDENT'S GUIDE TO BRAIN MRI: CORE PRINCIPLES OF PHYSICS AND SEQUENCES

**TEACHING POINTS**

Interpreting magnetic resonance imaging requires a basic knowledge of its physical principles, familiarity with the sequences, and understanding their individual significance in the main protocols used in brain studies.This educational review aims to provide a clear, concise, and understandable insight into the physical principles of MRI and the sequences used in the evaluation of the central nervous system (CNS) and their applications in assessing the major brain disorders.Multiple sequences, distinguished by the use of different pulses and gradients, yield information on the nature and behavior of various CNS structures and lesions, enabling a wide range of specific studies (brain tumors, epilepsy, demyelinating diseases, strokes, and cognitive disorders).A solid yet simplified understanding of MRI's physical principles and employed sequences can assist residents in their rotation and enhance their interpretation skills to approach the major CNS conditions.

**TABLE OF CONTENTS/OUTLINE**

Basic principles of MRI physics and sequences: the proton and the magnetic field;what happens in the MRI scanner;what is T1 and T2 relaxation;what is an MRI sequence.Main MRI sequences and their applications in CNS imaging: T1WI, T2WI, DWI, magnetic susceptibility sequences, angiographic and flow imaging, perfusion imaging, spectroscopy, functional MRI and MRI tractography.

## PHEE-8 LOW-DOSE IMAGING USING ULTRA-HIGH RESOLUTION MODE AND ADDED BEAM FILTRATION IN PHOTON-COUNTING-DETECTOR CT

Felix E. Diehn, MD (*Abstract Co-Author*) Nothing to Disclose
Julie B. Guerin, MD (*Abstract Co-Author*) Nothing to Disclose
Lifeng Yu, PhD (*Abstract Co-Author*) Nothing to Disclose
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Joseph R. Swicklik, RT, BS (*Abstract Co-Author*) Nothing to Disclose
Zhongxing Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Kelly K. Horst, MD (*Abstract Co-Author*) Nothing to Disclose
Michael R. Bruesewitz, RT (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Teaching points: 1. PCD-CT improves radiation dose efficiency over EID-CT because of improved photon-energy weighting, increased geometrical efficiency, reduced electronic noise, and small detector effect. 2. Ultra-high-resolution (UHR) acquisition mode on PCD-CT provides a better spatial resolution-noise tradeoff. 3. Added beam filtration such as tin (Sn) filter can further improve radiation dose efficiency in PCD-CT, like in EID-CT 4. Combining UHR and added Sn filter on PCD-CT can achieve ultra-low-dose imaging capability (as low as that in a chest x-ray exam) for some unenhanced CT exams.

**TABLE OF CONTENTS/OUTLINE**

Table of Contents/Outline: 1. Explain the four fundamental physical factors why PCD-CT has a better radiation dose efficiency over EID-CT a. Equal or optimal photon energy weighting b. elimination of septae between detector pixels c. reduced electronic noise d. small detector effect 2. In a phantom experiment, compare image quality and radiation dose efficiency between PCD-CT and EID-CT for multiple settings: a. Standard resolution (SR) vs. UHR mode b. 120 kV vs. 100 kV with Sn filter (100Sn) c. Multiple radiation dose levels d. Multiple reconstruction kernels 3. Demonstrate the feasibility of ultra-low-dose imaging in some un-enhanced patient exams on PCD-CT using both UHR mode and added Sn filter. Radiation dose in some of these exams can approach that in a chest x-ray, i.e., 0.1 mSv. a. Sinus b. Pediatric cystic fibrosis c. Lung cancer screening

## PHEE-9 ADVANCED BODY MRI SEQUENCES AND TECHNIQUES

MASAYA NISHIWAKI (*Abstract Co-Author*) Nothing to Disclose
Hiroaki Kobayashi (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To understand the issues with noise evaluation using Noise Standard Deviation (Noise SD) and Noise Power Spectrum (NPS). To explore apparent noise, a novel approach that addresses the shortcomings of conventional noise evaluation methods. To recognize the advantages of evaluating noise in clinical imaging. To identify the limitations of apparent noise and strategies to overcome them.

### TABLE OF CONTENTS/OUTLINE

A. Limitations of Noise Standard Deviation (SD) : A Simple Measurement Method that Does Not Account for Frequency Information B. Challenges of Noise Power Spectrum (NPS) : Complicated Analysis and Difficulties in Clinical Imaging Applications C. Advantages of Apparent Noise Evaluation D. Application of Apparent Noise Evaluation in Clinical Imaging E. Overcoming the Limitations of Noise SD and NPS with Apparent Noise Evaluation

PHEE-10

## GENERAL RADIOGRAPHY ARTIFACTS: A VISUAL REVIEW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Beth A. Schueler, PhD (*Abstract Co-Author*) Nothing to Disclose
Jill M. Lucas, ARRT, BS (*Abstract Co-Author*) Nothing to Disclose
Zaiyang Long, PhD (*Abstract Co-Author*) Nothing to Disclose
Lindsay Ranschau, BS, ARRT (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Identify radiographic image artifacts participants will learn how to recognize the appearance of image artifacts that may obscure pathology. Investigate the cause of artifacts learners will study potential sources of common artifacts. Implement artifact resolution methods participants will be equipped with practical techniques to minimize artifact occurrence, prompting the production of high-quality radiographic images.

### TABLE OF CONTENTS/OUTLINE

Radiographic artifacts can cause obscured or undiagnostic images, possibly requiring repeat imaging and radiographic room downtime. Our team has gathered image artifacts in many different types of equipment configurations and clinical scenarios. We will describe the investigation and diagnosis of artifact causes as well as resolution methods. Sharing this information with imaging technologists and radiologists will empower them to be able to minimize artifact occurrence and optimize image quality, facilitating accurate diagnosis and clinical decision-making. The following types of artifacts will be reviewed:system hardware-related, system software-related, patient-related, technologist-related, environment-related.

## BEYOND THE BASICS. MRI GADOLINIUM BASED CONTRASTS AGENTS: UPDATES AND GUIDELINES REVIEW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Karly Cristhelly Garrido Estrella, MD (*Abstract Co-Author*) Nothing to Disclose
Ana C. Gandara, MD (*Abstract Co-Author*) Nothing to Disclose
Sofia Arizaga, MD (*Abstract Co-Author*) Nothing to Disclose
Pamela L. Mendieta Rodriguez, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• To describe the classification of contrast agents in Magnetic resonance imaging based on the type and biodistribution.• To explain the main characteristics of Gadolinium.• To review Gadolinium-based contrast agents (GBCAs), describing their generalities and classifications.• To list the early and late adverse reactions GBCAs and explain Gadolinium deposition disease/symptoms associated with Gadolinium exposure, based on the different guidelines of the American College of Radiology (ACR) and European Society of Radiology (ESUR).• To define nephrogenic systemic fibrosis.• To review current recommendations according to ACR and ESUR guidelines on risk assessment, pregnancy, breastfeeding and waiting time between examinations.• To summarize information about the development of new GBCAs.

### TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Contrast agents in Magnetic Resonance Imaging.3. Gadolinium features.4. Gadolinium-Based Contrast Agents (GBCAs): Generalities, classifications, adverse reactions and risk factors, Gadolinium deposition disease (GDD)/symptoms associated with Gadolinium exposure (SAGE), Nephrogenyc systemic fibrosis (NSF), pregnancy and lactation, update and guidelines: risk assessment recommendations, waiting times between examinations recommendations.5. What’s new? Contrast agents in development.6. Conclusions.7. References.

PHEE-12

## DOSE REDUCTION IN INTERVENTIONAL CT PROCEDURES BY OPTIMIZING HELICAL SCAN PARAMETERS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Cum Laude**

Keith B. Quencer, MD (*Abstract Co-Author*) Nothing to Disclose
Matthew B. O'Brien, MD (*Abstract Co-Author*) Nothing to Disclose
Bryan R. Foster, MD (*Abstract Co-Author*) Royalties, RELX;Consultant, RELX
Lindsay S. DeWeese, PHD (*Abstract Co-Author*) Nothing to Disclose
Lindsay N. Douglas, PhD (*Abstract Co-Author*) Nothing to Disclose
Isaac J. Bailey, MS (*Abstract Co-Author*) Nothing to Disclose
Rachel Malinowski (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1) Define common CT procedures, workflow, and different scan mode options for procedures. 2) Discuss image quality requirements for diagnostic versus CT procedures. 3) Review protocol parameters relevant to dose optimization including automatic tube current and iterative reconstruction settings. 4) Identify strategies for CT dose optimization in CT procedures. 5) Understand that adjustments can be made to the helical portion of the procedure to significantly reduce patient dose.

### TABLE OF CONTENTS/OUTLINE

1) CT Procedures a) Common types of CT procedures 2) Scan mode options a) Workflow of procedures b) Helical versus CT scanner interventional scan modes Takeaway 1-2: Knowledge of scan mode options and parameters for common CT procedures is imperative for knowing where optimization is viable. 3) Protocol parameters to be adjusted to optimize the helical scan used in procedures a) Image quality requirements for diagnostic versus CT procedures b) Automatic tube current modulation image quality reference setting c) Iterative reconstruction Takeaway: Parameter adjustments are used to optimize procedure protocols based on image quality requirements. 4) Prior studies that have had success in CT dose optimization 5) Targeting the helical scan success at a single institution and future work a) Adjusting DRI and iDose4 resulted in 30-40% dose reduction b) Utilize what was learned to optimize pediatric procedures Takeaway: Results from a single institution demonstrate the feasibility of optimizing CT procedures.

PHEE-14

## DIXON METHOD AND IN-PHASE/OPPOSED-PHASE IMAGING: CLINICAL UTILITY AND PITFALLS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Aoi Uchida, MD (*Abstract Co-Author*) Nothing to Disclose
Masako Tokuhashi, MD (*Abstract Co-Author*) Nothing to Disclose
Juri Miyaji, MD (*Abstract Co-Author*) Nothing to Disclose
Takashi Katayama, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

In this presentation, our aim is to review the clinical utility and pitfalls of the different types of Dixon methods and in-phase (IP) and opposed-phase (OP) imaging in MRI. The Dixon method and IP/OP MR imaging are routinely used in various fields. Currently, several techniques with different characteristics are used, and there is no one perfect method that is suitable for all purposes. It is important for radiologists to be aware of the characteristics of the different types of Dixon methods, as improper interpretation of the Dixon method can lead to misdiagnosis. However, many radiologists find it difficult to understand the principles of MRI and also to understand how the principles of different techniques affect clinical practice. Simplified explanations or explanations for commercial purposes are provided to doctors, but they may not be sufficient to solve clinical problems. We have made efforts to provide explanations that are easy to understand for radiologists, without sacrificing accuracy, by referring to many clinical cases.

### TABLE OF CONTENTS/OUTLINE

Introduction/ About chemical shift/ IP/OP imaging/ Minimal basics of the Dixon method/ Advantages of the Dixon method 1. Uniform and selective fat suppression 2. Four (+ 1) kinds of images obtained from one scan 3. Quantification of fat and R2* values / Pitfalls 1. Underestimation of both fat and iron deposition (IP/OP imaging) 2. Swapping artifact (Dixon method) 3. Effect of an incomplete signal model (GRE conventional Dixon method) 4. Reversed echo time order (IP/OP imaging) 5. OP signal drop in the TSE Dixon method (TSE Dixon method using acquired data for OP image) 6. IP/OP images in the modified Dixon method / Conclusions

Sophie Anglaret, MD (*Abstract Co-Author*) Nothing to Disclose
Mohamed A. Haouari I, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Pelvic floor dysfunction constitutes a major public health issue. - Fluoroscopic defecography is considered as the best imaging study to explore obstructed defecation. When rectal opacification is combined with vaginal, bladder and small bowel opacification, the examination is called colpocystodefecography (CCD). - Like dynamic pelvic MR, CCD is very useful for identifying different pelvic floor disorders (rectal and pelvic organ prolapses, anismus, descending perineum syndrome?) and the interplay of the different compartments. - Although CCD does not allow pelvic floor muscles study, it provides optimal functional evaluation during defecation reproducing natural conditions for normal defecation (sitting position, soft stool consistency?). For this reason, dynamic pelvic MR and CCD should be considered as complementary examinations, particularly when MR is not conclusive (no rectal emptying obtained). - Good technique is necessary to unmask all the abnormalities presented by the patient, and methodical interpretation in line with the latest recommendations is mandatory to communicate the result of the examination to the prescribing physician in the right terminology and with the right anomalies quantification.

### TABLE OF CONTENTS/OUTLINE

- Describe the appropriate technique for the realization of the CCD according to the latest recommendations., with tips on how to overcome technical limitations and reduce radiation exposure. - Define the various pelvic floor disorders using pathological CCD exams examples. - Propose a synthetic reporting template using the consensual terminology.

### TEACHING POINTS

Diffusion tensor imaging (DTI) has firmly established as a cornerstone in clinic, offering unparalleled insights into brain microstructure. Traditionally employed for acute infarction assessment, it now finds common use in brain tumor treatment planning (tractography), evaluating transient metabolic failure during seizures, and assessing perivascular spaces and glymphatic clearance. The purposes of this Education Exhibit are 1. To offer a comprehensive and visually engaging overview of DTI, enabling readers to develop an intuitive understanding of DTI physics and to recognize its strengths and limitations. 2. Discuss the DTI fundamentals and recent advances towards bolstering the quality, speed, and reliability of data acquisition. 3. Graphically illustrate the underlying principles behind the transformation from directional diffusion data to the tensor matrix. 4. Discuss both qualitative and quantitative DTI measures, along with underlying biophysical mechanisms. 5. Review recent advances beyond traditional DTI, such as DTI-ALPS, FWE-DTI, IVIM-DTI, TBSS, and NODDI, etc.

### TABLE OF CONTENTS/OUTLINE

1. Introduction; 2. Why is a tensor needed in DTI? 3. DTI Data Acquisition: Echo Planar Imaging and its variants; 4. DTI Data Acquisition: Practical considerations; 5. Diffusion modeling and diffusion tensor Processing; 6. From directional diffusion data to tensor matrix; 7. Understanding the eigenvalues and the eigenvectors; 8. Diffusion Tensor Ellipsoid; 9. The basis of anisotropic water diffusion in the nervous system; 10. Qualitative Measures; 11. Quantitative DTI Measures; 12. Tensor Shape Classification; 13. Principal Diffusion Direction Map; 14. Fiber Tracking; 15. Beyond traditional DTI.

### TEACHING POINTS

1. Effective atomic number (Zeff) images can be calculated using photon-counting CT and dual-energy CT.2. The Zeff value of artificial dental materials can be used for dental forensics, because the value is a consistent physical indicator for dental materials and can be obtained with various imaging systems such as photon-counting CT, dual-energy CT and scanogram systems using a photon-counting detector.

### TABLE OF CONTENTS/OUTLINE

1. Forensic dentistry often confirms the identities of unidentified persons by comparing postmortem dental information with the antemortem treatment history. Zeff values of artificial dental materials provided by photon-counting CT (PC-CT) can improve identification accuracy. 2. Explanation of our algorithm for deriving Zeff images using PC-CT. 3. Accuracy evaluation of Zeff images from a multi-energy CT phantom consisting of known atomic number materials. 4. Phantom experiments using artificial dental materials. The atomic number for each artificial dental material was the same value regardless of the imaging systems, and even when the material was embedded in the dental head phantom, it indicated a consistent value. 5. We proposed a procedure for identifying unidentified persons using dental information for dental forensics. By combining quantitative analysis and qualitative analysis using PC-CT, the identification accuracy of undefined persons can be improved.

Joseph R. Swicklik, RT, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Photon-counting-detector (PCD) CT offers many advantages over energy-integrating-detector (EID) CT. However, access to PCD-CT is typically limited. Many CT practices face challenges in determining which exams should be performed using PCD-CT. Priority should be given to exams that would benefit patients the most. 2. PCD-CT provides clear benefits for exams requiring high spatial resolution, ultra-low radiation doses, or simultaneous high-resolution/high speed/spectral imaging 3. PCD-CT has not shown clear benefits in exams that only require smooth kernel reconstruction for soft tissue (e.g., routine abdomen and brain) and quantitative spectral imaging. 4. In PCD-CT, the ultra-high-resolution (UHR) mode is usually preferred, but it has limitations in tube capacity and scan speed compared to the standard-resolution (SR) mode.

### TABLE OF CONTENTS/OUTLINE

1. Background: PCD-CT vs. EID-CT 2. Describe the challenges in choosing between scanners and techniques on PCD-CT: a. UHR vs. SR b. Threshold vs. spectral images c. With or without Sn filter d. Flash mode vs. regular mode e. Metal artifact reduction (MAR) software vs. virtual monochromatic images (VMI) 3. Provide a practical guide on how to choose the right scanner and techniques: a. Compare image quality of PCD-CT (SR and UHR) and EID-CT in phantom scans b. List exam types and provide examples where PCD-CT has or hasn’t shown clear benefits over EID-CT c. Describe pros and cons of SR and UHR modes on PCD-CT d. Compare options for MAR: high-energy VMI vs. MAR software vs. threshold high images

PHEE-19

## THE IMPORTANCE OF ACQUIRED RESOLUTION IN THE AGE OF AI RECONSTRUCTIONS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Scott Robertson, PhD (*Abstract Co-Author*) Nothing to Disclose
Dorothy A. Lowell, MD (*Abstract Co-Author*) Nothing to Disclose
Alex K. Smith, PhD, MS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Novel Artificial Intelligence (AI)-assisted reconstructions are becoming more prevalent in all areas of radiology. While these reconstruction algorithms offer several major advantages compared with conventional reconstructions, such as improved image sharpness, higher signal-to-noise ratio (SNR), and overall better image quality, the connection between the acquired resolution and the resulting image resolution has become less apparent. In particular, the improved SNR provided by these AI reconstructions can be leveraged to reduce acquisition time (through reduced averages, increased readout bandwidth, etc.), while still delivering improved image quality. This may lead a naļve observer to reduce the acquisition resolution in an attempt to further reduce acquisition time. In this exhibit, we will review the connection between acquired, and final (interpolated) image resolution, focusing on how the DL reconstruction enhances the acquired resolution, as well as how reducing the acquisition resolution will negatively impact the final images. Potential pitfalls of reducing acquisition resolution will be demonstrated, and we will show an example of how reducing the acquisition resolution can acquire a BI-RADS non-compliant exam.

### TABLE OF CONTENTS/OUTLINE

1. Key components of a DL-based reconstruction algorithm, 2. How DL can enhance a conventional acquisition, 3. Comparison of conventional reconstruction to DL-based reconstruction, 4. The effect of reducing acquisition resolution on conventional and DL-based reconstructions, 5. Alternative methods to reduce acquisition time in the age of DL-based reconstructions, 6. Summary

## DEEP LEARNING FOR SUPER-RESOLUTION IN SCENARIOS WITH INSUFFICIENT PAIRED DATA IN MEDICAL IMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Yuichiro Hayashi, PhD (*Abstract Co-Author*) Nothing to Disclose
Kensaku Mori, PhD (*Abstract Co-Author*) Research Grant, Cybernet Systems Co, Ltd;Intellectual Property, Cybernet Systems Co, Ltd;Research Grant, J Morita Corporation;Intellectual Property, J Morita Corporation;Developer, J Morita Corporation
Masahiro Oda, PhD (*Abstract Co-Author*) Nothing to Disclose
YUNHENG WU (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The purposes of our exhibit are:1. To understand the concept of super-resolution (SR).2. To realize generative adversarial network which is a common deep learning model for SR.3. To recognize the challenges of insufficient paired data in performing SR on medical images.4. To learn about some deep-learning methods that overcome the challenge in medical image SR.5. To discuss the potential for future advancements in medical image SR with insufficient paired data.

### TABLE OF CONTENTS/OUTLINE

Deep Learning-Based Super-Resolution (SR) and Its Applications in Medical Imaging- Introduce what deep learning-based super-Resolution is.- Explain how SR technology is applied to medical images.Deep Learning Model for SR- Introduce what GAN is.- Explain why GAN can be used in SR.Challenge of Insufficient Paired Data- Explain why sufficient paired data is lacking in medical imaging.- Describe the impact of insufficient paired data on deep learning models.Methods for Overcoming Insufficient Paired Data in Medical Image- Data augmentation and paired data creation method through downsampling for SR model training.• Increasing sample diversity through methods such as rotation and flipping.• Creating training data pairs by downsampling HR (High Resolution) images to obtain LR (Low Resolution) images.- Precise registration and coarse-to-fine cascade training method for SR model training.• Improving the quality of training data by improving HR-LR image registration.• Coars-to-fine Cascade training method to gradually enhancing image details while reducing artifacts.Future Prospects and Discussion- Discuss artifacts generated by GAN in medical images.- Explore potential methods to minimize the generation of artifacts.

PHEE-20

## RE-EXPLAINING SOFT TISSUE CONTRAST ON MRI: TISSUE PROPERTY FILTERS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Certificate of Merit**

Daniel Cornfeld, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The Bloch equations are useful for plotting tissue signal as a function of time for a given pulse sequence but are limited for comparing the signal between tissues. Consequently, many radiologists have limited knowledge of how contrast is generated and disease is detected by the standard pulse sequences used in clinical practice. Through interactive plots and didactic text the exhibit will introduce the concept of tissue property filters as a way understanding what makes tissues and disease bright or dark on images. We explain T1, T2, and PD weighting both quantitatively and qualitatively. The filters are then used to explain how sequence parameters are chosen to optimise contrast between normal tissues and also between normal tissues and disease. Finally, we explain how these concepts are used to design sequences highly sensitive to disease and to understand the limitations of these sequences.

### TABLE OF CONTENTS/OUTLINE

A. Introduction to tissue property filters B. Explanation of Fast Spin Echo T1, T2, and PD C. Grey matter vs White matter - Contrast in Brain imaging D. Ligaments, Tendons, Fat, and Muscle - Contrast in MSK Imaging E. Quantification of T1, T2, and PD weighting F. Inversion Recovery: Why T2-STIR and T2-FLAIR work G. Inversion Recovery T1: Why T1-FLAIR and MP-RAGE work H. Future applications: Imaging white matter and fascia

## THE USE OF DIAGNOSTIC CT AND MR IN TREATMENT PLANNING FOR TRANS-ARTERIAL RADIOEMBOLIZATION OF HEPATOCELLULAR CARCINOMA--WHAT MEDICAL PHYSICISTS SHOULD KNOW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Huimin Wu, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhihua Qi, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To understand the roles of diagnostic CT and MR in the dosimetry guided treatment planning process for trans-arterial radioembolization of hepatocellular carcinoma (HCC); 2. To recognize the constituent series or sequences of a diagnostic CT and MR liver study based on their purposes and appearance; 3. To properly select the series or sequence to fuse with the non-diagnostic CT (as part of MAA mapping SPECT-CT) in the subsequent treatment planning process

### TABLE OF CONTENTS/OUTLINE

1. Brief overview of trans-arterial radioembolization of HCC; 2. The value of diagnostic images in treatment planning for trans-arterial radioembolization of HCC; 3. Brief overview of liver's segmental anatomy; 4. Brief overview of liver's vascular anatomy including hepatic arteries, portal veins, and hepatic veins; 5. Typical diagnostic CT liver protocols (a). Different phases of CT scans (b). Key anatomy identified on CT images (c). Appearance and possible artifacts; 6. Typical diagnostic MR liver protocols (focusing on purpose, appearance and possible artifacts for each type of sequences) (a). T2 weighted sequence (b). T1 weighted sequence (c). DIXON sequence (d). Diffusion weighted imaging sequence (e). Other advanced sequences; 7. Rationale for choosing the best series for treatment planning (a). Clinical consideration (b). Image CNR consideration (c). Artifact consideration (d). Image registration consideration.

Carrie Bartels, RT (*Abstract Co-Author*) Nothing to Disclose
Rachel Bladorn, BS, RT (*Abstract Co-Author*) Nothing to Disclose
Zahra Alyani Nezhad, BSc, MSc (*Presenter*) Nothing to Disclose

### TEACHING POINTS

(1) Improper contrast enhancement is a leading motivator for repeated CT examinations. (2) Many interacting factors influence contrast enhancement including physics-based, patient-related and contrast protocol-related. (3) Three physics (beam energy, beam hardening, scan duration), two patient (blood volume, cardiac output), and five contrast prescriptions (contrast volume, injection rate, iodine concentration, scan delay, saline flush) related factors will be quantitatively described giving the reader the ability to quantify the change in contrast enhancement when performing CT protocol optimization to achieve optimal contrast enhancement.

### TABLE OF CONTENTS/OUTLINE

This education exhibit will provide a survey of how iodinated contrast agent is required for specific CT indications. Then, ten different factors affecting CT enhancement will be described and placed into categories of: physics, patient, or contrast prescription. We will then present a categorization which places each factor into a scalar category (i.e., the factor scales CT number enhancement but doesn’t change the form of the enhancement curve in time) and a temporal category (i.e., the factor changes the temporal dynamics of the contrast enhancement curve). When possible, we will present a quantitative model explaining the impact of the factor on CT number enhancement. The interaction between factors will also be described. Lastly, we will present case examples demonstrating the factors described in this exhibit.

## EXPLANATION OF NON-PHYSICAL VALUES ON SPECTRAL MATERIAL DENSITY MAPS IN CT

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Cum Laude**

Giuseppe V. Toia, MD, MS (*Abstract Co-Author*) Research Consultant, General Electric Company;Research Grant, General Electric Company
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*) Consultant, Aidoc Medical Ltd;Consultant, Flowhow.ai;Consultant, medInt Holdings, LLC;Consultant, Alara, Inc;Consultant, AstoCT, Inc;Research Grant, General Electric Company;Research Grant, Canon Medical Systems Corporation
Aria Salyapongse, BS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Readers of this exhibit will come away understanding: (1) why non-iodine containing tissues (e.g., bone) may have positive iodine (water) material density map values, (2) why a radiologist may see negative material density values, (3) how the choice of bases affects the predicted iodine density in an iodine (water) map for an iodine-containing tissue, and (4) the conditions for material basis choices yielding accurate iodine density values.

### TABLE OF CONTENTS/OUTLINE

We will begin with a review of basic physics of material decomposition based on Alvarez and Macovski's 1976 work describing how any tissue can be described as a photoelectric and Compton scattering basis. We will then describe how the photoelectric and Compton basis can be extended to material basis pairs to characterize tissue in terms of material basis (i.e., iodine and water). Then we will explain the well-known problem of calcium in iodine (water) images. Then, we will present an explanation of why a radiologist might observe a negative value on a material density map. Next, we will describe how basis pair choice affects the measured iodine in an iodine-containing voxel with different background materials. Finally, we will conclude with a description of the conditions necessary for accurate iodine density based on the choice of basis materials.

Masafumi Harada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tosiaki Miyati, PhD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mayuka Seguchi (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. The viscosity measurement in vivo should be quantitively derived using DWI.2. The higher the viscosity according to material density, the lower the ADC.3. The viscosity depends on both concentration and temperature.4. Conversion of the ADC of biological tissue into viscosity using the DWI-viscosity function, utilizing the linear relationship between ADC and viscosity corresponding to the Stokes-Einstein equation.5. The DWI-viscosity measurement method we developed could be applied to patients with atherosclerotic plaque non-invasively, e.g., undergoing preoperative evaluation for carotid endarterectomy (CEA) or carotid artery stenting (CAS).

### TABLE OF CONTENTS/OUTLINE

• The Stokes-Einstein equation shows the linear relationship between the diffusion coefficient and viscosity. However, experimentally measuring the viscosity of living cells non-invasively is challenging.• Polymers with viscosity that mimic substances that make up living cells, for example, glycerin solutions.• The DWI viscosity function was determined from the two phantom experiments using glycerin solutions.• The slopes of the linear regression curves in the relationship between ADC and viscosity, that is, the DWI-viscosity function, decreased at elevated temperatures with a significant correlation (All, $R2 > 0.98$).• When comparing DWI viscosity with pathological findings for atherosclerotic plaques, a significant difference was observed between patients with and without symptoms ($P < 0.001$) and hemorrhage findings ($P < 0.05$).

## ARTIFICIAL INTELLIGENCE: WHAT EVERY RADIOLOGIST SHOULD KNOW

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Abhishek Mishra, DO (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1) Understand the intersection of artificial intelligence and radiology, exploring what exactly defines "artificial intelligence".2) Explore the foundational principles behind the integration of AI in radiology.3) Survey the diverse applications of AI in radiology, from image interpretation and diagnosis, to workflow optimization and more.4) Examine the AI techniques utilized in radiology, such as deep learning, convolutional neural networks, and natural language processing, elucidating their roles in medical images and reports.

### TABLE OF CONTENTS/OUTLINE

- Introduction to AI in Radiology:
- Define artificial intelligence and its relevance in the field of radiology.
- Discuss the technological advancements that have facilitated the integration of AI into radiology, such as improvements in computational power, availability of large datasets, and development of advanced algorithms.
- Overview of Different Application of AI in Radiology
- Image Interpretation: (1) Computer-Aided Detection (2) Automated Detection (3) Image Segmentation (4) Quantitative Analysis
- Decision Support: (1) Diagnostic Assistance (2) Treatment Planning (3) Risk Stratification
- Workflow Optimization: (1) Prioritization (2) Resource Allocation (3) Automation of Repetitive Tasks (4) Integration with clinical data
- Dictation: (1) Natural Language Processing (2) Contextual Assistance (3) Quality Assurance (4) Automated Reporting
- Review of Key AI Techniques (and examples in current practice)
- Machine learning
- Convolutional neural networks
- Deep Learning
- Natural Language Processing
- Computer Vision
- Knowledge Representation and Reasoning

Stefanie Lee, MBBS (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1.Explain the technology underpinning Photon Counting CT and discuss the differences between Photon Counting CT and current available CT technology. 2. Discuss the advantages and clinical applications of Photon Counting CT 3.Discuss the potential challenges and considerations that Radiology departments need to take into account before obtaining a Photon Counting CT scanner.

### TABLE OF CONTENTS/OUTLINE

Photon counting CT is one of the latest developments in CT scanner technology and holds significant promise, in areas of superior image quality and radiation dose reduction. This poster will aim to give an overview of this novel technology and what can be expected, in terms of clinical applications, benefits and potential challenges. The timeline of CT scanner technology development, culminating in the creation of the latest, photon counting CT scanner will be discussed.The poster will also elucidate the fundamental differences between photon counting CT and existing CT technology, such as dual energy CT. Clinical applications and advantages over conventional CT scanning technology will be presented. The poster also aims to discuss some of the potential problems and challenges that Radiology departments may face if they were to obtain this scanner, such as cost and infrastructure considerations.

Kenny H. Cha, PhD (*Abstract Co-Author*) Nothing to Disclose
Alexej Gossmann (*Abstract Co-Author*) Nothing to Disclose
Ravi K. Samala, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Regulatory science is the science of developing tools, methods, and data, including computational approaches, to stimulate innovation and facilitate the scientific regulatory evaluation of medical products. Increased attention and investment in radiology artificial intelligence (AI) enabled software as medical devices (AI-SaMDs) over the last decade has recently led to an exponential increase in AI-enabled devices authorized by the FDA. However, there are inconsistencies between performance results reported in the academic literature and the number and type of devices authorized for clinical use in the US. In this exhibit, we discuss issues related to regulatory science, in (a) data, (b) AI development and (c) AI performance assessment. We provide a comprehensive view of these regulatory science challenges and gaps and describe related Regulatory Science Tools (RSTs) made publicly available to reduce risk of AI development and facilitate consistent and rigorous evaluation.

### TABLE OF CONTENTS/OUTLINE

Challenges in radiology AI regulatory science are key factors limiting the advancement, development, and deployment of AI-SaMDs. The outline of this presentation is as follows: (1) Addressing patient data access, augmentation approaches using synthetic data, generative AI, and other in silico approaches. (2) Assessing the limitations in AI development including bias, subgroup analysis, continual learning, and post-market monitoring. (3) Developing evaluation methods for novel devices including metric selection, LLM-based devices, and triage, notification and rule-out devices. (4) Deliver resources to support device innovation and patient access to new technologies by use of FDA's RSTs.

## VISUALIZATION AND PROTECTION OF RADIATION FOR EYE LENS EXPOSED BY SINGLE WEARABLE DOSIMETER

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Masaki Fujisawa (*Abstract Co-Author*) Nothing to Disclose
Ryota Shindo (*Abstract Co-Author*) Nothing to Disclose
Koichi Chida, PhD (*Abstract Co-Author*) Nothing to Disclose
Yohei Inaba, PhD, RT (*Presenter*) Nothing to Disclose

### TEACHING POINTS

-To understand the importance of visualizing and monitoring the radiation dose for eye lenses by wearable radio-photoluminescence (RPL) glass dosimeter. -To understand the need for managing the occupational dose to reduce radiation exposure for eye lenses in radiology exams. -To understand the importance of protecting medical staffs or caregivers attending to patients from radiation.

### TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS In this study, we utilized radio-photoluminescence (RPL) silver-activated phosphate glasses as the lens body of over-glass eyewear. The wearable RPL dosimeter developed successfully exhibited RPL emission in proportion to the X-ray irradiation dose. Moreover, we demonstrated the feasibility of the developed dosimeter for visualization and protection at the same time. OUTLINE Growing interest is being paid for local radiation exposure on the human eye triggered by the recommendation given by International Commission on Radiological Protection (ICRP). The risk of cataracts should be more strictly controlled and managed under the new regulation, effective in Japan in April 2021. Optical observation of the phosphate-glass lens for the wearable device successfully exhibited RPL emission after X-ray irradiation in different schemes, including clinical conditions. To evaluate the radiation shielding functions of the developed wearable RPL dosimeter, commercially available RPL dosimeters were placed in front and backward of the RPL lens during the irradiation. Results suggested that the developed wearable device has the potential to accomplish convenient dosimetry for local radiation exposure for human eyes as well as radiation protection functions in a single wearable device.

### TEACHING POINTS

Photon counting detector CT (PCD CT) is becoming popular worldwide, and CT vendors other than Siemens Healthineers, which was the first to launch a commercial scanner, are also developing PCDCT. PCDCT is superior to conventional CT in spatial- and low-contrast resolution and is expected to reduce radiation dose. However, there is a limit to the improvement of spatial- and low contrast resolution, and radiation dose cannot be reduced without limitation. Spectral imaging also has various limitations at present. This educational exhibit will outline the current technical capabilities of PCD CT and discuss how we might utilize PCD CT in clinical practice.

### TABLE OF CONTENTS/OUTLINE

1. Current technical issues of PCD CT 1) Charge sharing, 2) K-escape, 3) Compton scatter, 4) Pulse pile-up2. To what extent can PCD CT improve spatial resolution? - limitation factors for spatial resolution3. To what extent can low contrast resolution be improved by PCD CT?4. Current radiation dose reduction in PCD CT5. When will the K-edge imaging be realized?6. Do the detector materials affect the diagnostic capability of PCD CT?7. Which areas of clinical practice will be advanced by introduction of the PCD CT?

Giovanni Mattiello, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Interpreting magnetic resonance imaging requires a basic knowledge of its physical principles, familiarity with the sequences, and understanding their individual significance in the main protocols used in brain studies.This educational review aims to provide a clear, concise, and understandable insight into the physical principles of MRI and the sequences used in the evaluation of the central nervous system (CNS) and their applications in assessing the major brain disorders.Multiple sequences, distinguished by the use of different pulses and gradients, yield information on the nature and behavior of various CNS structures and lesions, enabling a wide range of specific studies (brain tumors, epilepsy, demyelinating diseases, strokes, and cognitive disorders).A solid yet simplified understanding of MRI's physical principles and employed sequences can assist residents in their rotation and enhance their interpretation skills to approach the major CNS conditions.

### TABLE OF CONTENTS/OUTLINE

Basic principles of MRI physics and sequences: the proton and the magnetic field;what happens in the MRI scanner;what is T1 and T2 relaxation;what is an MRI sequence.Main MRI sequences and their applications in CNS imaging: T1WI, T2WI, DWI, magnetic susceptibility sequences, angiographic and flow imaging, perfusion imaging, spectroscopy, functional MRI and MRI tractography.

Zhongxing Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Kelly K. Horst, MD (*Abstract Co-Author*) Nothing to Disclose
Michael R. Bruesewitz, RT (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Teaching points: 1. PCD-CT improves radiation dose efficiency over EID-CT because of improved photon-energy weighting, increased geometrical efficiency, reduced electronic noise, and small detector effect. 2. Ultra-high-resolution (UHR) acquisition mode on PCD-CT provides a better spatial resolution-noise tradeoff. 3. Added beam filtration such as tin (Sn) filter can further improve radiation dose efficiency in PCD-CT, like in EID-CT 4. Combining UHR and added Sn filter on PCD-CT can achieve ultra-low-dose imaging capability (as low as that in a chest x-ray exam) for some unenhanced CT exams.

### TABLE OF CONTENTS/OUTLINE

Table of Contents/Outline: 1. Explain the four fundamental physical factors why PCD-CT has a better radiation dose efficiency over EID-CT a. Equal or optimal photon energy weighting b. elimination of septae between detector pixels c. reduced electronic noise d. small detector effect 2. In a phantom experiment, compare image quality and radiation dose efficiency between PCD-CT and EID-CT for multiple settings: a. Standard resolution (SR) vs. UHR mode b. 120 kV vs. 100 kV with Sn filter (100Sn) c. Multiple radiation dose levels d. Multiple reconstruction kernels 3. Demonstrate the feasibility of ultra-low-dose imaging in some un-enhanced patient exams on PCD-CT using both UHR mode and added Sn filter. Radiation dose in some of these exams can approach that in a chest x-ray, i.e., 0.1 mSv. a. Sinus b. Pediatric cystic fibrosis c. Lung cancer screening

### TEACHING POINTS

Review various forms of accelerated image acquisition. Discuss different methods for improving image quality. Address abdominopelvic applications of deep learning. Learn with real clinical applications and case examples

### TABLE OF CONTENTS/OUTLINE

1. Introduction a. Discuss vendors and proprietary sequence naming b. Stress importance of innovation and constant improvement for high quality body MRI 2. Sequences and techniques with physics explanations and example applications A. Keyhole Imaging i. HCC screening ii. To counter transient tachypnea with Eovist B. Compressed Sensing i. Breath-hold MRCP ii. Urography C. Radial acquisition a. Motion resistant T2b. High-resolution post contrast imaging D. Radial + Compressed Sensing i. Free breathing post contrast imaging ii. Dynamic contrast enhancement (prostate) E. Motion corrected subtraction F. Simultaneous Multi-Slice i. Acceleration ii. Increased NEX for same time G. Zoomed Diffusion i. Advantages over standard diffusion ii. Prostate, kidney, pancreas H. Readout Segmented Diffusion i. Reduction of susceptibility artifact ii. Rectal, prostate I. Deep Learning i. Advantages, disadvantages ii. Large FOV spin echo iii. Small FOV spin echo iv. Single shot spin echo 3. Miscellaneous Quality Improvement i. Microenema ii. FOV control iii. Secretin for duodenal masses iv. Saturation bands v. Dark oral contrast 4. Conclusion and References

ROEE

## Radiation Oncology Education Exhibits

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Sub-Events**

### ROEE-1 NAVIGATING THE MAZE: EVALUATING IMAGING FEATURES POST CHEMORADIATION IN GLIOBLASTOMA MULTIFORME

Thomaz R. Mostardeiro, MD (*Abstract Co-Author*) Nothing to Disclose
Mike Dohopolski, MD (*Abstract Co-Author*) Nothing to Disclose
Fabricio S. Feltrin, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza G. Schmitt, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Glioblastoma multiforme (GBM) is the most common primary brain malignancy in adults. Treatment involves maximal surgical resection followed by adjuvant chemoradiation. Stereotactic Ablative Radiotherapy (SABR) is a new, evolving paradigm, in the adjuvant management of newly diagnosed GBM. Post-treatment imaging features include: tumoral pseudo-progression, progression outside the radiation field, progression inside the radiation field, complete resolution, partial response, and treatment-induced changesTumoral pseudo-progression in GBM poses challenges on follow-up imaging, often mimicking solid tumor enhancement. It's more common with SABR.Perfusion and diffusion-weighted imaging are crucial in distinguishing pseudo-progression from recurrence. GBM recurrence typically exhibits high perfusion (highly vascular nature) and restricted diffusion (ADC values lower than 1300 x 10-6 mm2/s), while pseudo-progression shows lower perfusion and higher ADC values. Tumoral morphological features (e.g., increased infiltration) tend to represent tumor growth, while a well-defined margin is more common in pseudo-progression. Early recognition and differentiation of imaging features are essential for timely intervention in patients with incomplete response/recurrence.

**TABLE OF CONTENTS/OUTLINE**

1- Introduction 2- Radiation Therapy in Glioblastoma Multiforme 3- Monitoring treatment response after chemoradiation 4- Neuroimaging findings after chemoradiation: 4.1) Tumoral pseudo-progression; 4.2) Progression outside the radiation field; 4.3) Progression inside the radiation field; 4.4) Complete resolution; 4.5) Partial response; 4.6) Treatment-induced changes. 5- Summary

### ROEE-2 PRE-TREATMENT AND POST-TREATMENT IMAGING OF LARYNX CARCINOMA: RADIOLOGIC AND LARYNGOSCOPIC CORRELATION

Philip R. Chapman, MD (*Abstract Co-Author*) Nothing to Disclose
Edina C. Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Zack Nigogosyan, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Describe the work-up and staging for larynx carcinoma 2. Explore laryngoscopic and radiographic imaging (ex. CT, PET) correlation in larynx carcinoma 3. Discuss how laryngoscopic and radiographic findings affect the work-up and management of larynx carcinoma 4. Understand imaging considerations for treatment planning and delivery of radiation therapy for larynx carcinoma 5. At the completion of this course, the participant will be able to: •Understand the role of laryngoscopy and radiologic imaging in the work-up and staging for localized larynx carcinoma •Determine situations in which findings on laryngoscopy and imaging may provide complementary information in affecting target delineation and subsequent radiation treatment •Understand imaging features post-treatment since it can be difficult to differentiate post-treatment changes from residual tumor or recurrent tumor •Understand common surveillance imaging techniques used to monitor treatment side effects

**TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Work-up for larynx carcinoma 3. Clinical examination, laryngoscopic and radiographic findings correlation in relation to management 4. Radiation treatment planning considerations in larynx carcinoma 5. Imaging with laryngoscopic correlation of larynx cancer after treatment 6. Methods of monitoring treatment response with clinical examination, CT neck and PET/CT 7. Common surveillance imaging techniques (ex. carotid ultrasound, CT chest) used to monitor treatment side effects 8. Summary

### ROEE-3 MUSCULOSKELETAL COMPLICATIONS OF RADIATION THERAPY AND IMMUNOTHERAPY

Arash Azhideh, MD, MPH (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Identify the role of imaging in evaluation of post-therapeutic complications affecting musculoskeletal (MSK) system in the cases of radiation therapy and immunotherapy· Describe the MSK complications in response to immunotherapy· Discuss post-radiation imaging findings

**TABLE OF CONTENTS/OUTLINE**

Musculoskeletal complications can occur as a result of exposure to bone and soft tissues surrounding the radiation area. It can manifest acutely during radiotherapy or afterward. These include alteration in bone density, pathologic fractures, osteonecrosis, or late post-radiation induced neoplasms. Immunotherapy is another revolutionary approach to cancer treatment with novel mechanism of action with T-cell and immune activation against cancer cells. Immune-mediated adverse effects affecting the muscles, bones, joints, and connective tissue lead to different patterns of findings on imaging. We aim to assess the post-immunotherapy and post-radiation imaging findings that affect the musculoskeletal system:§ Post- immunotherapy:· Arthritis/polyarthritis· Tenosynovitis· Myositis/necrotizing myositis· Fasciitis· Enthesopathy· Rhabdomyolysis· Chondrocalcinosis· Fracture (osteoporotic)· Osteitis§ Post-radiation changes:ü Bone and joints:· Osteonecrosis· Pathologic fracture· Radiation-induced neoplasms: osteochondroma, sarcoma· Osteopenia· Increased bone density· Sacroiliac joint abnormalities (widening, irregularity)· Radiation-induced osteochondroma· Bone marrow reconversion· Bone marrow osteitis· Growth impairment and physeal injuryü Soft tissue:· Soft tissue fibrosis· Myositis· Recall myositis· Lymphedema· Dystrophic soft tissue calcification· Secondary sarcoma

## ROEE-4 IMAGING FOR PANCREAS RADIATION PLANNING

Yulia Romalis, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

To elucidate which radiographic features are important in radiation therapy treatment planning and how these finding influence management.

**TABLE OF CONTENTS/OUTLINE**

Understand the CT Protocol for Pancreas Cancer?Define the resectability criteria for pancreas cancer?Identify resectable, borderline, and unresectable pancreas lesions on CT and MR imaging?Understand the generic process of pancreas cancer radiation volumes, dosing, and importance of accurate GTV delineation for dose escalation particularly in unresectable cases

## ROEE-5 RADIATION-INDUCED IMAGING CHANGES OF THORACOLUMBAR SPINE: WHAT RADIOLOGISTS NEED TO KNOW?

Mengya Sun (*Abstract Co-Author*) Nothing to Disclose
Guanglei Tang, MBBS (*Abstract Co-Author*) Nothing to Disclose
Yang Peng (*Abstract Co-Author*) Nothing to Disclose
Chang Li (*Abstract Co-Author*) Nothing to Disclose
Jian Guan, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To review the pathological changes and imaging appearance of thoracolumbar spine after radiotherapy; 2. To know special imaging appearance of thoracolumbar spine after radiotherapy; 3. To realize the relationship between involved extent of spine after radiotherapy and radiation disease; 4. To learn diagnosis and differential diagnosis for radiotherapy related complications by imaging appearance of thoracolumbar spine

**TABLE OF CONTENTS/OUTLINE**

1. Pathological changes and routine imaging appearance: (1) Pathological changes of thoracolumbar spine after radiotherapy; (2) CT and MRI appearance of thoracolumbar spine after radiotherapy during different periods 2. Special imaging appearance: (1) Imaging appearance of thoracolumbar spine after radiotherapy for different tumors (thoracic tumor, abdominal tumor and pelvic tumor); (2) Imaging appearance of thoracolumbar spine after special radiotherapy (radioactive stent, radio- active particles, et al); 3. Relationship between involved extent of spine after radiotherapy and radiation disease: (1) Assistance for diagnosis of recent radiation diseases; (2) Assistance for diagnosis of long-term complications; (3) Assistance for differential diagnosis of radiation diseases; (4) Assistance for therapeutic evaluation (such as ovarian suspension, tumor metastasis or recurrence, et al)

## ROEE-6 QA ASPECTS OF MRI FOR STEREOTACTIC RADIOSURGERY

Joshua P. Yung, PhD (*Abstract Co-Author*) Nothing to Disclose
R. Jason Stafford, PhD (*Abstract Co-Author*) Nothing to Disclose
Tina Briere, PHD (*Abstract Co-Author*) Nothing to Disclose
Chris M. Walker, PhD (*Presenter*) Researcher, Siemens AG

**TEACHING POINTS**

1. Understand the physical principles behind geometric distortions in MRI and how to reduce them. 2. Appreciate the rigorous quality assurance needed to reliable generate images with geometric fidelity sufficient for radiosurgery. 3. Know how to evaluate an imaging study to ensure it is of sufficient accuracy to be utilized for treatment planning.

**TABLE OF CONTENTS/OUTLINE**

1. An overview of stereotactic radiosurgery in focused on the brain. 2. A description of the physical processes that lead to geometric distortion in MRI images. 3. System quality control measures to ensure geometric accuracy. 4. Protocol design characteristics to ensure geometric accuracy. 5. Case studies and experience sharing from our institutions brain radiosurgery practice.

## ROEE-7 RADIATION PNEUMONITIS IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS WITH ARTIFICIAL-INTELLIGENCE SCREENED INTERSTITIAL LUNG DISEASE

Chris McIntosh (*Abstract Co-Author*) Nothing to Disclose
Andrea Bezjak, MD (*Abstract Co-Author*) Nothing to Disclose

### TEACHING POINTS

Define vascular compression syndromes and explain their significance.List common vascular compression syndromes (like Thoracic Outlet Syndrome, Nutcracker Syndrome, etc.), detailing the neurovascular structures involved in each syndrome.Discuss typical clinical manifestations that correlate with each affected structure, enhancing clinical relevance.Emphasize the role of CT imaging in the diagnosis of these syndromes, providing examples of key CT features for different syndromes.Use images to illustrate typical radiological signs that aid in the diagnosis.Include brief case studies where specific CT features led to a diagnosis.Encourage vigilance and thorough assessment using CT imaging for patients presenting with symptoms suggestive of vascular compression.

### TABLE OF CONTENTS/OUTLINE

IntroductionDefinition of vascular compression SyndromesOverview of vascular compression SyndromesDefinition and general pathophysiologyExamples of common SyndromesAffected neurovascular structuresDetailed list of neurovascular structures commonly entrappedCorrelation with anatomical locationsClinical manifestationsSymptoms associated with each SyndromeHow these symptoms correlate with the entrapped structuresRole of CT Imaging in diagnosisAdvantages of using CT imagingComparison with other diagnostic modalitiesSpecific CT findings for each SyndromeVisual aids: Diagrams and images demonstrating typical featuresManagement and Treatment OverviewGeneral treatment approachesImportance of early diagnosis and interventionConclusion

## VAEE-11 RADIOLOGISTS TOOLKIT: MULTIMODAL ASSESEMENT AND TREATMENT OF RENAL VASCULATURE PAHOLOGY

Luis Enrique Nunez Castellanos (*Abstract Co-Author*) Nothing to Disclose
Augstin Z. Guzman Mercado, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Describe normal renal vasculature anatomy, common variants and its clinical significance.• Understand normal nephrogram on contrast enhanced CT, radiologic signs translating on pathologic entities.• Learn the main findings on the multiple imaging methods including ultrasound, CEUS, CT, MR, Gammagram and Angiography.• Describe epidemiology, pathogenesis, etiology main imaging features, the main vascular pathologies• Understand the current role of the radiologist in the diagnosis and treatment of renal vascular pathologies.

### TABLE OF CONTENTS/OUTLINE

• Anatomy: normal anatomy, anatomical variants,• Multimodal approach: Ultrasound, Doppler, CEUS, computed tomography• Epidemiology, pathogenesis, etiology, main imaging features and treatment of vascular pathology.• Venous pathology: thrombosis, tumor thrombosis, compression syndromes.• Arterial pathology: fibromuscular dysplasia, stenosis, occlusion, pseudoaneurysm, arteriovenous fistula, active bleeding.• Endovascular treatment: Dianostic angiography, stenosis angioplasty, pseudoaneurysm / arteriovenous fistula embolization, active bleeding embolization.

## VAEE-12 VENOUS ANEURYSMS

**Awards**

Sudhakar K. Venkatesh, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Safa Hoodeshenas, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1)To highlight the clinical significance of venous aneurysms with focus on their potential complications.2)To discuss the role of multimodality imaging in the evaluation of venous aneurysms3)To illustrate various types of venous aneurysms with case examples4)To describe the interventional management of venous aneurysms

**TABLE OF CONTENTS/OUTLINE**

1) Definition2) Classification of venous aneurysms3) Pathophysiology and risk factors4) Complications- thrombosis, infection, rupture, and pulmonary embolism5) Role of Imaging- Ultrasound, CT, MRI, Nuclear medicine, venography (CTV, MRV, DSA)6) Interventional management of venous aneurysms- Indications, types7) Pictorial review of venous aneurysms• Abdominal veins: Splenic, Portal, Superior Mesenteric, Hepatic Veins, Inferior Vena Cava, Iliac Veins• Thoracic veins: Pulmonary Veins, Superior Vena Cava, Azygos vein, brachiocephalic vein, Chest wall veins (embryonic and dorsal scapular veins)• Upper and lower extremities: Superficial and Deep, Popliteal Vein, Subclavian Vein, Perforator Veins• Cerebral, Head and Neck Veins- Internal Jugular Vein, Calcarine, Vein of Galen

## VAEE-13 UNVEILING ABDOMINAL VASCULAR COMPRESSION SYNDROMES: WHAT THE RADIOLOGIST NEEDS TO KNOW?

Natalia H. Concatto, MD (*Abstract Co-Author*) Nothing to Disclose
Samuel Freitas (*Abstract Co-Author*) Nothing to Disclose
Henrique M. Guerra, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- Abdominal vascular compression syndromes comprise a diverse group of conditions characterized by either the compression of a vascular structure or an anatomical structure being compressed by a vessel.- Computed tomography is integral to the diagnostic process, providing crucial imaging data that aids radiologists in identifying these syndromes.- However, it is important to note that imaging findings associated with vascular compression can frequently appear in asymptomatic individuals, raising concerns about potential overdiagnosis.- Therefore, a comprehensive diagnostic approach, incorporating clinical symptoms and additional testing, is essential to ensure accurate diagnosis and appropriate management of vascular compression syndromes.

**TABLE OF CONTENTS/OUTLINE**

1. Introduction:- Definition and scope of vascular compression syndromes- Importance of computed tomography (CT) in the diagnostic.2. Radiological Considerations of each syndrome- Key imaging findings for each syndrome- Role of CT imaging in detailed anatomical assessment.3. Clinical Approach- Common symptoms and clinical manifestations- Importance of correlating imaging findings with clinical symptoms and additional diagnostic tests.4. Conclusion- Future directions in imaging techniques and clinical management of vascular compression syndromes.

## VAEE-14 UNTANGLE THE YARN BALL: A WALKTHROUGH MAJOR VASCULAR MALFORMATIONS

**TEACHING POINTS**

Review the 2018 ISSVA Classification of Vascular Anomalies.Review CT and MR imaging protocol for vascular analysis.Review the imaging characteristics of common vascular anomalies.Propose an algorithmic imaging evaluation of vascular malformations.Expose illustrative cases of vascular malformations and their clinical correlations.

**TABLE OF CONTENTS/OUTLINE**

2018 ISSVA Classification of Vascular Anomalies: - Vascular tumors. - Vascular malformations: Simple; Combined; Vascular anomalies of major named vessels; Vascular anomalies associated with others anomalies. - Unclassified anomalies. Explanation and exemplification of non-central nervous system vascular malformations. Subdivision of vascular malformations into high-flow and low-flow and their imaging characteristics. CT and MR protocols and reconstruction techniques, systematically mentioned in the interpretation of our cases. Imaging findings of vascular malformations across modalities (computerized tomography, magnetic resonance imaging, ultrasound and Doppler). Correlation beetween imaging and clinical signs of non-central nervous system vascular malformations. Practical information for effective reporting and necessary information for intervention planning.

## VAEE-15 PRECISION IN RECONSTRUCTIVE SURGERY: CHARTING PERFORATOR ARTERIES WITH CT

**Awards**

Janaina Moreira (*Abstract Co-Author*) Nothing to Disclose
Marcos Antonio Tebet Filho (*Abstract Co-Author*) Nothing to Disclose
Luana Paschoal, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

The rising occurrence of end-stage renal disease and its impact on healthcare have spurred increased attention to vascular access provision. Hemodialysis vascular access is the predominant method for renal replacement therapy, primarily achieved through arteriovenous fistula creation.An arteriovenous fistula is established by connecting a native artery to a vein, with the goal of providing long-term access for hemodialysis in individuals with end-stage renal disease until they can undergo a kidney transplant. Typically conducted in the upper extremities, preferably the non-dominant arm, the most common connections are made between the radial artery and the cephalic vein.When conducted with meticulous methodology, ultrasound assessment of AV access enables thorough evaluation from its inception to potential complications, like failure of maturation, stenotic vascular lesions, thrombosis, hematoma, aneurysms or pseudoaneurysms, and infection.

### TABLE OF CONTENTS/OUTLINE

- Review expected ultrasound findings expected for a patent arteriovenous fistula for hemodialysis.- Evaluate the most common complications and their presentation on ultrasound.

## VAEE-18 CT ASSESSMENT OF ENDOLEAKS AFTER ENDOVASCULAR AORTIC ANEURYSM REPAIR: AN UPDATED REVIEW

Fabiana Campos, MD (*Abstract Co-Author*) Nothing to Disclose
Thiago Vieira, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jose de Arimateia B. Araujo Filho, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Roddie Moraes Neto, MD (*Abstract Co-Author*) Nothing to Disclose
Rodrigo Azambuja, MD (*Abstract Co-Author*) Nothing to Disclose
Daniel L. Cardoso, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Recognize the imaging anatomy of the abdominal aorta (AA) and its main branches. Understand the primary concepts related to the clinical and surgical management of abdominal aortic aneurysm (AAA). Familiarize with the main aspects of the pre- and post-operative imaging evaluation of AAA. Recognize endovascular aneurysm repair (EVAR) complications, with focus on endoleaks. Comprehend the key principles and potential applications of artificial intelligence (AI) for prediction and detection of complications after EVAR, including endoleak.

### TABLE OF CONTENTS/OUTLINE

1. INTRODUCTION: AA and its branches anatomy and relationship with other abdominal structures. AAA imaging patterns on Computed Tomography Angiography (CTA). AAA criteria to intervene and how to proceed (open surgery x EVAR). How to evaluate and follow the patient after surgery. EVAR complications. 2. DIAGNOSIS AND IMAGING FINDINGS: Endoleak - What are the mechanisms? How to identify How to proceed? 3. FUTURE PERSPECTIVES: ARTIFICIAL INTELLIGENCE: AI for diagnosing and predicting EVAR complications. 4. SUMMARY AND SYSTEMATIC APPROACH. 5. TAKE HOME MESSAGES.

## VAEE-19 IMAGING FINDINGS OF INFLAMMATORY AND INFECTIOUS CONDITIONS OF THE AORTA

Thiago Vieira, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Publio C. Viana, MD (*Abstract Co-Author*) Nothing to Disclose
Alexandre Pasquali (*Abstract Co-Author*) Nothing to Disclose
Davi D. Romao, MD (*Abstract Co-Author*) Nothing to Disclose
Vitor D. Bichuette, MD (*Abstract Co-Author*) Nothing to Disclose
Alexandre M. Pereira, MD (*Abstract Co-Author*) Nothing to Disclose
Rodrigo Azambuja, MD (*Abstract Co-Author*) Nothing to Disclose
Luana Silva, MD (*Abstract Co-Author*) Nothing to Disclose
Paola Beninca, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Aorta can be affected by inflammatory and infectious conditions.Radiologists play a crucial role in early recognition and prompt treatment, which are essential to prevent complications and improve patient outcomes.Distinguishing between these affections solely by image finginds can be difficult because aortitis imaging can vary depending on the underlying cause and the specific type of aortitis. The purpose of this exibition is to:- Recognize the various diseases and pathogens involved in aortitis.- Review imaging findinds of aortitis (inflamatory and infectious).- How to differentiate different diseases involving the aorta by image.

### TABLE OF CONTENTS/OUTLINE

1) Introduction2) Types of aortitis and their different examples3) Large, medium and small vessel vasculites4) Other conditious and infections conditions that affects the aorta5) Infectious conditions of the aorta

## VAEE-2 PORTAL VEIN FLOW AND HEPATIC TRANSPLANT: UNDERSTANDING REGENERATION MECHANISMS AND HOW TO CALCULATE IT - A TUTORIAL

Nicolas Bastidas (*Abstract Co-Author*) Nothing to Disclose
Estefan Ramos Isaza, MD (*Abstract Co-Author*) Nothing to Disclose
John A. Betancourt, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Fernanda Gomez (*Abstract Co-Author*) Nothing to Disclose
Pedro Rey (*Abstract Co-Author*) Nothing to Disclose

**TEACHING POINTS**

Understanding the Pitfalls and Physical Principles of Doppler Analysis.Evaluating Spectral Parameters During Pre- and Post-hepatic Transplantation.Explaining the Importance of Portal Vein Flow Calculation During Pre- and Post-Hepatic Transplantation.Making Reproducible Measurement of Portal Vein Flow Step by Step.

**TABLE OF CONTENTS/OUTLINE**

Doppler Principles and PitfallsFundamentals of Regeneration in Hepatic TransplantationSpectral Doppler ParametersCalculation of Portal Vein FlowKey PointsPortal Doppler is indicated in the perioperative evaluation of liver transplant patients. The assessment of portal vein volume flow (PVF) is used to define the feasibility of the intervention, the need for additional procedures to correct portal flow and to determine prognosis. This work provides an educational approach, showing how to perform PVF measurement by Doppler analysis, evaluating the necessary aspects to make its calculation reproducible, as well as its relationship with parenchymal regeneration when compared with volumetric data obtained by other diagnostic images.

## VAEE-20 INFERIOR VENA CAVA ANOMALIES: GIVING DIRECTIONS

Lucia A. Chagas, MD (*Abstract Co-Author*) Nothing to Disclose
Bernardo S. Oliveira, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Ricardo D. Sartim, MD (*Abstract Co-Author*) Nothing to Disclose
Renato D. Teixeira, MD (*Abstract Co-Author*) Nothing to Disclose
Luciana P. Baptista, MD (*Abstract Co-Author*) Nothing to Disclose
Daniel Giunchetti Strabelli, MD (*Abstract Co-Author*) Nothing to Disclose
Lucas d. Gomes de Farias, MD, PhD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purpose of this exhibit is: 1. To review usual and unusual cases of anomalies of the inferior vena cava (IVC). 2. To correlate important findings with the anatomy, embryology, and pathophysiology, focusing on their clinical-radiological correlations. 3. To discuss image findings according to subgroups and classifications, in order to enhance surgeons and radiologists' skills. 4. To highlight their characteristics in order to radiologists with these conditions, preventing unfavorable patient outcome. 5. To review CT and MRI protocols in the evaluation of patients with IVC anomalies.

**TABLE OF CONTENTS/OUTLINE**

1. Applied embryology and anatomy of the IVC. 2. CT and MRI protocols in the evaluation of patients with suspected IVC anomalies. 3. Applications: a case-based review: (a) congenital absence (b) hypoplasia (c) Pre-renal: azygos continuation of IVC (d) Renal: retroaortic left renal vein, circumaortic venous collar (e) Post-renal: transposition or left-sided IVC, duplication of IVC, retrocaval or circumcaval ureter, absent infrarenal inferior vena cava, marsupial cava or preaortic iliac confluence (f) Miscellaneous and other findings 4. Sample cases of pearls, pitfalls, diagnostic difficulties, and mimics. 5. Future directions 6. Summary and take-home messages.

## VAEE-21 'IT WAS NOT JUST A PLAQUE!'. UNVEILING THE ENIGMA OF NON-ATHEROSCLEROTIC ARTERIAL DISORDERS

Andre P. Romualdo (*Abstract Co-Author*) Nothing to Disclose
Igor R. Oliveira, MD (*Abstract Co-Author*) Nothing to Disclose
Andrei S. Albuquerque, MD (*Abstract Co-Author*) Nothing to Disclose
Bruna Carvalho, MD (*Abstract Co-Author*) Nothing to Disclose
Hermes Vinicius Pedrini Pereira, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Review the histopathologic characteristics of nonatherosclerotic arterial diseases. Review CT and MR imaging protocols for vessel analysis. Expose illustrative cases of nonatherosclerotic arterial conditions and its clinical correlations. Define differential diagnosis according to imaging pattern and vascular distribution. Tips on how to identify minimal and initial findings before clinical manifestations.

**TABLE OF CONTENTS/OUTLINE**

Concepts of arterial wall histology and pathophysiology of inflammatory and noninflammatory arterial nonatherosclerotic diseases. Correlation between Imaging patterns and histological sub-types of arterial diseases. CT and MR protocols and reconstruction techniques, systematically mentioned in the interpretation of our cases. Imaging aspects of acute vascular events, from large to small sizes artery branches. Evolution of the vascular involvement, from minimal wall irregularities to dissections, aneurysm formation and occlusive arterial events. Other arterial wall abnormalities that may have clinical repercussions (compressive syndromes). Correlation between Imaging and clinical signs. Risk factors and pre-existing conditions that can help us think about nonatherosclerotic arterial diseases. Practical information for effective reporting and necessary information for intervention planning, including the critical imaging findings that needs immediate intervention.

## VAEE-22 TO ENDOLEAKS AND BEYOND: A PICTORIAL REVIEW OF ENDOVASCULAR ANEURYSM REPAIR IMAGING AND ITS COMPLICATIONS

Yukiyoshi Kimura, MD (*Abstract Co-Author*) Nothing to Disclose
Angel Garrido Urincho, MD (*Abstract Co-Author*) Nothing to Disclose
Genier Fabian Castano Lizarazo, MD (*Abstract Co-Author*) Nothing to Disclose
Tatiana J. Ludena Camacho I, MD (*Abstract Co-Author*) Nothing to Disclose
Aura Maria M. Gonzalez Peralta, MD, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• To understand preprocedural imaging evaluation to produce detailed and clinically useful imaging reports that assist interventionalists in the appropriate patient selection to achieve successful EVAR.• To review the abdominal aortic aneurysm imaging characteristics that must be accurately described for endovascular aortic aneurysm repair planning.• To describe the CT imaging findings of EVAR complications and the key features for the diagnosis.• To analyze therapeutic approaches considering and review various current secondary reintervention approaches that are usually employed for treatment.• To discuss surveillance recommendations after EVAR for timely detecting and evaluating the most common complications, considering evidence-based guidelines that provide a background to facilitate safe, cost-effective, and clinically relevant imaging.

**TABLE OF CONTENTS/OUTLINE**

• Introduction• Vascular Anatomy• Pretreatment Imaging Assessment. What to report?• CT angiography technique• EVAR complication classification• a. Endograft device-related complications• b. Systemic complication• Surveillance Considerations• Take home points• Conclusion

## VAEE-23 OPTIMIZING VESSEL WALL IMAGING FOR CEREBROVASCULAR ASSESSMENT AND INTEGRATING IT INTO STROKE WORKUP STANDARDS OF CARE

Gador Canton (*Abstract Co-Author*) Nothing to Disclose

Javid Azadbakht, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Conventional luminal imaging may fail to fully characterize vessel wall pathologies, leading to difficulties in distinguishing between various causes of cerebrovascular diseases.• Vessel wall imaging (VWI) enables direct visualization of vessel wall, aiding in distinguishing different causes of cerebrovascular diseases that need different prognostic and management considerations.• For capturing small intracranial artery lesions high spatial resolution and blood suppression techniques are crucial, but they prolong the acquisition time. Acceleration techniques have been developed for both pre-reconstruction (mostly based on parallel imaging) and post-reconstruction (mostly exploiting AI techniques) stages.• Refining VWI protocols in stroke patients to achieve faster acquisitions and higher-quality images can foster the adoption and recognition of the value of VWI in stroke work-up and secondary stroke prevention.

### TABLE OF CONTENTS/OUTLINE

1. Protocol optimization for VWI1.1. Technical optimizations for imaging acceleration of vessel wall MRI protocols1.1.1. AI reconstructions1.1.2. CAIPI1.1.3. CS1.2. Blood suppression approaches1.2.1. DANTE1.2.2. MSDE1.2.3. 3D VRFA TSE1.3. Carotid and intracranial VWI protocols1.4. Multi-contrast protocols2. Findings on standard of care VWI for stroke workup2.1. Differentiating various arterial diseases leading to stroke2.2. Characterizing atherosclerotic plaques and discussing features of vulnerability2.3. Detecting arteriogenic sources of emboli in cases of cryptogenic stroke2.4. Discussing clinical pitfalls and technical difficulties of VWI in stroke patients

## VAEE-24 BEYOND COLOR: SUPPLEMENTING DIAGNOSTIC EVALUATION IN DOPPLER ULTRASOUND WITH B-FLOW IMAGING

Ricardo Lange Filho, MD (*Abstract Co-Author*) Nothing to Disclose

Matheus Tonholo Ikedo, MD (*Abstract Co-Author*) Nothing to Disclose
Mateus Esmeraldo, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

B-Flow is a type of technology in ultrasound that allows the visualization of blood flow by representing echoes in shades of gray that vary according to reflector speed and dynamics. B-Flow complements the capabilities of traditional Doppler imaging, offering several significant enhancements: Higher frame rate and improved spatial resolution compared to color flow; Reduced dependency on the angle of scanning; Avoids vessel wall overlap, with no overlay techniques.The purpose of this exhibit is to review current clinical applications of B-flow imaging and explore how it can supplement Doppler evaluations, enhancing diagnostic certainty. B-flow imaging facilitates the visualization of specific pathological conditions and provides a practical method for capturing illustrative images that are beneficial for radiologists and referring physicians to understand the examination.

### TABLE OF CONTENTS/OUTLINE

Introduction a. Overview of coded excitation technology b. Advantages and tradeoffs in ultrasound imaging Clinical Applications a. Evaluation of hepatic vasculature b. Visualization of intratumoral vessels c. Renal blood flow and kidney transplant assessment d. Utilization in perinatology and fetal echocardiography e. Imaging of artery stenosis and plaque morphology f. Diagnosis of arterial dissection and fibromuscular dysplasia g. Assessment of arteriovenous fistulas h. Investigation of venous thrombosis (acute and chronic) i. Evaluation of peripheral arterial disease and bypass surgery outcomes Discussion of current evidence and its limitations a. Review of evidence quality and limitations in B-Flow studies Future Perspectives a. Potential applications and areas for further investigation

## VAEE-25 NON-TRAUMATIC CTA IMAGING OF THE UPPER EXTREMITY

Kevin R. Kalisz, MD (*Abstract Co-Author*) Reviewer, Oakstone Publishing, LLC;Consultant, VoxelMetrix, LLC
Julia M. Asmar, MD (*Abstract Co-Author*) Nothing to Disclose

Jennifer L. Smith, MD (*Abstract Co-Author*) Nothing to Disclose
Katherine A. Cheng, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Computed Tomographic Angiography (CTA) of the upper extremity can provide non-invasive assessment of non-traumatic pathologies, including embolic disease, vasculitis, and post surgical assessment of arteriovenous fistula (AVF) and arteriovenous graft (AVG) complications. Knowledge of both the conventional and variant anatomy and spectrum of disease by the radiologist is important for communication with referring services. Teaching points include a review of conventional and variant anatomy with emphasis on the utilization of 3D reformats and curved planar reconstruction (CPR), imaging protocols, and review of spectrum of pathologies.

### TABLE OF CONTENTS/OUTLINE

1. Review imaging protocols and tailoring them to the clinical scenario2. Emphasize the conventional arterial anatomy of the upper extremity along with common variant anatomy3. Illustrate the clinical scenarios that can result in arterial stenosis and/or occlusion including infection and vasculitis4. Compare and contrast the spectrum of expected appearances of AVFs and AVGs versus complications in the post-surgical state

## VAEE-26 DEEP LEARNING: IMAGING CHARACTERISTICS OF DEEP VENOUS THROMBOSIS AND ASSOCIATED BENIGN CONDITIONS

Steven Sauk,

Christopher O'Sullivan, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. Pathophysiology of thrombus formation 2. Clinical importance and diagnostic challenges 3. Imaging characteristics of acute and chronic venous thrombosis on ultrasound (US), computed tomography (CT), and magnetic resonance (MR) imaging 4. Diseases associated with thrombosis 5. Complications 6. Role of interventional radiology in management

**TABLE OF CONTENTS/OUTLINE**

I. Mechanism of clot formation II. Risk factors III. Imaging characteristics and differentiation of benign from malignant thrombus and mimics a. US b. CT c. MR d. Venography IV. Benign diseases a. Head and neck i. Acute jugular thrombosis ii. Lemierre syndrome b. Chest i. Thoracic outlet syndrome ii. Central venous thrombosis c. Abdomen and pelvis i. Budd-Chiari ii. Duodeno-caval fistula iii. Portomesenteric venous thrombus iv. Mondor disease v. Inflammatory/infectious-associated thrombophlebitis vi. Ovarian vein thrombus vii. May-Thurner syndrome viii. Iliocaval thrombosis d. Extremities i. Deep venous thrombosis ii. Superficial thrombosis and thrombophlebitis V. Complications a. Acute i. Pulmonary and septic emboli/infarcts ii. Phlegmasia cerulea dolens iii. Acute mesenteric venous ischemia b. Chronic i. Chronic mesenteric ischemia ii. Portal biliopathy iii. Post-thrombotic syndrome VI. Role of interventional radiology in management a. General algorithms and strategy i. Conservative management options ii. Percutaneous intervention options 1. Thrombectomy tools and stents a. Splanchnic system b. Lower extremities

## VAEE-27 CT ANGIOGRAPHY OF THE LOWER EXTREMITY ARTERIES: AN ILLUSTRATED GUIDE TO ANATOMY, PATHOLOGY, NORMAL AND ABNORMAL POST-OPERATIVE IMAGING

Panos K. Prassopoulos, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Vasileios Rafailidis, MD (*Abstract Co-Author*) Nothing to Disclose
Sasan Partovi, MD (*Abstract Co-Author*) Nothing to Disclose
Alba R. Pugliesi, MD (*Abstract Co-Author*) Nothing to Disclose
Elisavet Psoma (*Abstract Co-Author*) Nothing to Disclose
Angeliki Papachristodoulou, MD, MSc (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To familiarize with normal lower extremity arterial anatomy, significant anatomic variations and collateral circulation in patients with steno-occlusive disease. 2. Specific patterns and anatomic distribution of steno-occlusive disease will be associated with underlying pathology. 3. To show educational cases of the spectrum of atherosclerotic disease, with emphasis on CT angiography, including thrombotic embolic disease. Rare non-atherosclerotic entities will also be presented, such as mid-aortic syndrome, small aorta syndrome, popliteal artery entrapment and aortitis.4. To present post-treatment complications in the peri-procedural and long-term period. 5. To underline the role of contrast-enhanced ultrasound by correlation to CTA in selected cases.

**TABLE OF CONTENTS/OUTLINE**

1. Lower extremity arterial anatomy a. Normal pattern terminology b. Variations c. Systemic-systemic systemic-visceral collaterals 2. Disease categories a. Atherosclerosis b. Patterns and pathology of steno-occlusive disease c. Inflammatory d. Congenital e. Functional 3. Normal post-operative imaging a. Endarterectomy b. Stenting: iliac, femoral, popliteal c. Bypass grafting: various anatomic types 4. Post-treatment complications a. Stent: neointimal hyperplasia, restenosis, thrombosis, fracture, displacement, endoleak b. Bypass grafting: thrombosis, infection c. Trauma: pseudoaneurysm, hemorrhage, arteriovenous fistula d. Correlation of CEUS with CTA

## VAEE-28 EXPLORING THE UNIVERSE OF THROMBI: A RADIOLOGIST'S PERSPECTIVE

Martin M. Pesce, MD (*Abstract Co-Author*) Nothing to Disclose
Leandro J. Pacini (*Abstract Co-Author*) Nothing to Disclose
Rodrigo S. Loto, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

• Pathophysiology of Thrombosis. • Imaging Modalities for Thrombi Detection. • Differentiating Thrombi from Other Conditions. Radiologic clues. • Protocoling is crucial for correct diagnosis. Artifacts and potential pitfalls. • Show the main imaging findings through different case examples of our institution.

**TABLE OF CONTENTS/OUTLINE**

Thrombosis occurs when there is a disruption in the balance between thrombogenic factors and protective mechanisms. In recent years, research in thromboembolic diseases has been inundated with new observations, making it worthwhile to strive for the evaluation of thrombotic mechanisms in individuals suffering from or predisposed to thromboembolic diseases. Table of contents: • Introduction. General concepts. • Thrombogenesis. • Composition, location, and types of thrombi. • Thromboinflammation. Thrombus age? • CT protocols technique: Possible scenarios. • Thrombosis and infections. What do we know beyond covid? • Malignant/benign tumors. Thrombosis and cancer. Micro and macrovascular invasion. Complications: thrombotic and nonthrombotic embolism (pulmonary tumor thrombotic microangiopathy). • Thrombosis in unusual sites. • Collateral circulation: a practical review. • Take-home points.

## VAEE-29 VARICOCELE: ULTRASOUND FEATURES AND EMBOLISATION. UPDATE FOR RADIOLOGIST

**Awards**
**Certificate of Merit**

Nicolas Rodriguez Ramirez, MD (*Abstract Co-Author*) Nothing to Disclose
Rodrigo Pastorin (*Abstract Co-Author*) Nothing to Disclose
Elena Romero (*Abstract Co-Author*) Nothing to Disclose
Xiaqun Xu (*Abstract Co-Author*) Nothing to Disclose
Itxaso Galan-Gonzalez (*Abstract Co-Author*) Nothing to Disclose
Lorena Melian Iribar, MD (*Abstract Co-Author*) Nothing to Disclose
Ana Ines Rubio Aguilera, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Become familiar with the correct performance of ultrasound examination of varicocele.2) Learn the typical sonographic findings. 3) Recognize the ultrasound appearance of the normal and pathological pampiniform plexus of veins. 4) Learn the recommendations for the performance of varicocele embolization.

**TABLE OF CONTENTS/OUTLINE**

Varicoceles are relatively common in asymptomatic men and even more prevalent in subfertile/infertile men or chronic scrotal discomfort, being the most common cause of potentially correctable male infertility. Ultrasound (US) is the preferred method for evaluation and a standardized protocol should be followed. A grey-scale and color Doppler examination should be performed bilaterally, with spectral Doppler analysis. Most investigators recommend examining the patient in both supine and erect positions, as well as during Valsalva. Testicular volume correlates with testicular function in infertile patients and those with varicocele, making it important to measure. It is important to measure the largest dilated vein and document the patient's position and sampling site, regardless of its location. Venous reflux causes testicular damage, which can be reversed by eliminating reflux. Spectral Doppler analysis measures reflux duration, which is essential. Regarding the treatment, percutaneous embolization is a highly effective and minimally invasive procedure that successfully treats lesions such as varicoceles.

## VAEE-3 FOUR-DIMENSIONAL (4D) FLOW MR IN VASCULAR DISEASE

Albert Hsiao, MD, PhD (*Abstract Co-Author*) Co-founder, Arterys Inc;Shareholder, Arterys Inc;Co-founder, Vektor.AI;Shareholder, Vektor.AI;Research Grant, Bayer AG;Research Grant, General Electric Company;Research Grant, KA Imaging

Melina Hosseiny, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

4D Flow: Tailoring Acquisition for Vascular DiseaseWhat is 4D Flow?Acquisition parameters: FOV, Resolution, Velocity encoding speedPost-processing and phase-error correctionHemodynamic measurements: flow and pressurea)Pressure from modified Bernoulli equation to assess arterial stenosisb)Flow to assess shunt severityc)Flow to assess severity of venous stenosisd)Conservation of mass / flowCase examples:1) Applications in Arterial diseases:-Coarctation-Aortic dissection-Vasculitis-Aneurysm2) Applications in Vascular Malformations:-Case examples in extremity and neurovascular AVMs-Bulk flow decreases following successful therapy, whether interventional embolization or radiotherapy3)Applications in Abdominopelvic Venous Disease:-Pelvic congestion-May-Thurner-Nutcracker-POTS and Ehlers-Danlos

**TABLE OF CONTENTS/OUTLINE**

Outline:1. Introduction to 4D Flow and Clinical Applications in Vascular Disease2. Assessing hemodynamic significance: stenoses and shunts3. Vascular malformations: high flow, low flow and hemodynamic changes with therapy4. Hemodynamics of aortic dissection: tears and fenestrations5. Pelvic congestion and venous disease

## VAEE-30 VASCULITIS VENTURES: A RADIOLOGIST'S JOURNEY THROUGH LARGE VESSEL INFLAMMATION PATTERNS

Simona Manole, MD (*Abstract Co-Author*) Nothing to Disclose
Ioana Popescu, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

This presentation aims to:- Sensitize radiologists to vasculitides and the dynamic nature of studying these intricate conditions.- Outline the classification and characteristics of vasculitides, with a dedicated focus on large vessel vasculitis.- Underscore the key imaging features of large vessel vasculitis, predominantly through illustrative CTA case studies.- Explore the diagnostic challenges, including the identification of complications and even differentiation from mimicking entities.- Highlight the pivotal role of the radiologist within the multidisciplinary team in the diagnosis and management of vasculitides.

**TABLE OF CONTENTS/OUTLINE**

1. Prepare Your Backpacks! - Introduction to vasculitis2. Choosing the Route - Anatomy of the main vessels and their branches3. Finding Your Way in the Dark(room) - Vascular imaging techniques and features 4. Learning the Language - The Revised International Chapel Hill Consensus Conference nomenclature of vasculitides5. Hop On and Let’s Go! - Example cases of primary large vessel vasculitides6. Still on the Road - Example cases of secondary large vessel vasculitides7. Let’s take a Detour! - Example cases of pulmonary large vessel vasculitides8. Navigating Obstacles - Complications of vasculitides9. Avoiding Wrong Turns - Differential diagnosis and mimickers of vasculitis10. It’s Better with Friends - Multidisciplinary approach to vasculitis management11. A Journey to Remember! - Take home messages

## VAEE-31 DOPPLER ULTRASOUND OF THE TEMPORAL ARTERY, PICTORIAL ESSAY OF CASES THAT THE RADIOLOGIST SHOULD KNOW

Marcelo R. Silva, MD (*Abstract Co-Author*) Nothing to Disclose
Fabio Yoshimura (*Abstract Co-Author*) Nothing to Disclose
Antonella Folchini (*Abstract Co-Author*) Nothing to Disclose

Victor A. Jabour, MD (*Abstract Co-Author*) Nothing to Disclose
Matheus M. Marcelino Dias, MD (*Abstract Co-Author*) Nothing to Disclose
Cesar Passos Braga, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

The purposes of this exhibit are:1. Importance of learning the anatomy of the temporal artery and its branches.2. Understand the ultrasound technique to better perform the exam.3. Understand the different types of temporal artery aneurysm and their different findings in B mode and color.4. Know the ultrasound manifestation of temporal arteritis and the expected pattern after effective clinical treatment.

**TABLE OF CONTENTS/OUTLINE**

1. Anatomy of the temporal artery and its branches.2. Ultrasound technique used to evaluate the temporal artery, the main adjustments, parameters and what should be analyzed.3. Illustrate with case reports from our department the main pathologies:- Pseudoaneurysm- Fusiform aneurysm- Saccular aneurysm- Temporal arteritis

## VAEE-4 NEW HORIZON OF CT IMAGE PROCESSING: INNOVATIVE DOSE REDUCING CTA SUBTRACTION TECHNIQUE

Katsumi Tsujioka, RT (*Abstract Co-Author*) Researcher, Canon Medical Systems Corporation
Emi Tomita (*Abstract Co-Author*) Nothing to Disclose
Takeo Uetsuki, BMedSc (*Abstract Co-Author*) Nothing to Disclose
Nobuaki Idobata (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Subtraction Computed Tomography Angiography (CTA) can accurately evaluate the vascular lumen in cases of high calcification, however, to perform the subtraction technique it is necessary to obtain non-contrast images as a mask in addition to the contrast enhanced images. Using recently developed image positioning technique in helical imaging, we propose a CTA subtraction that does not require the non-contrast mask images.

**TABLE OF CONTENTS/OUTLINE**

[1] We propose a method to obtain non-contrast enhanced axial Images during positioning imaging and to omit the additional non-contrast imaging. [2] Subtraction CTA is a method in which only blood vessels are extracted by subtracting non-contrast images from CTA images. It is effective for the assessment of the vascular lumen, however, in addition to the CTA image, a non-contrast image mask must be acquired for the subtraction process, which increases the radiation exposure. [3] Non-contrast axial images can be obtained using low-dose helical positioning with an additive filter. [4] After obtaining CTA images, the positioning images and CTA images are reconstructed under the same conditions. The subtraction with non-rigid positioning is performed using a 3D workstation. [5] The subtraction CTA using positioning images and CTA images, does not require the additional exposure for mask image acquisition, but still facilitates observation and evaluation of the vessel lumen.

## VAEE-5 WISDOM OF EVALUATING ENDOLEAK WITH 4D CT -HOW TO RELIABLY ACQUIRE IMAGES WITH LOW RADIATION DOSE AND SHORT SCANNING TIME-

Takashi Nishiyama (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

It is possible to differentiate the type of Endoleak using 4D CT However, there are issues with the extension of scanning time and the tradeoff relationship between radiation dose and number of frames. This time, we have developed imaging method that reduces radiation dose by 40% and increases the number of frames by 2.25 times compared to conventional methods.

**TABLE OF CONTENTS/OUTLINE**

We have developed method for differentiating Endoleak types using 4D CT, which reduces the radiation dose by 40% and increases the number of frames by 2.25 times compared to conventional methods. When it is difficult to maintain body position and hold breath for long time, it is necessary to accurately predict the time from just before contrast to the peak of CTA to minimize the scanning time. Therefore, we used Test Bolus Tracking, which allows us to start scanning at optimal timing. Furthermore, to obtain a high number of frames while reducing the radiation dose, we generated 120 bpm pulse generated from a simulated ECG and performed intermittent scanning As a result, we observed retrograde blood flow from the distal inferior mesenteric artery to the proximal inferior mesenteric artery at low radiation dose and short scanning time and could diagnose type II Endoleak. This method is effective in reducing scanning time, decreasing radiation dose, and increasing the number of frames, which are the issues of 4D CT.

## VAEE-6 VASCULAR ABNORMALITIES OF HAND AND WRIST- STATE-OF-THE ART MULTIMODALITY IMAGING

**Awards**
**Cum Laude**

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To review the vascular anatomy and pathologies of the hand and wrist 2. To discuss the state-of-the-art imaging modalities in the evaluation of these vascular abnormalities 3. To illustrate the imaging appearances of various vascular abnormalities of hand and wrist

**TABLE OF CONTENTS/OUTLINE**

1. INTRODUCTION 2. VASCULAR ANATOMY OF THE HAND AND WRIST- including superficial and deep palmar arches, metacarpal and digital arteries 3. IMAGING MODALITIES- Ultrasound, doppler, CT, MRI, DSA 4. CT TECHNIQUES- CT Angiography (CTA), Multiphasic acquisitions, Dynamic CTA, multienergy CT, High-resolution photon counting CT 5. MRI TECHNIQUES- Standard MRI, Conventional MRA, 3D T1w acquisitions, Time-resolved MRA, Non contrast MRI techniques - e.g. NATIVE 6. STANDARD CT AND MRI PROTOCOL 7. REVIEW AND ILLUSTRATION OF THE FOLLOWING VASCULAR ABNORMALITIES WITH CASE EXAMPLES a) a. Anatomical variations- Persistent median artery, arch variations; a. Trauma/Iatrogenic; b. Occupational- Hypothenar hammer syndrome, Hand arm vibration syndrome; c. Thromboembolus; d. Thromboangiitis obliterans, Raynaud disease; e. Vasoocclusive disease (including paraneoplastic syndrome); f. Frostbite; g. Intra-arterial drug injection/drugs/chemicals; h. Vasculitis/Autoimmune/rheumatic diseases; i. Infections ; j. Aneurysms/ Pseudoaneurysms; k. Vascular malformations- Arterial, venous, lymphatic; l. Vascular tumors- Pyogenic granuloma, spindle cell hemangioma, intravascular endothelial cell hyperplasia; m. Perivascular tumors- Glomus tumor, myopericytoma; n. Extrinsic compression by tumors; o. Hand transplant workup 8. PITFALLS 9. MISSES

## VAEE-7 OMC! OH, MY COATED ANEURYSM: A MULTIMODALITY IMAGING GUIDE OF MYCOTIC ANEURYSMS FROM HEAD TO TOE

Daniel Kowal, MD (*Abstract Co-Author*) Speaker, Samsung Electronics Co, Ltd
Mansha A. Khubchandani, MD (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Mycotic aneurysms represent a rare yet perilous vascular condition, impacting the aorta and visceral, peripheral and cerebral arteries. They stem from the dilation and deterioration of the arterial wall triggered by bloodstream infection or septic embolization, often from infective endocarditis. Early detection and swift intervention are paramount for mitigating mortality. However, diagnosis can be hindered by nonspecific presenting symptoms, often resulting in advanced-stage diagnosis or delayed complications like rupture or fistula formation. While clinical factors and biomarkers may heighten suspicion, they

lack specificity in diagnosis. Advanced imaging modalities like CT angiography and MRI have superseded conventional angiography as minimally invasive tools for both detecting suspected cases and characterizing confirmed cases, aiding in vascular mapping and treatment planning. Imaging findings include lobulated pseudoaneurysm, irregular wall, aneurysmal thrombosis and perianeurysmal gas, edema, abscess, soft tissue mass and lymphadenopathy. Familiarity with these imaging appearances can guide appropriate management, which typically entails a combination of antibiotic therapy, surgical debridement, revascularization, or endovascular procedures based on individual patient characteristics. This educational exhibit endeavors to immerse radiologists in a captivating cinematic journey throughout the body while highlighting the intricacies of mycotic aneurysms.

**TABLE OF CONTENTS/OUTLINE**

Introduction Pathogenesis Clinical features and complications Multimodality imaging examples of mycotic aneurysms spanning from head to toe Management Summary Limitation References

## VAEE-8 BEYOND ANEURYSMS: ANATOMY, EMBRYOLOGY AND PATHOLOGIES OF THE ABDOMINAL AORTA WITH IMPLICATIONS FOR MODERN ENDOVASCULAR MANAGEMENT

**Awards**
**Certificate of Merit**

Richard D. White, MBChB, FRCR (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1) Highlight the embryological development of the abdominal aorta, with schematic illustrations. 2) Discuss anatomy and key anatomical variants of the abdominal aorta, with case examples. 3) Illustrate a broad spectrum of a pathologies of the abdominal aorta, with clinical correlation and discussion of the implications for modern endovascular management

**TABLE OF CONTENTS/OUTLINE**

1) Embryology. 2) Anatomy and variants. 3) Pathologies. a. Aneurysm. b. Acute aortic syndromes. c. Fistulas. d. Mid-aortic syndrome. e. Ischemia. f. Inflammatory / infective. g. Trauma. h. Iatrogenic. i. Post-surgical / endovascular appearances. j. Miscellaneous.

## VAEE-9 THE RESIDENT'S GUIDE TO ACUTE VASCULAR IMAGING: AN ABC APPROACH

Richard D. White, MBChB, FRCR (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

- By taking an ABC approach, highlight a range of acute vascular pathologies that residents might encounter, with pearls, pitfalls and clinical relevance.

**TABLE OF CONTENTS/OUTLINE**

1. Aneurysm 2. Bleeding 3. CTA protocols 4. Dissection 5. Embolism 6. Fistula 7. Gating 8. Hematoma 9. IVC 10. Jugular (and other neck findings) 11. Kidney and other solid organ injury 12. Line misplacement 13. Mesenteric 14. Non-contrast 15. Organ infarction 16. Pseudoaneurysm 17. Query dissection? 18. Rupture 19. SVC 20. Thoracic aortic injury 21. Ulceration 22. Vasculitis 23. White limb 24. X-ray artefacts: mimics of pathology on CT 25. Y-grafts and other post-surgical findings 26. Zebra spleen

## RADIOLOGISTS TOOLKIT: MULTIMODAL ASSESEMENT AND TREATMENT OF RENAL VASCULATURE PAHOLOGY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Luis Enrique Nunez Castellanos (*Abstract Co-Author*) Nothing to Disclose
Augstin Z. Guzman Mercado, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Describe normal renal vasculature anatomy, common variants and its clinical significance.• Understand normal nephrogram on contrast enhanced CT, radiologic signs translating on pathologic entities.• Learn the main findings on the multiple imaging methods including ultrasound, CEUS, CT, MR, Gammagram and Angiography.• Describe epidemiology, pathogenesis, etiology main imaging features, the main vascular pathologies• Understand the current role of the radiologist in the diagnosis and treatment of renal vascular pathologies.

### TABLE OF CONTENTS/OUTLINE

• Anatomy: normal anatomy, anatomical variants,• Multimodal approach: Ultrasound, Doppler, CEUS, computed tomography• Epidemiology, pathogenesis, etiology, main imaging features and treatment of vascular pathology.• Venous pathology: thrombosis, tumor thrombosis, compression syndromes.• Arterial pathology: fibromuscular dysplasia, stenosis, occlusion, pseudoaneurysm, arteriovenous fistula, active bleeding.• Endovascular treatment: Dianostic angiography, stenosis angioplasty, pseudoaneurysm / arteriovenous fistula embolization, active bleeding embolization.

## UNVEILING ABDOMINAL VASCULAR COMPRESSION SYNDROMES: WHAT THE RADIOLOGIST NEEDS TO KNOW?

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Natalia H. Concatto, MD (*Abstract Co-Author*) Nothing to Disclose
Samuel Freitas (*Abstract Co-Author*) Nothing to Disclose
Henrique M. Guerra, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- Abdominal vascular compression syndromes comprise a diverse group of conditions characterized by either the compression of a vascular structure or an anatomical structure being compressed by a vessel.- Computed tomography is integral to the diagnostic process, providing crucial imaging data that aids radiologists in identifying these syndromes.- However, it is important to note that imaging findings associated with vascular compression can frequently appear in asymptomatic individuals, raising concerns about potential overdiagnosis.- Therefore, a comprehensive diagnostic approach, incorporating clinical symptoms and additional testing, is essential to ensure accurate diagnosis and appropriate management of vascular compression syndromes.

### TABLE OF CONTENTS/OUTLINE

1. Introduction:- Definition and scope of vascular compression syndromes- Importance of computed tomography (CT) in the diagnostic.2. Radiological Considerations of each syndrome- Key imaging findings for each syndrome- Role of CT imaging in detailed anatomical assessment.3. Clinical Approach- Common symptoms and clinical manifestations- Importance of correlating imaging findings with clinical symptoms and additional diagnostic tests.4. Conclusion- Future directions in imaging techniques and clinical management of vascular compression syndromes.

### TEACHING POINTS

Review the 2018 ISSVA Classification of Vascular Anomalies.Review CT and MR imaging protocol for vascular analysis.Review the imaging characteristics of common vascular anomalies.Propose an algorithmic imaging evaluation of vascular malformations.Expose illustrative cases of vascular malformations and their clinical correlations.

### TABLE OF CONTENTS/OUTLINE

2018 ISSVA Classification of Vascular Anomalies: - Vascular tumors. - Vascular malformations: Simple; Combined; Vascular anomalies of major named vessels; Vascular anomalies associated with others anomalies. - Unclassified anomalies. Explanation and exemplification of non-central nervous system vascular malformations. Subdivision of vascular malformations into high-flow and low-flow and their imaging characteristics. CT and MR protocols and reconstruction techniques, systematically mentioned in the interpretation of our cases. Imaging findings of vascular malformations across modalities (computerized tomography, magnetic resonance imaging, ultrasound and Doppler). Correlation beetween imaging and clinical signs of non-central nervous system vascular malformations. Practical information for effective reporting and necessary information for intervention planning.

### TEACHING POINTS

1. To understand the concept of perforator and its use in flaps (angiosome model). 2. To review the imaging protocols for CT of perforator arteries for preoperative planning of the most commonly used flaps. 3. To show the MIP (Maximum Intensity Projection), MPR (Multiplanar Reformation) and VR (Volume Rendering) image reconstructions for each flap. 4. To specify how to communicate the relevant information to the surgeon in the image reconstructions and radiology report.

### TABLE OF CONTENTS/OUTLINE

1. Introduction: 1.1 Angiosome. 1.2 Characteristics of perforator arteries and the "ideal" one. 2. General CT technical parameters for image acquisition and specific protocols for each flap. 3. Most commonly used flaps: anatomy, general considerations, reconstructions and radiological report. 3.1. Deep Inferior Epigastric Perforator (DIEP) flap. 3.2. Thoracodorsal Artery Perforator (TAP) flap. 3.3. Anterolateral thigh (ALT) flap. 3.4. Superior gluteal artery perforator (SGAP) flap. 3.5. Peroneal artery flap and musculocutaneous flaps of the lower limbs. 4. Conclusions. 5. Bibliography.

### TEACHING POINTS

The rising occurrence of end-stage renal disease and its impact on healthcare have spurred increased attention to vascular access provision. Hemodialysis vascular access is the predominant method for renal replacement therapy, primarily achieved through arteriovenous fistula creation.An arteriovenous fistula is established by connecting a native artery to a vein, with the goal of providing long-term access for hemodialysis in individuals with end-stage renal disease until they can undergo a kidney transplant. Typically conducted in the upper extremities, preferably the non-dominant arm, the most common connections are made between the radial artery and the cephalic vein.When conducted with meticulous methodology, ultrasound assessment of AV access enables thorough evaluation from its inception to potential complications, like failure of maturation, stenotic vascular lesions, thrombosis, hematoma, aneurysms or pseudoaneurysms, and infection.

### TABLE OF CONTENTS/OUTLINE

- Review expected ultrasound findings expected for a patent arteriovenous fistula for hemodialysis.- Evaluate the most common complications and their presentation on ultrasound.

### TEACHING POINTS

Recognize the imaging anatomy of the abdominal aorta (AA) and its main branches. Understand the primary concepts related to the clinical and surgical management of abdominal aortic aneurysm (AAA). Familiarize with the main aspects of the pre- and post-operative imaging evaluation of AAA. Recognize endovascular aneurysm repair (EVAR) complications, with focus on endoleaks. Comprehend the key principles and potential applications of artificial intelligence (AI) for prediction and detection of complications after EVAR, including endoleak.

### TABLE OF CONTENTS/OUTLINE

1. INTRODUCTION: AA and its branches anatomy and relationship with other abdominal structures. AAA imaging patterns on Computed Tomography Angiography (CTA). AAA criteria to intervene and how to proceed (open surgery x EVAR). How to evaluate and follow the patient after surgery. EVAR complications. 2. DIAGNOSIS AND IMAGING FINDINGS: Endoleak - What are the mechanisms? How to identify How to proceed? 3. FUTURE PERSPECTIVES: ARTIFICIAL INTELLIGENCE: AI for diagnosing and predicting EVAR complications. 4. SUMMARY AND SYSTEMATIC APPROACH. 5. TAKE HOME MESSAGES.

### TEACHING POINTS

Review the histopathologic characteristics of nonatherosclerotic arterial diseases. Review CT and MR imaging protocols for vessel analysis. Expose illustrative cases of nonatherosclerotic arterial conditions and its clinical correlations. Define differential diagnosis according to imaging pattern and vascular distribution. Tips on how to identify minimal and initial findings before clinical manifestations.

### TABLE OF CONTENTS/OUTLINE

Concepts of arterial wall histology and pathophysiology of inflammatory and noninflammatory arterial nonatherosclerotic diseases. Correlation between Imaging patterns and histological sub-types of arterial diseases. CT and MR protocols and reconstruction techniques, systematically mentioned in the interpretation of our cases. Imaging aspects of acute vascular events, from large to small sizes artery branches. Evolution of the vascular involvement, from minimal wall irregularities to dissections, aneurysm formation and occlusive arterial events. Other arterial wall abnormalities that may have clinical repercussions (compressive syndromes). Correlation between Imaging and clinical signs. Risk factors and pre-existing conditions that can help us think about nonatherosclerotic arterial diseases. Practical information for effective reporting and necessary information for intervention planning, including the critical imaging findings that needs immediate intervention.

Javid Azadbakht, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Conventional luminal imaging may fail to fully characterize vessel wall pathologies, leading to difficulties in distinguishing between various causes of cerebrovascular diseases.• Vessel wall imaging (VWI) enables direct visualization of vessel wall, aiding in distinguishing different causes of cerebrovascular diseases that need different prognostic and management considerations.• For capturing small intracranial artery lesions high spatial resolution and blood suppression techniques are crucial, but they prolong the acquisition time. Acceleration techniques have been developed for both pre-reconstruction (mostly based on parallel imaging) and post-reconstruction (mostly exploiting AI techniques) stages.• Refining VWI protocols in stroke patients to achieve faster acquisitions and higher-quality images can foster the adoption and recognition of the value of VWI in stroke work-up and secondary stroke prevention.

### TABLE OF CONTENTS/OUTLINE

1. Protocol optimization for VWI1.1. Technical optimizations for imaging acceleration of vessel wall MRI protocols1.1.1. AI reconstructions1.1.2. CAIPI1.1.3. CS1.2. Blood suppression approaches1.2.1. DANTE1.2.2. MSDE1.2.3. 3D VRFA TSE1.3. Carotid and intracranial VWI protocols1.4. Multi-contrast protocols2. Findings on standard of care VWI for stroke workup2.1. Differentiating various arterial diseases leading to stroke2.2. Characterizing atherosclerotic plaques and discussing features of vulnerability2.3. Detecting arteriogenic sources of emboli in cases of cryptogenic stroke2.4. Discussing clinical pitfalls and technical difficulties of VWI in stroke patients

### TEACHING POINTS

B-Flow is a type of technology in ultrasound that allows the visualization of blood flow by representing echoes in shades of gray that vary according to reflector speed and dynamics. B-Flow complements the capabilities of traditional Doppler imaging, offering several significant enhancements: Higher frame rate and improved spatial resolution compared to color flow; Reduced dependency on the angle of scanning; Avoids vessel wall overlap, with no overlay techniques.The purpose of this exhibit is to review current clinical applications of B-flow imaging and explore how it can supplement Doppler evaluations, enhancing diagnostic certainty. B-flow imaging facilitates the visualization of specific pathological conditions and provides a practical method for capturing illustrative images that are beneficial for radiologists and referring physicians to understand the examination.

### TABLE OF CONTENTS/OUTLINE

Introduction a. Overview of coded excitation technology b. Advantages and tradeoffs in ultrasound imaging Clinical Applications a. Evaluation of hepatic vasculature b. Visualization of intratumoral vessels c. Renal blood flow and kidney transplant assessment d. Utilization in perinatology and fetal echocardiography e. Imaging of artery stenosis and plaque morphology f. Diagnosis of arterial dissection and fibromuscular dysplasia g. Assessment of arteriovenous fistulas h. Investigation of venous thrombosis (acute and chronic) i. Evaluation of peripheral arterial disease and bypass surgery outcomes Discussion of current evidence and its limitations a. Review of evidence quality and limitations in B-Flow studies Future Perspectives a. Potential applications and areas for further investigation

## NON-TRAUMATIC CTA IMAGING OF THE UPPER EXTREMITY

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Kevin R. Kalisz, MD (*Abstract Co-Author*) Reviewer, Oakstone Publishing, LLC;Consultant, VoxelMetrix, LLC
Julia M. Asmar, MD (*Abstract Co-Author*) Nothing to Disclose
Lynne M. Hurwitz Koweek, MD (*Abstract Co-Author*) Departmental Research Grant, Siemens AG;Departmental Research Grant, HeartFlow, Inc;Departmental Research Grant, Verily Lifesciences LLC
Jennifer L. Smith, MD (*Abstract Co-Author*) Nothing to Disclose
Katherine A. Cheng, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Computed Tomographic Angiography (CTA) of the upper extremity can provide non-invasive assessment of non-traumatic pathologies, including embolic disease, vasculitis, and post surgical assessment of arteriovenous fistula (AVF) and arteriovenous graft (AVG) complications. Knowledge of both the conventional and variant anatomy and spectrum of disease by the radiologist is important for communication with referring services. Teaching points include a review of conventional and variant anatomy with emphasis on the utilization of 3D reformats and curved planar reconstruction (CPR), imaging protocols, and review of spectrum of pathologies.

### TABLE OF CONTENTS/OUTLINE

1. Review imaging protocols and tailoring them to the clinical scenario2. Emphasize the conventional arterial anatomy of the upper extremity along with common variant anatomy3. Illustrate the clinical scenarios that can result in arterial stenosis and/or occlusion including infection and vasculitis4. Compare and contrast the spectrum of expected appearances of AVFs and AVGs versus complications in the post-surgical state

Sanjeev Bhalla, MD (*Abstract Co-Author*) Advisory Board, Precisa Gravimetrics AG
Daniel R. Ludwig, MD (*Abstract Co-Author*) Nothing to Disclose
Joaquin Martinez Pereira, MD (*Abstract Co-Author*) Nothing to Disclose
Christopher O'Sullivan, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. Pathophysiology of thrombus formation 2. Clinical importance and diagnostic challenges 3. Imaging characteristics of acute and chronic venous thrombosis on ultrasound (US), computed tomography (CT), and magnetic resonance (MR) imaging 4. Diseases associated with thrombosis 5. Complications 6. Role of interventional radiology in management

### TABLE OF CONTENTS/OUTLINE

I. Mechanism of clot formation II. Risk factors III. Imaging characteristics and differentiation of benign from malignant thrombus and mimics a. US b. CT c. MR d. Venography IV. Benign diseases a. Head and neck i. Acute jugular thrombosis ii. Lemierre syndrome b. Chest i. Thoracic outlet syndrome ii. Central venous thrombosis c. Abdomen and pelvis i. Budd-Chiari ii. Duodeno-caval fistula iii. Portomesenteric venous thrombus iv. Mondor disease v. Inflammatory/infectious-associated thrombophlebitis vi. Ovarian vein thrombus vii. May-Thurner syndrome viii. Iliocaval thrombosis d. Extremities i. Deep venous thrombosis ii. Superficial thrombosis and thrombophlebitis V. Complications a. Acute i. Pulmonary and septic emboli/infarcts ii. Phlegmasia cerulea dolens iii. Acute mesenteric venous ischemia b. Chronic i. Chronic mesenteric ischemia ii. Portal biliopathy iii. Post-thrombotic syndrome VI. Role of interventional radiology in management a. General algorithms and strategy i. Conservative management options ii. Percutaneous intervention options 1. Thrombectomy tools and stents a. Splanchnic system b. Lower extremities

## CT ANGIOGRAPHY OF THE LOWER EXTREMITY ARTERIES: AN ILLUSTRATED GUIDE TO ANATOMY, PATHOLOGY, NORMAL AND ABNORMAL POST-OPERATIVE IMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Panos K. Prassopoulos, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Vasileios Rafailidis, MD (*Abstract Co-Author*) Nothing to Disclose
Sasan Partovi, MD (*Abstract Co-Author*) Nothing to Disclose
Alba R. Pugliesi, MD (*Abstract Co-Author*) Nothing to Disclose
Elisavet Psoma (*Abstract Co-Author*) Nothing to Disclose
Angeliki Papachristodoulou, MD, MSc (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To familiarize with normal lower extremity arterial anatomy, significant anatomic variations and collateral circulation in patients with steno-occlusive disease. 2. Specific patterns and anatomic distribution of steno-occlusive disease will be associated with underlying pathology. 3. To show educational cases of the spectrum of atherosclerotic disease, with emphasis on CT angiography, including thrombotic embolic disease. Rare non-atherosclerotic entities will also be presented, such as mid-aortic syndrome, small aorta syndrome, popliteal artery entrapment and aortitis.4. To present post-treatment complications in the peri-procedural and long-term period. 5. To underline the role of contrast-enhanced ultrasound by correlation to CTA in selected cases.

### TABLE OF CONTENTS/OUTLINE

1. Lower extremity arterial anatomy a. Normal pattern terminology b. Variations c. Systemic-systemic systemic-visceral collaterals 2. Disease categories a. Atherosclerosis b. Patterns and pathology of steno-occlusive disease c. Inflammatory d. Congenital e. Functional 3. Normal post-operative imaging a. Endarterectomy b. Stenting: iliac, femoral, popliteal c. Bypass grafting: various anatomic types 4. Post-treatment complications a. Stent: neointimal hyperplasia, restenosis, thrombosis, fracture, displacement, endoleak b. Bypass grafting: thrombosis, infection c. Trauma: pseudoaneurysm, hemorrhage, arteriovenous fistula d. Correlation of CEUS with CTA

## EXPLORING THE UNIVERSE OF THROMBI: A RADIOLOGIST'S PERSPECTIVE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Martin M. Pesce, MD (*Abstract Co-Author*) Nothing to Disclose
Leandro J. Pacini (*Abstract Co-Author*) Nothing to Disclose
Rodrigo S. Loto, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

• Pathophysiology of Thrombosis. • Imaging Modalities for Thrombi Detection. • Differentiating Thrombi from Other Conditions. Radiologic clues. • Protocoling is crucial for correct diagnosis. Artifacts and potential pitfalls. • Show the main imaging findings through different case examples of our institution.

### TABLE OF CONTENTS/OUTLINE

Thrombosis occurs when there is a disruption in the balance between thrombogenic factors and protective mechanisms. In recent years, research in thromboembolic diseases has been inundated with new observations, making it worthwhile to strive for the evaluation of thrombotic mechanisms in individuals suffering from or predisposed to thromboembolic diseases. Table of contents: • Introduction. General concepts. • Thrombogenesis. • Composition, location, and types of thrombi. • Thromboinflammation. Thrombus age? • CT protocols technique: Possible scenarios. • Thrombosis and infections. What do we know beyond covid? • Malignant/benign tumors. Thrombosis and cancer. Micro and macrovascular invasion. Complications: thrombotic and nonthrombotic embolism (pulmonary tumor thrombotic microangiopathy). • Thrombosis in unusual sites. • Collateral circulation: a practical review. • Take-home points.

### TEACHING POINTS

1) Become familiar with the correct performance of ultrasound examination of varicocele.2) Learn the typical sonographic findings. 3) Recognize the ultrasound appearance of the normal and pathological pampiniform plexus of veins. 4) Learn the recommendations for the performance of varicocele embolization.

### TABLE OF CONTENTS/OUTLINE

Varicoceles are relatively common in asymptomatic men and even more prevalent in subfertile/infertile men or chronic scrotal discomfort, being the most common cause of potentially correctable male infertility. Ultrasound (US) is the preferred method for evaluation and a standardized protocol should be followed. A grey-scale and color Doppler examination should be performed bilaterally, with spectral Doppler analysis. Most investigators recommend examining the patient in both supine and erect positions, as well as during Valsalva. Testicular volume correlates with testicular function in infertile patients and those with varicocele, making it important to measure. It is important to measure the largest dilated vein and document the patient's position and sampling site, regardless of its location. Venous reflux causes testicular damage, which can be reversed by eliminating reflux. Spectral Doppler analysis measures reflux duration, which is essential. Regarding the treatment, percutaneous embolization is a highly effective and minimally invasive procedure that successfully treats lesions such as varicoceles.

## VASCULITIS VENTURES: A RADIOLOGIST'S JOURNEY THROUGH LARGE VESSEL INFLAMMATION PATTERNS

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Simona Manole, MD (*Abstract Co-Author*) Nothing to Disclose
Ioana Popescu, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This presentation aims to:- Sensitize radiologists to vasculitides and the dynamic nature of studying these intricate conditions.- Outline the classification and characteristics of vasculitides, with a dedicated focus on large vessel vasculitis.- Underscore the key imaging features of large vessel vasculitis, predominantly through illustrative CTA case studies.- Explore the diagnostic challenges, including the identification of complications and even differentiation from mimicking entities.- Highlight the pivotal role of the radiologist within the multidisciplinary team in the diagnosis and management of vasculitides.

### TABLE OF CONTENTS/OUTLINE

1. Prepare Your Backpacks! - Introduction to vasculitis2. Choosing the Route - Anatomy of the main vessels and their branches3. Finding Your Way in the Dark(room) - Vascular imaging techniques and features 4. Learning the Language - The Revised International Chapel Hill Consensus Conference nomenclature of vasculitides5. Hop On and Let’s Go! - Example cases of primary large vessel vasculitides6. Still on the Road - Example cases of secondary large vessel vasculitides7. Let’s take a Detour! - Example cases of pulmonary large vessel vasculitides8. Navigating Obstacles - Complications of vasculitides9. Avoiding Wrong Turns - Differential diagnosis and mimickers of vasculitis10. It’s Better with Friends - Multidisciplinary approach to vasculitis management11. A Journey to Remember! - Take home messages

## NEW HORIZON OF CT IMAGE PROCESSING: INNOVATIVE DOSE REDUCING CTA SUBTRACTION TECHNIQUE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Katsumi Tsujioka, RT (*Abstract Co-Author*) Researcher, Canon Medical Systems Corporation
Emi Tomita (*Abstract Co-Author*) Nothing to Disclose
Takeo Uetsuki, BMedSc (*Abstract Co-Author*) Nothing to Disclose
Nobuaki Idobata (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Subtraction Computed Tomography Angiography (CTA) can accurately evaluate the vascular lumen in cases of high calcification, however, to perform the subtraction technique it is necessary to obtain non-contrast images as a mask in addition to the contrast enhanced images. Using recently developed image positioning technique in helical imaging, we propose a CTA subtraction that does not require the non-contrast mask images.

### TABLE OF CONTENTS/OUTLINE

[1] We propose a method to obtain non-contrast enhanced axial Images during positioning imaging and to omit the additional non-contrast imaging. [2] Subtraction CTA is a method in which only blood vessels are extracted by subtracting non-contrast images from CTA images. It is effective for the assessment of the vascular lumen, however, in addition to the CTA image, a non-contrast image mask must be acquired for the subtraction process, which increases the radiation exposure. [3] Non-contrast axial images can be obtained using low-dose helical positioning with an additive filter. [4] After obtaining CTA images, the positioning images and CTA images are reconstructed under the same conditions. The subtraction with non-rigid positioning is performed using a 3D workstation. [5] The subtraction CTA using positioning images and CTA images, does not require the additional exposure for mask image acquisition, but still facilitates observation and evaluation of the vessel lumen.

## WISDOM OF EVALUATING ENDOLEAK WITH 4D CT -HOW TO RELIABLY ACQUIRE IMAGES WITH LOW RADIATION DOSE AND SHORT SCANNING TIME-

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Takashi Nishiyama (*Presenter*) Nothing to Disclose

### TEACHING POINTS

It is possible to differentiate the type of Endoleak using 4D CT However, there are issues with the extension of scanning time and the tradeoff relationship between radiation dose and number of frames. This time, we have developed imaging method that reduces radiation dose by 40% and increases the number of frames by 2.25 times compared to conventional methods.

### TABLE OF CONTENTS/OUTLINE

We have developed method for differentiating Endoleak types using 4D CT, which reduces the radiation dose by 40% and increases the number of frames by 2.25 times compared to conventional methods. When it is difficult to maintain body position and hold breath for long time, it is necessary to accurately predict the time from just before contrast to the peak of CTA to minimize the scanning time. Therefore, we used Test Bolus Tracking, which allows us to start scanning at optimal timing. Furthermore, to obtain a high number of frames while reducing the radiation dose, we generated 120 bpm pulse generated from a simulated ECG and performed intermittent scanning As a result, we observed retrograde blood flow from the distal inferior mesenteric artery to the proximal inferior mesenteric artery at low radiation dose and short scanning time and could diagnose type II Endoleak. This method is effective in reducing scanning time, decreasing radiation dose, and increasing the number of frames, which are the issues of 4D CT.

## VASCULAR ABNORMALITIES OF HAND AND WRIST- STATE-OF-THE ART MULTIMODALITY IMAGING

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

**Awards**
**Cum Laude**

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1. To review the vascular anatomy and pathologies of the hand and wrist 2. To discuss the state-of-the-art imaging modalities in the evaluation of these vascular abnormalities 3. To illustrate the imaging appearances of various vascular abnormalities of hand and wrist

### TABLE OF CONTENTS/OUTLINE

1. INTRODUCTION 2. VASCULAR ANATOMY OF THE HAND AND WRIST- including superficial and deep palmar arches, metacarpal and digital arteries 3. IMAGING MODALITIES- Ultrasound, doppler, CT, MRI, DSA 4. CT TECHNIQUES- CT Angiography (CTA), Multiphasic acquisitions, Dynamic CTA, multienergy CT, High-resolution photon counting CT 5. MRI TECHNIQUES- Standard MRI, Conventional MRA, 3D T1w acquisitions, Time-resolved MRA, Non contrast MRI techniques - e.g. NATIVE 6. STANDARD CT AND MRI PROTOCOL 7. REVIEW AND ILLUSTRATION OF THE FOLLOWING VASCULAR ABNORMALITIES WITH CASE EXAMPLES a) a. Anatomical variations- Persistent median artery, arch variations; a. Trauma/Iatrogenic; b. Occupational- Hypothenar hammer syndrome, Hand arm vibration syndrome; c. Thromboembolus; d. Thromboangiitis obliterans, Raynaud disease; e. Vasoocclusive disease (including paraneoplastic syndrome); f. Frostbite; g. Intra-arterial drug injection/drugs/chemicals; h. Vasculitis/Autoimmune/rheumatic diseases; i. Infections ; j. Aneurysms/ Pseudoaneurysms; k. Vascular malformations- Arterial, venous, lymphatic; l. Vascular tumors- Pyogenic granuloma, spindle cell hemangioma, intravascular endothelial cell hyperplasia; m. Perivascular tumors- Glomus tumor, myopericytoma; n. Extrinsic compression by tumors; o. Hand transplant workup 8. PITFALLS 9. MISSES

## OMC! OH, MY COATED ANEURYSM: A MULTIMODALITY IMAGING GUIDE OF MYCOTIC ANEURYSMS FROM HEAD TO TOE

Sunday, Dec. 1 9:00AM - 6:00PM Room: LEARNING CENTER

Daniel Kowal, MD (*Abstract Co-Author*) Speaker, Samsung Electronics Co, Ltd
Mansha A. Khubchandani, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Mycotic aneurysms represent a rare yet perilous vascular condition, impacting the aorta and visceral, peripheral and cerebral arteries. They stem from the dilation and deterioration of the arterial wall triggered by bloodstream infection or septic embolization, often from infective endocarditis. Early detection and swift intervention are paramount for mitigating mortality. However, diagnosis can be hindered by nonspecific presenting symptoms, often resulting in advanced-stage diagnosis or delayed complications like rupture or fistula formation. While clinical factors and biomarkers may heighten suspicion, they lack specificity in diagnosis. Advanced imaging modalities like CT angiography and MRI have superseded conventional angiography as minimally invasive tools for both detecting suspected cases and characterizing confirmed cases, aiding in vascular mapping and treatment planning. Imaging findings include lobulated pseudoaneurysm, irregular wall, aneurysmal thrombosis and perianeurysmal gas, edema, abscess, soft tissue mass and lymphadenopathy. Familiarity with these imaging appearances can guide appropriate management, which typically entails a combination of antibiotic therapy, surgical debridement, revascularization, or endovascular procedures based on individual patient characteristics. This educational exhibit endeavors to immerse radiologists in a captivating cinematic journey throughout the body while highlighting the intricacies of mycotic aneurysms.

### TABLE OF CONTENTS/OUTLINE

Monday, Dec. 2 9:00AM - 9:30AM Room: LEARNING CENTER

**Sub-Events**

## M2-SPBR-1 PRECISION ENHANCEMENT IN ULTRASOUND-BASED BREAST CANCER DETECTION: A CLINICAL VALIDATION STUDY OF VIS-BUS TECHNOLOGY

Hyuksool Kwon (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic performance of Vis-BUS, powered by Barreleye Inc., a state-of-the-art AI-driven ultrasound tool designed to accurately distinguish between benign and malignant breast lesions. The study aims to validate the effectiveness of Vis-BUS, with a focus on improving diagnostic accuracy in breast cancer screening and identifying factors that affect performance.

### METHODS AND MATERIALS

Vis-BUS comprises two components: Lesion detection AI and Lesion analysis AI. The Lesion detection AI employs a b-mode image to identifies the location of the lesion. The neural networks are trained with 19k breast b-mode images using stochastic gradient descent method. The dataset consisted of 258 breast ultrasound examinations categorized by Vis-BUS into benign and malignant findings. The diagnostic accuracy was evaluated using the Area Under the Receiver Operating Characteristic (AUROC) and the Area Under the Precision-Recall Curve (AUPRC). Logistic regression analyzed factors associated with diagnostic discrepancies, specifically examining lesion size, calcification presence, and BI-RADS categories.

### RESULTS

Participants in the study had an average age of 48.2 years (SD = 11.0), and the average lesion size was 1.72 cm (SD = 1.40). Vis-BUS exhibited high diagnostic accuracy, as evidenced by an AUROC of 0.964 and an AUPRC of 0.967. Analysis of 33 misdiagnosed cases (12.79% error rate) revealed significant factors contributing to diagnostic errors. Lesion size showed a statistically significant influence, with an Odds Ratio (OR) of 1.79 (95% CI: 1.11 to 2.87; p=0.016), indicating increased misclassification risks with smaller lesions. The absence of calcification significantly affected outcomes, with an OR of 3.625 (95% CI: 1.23 to 10.69; p=0.020). Lower BI-RADS categories also correlated with increased diagnostic errors, with an OR of 1.42 (95% CI: 1.15 to 1.76; p=0.001). Interestingly, breast density was not a significant factor, highlighting the software's effectiveness across various breast types.

### CONCLUSION

The study confirms that Vis-BUS is a robust tool for breast cancer screening, capable of distinguishing between benign and malignant lesions with high accuracy. The identified predictive factors for misclassification provide targeted areas for further software refinement, especially in improving sensitivity towards benign conditions.

### CLINICAL RELEVANCE/APPLICATION

Vis-BUS's ability to deliver high accuracy in breast cancer detection is critical for clinical settings, where early and accurate diagnosis is paramount. Integrating Vis-BUS into routine screening practices can significantly enhance diagnostic accuracy, reduce misdiagnosis rates, and ensure timely and appropriate patient management.

## M2-SPBR-10 A MULTIMODAL DEEP LEARNING MODEL BASED ON PET/CT IMAGES AND ASSOCIATED REPORTS FOR BREAST CANCER SURVIVAL PREDICTION AND ANALYSIS

Ritse M. Mann, MD, PhD (*Abstract Co-Author*) Researcher, Siemens AG;Consultant, Siemens AG;Researcher, Bayer AG;Consultant, Bayer AG;Researcher, Medtronic plc;Consultant, Medtronic plc;Researcher, Becton, Dickinson and Company;Consultant, Becton, Dickinson and Company;Researcher, ScreenPoint Medical BV
Luyi Han (*Abstract Co-Author*) Nothing to Disclose
Yuan Gao, MS (*Abstract Co-Author*) Nothing to Disclose
Tianyu Zhang (*Abstract Co-Author*) Nothing to Disclose
Tao Tan (*Abstract Co-Author*) Nothing to Disclose
Xin Wang, MS (*Abstract Co-Author*) Nothing to Disclose
Chunyao Lu (*Abstract Co-Author*) Nothing to Disclose
Xinglong Liang (*Presenter*) Nothing to Disclose

### PURPOSE

To predict 5-year survival and risk scores for breast cancer patients using PET/CT images and accompanying reports.

### METHODS AND MATERIALS

In total 795 paired cases of PET/CT scans and reports of breast cancer patients at in-house medical center were retrospectively collected from 2008 to 2020 with 85% cases allocated for training (using 5-fold cross-validation) and 15% for testing. The multimodal model comprises two branches: one utilizing a pre-trained natural language processing model for report feature extraction and another based on convolutional neural network for image feature extraction. Pseudo masks of PET/CT scans generated using our trained tumor segmentation model were also utilized as inputs for the image input branch. The extracted features were fed into a Multi-Layer Perceptron to predict 5-year survival (alive or not) and into an attention-based multiple-instance learning model to predict risk scores. Performance was evaluated using the area under the receiver operating characteristic curve (AUC), accuracy, and the concordance index (C-index), hazard ratio (HR).

### RESULTS

The performance of the model using both images and reports was significantly better than each system individually in a single-modal setting for 5-year survival (AUC-Multimodal = 0.847, Accuracy=0.850, 95% CI [0.783,0.908]; AUC-Image=0.746, P<0.0001, Accuracy=0.758 95% CI [0.683 ,0.825]; AUC-Report=0.788, P<0.0001, Accuracy=0. 800 95% CI [0.716,0.867]) and for survival analysis (C-index-Multimodal=0.717 95% CI [0.649, 0.773], HR=2.78 95% CI [1.55,5.00]; C-index- Image=0.656 95% CI [0.583, 0.726], HR=1.72 95% CI [0.99,2.99]; C-index-Report=0.694 95% CI [0.623, 0.758], HR=7.41 95% CI [3.82,14.34]).

### CONCLUSION

Combining PET/CT images and associated reports in a deep learning based multi-modal prediction model improves prediction of breast cancer survival over the use of either modality alone.

### CLINICAL RELEVANCE/APPLICATION

This multi-modal approach may serve as a new avenue for breast cancer prognostication, and a blueprint for prognostication in other diseases. It can potentially be extended to include all types of information in the electronic medical record. By extracting different types of relevant information for clinical decision making it may support individualized treatment and care for breast cancer patients.

## M2-SPBR-11 V-NET DEEP LEARNING SEGMENTATION OF BREAST LESIONS ON 3T DCE-MR IMAGES

Nicolo Cardobi, MD (*Abstract Co-Author*) Nothing to Disclose
Stefania Montemezzi, MD (*Abstract Co-Author*) Nothing to Disclose
Pier Giorgio Esposito (*Abstract Co-Author*) Nothing to Disclose
Carlo Cavedon, DPhil (*Abstract Co-Author*) Nothing to Disclose
Marina Fedon Vocaturo (*Abstract Co-Author*) Nothing to Disclose
Giuseppe Cardano (*Abstract Co-Author*) Nothing to Disclose
Luisa Altabella (*Presenter*) Nothing to Disclose

### PURPOSE

In medical imaging, lesion segmentation is a crucial step for monitoring tumor progression and/or extracting radiomic features to characterize lesions. Traditionally, this task relies on time consuming manual input, affected by operator variability and impacting subsequent analysis. Automated approaches aim to mitigate this variability. This study focuses on developing an automated deep learning (DL) segmentation model for malignant breast lesion segmentations on DCE-MRI based on V-Net architecture.

### METHODS AND MATERIALS

A retrospective study involved 131 women who underwent DCE-MRI before neoadjuvant chemotherapy (NAC) between January 2016 and November 2021 on a 3T MRI scanner. Manual segmentation of the second subtracted post-contrast image was used to train a V-Net algorithm. A two-stage approach was employed, consisting in a first model to segment the whole breast and a second model to segment lesions within the breast ROI. More precisely, in the first step, raw breast segmentations, with ample borders, were used to train an initial V-Net architecture to obtain a breast mask prediction, producing a model that effectively restricts the area for further lesion detection. Then images were divided into smaller 3D patches to capture fine-grained features. V-Net model was applied to the non-empty tiles of the breast image to identify lesion. A final fine tuning on the lesion patch was performed to set the threshold and reduce false positives. Several parameters in terms of percentage of background patches used and binarization threshold were evaluated to obtain the best performing model.

### RESULTS

Using 100% background patches and 0.6 threshold yields the best performance, with fewer outliers and higher overall accuracy, with a median 0.9998 (IQR: 0.9995-0.9999) both for train an test. This results in a median Dice score of 0.77 (IQR 0.66-0.83) for the training set and 0.71 (IQR 0.51-0.82) for the test set comparing human and automated segmentation tasks. Furthermore, automatic segmentation was approximately 5 times faster than manual segmentation.

### CONCLUSION

Preference was shown for utilizing all image information (100% background) and employing a higher threshold to reduce false positives. Despite satisfactory results, improvements are possible through dataset augmentation, architectural modifications, and hardware upgrades.

### CLINICAL RELEVANCE/APPLICATION

The proposed automated segmentation achieved its primary goal of reducing human operator variability and providing a time-efficient segmentation. While reducing operator variability and providing efficient segmentation, human supervision is still necessary to address false positives and fine-tune thresholds.

## M2-SPBR-2 FULLY AUTOMATED INTERPRETATION OF ABBREVIATED BREAST MRI BY MACHINE LEARNING

Christiane K. Kuhl, MD, PhD (*Abstract Co-Author*) Advisory Board, Guerbet SA;Speaker, Bracco Group;Speaker, Bayer AG
Gustav Mueller-Franzes, PhD (*Abstract Co-Author*) Nothing to Disclose
Daniel Truhn, MD (*Abstract Co-Author*) Research Consultant, Aristra Medical
Maike Bode, MD (*Abstract Co-Author*) Nothing to Disclose
Debora Jutz (*Presenter*) Nothing to Disclose

### PURPOSE

Abbreviated breast MRI (AB-MRI) is increasingly used for screening of breast cancer. Artificial Intelligence (AI) models for the detection of breast cancer in AB-MRI can potentially support radiologists. Here, we compare an AI model working on the full diagnostic MRI protocol (FDP) vs. an AI model working on the AB-MRI protocol (AP).

**METHODS AND MATERIALS**

In a retrospective study on 7,835 patients, who received breast MRI examinations between 2010 and 2017, two neural network architectures (ResNet18 and ResNet50) were trained both on the full diagnostic protocol and on the abbreviated protocol. Receiver operator characteristics, sensitivities and specificities were compared using five-fold cross validation.

**RESULTS**

The ResNet18 network trained on the FDP achieved an AUC of 0.911±0.007, while the same neural network trained on the AP had an AUC of 0.905±0.002. Sensitivity and specificity were 0.825±0.043 and 0.857±0.027 for the neural network trained on the FDP, and 0.793±0.034 and 0.876±0.035 for the neural network trained on the AP. The ResNet50 network achieved AUCs of 0.904±0.004 and 0.911±0.004 trained on the FDP and the AP respectively. Sensitivity and specificity were 0.823±0.049 and 0.849±0.036 for the neural network trained on the FDP, and 0.791±0.027 and 0.891±0.011 for the neural network trained on the AP.

**CONCLUSION**

Neural networks trained on the AP achieve accuracies comparable to networks trained on the FDP, thus questioning the need for the FDP when using AI models.

**CLINICAL RELEVANCE/APPLICATION**

The abbreviated protocol could be used to increase throughput of examinations in the screening setting. In line with existing literature on human reader studies we did not find evidence that the FDP is superior to the AP when using AI models.

## M2-SPBR-3 INTEGRATION OF MULTI-INFORMATION FROM TIME-INTENSITY CURVE AND BI-RADS SCORE IN A DEEP LEARNING MODEL FOR DISCRIMINATION OF BENIGN AND MALIGNANT BREAST LESIONS USING DCE-MRI

Yanfen Cui (*Abstract Co-Author*) Nothing to Disclose
Zaiyi Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Yanting Liang (*Abstract Co-Author*) Nothing to Disclose
Chu Han (*Abstract Co-Author*) Nothing to Disclose
Chinting Wong (*Abstract Co-Author*) Nothing to Disclose
Zhenwei Shi, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a deep learning model on DCE-MRI scans for discrimination of benign and malignant breast lesions.

**METHODS AND MATERIALS**

A retrospective analysis was conducted on multi-phase DCE-MRI scans obtained from over 2805 patients between January 2010 and July 2023 from three different hospitals. The deep learning (DL) framework employed a Vision Transformer architecture and consisted of two stages: transfer learning using an in-house pre-trained MRI foundation model and fine-tuning. In the pre-training stage, a contrastive learning algorithm (MoCoV3) was applied to 14,070 MRI scans. The fine-tuning process incorporated multi-phase of DCE-MRI scans to mimic the time-intensity curve (TIC) and integrate diagnostic BI-RADS scores, with the aim of minimizing the risk of false-positive results. A Breast tumor Benign and Malignant (B2M) score was generated by the deep learning model and its performance was evaluated using metrics such as the area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity. To enhance interpretability, the Grad-CAM method was employed to visualize the attention heatmap of the deep learning model.

**RESULTS**

The training dataset consisted of 1705 patients with 1806 lesions (median age, 46.5 years [IQR, 31.2-68.4 years]) from center A, while the two external test datasets included over 315 patients with 336 lesions and 785 patients with 902 lesions (median age, 44.6 years [IQR, 39.5-77.2 years]). The B2M score exhibited significant association with discrimination of benign and malignant breast tumors, with odds ratio of 4.12 [95% CI: 3.57,4.75]; P < .001. The final model demonstrated excellent performance in the internal validation dataset (AUC, 0.95) and the external test datasets (AUC range, 0.92-0.96). The accuracy and sensitivity were 0.89 and 0.92 in test dataset 1, and 0.83 and 0.92 in test dataset 2, respectively.

**CONCLUSION**

This study developed a prediction model that combined multi-information from DCE-MRI scans and integrated BI-RADS scores showed excellent performance for discriminating benign and malignant breast lesions.

**CLINICAL RELEVANCE/APPLICATION**

The developed predictive model enables a comprehensive assessment of breast lesions, aiding in accurate diagnosis and treatment planning for breast cancer patients.

## M2-SPBR-4 SUPER-RESOLUTION ULTRASOUND RADIOMICS TO PREDICT POSTOPERATIVE UPSTAGING OF DUCTAL CARCINOMA IN SITU

Jianhua Zhou, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Liang Yang (*Presenter*) Nothing to Disclose

**PURPOSE**

We aimed to develop a model for predicting the postoperative upstaging of DCIS based on super resolution (SR) ultrasound images.

**METHODS AND MATERIALS**

In this multicenter retrospective study, patients with biopsy-proven DCIS underwent ultrasound examination were included from 4 independent centers between January 2015 and June 2023 (center 1, training and validation set; center 2, 3 and 4, external test set). We used a super-resolution reconstruction algorithm to enhance the resolution of original high resolution (HR) ultrasound images and obtain SR images. The selected HR radiomics features and SR radiomics features were combined with clinical features to construct the HR fusion model and SR fusion model, respectively. The diagnostic performance of the models and radiologists were then evaluated using area under receiver operating characteristic curve (AUC) and decision curve analysis.

**RESULTS**

A total of 681 women (median age, 47 years; interquartile range, 42-54) with 681 biopsy-proven DCIS lesions were included, with 106 lesions in validation set and 153 lesions in external test set. The SR Fusion model achieved an AUC of 0.819 (0.732-0.890) in the validation set and 0.800 (95% CI 0.728-0.860) in the external test set, outperforming radiologists (AUC = 0.62, 95% CI 0.58-0.65; P < 0.001), clinical model (AUC = 0.682, 95% CI 0.602-0.755; P = 0.016) and HR Fusion model (AUC = 0.724, 95% CI 0.646-0.793; P = 0.034) in the external test set.

**CONCLUSION**

The SR Fusion model integrating SR features and clinical features can effectively predict the postoperative upstaging of DCIS.

**CLINICAL RELEVANCE/APPLICATION**

The radiomics model can effectively predict the upstaging of DCIS and the super-resolution images can improve the performance of radiomics model compared to the original ultrasound images.

## M2-SPBR-6 ASSESSMENT OF BREAST POSITIONING IN DIGITAL MAMMOGRAPHY: PERFORMANCE OF AN ARTIFICIAL INTELLIGENT QUALITY CONTROL SYSTEM AND AGREEMENT WITH RADIOGRAPHERS

Huizhi Cao (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to assess breast positioning in digital mammography using an artificial intelligent quality control system (AIQCS) and determine the agreement between the AI system and radiographers.

**METHODS AND MATERIALS**

Breast positioning assessment was conducted using an AI system (Edison, GE Healthcare) and by four radiographers on 223 examinations of women. Nine image quality criteria were employed for craniocaudal and mediolateral-oblique views, covering various aspects of breast positioning. The area under the receiver operating characteristic curve (AUC) was calculated to predict poor imaging quality by the AI system based on criteria such as incomplete gland, incomplete pectoralis muscle, and exposure. Intraclass correlation and Cohen's kappa coefficient (?) were used to evaluate correlation and agreement between radiographers and AI.

**RESULTS**

The AUC for poor imaging quality prediction by the AI system ranged from 0.903 to 0.982, with an overall accuracy of 0.958. Intraclass correlation for the pectoral nipple line between radiographers and AI was >0.80. Substantial to almost perfect agreement (? >0.85) was observed between radiographers and AI for the nipple in profile criterion. Agreement varied from slight to moderate (? = 0.40-0.65) for other criteria, with higher agreement observed between pairs of radiographers (mean ? = 0.70) than between radiographers and AI (mean ? = 0.61).

**CONCLUSION**

AI shows promise in evaluating breast position criteria in mammography, reducing subjectivity. However, varying agreement between radiographers and AI was observed.

**CLINICAL RELEVANCE/APPLICATION**

Accurate breast positioning with AI systems is crucial for quality control in mammography, ultimately contributing to optimal image quality and improved diagnostic accuracy.

## M2-SPBR-7 A MULTIPARAMETRIC MRI-BASED RADIOMIC MODEL FOR STRATIFYING POSTOPERATIVE RECURRENCE IN LUMINAL B BREAST CANCER

Sicong Huang (*Abstract Co-Author*) Nothing to Disclose
Maosheng Xu, MD (*Abstract Co-Author*) Nothing to Disclose
Ruixin Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop an MRI-based radiomics model to assess the likelihood of recurrence in Luminal B breast cancer.

**METHODS AND MATERIALS**

The study analyzed medical images and clinical data from 244 patients with Luminal B breast cancer. Of 244 patients, 35 had experienced recurrence and 209 had not. The patients were randomly divided into the training set (51.5 ± 12.5 years old; n = 171) and the test set (51.7 ± 11.3 years old; n = 73) in a ratio of 7:3. The study employed univariate and multivariate Cox regression along with the least absolute shrinkage and selection operator (LASSO) regression methods to select radiomic features and calculate a risk score. A combined model was constructed by integrating the risk score with the clinical and pathological characteristics.

**RESULTS**

The study identified two radiomic features (GLSZM and GLRLM) from DCE-MRI were used to calculate a risk score. The AUCs were 0.860 and 0.868 in the training set, and 0.816 and 0.714 in the testing set for 3- and 5-year recurrence risk, respectively. The combined model incorporating the risk score, pN, and endocrine therapy showed improved predictive power, with AUCs of 0.857 and 0.912 in the training set and 0.943 and 0.945 in the testing set for 3- and 5-year recurrence risk, respectively. The calibration curve of the combined model showed good consistency between predicted and measured values.

**CONCLUSION**

Our study developed an MRI-based radiomic model that integrates clinical and radiomic features to assess the likelihood of recurrence in Luminal B breast cancer. The model shows promise for improving clinical risk stratification and treatment decision-making.

**CLINICAL RELEVANCE/APPLICATION**

This study developed a predictive model for the recurrence of Luminal B breast cancer based on DCE-MRI radiomic features. Due to the importance of proper diagnosis and evaluation in treating Luminal B breast cancer, the algorithm proposed herein may offer a high degree of clinical utility in guiding personalized treatment.

## M2-SPBR-8 ASSESSING MAMMOGRAPHY POSITIONING QUALITY AND VARIABILITY BETWEEN AND WITHIN BREAST SCREENING PROGRAMS DURING THE COVID-19 PANDEMIC: A MULTICENTRE STUDY USING A.I. TO EVALUATE POPULATION-LEVEL UNMET MAMMOGRAPHY POSITIONING CRITERIA

Laurie R. Margolies, MD (*Presenter*) Stock options, Nuevozen Corporation Medical Advisory Board, Screenpoint Medical

### PURPOSE

This multicentre study aimed to evaluate the impact of COVID-19-related safety measures, such as the use of personal protective equipment (PPE) and service suspensions, on mammography positioning quality and its variability across breast screening programs (BSPs) in North America and Europe. The study sought to determine whether these pandemic-induced operational changes influenced the consistency of mammographic imaging quality between and within BSPs.

### METHODS AND MATERIALS

A total of 249,817 screening mammograms from seven BSPs, collected between December 1, 2019, and February 28, 2021, were included. Relative variability of unmet positioning criteria rates was assessed using the Coefficient of Variation (CV) between and within BSPs and MUs in that period. Unmet positioning criteria rates pre-post first onset of COVID-19 were assessed on a subset of 50,000 mammograms obtained during the 10 weeks preceding March 15, 2019, and the 10 weeks following the resumption of services post the first COVID-19 wave. Mammography positioning and compression criteria were assessed for all mammograms using AI algorithms (Densitas intelliMammo® ), and included 19 image-level criteria and an overall (PGMI=Perfect/Good/Moderate/Inadequate) study-level score. Ethics approvals were obtained from all participating BSPs.

### RESULTS

There were no statistically significant changes in the unmet positioning criteria rates before and after the initial COVID-19 wave across the BSPs (all p-values > 0.05), indicating that pre-pandemic quality levels were maintained. However, the study highlighted significant variability in unmet positioning criteria both between and within BSPs; the CV ranged from 9.51% for under/over compression to 60.25% for inadequate (PGMI=I) quality studies, with overall median variability across BSPs noted at 83.46%.

### CONCLUSION

The findings demonstrate that despite the disruptions caused by the COVID-19 pandemic, that would have included PPE use and other safety protocols, mammography positioning quality within the BSPs remained consistent with pre-pandemic levels.Limitations: Technologist experience, training protocols, and patient-specific characteristics, which could influence the observed variability, were not available for analysis.

### CLINICAL RELEVANCE/APPLICATION

The observed variability in error rates of images accepted for interpretation both between and within BSPs underscores the challenges in achieving uniform standards of mammographic quality across different operational environments. The results highlight the need for continued and perhaps increased attention to mammographic image quality as the study suggests that too many exams with unmet positioning criteria may be being accepted for interpretation.

## M2-SPBR-9 POST-MARKET SURVEILLANCE OF AI IN A BREAST CANCER SCREENING SETTING

Adnan Taib (*Abstract Co-Author*) Nothing to Disclose
Yan Chen, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Artificial intelligence (AI) models are likely to be updated whilst already embedded into screening workflows. Testing these new models through traditional research methods may be too slow in determining if these new models are safe to the public. We outline a method of rapidly evaluating different versions of the same AI model using the same Personal Performance in Mammographic Screening (PERFORMS) external quality assurance (EQA) scheme used to test humans.

### METHODS AND MATERIALS

In this study, ten PERFORMS test sets including 1200 breasts sourced from multiple centres in the United Kingdom National Health Service breast cancer screening programme were evaluated by three consecutive versions of the same commercially available AI algorithm between 2022-2024. Version (V) 1 was the earliest version of the AI, whilst V3 was the most recent. Test sets contained a mixture of challenging cases including interval cancers specially selected by an expert panel of radiologists. Each breast was considered separately. For pathologically proven malignancies a lesion level analysis was conducted, where the location of marked regions of interest were considered for AI. The highest score was recorded per lesion. For non-malignant breasts, a breast level analysis was conducted, where the highest score per breast was recorded. Sensitivity and specificity were calculated for AI. The study was powered to detect a medium-sized effect (odds ratio, 3.5 or 0.29) for sensitivity.

### RESULTS

Three versions of the same AI model were monitored using a test set comprising of 882 non-malignant breasts and 328 malignant lesions. When using the developer's suggested recall score threshold, the sensitivities for AI V1, V2 and V3 were 87%, 89% and 83% respectively. AI V3 exhibited significant variation in its sensitivity when compared to V2 (OR 0.60, p=.027). When comparing specificity at the same threshold, no difference was observed between V1 (87%), V2 (88%) and V3 (90%), p=.18.

### CONCLUSION

Reliability testing of updated AI models already integrated into clinical practice is of paramount importance to detect for performance drift during updates and to assist in the recalibration of AI recall thresholds.

## CLINICAL RELEVANCE/APPLICATION

Rapidly testing newer versions of the same AI model on the same homogenous EQA test sets may enable the detection of subtle changes in performance. Such methods could inform a novel framework used in the post-market surveillance of AI models.

## M2-SPCA-1 SYNTHETIC EXTRACELLULAR VOLUME FRACTION DERIVED USING DEEP LEARNING WITH A CONVOLUTIONAL NEURAL NETWORK

Yusuke Kobayashi (*Abstract Co-Author*) Nothing to Disclose
Takuya Matsuda (*Abstract Co-Author*) Nothing to Disclose
Wataru Toshimori (*Abstract Co-Author*) Nothing to Disclose
Teruhito Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuki Tanabe (*Abstract Co-Author*) Nothing to Disclose
Takaaki Hosokawa (*Abstract Co-Author*) Nothing to Disclose
Kazuki Yoshida, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The extracellular volume fraction obtained using cardiac computed tomography (CT)-extracellular volume fraction (CT-ECV) was used to assess myocardial fibrosis. However, laboratory blood hematocrit (Hct) measurements are also required. We hypothesized that the application of deep learning (DL) with a convolutional neural network (CNN) can predict Hct from calcium score images and calculate ECVDL without requiring a blood sampling.

### METHODS AND MATERIALS

We enrolled 270 patients who underwent cardiac CT and laboratory blood hematocrit examinations on the same day. We cropped five axial calcium score images (five-slice gaps) from the bronchial bifurcation level. Among them, 216 (864 axial images), 54 (216 axial images), and 40 patients (200 axial images) were assigned to the training dataset for DL model development, validation, and testing, respectively. Furthermore, in the test dataset, we evaluated ECV estimation using HctDL. The original ECV was calculated by blood sampling Hct using dedicated software. ECVDL was calculated using the HctDL. The correlations between Hct and HctDL, original ECV, and ECVDL were assessed using Spearman's rank correlation test and a Bland-Altman analysis.

### RESULTS

No significant difference was found between Hct and HctDL at the patient level (35.5 ± 4.0% vs. 36.2 ± 2.9%, respectively, $p = 0.26$). HctDL and Hct levels were moderately correlated ($r = 0.65$, $p < 0.01$). Bland-Altman analysis showed slight bias (-0.681%) between HctDL and Hct with 95% limits of agreement of -6.6 and 5.3. There was no significant difference between ECV and ECVDL at the patient level (28.6%, 26.6-32.9% vs. 28.2%, 25.8-33.3 %, respectively; $p = 0.36$). ECVDL and original ECV were strongly correlated ($r = 0.99$, $p < 0.001$). The Bland-Altman analysis showed slight bias (0.227%) between ECVDL and the original ECV with 95% limits of agreement of -2.78 and 3.24 at the patient level.

### CONCLUSION

A reliable ECV estimation can be achieved using calcium score images and DL with a CNN. The ECVDL values calculated from HctDL showed excellent agreement with the original ECV, indicating the robustness of the ECV estimation without the need for blood sampling.

### CLINICAL RELEVANCE/APPLICATION

Hct derived from calcium score images using DL with a CNN enables the accurate quantification of the myocardial extracellular volume fraction by cardiac CT without the need for blood sampling. Overcoming blood sampling limitations could expand the usefulness of CT-ECV for myocardial tissue characterizations.

## M2-SPCA-10 AI-ENABLED CARDIAC CHAMBERS VOLUMETRY IN CORONARY ARTERY CALCIUM (CAC) SCANS (AI-CAC) SIGNIFICANTLY IMPROVES ON AGATSTON CAC SCORE FOR PREDICTING ALL CARDIOVASCULAR EVENTS: THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

Morteza Naghavi (*Presenter*) Nothing to Disclose

**PURPOSE**

Coronary artery calcium (CAC) scans contain valuable information beyond the Agatston Score which is currently reported for predicting coronary heart disease (CHD) only. We examined whether new artificial intelligence (AI) algorithms applied to CAC scans may provide significant improvement in prediction of all cardiovascular disease (CVD) events in addition to CHD, including heart failure, atrial fibrillation, stroke, resuscitated cardiac arrest, and all CVD-related deaths.

**METHODS AND MATERIALS**

We applied AI-enabled automated cardiac chambers volumetry and automated calcified plaque characterization to CAC scans (AI-CAC) of 5830 individuals (52.2% women, age 61.7±10.2 years) without known CVD that were previously obtained for CAC scoring at the baseline examination of the Multi-Ethnic Study of Atherosclerosis (MESA). We used 15-year outcomes data and assessed discrimination using the time-dependent area under the curve (AUC) for AI-CAC versus the Agatston Score.

**RESULTS**

During 15 years of follow-up, 1773 CVD events accrued. The AUC at 1-, 5-, 10-, and 15-year follow up for AI-CAC vs Agatston Score was (0.784 vs 0.701), (0.771 vs. 0.709), (0.789 vs.0.712) and (0.816 vs. 0.729) ($p<0.0001$ for all), respectively. The category-free Net Reclassification Index of AI-CAC vs. Agatston Score at 1-, 5-, 10-, and 15-year follow up was 0.31, 0.24, 0.29 and 0.29 ($p<.0001$ for all), respectively. AI-CAC plaque characteristics including number, location, and density of plaque plus number of vessels significantly improved NRI for CAC 1-100 cohort vs. Agatston Score (0.342).

**CONCLUSION**

In this multi-ethnic longitudinal population study, AI-CAC significantly and consistently improved the prediction of all CVD events over 15 years compared with the Agatston score.

**CLINICAL RELEVANCE/APPLICATION**

Opportunistic screening of enlarged cardiac chambers in non-contrast CT scans enables detection of asymptomatic patients at high risk for CVD.

## M2-SPCA-3 PRECISION OF AUTOMATED CARDIAC CHAMBERS AND GREAT VESSEL VOLUME SEGMENTATION IN DIFFICULT CASES USING AN OPEN SOURCE FULL BODY SEGMENTATION MODEL

Matthias S. May, MD (*Abstract Co-Author*) Speakers Bureau, Siemens AG
Leonard Stepansky (*Abstract Co-Author*) Nothing to Disclose
Lisa Sommerfeld (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the precision of automated cardiac and great vessel segmentation using the 'Total Segmentator' (TS) by Wasserthal et al. in patients with structural abnormalities.

**METHODS AND MATERIALS**

The study involved 89 CT scans, including a control group of clinical routine cases and 13 balanced study groups representing various structural abnormalities (Chest wall deformities, hypertrophic cardiomyopathies (HCM), aortic, mitral or tricuspid valve replacement, left ventricular assist devices (LVAD), newborns (under age one), preschool children (age one to four), elementary school children (age five to nine), secondary school children (age ten to sixteen), adults with transposition of the great arteries (TGA), situs inversus or Fontan circulation). Imaging was retrospectively chosen from multiple CT scanners from the years 2012 to 2024, utilizing soft tissue kernel and intravenous contrast agents. Automated segmentation of six mediastinal structures (left and right atrium and ventricle, aorta, pulmonary artery) was followed by manual corrections. Statistical analysis with the dice coefficient and surface dice ensued.

**RESULTS**

The model performed well (dice=0.9) on clinical routine cases. It did not perform significantly (pgt0.05) inferior on patients with chest wall deformities (dice=0.87), HCMs (dice=0.88), aortic (dice=0.87), mitral (dice=0.88) and tricuspid valve replacements (dice=0.88). LVADs were segmented adequate (dice=0.87), except for the left heart (atrium surface dice=0.2, ventricle dice=0.69). In children below one year of age, the TS didn't reliably detect the structures (dice=0.23). The precision increased with age. Only the great arteries were segmented inferior in patients between 10 and 16 years (total dice=0.88, aorta surface dice=0.51, pulmonary surface dice=0.37). In adults with congenital heart disease the algorithm performed inferior than on the clinical routine collective with a dice of 0.46 in patients with TGA, 0.38 in patients with a situs inversus and 0.43 in patients with Fontan circulation.

**CONCLUSION**

The algorithm provides dependable results for segmentation in clinical routine patients, patients with chest wall deformities, HCM and replaced heart valves. In patients with a LVAD only the segmentation of the left heart is inconsistent. Patients aged 0 to 9 need manual segmentation. Adolescents between 10 and 16 years of age had good results of the heart chambers, but the great arteries were limited. In adults with congenital heart disease the algorithm does not perform adequate.

**CLINICAL RELEVANCE/APPLICATION**

These findings indicate that in clinical practice, full body algorithms are sufficient for most heart measurements, but corrections are required for certain pathologies and age groups.

## M2-SPCA-5 OPTIMIZING AI THRESHOLDS FOR THE DETECTION OF ACTIONABLE CORONARY ARTERY CALCIUM IN CHEST CT IMAGING: A VALIDATION STUDY AGAINST HUMAN SCORING

Travis Browning, MD (*Abstract Co-Author*) Consultant, Change Healthcare

Wyatt Miller (*Abstract Co-Author*) Nothing to Disclose
Ann Marie Navar (*Abstract Co-Author*) Nothing to Disclose
Fernando U. Kay, MD, PhD (*Presenter*) Research Grant, Edwards Lifesciences Corporation

**PURPOSE**

We implemented an AI software to quantify coronary artery calcium volume (AI-CACvol) in chest CT scans at UT Southwestern in September 2022. Our goal was to retrospectively establish optimal detection thresholds for actionable CAC and validate their performance in a post-implementation population. AI results were compared against qualitative human CAC scoring (H-CACqual).

**METHODS AND MATERIALS**

Eligible patients had undergone a non-contrast chest CT and a cardiac CT with Agatston CAC scoring (CACscore, standard of reference). CACvol was calculated using commercially available AI software (AI Rad Companion, Siemens), and H-CACqual involved subjective CAC scoring by a board-certified radiologist following 2016 SCCT/STR guidelines.

**RESULTS**

The derivation cohort included 333 patients (59% female, median age 62 years, range 28-92 years). Median AI-CACvol was 21.0 $mm^3$ (IQR: 193.0 $mm^3$); median CACscore was 30.7 AU (IQR: 250.0 AU). The Pearson's correlation coefficient for log-transformed AI-CACvol and CACscore was 0.91 (95% CI: 0.88-0.92). H-CACqual showed significant association with CACscore, Spearman's correlation coefficient 0.90 (95% CI: 0.88-0.92). ROC curve analysis for detecting CACscore = 100 AU showed an AUC of 0.97 for AI-CACvol vs. 0.92 for H-CACqual ($p < 0.001$). Optimal thresholds were 70.1 $mm^3$ for AI-CACvol and "moderate" or greater for H-CACqual. In the prospective cohort of 39 patients (75% female, median age 67 years, range 46-80 years), median CACscore was 43 AU (IQR: 215 AU). Using the optimized threshold, AI-CACvol achieved 100% sensitivity and 88% specificity for detecting higher-risk patients, compared with 71% sensitivity and 100% specificity for H-CACqual.

**CONCLUSION**

AI-CACvol correlates strongly with the Agatston method and could be a precise, accessible metric for opportunistic cardiovascular risk screening.

**CLINICAL RELEVANCE/APPLICATION**

AI-CACvol is offering high-performance thresholds that might inform future automated best practice alerts.

## M2-SPCA-7 DEEP LEARNING FOR CORONARY ARTERY CENTERLINE EXTRACTION FROM CORONARY CT ANGIOGRAPHY

Antonio Esposito, MD (*Abstract Co-Author*) Support, Bracco Group;Speakers Bureau, Bayer AG
Alberto Colombo (*Abstract Co-Author*) Nothing to Disclose
Davide Vignale (*Abstract Co-Author*) Nothing to Disclose
Anna Palmisano, MD (*Abstract Co-Author*) Nothing to Disclose
Francesco Pisu (*Presenter*) Nothing to Disclose

**PURPOSE**

Coronary Computed Tomography angiography (CCTA) represents the non-invasive imaging of choice for the assessment of coronary artery disease (CAD). Multi-planar reconstructions of vessels by means of centerlines enable stenosis detection and plaque identification and are needed to extract radiomic features for research. However, manual delineation is unfeasible and commercially available tools are not suitable for research due to several limitations: inaccurate tracing of centerlines, particularly near bifurcations; frequent errors in mapping the lumen centerline requiring manual edits; and a lack of automated batch processing capabilities. Aim of the present study is to develop a fully-automated deep-learning (DL) based method to accurately extract topology-preserving coronary centerlines from CCTA images.

**METHODS AND MATERIALS**

A 2D U-Net model was trained to segment the coronary lumen. For each anatomical axis, the network predicted the likelihood of each voxel belonging to the lumen, followed by a majority voting retaining voxels selected by at least two views. Lumen meshes were extracted via marching cubes and clipped at the ostia. Centerline extraction involved tracing the paths of steepest descent of the eikonal solution solved on the embedded Voronoi diagram. Performance were evaluated based on overlap with manual annotations through Intersection over Union (IoU), F1-score, total overlap (OV) and average distance (AD). The model was trained on 64 CCTA - 40 from the public ASOCA dataset and 24 from our institution - and evaluated on 20 unseen cases presenting different CAD severity scores. CCTA were acquired using multi-vendor scanners with prospective and retrospective ECG gating and reconstructed at end-diastolic, end-systolic and in 10% increments. In-plane resolution was 0.3-0.4 mm and slice thickness was 0.3-0.62 mm.

**RESULTS**

The method showed high accuracy in segmentation and centerline extraction. Class-specific mean IoU was 76%±3 and F1-score was 0.87±0.02. Mean centerline OV was 92%±0.09, with AD of 0.48mm±0.06 from the reference, which was close to the mean voxel size. It was also computationally efficient, with the entire pipeline processing an exam in approximately 50 seconds.

**CONCLUSION**

This study confirms the effectiveness of a DL-based method for automated centerline extraction from CCTA. The approach extracts highly accurate centerlines in a short time, making it suitable for clinical workflows, large-scale studies and precise segmental analysis of periluminal tissue.

**CLINICAL RELEVANCE/APPLICATION**

The proposed pipeline supports rapid and accurate coronary centerline extraction, thus potentially speeding up stenosis and plaque characterization, crucial for timely and effective patient care in cardiology.

## M2-SPCA-8 REAL-WORLD CLINICAL DEPLOYMENT AND VALIDATION OF MACHINE-LEARNING ALGORITHM FOR CORONARY ARTERY CALCIUM SCORING ON LUNG CANCER SCREENING LOW DOSE CT EXAMS: INITIAL INSIGHTS

Leslie Ciancibello, RT (*Abstract Co-Author*) Nothing to Disclose
Cody R. Johnson, MD (*Abstract Co-Author*) Nothing to Disclose
Amit Gupta, MD (*Abstract Co-Author*) Nothing to Disclose
Robert C. Gilkeson, MD (*Abstract Co-Author*) Research Consultant, Riverain Technologies, LLC;Research support, Koninklijke Philips NV;Research support, Siemens AG;Research support, General Electric Company;Consultant, HeartFlow, Inc
Syed Muhammad Awais Bukhari, MD (*Abstract Co-Author*) Nothing to Disclose
Joshua Hunter, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate, in a real-world clinical setting, the accuracy of a machine learning algorithm (MLA) in coronary artery calcium (CAC) scoring on lung cancer screening (LCS) low-dose CT (LDCT) chest exams and the potential to replace dedicated CAC scoring exams.

**METHODS AND MATERIALS**

49 patients (55% female, 61 ± 6 y/o) were identified who underwent ECG-gated cardiac CT (CCT) for CAC scoring and LCS LDCT on the same day since real-world deployment of a MLA (Bunkerhill Inc., CAC Version 1.3.0) that computes CAC score on LDCT. To further evaluate reliability of the MLA's scoring, manual scoring on LDCT was also performed. Agatston CAC scores and resultant risk category were recorded for all three methods. Performance metrics of LDCT-derived scores were calculated with the CCT-derived score as ground truth. Mean difference in scores and agreement on risk category were evaluated with Bland-Altman analysis and Cohen's kappa, respectively.Dose length product (DLP) was recorded for radiation analysis. A cardiothoracic radiologist performed a subjective visual analysis to determine the preferred calcium score between CCT and LDCT exam for all patients.

**RESULTS**

On LDCT, the MLA achieved accuracy, sensitivity and specificity of .94, .95 and .91, respectively, for detection of CAC. The MLA's risk category matched CCT's in 78% of exams and differed by one in the rest, signifying excellent agreement (Kappa = 0.84). Bland-Altman analysis revealed a mean difference of 4.1 in CAC score (p = 0.85; Wilcoxon matched pairs test). Separately, MLA and manual scoring of LDCT agreed on risk category in 76% of exams and differed by one in the rest, signifying excellent agreement (Kappa = 0.83). Average DLP (mGy·cm) was 72.7 ± 15.8 in CCT and 125.0 ± 24.2 in LDCT, demonstrative of potential to reduce radiation exposure by 35% if LDCT CAC score is used. Radiologist's subjective preference for CAC score by exam type was CCT in 35%, LDCT in 16%, and no preference in 49% of cases.

**CONCLUSION**

In real-world clinical use, the MLA demonstrated excellent accuracy in computing and risk stratifying CAC from LCS LDCT exams. Cases of clinically relevant differences in CAC score highlight how radiologists must serve as gatekeepers of AI; for example, noting possible sources of MLA errors to infer inaccuracies in automated CAC scores. The reliability of MLA-assisted CAC scoring on LDCT shows that ECG-gated CCT may be unnecessary in most patients undergoing LCS, which could potentially reduce radiation by 35% in a population vulnerable to radiation's harms.

**CLINICAL RELEVANCE/APPLICATION**

MLA tools for CAC scoring on LDCT exams in real-world clinical practice are reasonably accurate and, in the future, can potentially replace dedicated CAC scoring exams to reduce radiation exposure in most patients undergoing LCS.

## M2-SPCA-9 IMPROVING THE QUALITY OF ENERGY-INTEGRATING CARDIAC CT WITH HIGH RESOLUTION RECONSTRUCTION AND AI-DENOISING TO APPROACH STATE-OF-THE-ART PHOTON COUNTING DETECTOR CT

Jeffrey Marsh JR, BS (*Abstract Co-Author*) Nothing to Disclose
Shaojie Chang, PhD (*Abstract Co-Author*) Nothing to Disclose
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Kevin J. Treb, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Recent introduction of photon counting detector CT (PCD-CT) has shown high-resolution (HR) and improved quantitative accuracy in coronary CT angiography (cCTA). However, the limited number of PCD-CT scanners constrains its impact as 99% of CT scanners are based on energy-integrating detectors (EID). This study aims to improve the image quality of EID-CT in cCTA, leveraging HR reconstruction and AI denoising techniques to approach the performance of state-of-the-art PCD-CT.

**METHODS AND MATERIALS**

Ten cCTA patients were scanned on EID-CT scanners (Force, Siemens) and two sets of images were reconstructed: routine images (Bv40 kernel), and sharp images (Bv59 kernel). Iterative reconstruction (IR) at strengths 1 and 4 were applied. A U-Net architecture convolutional neural network (CNN) was developed and trained for denoising. Briefly, thicker slice (3 mm) images with lower noise were reconstructed, serving as the label. A noise map was generated by subtracting the IR4 and IR1 reconstructions of thin slice (0.6 mm), which were then added to the labels to create noisy input to the network. Standard data augmentation techniques were applied and mean square error served as the loss function. The trained model was tested on an independent patient cohort of 5 cCTA cases, each of whom had undergone both EID-CT and PCD-CT (NAEOTOM Alpha, Siemens) scans on the same day. EID-CT images reconstructed with Bv59 and 0.6 mm slice thickness were processed through the trained model. The AI output ("sharp-denoised" EID-CT image) was compared to both routine EID-CT (Bv40) and HR PCD-CT images (Bv60 with 0.2 mm slice thickness).

**RESULTS**

AI output images demonstrated an 80% average reduction in noise compared to the input images. Difference images between AI inputs and outputs showed noise without any observable edge structures, confirming that the spatial resolution of the input images was maintained. Compared to the routine EID-CT (Bv40), AI output images showed substantial improvement in spatial resolution without increasing image noise. The AI output images more closely matched the quality of PCD-CT images in terms of spatial resolution and noise, particularly in resolving small coronary calcifications and small branches of coronary arteries not visible with routine EID-CT.

**CONCLUSION**

With sharper reconstructions and AI denoising, the quality of cardiac CT images from EID-CT can be enhanced, approaching the performance of state-of-the-art PCD-CT.

**CLINICAL RELEVANCE/APPLICATION**

Improving the quality of readily available EID-CT with AI may be a cost-effective and accessible alternative to purchasing a PCD-CT to improve cardiac CT image quality, which has a potential for widespread impact given the large installed base of EID-CT.

### PURPOSE

To segmentate intercostal muscle by using deep-learning (DL)-based automatic segmentation on computed tomography (CT) and evaluate the association between volume or density of intercostal muscles with respiratory dysfunction as well as the degree of pulmonary fibrosis and breathlessness in chronic interstitial pneumonia (IP)

### METHODS AND MATERIALS

DL-based automated intercostal muscle segmentation algorithm was applied on unenhanced chest CT in 36 patients with chronic IP, which consists in 10 idiopathic pulmonary fibrosis, 17 connective tissue disease-related IP and 9 IP with other etiology. Volumes of 1st to 7th bilateral intercostal muscles (VICM), lean VICM and mean CT density (MCTD) of ICM were measured. The associations of the 3 measured values with pulmonary function test parameters as well as the ratio of honeycomb area to the total lung fields (%HA) quantified as the extent of pulmonary fibrosis were examined with Spearman's rank correlation coefficients. The 3 measured values were also compared between 2 sub-groups classified according to the presence of IPF or that of strong breathlessness based on modified medical research council dyspnea scale (mMRC) using the Mann-Whitney U tests.

### RESULTS

%FVC of the included IP patients ranged from 35 to 129 (81.8±22.3). Measured VCIM varied from 98.3 to 344.1 mm3 (223±60 mm3). In addition to positive association with height and body weight, lean VCIM correlated positively with %FVC (r=0.385, p=0.021) and %DLco (r=0.443, p=0.008), and negatively with %HA (r=-0.512, p=0.002). VCIM tended to be lower in 7 strong breathless IP patients (182±56 mm3) with mMRC of 2 to 4 as compared with 29 weak breathless IP patients with mMRC of 0 to 1 (233±57 mm3) (p=0.063). MCTD of CIM in 26 non-IPF patients (3.3±12.0 HU) was lower than that in 10 IPF patients (-7.4±13.7 HU) (p=0.020).

### CONCLUSION

Despite small amount in the measurement, lean VCIM quantified with DL-based automatic segmentation demonstrated to decrease as the restrictive or diffusing impairment got prominent or the pulmonary fibrosis got enlarged. Moreover, the decrease in measured VCIM was implied in association with exacerbation of the breathlessness.

### CLINICAL RELEVANCE/APPLICATION

DL-based automatic VCIM measurement can be sensitive to temporal change in VCIM and useful for the objective evaluation of therapeutic effect by respiratory rehabilitation in chronic IP patients.

## M2-SPCH-2 QUANTITATIVE EVALUATION OF DISEASE SEVERITY OF CONNECTIVE TISSUE DISEASE ASSOCIATED INTERSTITIAL LUNG DISEASE USING LOW-DOSE PHOTON COUNTING CT

Zhoumeng Ying (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose
Lan Song, MD (*Abstract Co-Author*) Nothing to Disclose
Yang Yu, MENG (*Abstract Co-Author*) Employee, Siemens AG
Zhenchen Zhu, MD, MEng (*Presenter*) Nothing to Disclose

### PURPOSE

Patients with connective tissue disease (CTD)-associated interstitial lung disease (CTD-ILD) usually require long-term follow-up of high-resolution CT examination and are thus at increased risk of radiation exposure. The goal of the study is to assess whether the Sn-filtered low-dose photon-counting detector (PCD) CT (PCD-LDCT) can quantify the severity of CTD-ILD.

### METHODS AND MATERIALS

Patients were prospectively recruited from a CTD-ILD cohort between November 2023 and April 2024. Patients received standard-dose PCD-CT (PCD-SDCT) followed by PCD-LDCT on the same day. CT images of 1mm slice thickness were constructed with Bl60 and Qr56 kernel. Total visual extent (TVE) was rated manually on Bl60 PCD-SDCT images. CTD-ILD was classified into extensive and limited group using combined forced vital capacity (FVC)% predicted and TVE. The normal lung volume percentage (NL%: -700~-950 HU), ILD volume% (ILD%: -200~-700 HU) and mean lung density (MLD) were individually calculated by CT Pulmo 3D from Qr56 images and compared between the radiation protocols using paired student t-test. Receiver operating characteristic (ROC) analysis and Pearson correlation analysis were performed with PCD-LDCT-derived parameters.

### RESULTS

Twenty-six patients (mean 57 ± 10 years old; 18 females) were included. The effective dose of PCD-LDCT was nearly 7 times lower than PCD-SDCT (0.33 vs. 2.30 mSv). TVE rated by 2 radiologists reached substantial agreement (weighted ? = 0.81). Lower NL% (83.8% vs. 75.0%, P = 0.006), higher ILD% (11.4% vs. 19.4%, P = 0.004) and higher MLD (-817 HU vs. -766 HU, P = 0.002) were found in extensive CTD-ILD compared with limited group. NL% had significant moderate correlation with FVC% predicted (r = 0.43, P = 0.03) and strong correlation with DLCO% predicted (r = 0.70, P < 0.001). ROC analysis indicated ILD% (AUC = 0.846, cutoff = 17.9, sensitivity = 63.3%, specificity = 93.3%), NL% (AUC = 0.827, cutoff = 78.9, sensitivity = 72.7%, specificity = 93.3%) and MLD (AUC = 0.833, cutoff = -803, sensitivity = 81.8%, specificity = 80.0%) had good performance for extensive CTD-ILD discrimination. The PCD-LDCT quantitative parameters reached comparable results to that of PCD-SDCT for ILD% (mean absolute difference, MAD = 0.76%, P = 0.07) and MLD (MAD = 4 HU, P = 0.343), except for NL% (MAD = 2.1%, P < 0.001).

### CONCLUSION

Our results highlight the potential of PCD-LDCT in quantitative evaluation of CTD-ILD severity while significantly reducing radiation exposure for patients.

### CLINICAL RELEVANCE/APPLICATION

Our study proposes an easy approach to quantify CTD-ILD severity using PCD-LDCT and demonstrated their correlation with pulmonary function test. Besides, the result of our study brings promise to those patients who are at increased risk of radiation exposure.

## M2-SPCH-3 PUSHING THE LIMIT OF SPATIAL RESOLUTION IN PHOTON-COUNTING-DETECTOR CT FOR IMAGING INTERSTITIAL LUNG DISEASE USING A DEDICATED HIGH-RESOLUTION CONVOLUTIONAL NEURAL NETWORK

Chi Wan Koo, MD (*Abstract Co-Author*) Nothing to Disclose

Zhongxing Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To clinically evaluate an ultra-high-resolution convolutional neural network (UHR-CNN) developed to reduce noise and achieve the highest spatial resolution on photon-counting-detector (PCD) CT for interstitial lung disease (ILD).

### METHODS AND MATERIALS

A PCD-CT (Alpha, Siemens) scanned 50 patients with suspected ILD using the UHR mode (120x0.2 mm). Three methods were used to reconstruct the images: (1) Clinical standard of care: medium sharp kernel (Qr56) with iterative reconstruction (IR) and a pixel size of 0.41 mm (410-mm FOV and 1024 matrix), (2) sharpest quantitative kernel (Qr89) with IR and 0.15 mm pixel size (150-mm FOV and 1024 matrix), (3) Qr89 with UHR-CNN, 0.15 mm pixel size (150-mm FOV and 1024 matrix). Three thoracic radiologists evaluated these reconstruction methods for each case in a randomized, blinded fashion. Radiologists rated the likelihood of each of five imaging findings: reticulation, ground-glass opacities (GGO), mosaic pattern, traction bronchiectasis, honeycombing, lower lobe predominance, peripheral lung predominance, and probability of usual interstitial pneumonia (UIP) (5-point scale: 1=very low probability, 2=low probability, 3=indeterminate, 4=high probability, 5=very high probability). Magnitude score (the absolute difference of confidence scores from 3 [equivocal]) was used for analysis (higher scores indicated greater confidence). Radiologists also rated subjective image quality in terms of noise, artifacts (1-4, 4= excellent), spatial resolution, and overall image quality (1-5, 5=excellent).

### RESULTS

Qr89-HR-CNN had the highest overall diagnostic image quality among the 3 reconstructions: 4.68 vs 3.95 (Qr89-IR) vs 3.97 (Qr56-IR), p<0.001. The magnitude scores in Qr89-HR-CNN were significantly higher than Qr56-IR for imaging findings of reticulation (1.56 vs 1.37; p <0.001), GGO (1.67 vs 1.55; p <0.001), mosaic pattern (1.43 vs 1.37, p<0.05), traction bronchiectasis (1.75 vs 1.57, p<0.001), peripheral lung predominance (1.61 vs 1.57, p<0.05). No significant difference was found for honeycombing, lower lung predominance and diagnosis of UIP (p>0.05).

### CONCLUSION

The sharpest quantitative reconstruction available on the PCD-CT (0.15 mm) with the proposed UHR-CNN denoising method improved the overall diagnostic image quality and reader confidence for presence or absence of imaging findings of reticulation, GGO, mosaic pattern, traction bronchiectasis, and peripheral lung predominance in patients with suspected ILD.

### CLINICAL RELEVANCE/APPLICATION

The highest spatial resolution achievable with PCD-CT is not currently utilized clinically. Our proposed UHR-CNN decreased noise at increased resolution, which is likely beneficial in the diagnosis of interstitial lung disease.

## M2-SPCH-4 DEFINING QUANTITATIVE RISK THRESHOLDS FOR INTERSTITIAL LUNG ABNORMALITIES (ILA) AND THEIR PROGNOSTIC ASSOCIATIONS IN ASIAN HEALTH SCREENING POPULATIONS

Kyubin Kim, MD (*Abstract Co-Author*) Nothing to Disclose
Seungbaek Hong, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jong Eun Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Jiyun Ok (*Abstract Co-Author*) Nothing to Disclose
Yeon Joo Jeong, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study is to define quantitative risk thresholds for ILAs with correlation to long-term prognostic outcomes using deep learning-based ILA quantification at CT scans of an Asian health screening population.

**METHODS AND MATERIALS**

This retrospective study included participants aged 50 years or older who underwent chest CT scans at two health screening centers over a 7-year period (2007-2013). ILA status was classified as none, equivocal ILA, and ILA (either nonfibrotic or fibrotic), assessed visually. The extent of ILA was quantitatively assessed using a deep learning-based approach for ILA quantification. Multivariable Cox proportional hazards models were utilized to evaluate the association between the extent of ILA and the hazards of disease-related adverse events (lung cancer development, interstitial lung disease development, and disease-specific mortality) and all-cause mortality.

**RESULTS**

A total of 2427 participants were included in this study. ILAs were visually identified in the CT scans of 55 individuals (2%), and equivocal ILAs were observed in 63 individuals (3%). The mean extent of ILA, as measured by the quantitative system, was 3.3% for the ILA group and 0.5% for the equivocal ILA group. When dividing the groups by setting thresholds of 0-1%, 1-3%, 3-5%, and 5% or more according to ILA extent, the groups with 5% or more ILA and 3-5% ILA were independently associated with disease-related adverse events (HR, 28.2; 95% CI: 8.2, 96.6; P < .001, and HR, 5.8; 95% CI: 1.7, 20.0; P = 0.005, respectively) and all-cause mortality (HR, 5.2; 95% CI: 1.6, 16.9; P = 0.005, and HR, 5.4; 95% CI: 2.3, 12.7; P < .001, respectively) compared with those having no ILA.

**CONCLUSION**

The threshold for ILA extent associated with long-term prognostic outcomes, determined by deep learning-based ILA quantification, was evaluated to be 3% or more of the total lung volume.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning-based ILA quantification can be used to evaluate long-term prognostic outcomes in health screening populations.

## M2-SPCH-6 THE CAPABILITY OF DEEP-RADIOMICS TO PREDICT PATHOLOGICAL RESPONSE TO NEOADJUVANT IMMUNOCHEMOTHERAPY IN NON-SMALL CELL LUNG CANCER: A RETROSPECTIVE MULTICENTER STUDY

Guoliang Shao (*Abstract Co-Author*) Nothing to Disclose
Xiaoyun Liang (*Abstract Co-Author*) Nothing to Disclose
Yuanxin Ye (*Abstract Co-Author*) Nothing to Disclose
Yuchi Tian (*Presenter*) Nothing to Disclose

**PURPOSE**

To establish a predictive model that combines radiomics, deep learning and clinical features for predicting the pathological complete response (pCR) of non-small cell lung cancer (NSCLC) patients after neoadjuvant immunochemotherapy (NIT).

**METHODS AND MATERIALS**

We retrospectively collected patients from three centers, of which center 1 was split into training and internal testing cohorts in a 7:3 ratio, and centers 2 and 3 were combined into an external testing cohort. In this study, tumor segmentation was performed on chest CT images before (pre-NIT) and after (post-NIT) neoadjuvant therapy. Radiomics features were extracted using Pyradiomics to build pre-NIT and post-NIT feature groups. And delta 1, 2, and 3 feature groups were built based on three delta radiomics formulas. For deep learning (DL) features, a pretrained 3D Restnet-18 was used to extract features from the post-NIT images, and the outputs of 512 neurons from the last fully connected layer of the network were used as DL features to build DL feature group. The most meaningful features were selected using the mRMR and LASSO. A logistic regression classifier was then applied to create a classification model to predict the pathological response (pCR or non-pCR). We refer to the probability predicted from radiomics features as the Rad-scores, and from DL features as the Deep-scores. Finally, Rad-scores, Deep-scores, and meaningful clinical features were used to build a combined model and plot a nomogram. The model was validated in the internal and external testing cohorts. The ROC and DCA curves were employed to evaluate model performance.

**RESULTS**

A total of 178 patients were enrolled in the current study. In conventional radiomics, the efficacy of post-NIT model was better than the pre-NIT, with AUCs of 0.825(training) and 0.832(testing), respectively. In delta radiomics model, delta1 had best efficacy, with the AUC of 0.942 and 0.810, respectively. Subsequently, the post-NIT and delta1 features were further constructed as the combined model 1 with AUCs of 0.939 and 0.849, respectively. The AUCs of the DL model were 0.832 and 0.818, respectively. Only iRECIST clinical factor (p = 0.007) was combined with the radiomics and the DL features to establish the combined model 2, which achieved the best performance among all the models, with AUCs of 0.955, 0.882, and 0.839 for the training, internal and external testing cohorts, respectively.

**CONCLUSION**

Our results demonstrated that combination of three dimensional features can provide complementary information to predict pCR more accurately.

**CLINICAL RELEVANCE/APPLICATION**

Deep-radiomics model provides a noninvasive promising way to predict pCR to NIT in NSCLC patients, and facilitates personalized clinical decision making.

## M2-SPCH-7 ROLE OF PRONE CT IN ASSESSING INTERSTITIAL LUNG ABNORMALITIES

David A. Masahiro Yanagawa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jiyoung Song, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We aimed to evaluate whether supine chest CT alone suffices for diagnosing interstitial lung abnormality (ILA), thereby reducing prone chest CT.

**METHODS AND MATERIALS**

We retrospectively identified patients who underwent prone chest CT from January 2021 to July 2023 within one month after supine chest CT due to suspected ILA to constitute 69 age, sex-matched subjects (23 each of normal, non-fibrotic ILA, and fibrotic ILA). Five multi-national thoracic radiologists independently rated ILA suspicion scores on a 5-point scale on supine CT images (session 1). For suspected ILA cases, fibrosis scores (1 to 5-point) and ILA extent (1-100%) were rated. After a one-month washout, matched supine-prone CT images were provided (session 2). We compared the area under the receiver operating characteristic curves (AUCs) of ILA suspicion scores across ILA types and sessions. We classified each reader's ILA suspicion and fibrosis scores into four diagnostic groups (normal, non-fibrotic ILA, indeterminate-type ILA, fibrotic ILA) and evaluated interrater agreement using Fleiss' kappa and Gwet's AC 1: ILA suspicion scores of 1-2, normal; 3-5, positive ILA; fibrosis scores of 1-2, non-fibrotic ILA; 3, indeterminate-type ILA; 4-5, fibrotic ILA. For ILA extent, we evaluated the Pearson correlation coefficients and the differences between sessions within readers using a linear mixed model.

**RESULTS**

For non-fibrotic ILA, the pooled AUC of the five readers significantly increased from session 1 to session 2 (0.76 to 0.92, P<0.001), while no significant differences were observed for fibrotic ILA (0.94 and 0.99, P=0.06). The interrater agreement significantly increased from session 1 to session 2 for non-fibrotic ILA (Fleiss' kappa from 0.25 to 0.51, P=0.004; Gwet's AC1 from 0.44 to 0.65, P=0.004), while there was no significant difference for fibrotic ILA (Fleiss' kappa 0.63 and 0.72, P=0.082; Gwet's AC1 0.70 and 0.80, P=0.064 in session 1 and 2). Regarding extent, fibrotic ILA showed higher intra-reader correlation coefficients (0.74) compared to non-fibrotic ILA (0.44). Mean ILA extent decreased in non-fibrotic ILA (6.7% to 5.2%, P<0.001) and fibrotic ILA (10.0% to 8.0%, P<0.001) from session 1 to 2.

**CONCLUSION**

For fibrotic ILA, diagnostic accuracy and inter-reader agreement were substantial with supine CT alone while non-fibrotic ILA benefited by adding prone CT. However, sole supine CT interpretation led to overestimating ILA extent by 1-2% regardless of ILA types.

**CLINICAL RELEVANCE/APPLICATION**

By demonstrating that supine CT alone accurately diagnoses fibrotic ILA, our study supports omitting prone CT in cases of fibrotic ILA, thereby streamlining the diagnostic process, reducing patient discomfort, radiation exposure, and costs.

## M2-SPCH-8 QUANTIFICATION AND ANALYSIS USING ARTIFICIAL INTELLIGENCE OF THE LUNG IN PATIENTS WITH IDIOPATIC PULMUNARY FIBROSIS TRATED WITH NINTEDANIB AND CORRELATION WITH DLCO% AND FVC%

Francesco Turco (*Abstract Co-Author*) Nothing to Disclose
Francesco Manti (*Abstract Co-Author*) Nothing to Disclose
Anna Ferrarelli (*Abstract Co-Author*) Nothing to Disclose
Domenico Barresi (*Abstract Co-Author*) Nothing to Disclose
Domenico Lagana (*Abstract Co-Author*) Nothing to Disclose
Alessia Mondelli, MD (*Abstract Co-Author*) Nothing to Disclose
Corrado Pelaia (*Abstract Co-Author*) Nothing to Disclose
Caterina Battaglia, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

High-resolution computed tomography has allowed over the years the diagnosis and follow-up of interstitial pulmonary diseases, in particular idiopathic pulmonary fibrosis. In recent years, the need for quantitative data has given rise to new Score to predict the prognosis of patients suffering from this disease and also the arise of new dedicated software from Artificial intelligence. The goal of the study was to evaluate in our pool of patient how the application of a quantitative score and analysis using AI software applied to CT images can predict the effectiveness of the drug Nintedanib compared to Esbriet both used for years to stop the progression of the disease

**METHODS AND MATERIALS**

We retrospectively enrolled 74 patients diagnosed with IPF from 2018 to 2023 before and one year after starting therapy with Esbriet or Nintedanib. We applied on CT images a radiological visual score to evaluate the percentage of parenchyma preserved based on a score ranging from 0 to 5 points assigned to the upper and lower lobes bilaterally reaching a scale of values from 0 to 20. Then, we analyzed the same TC scans using 3D slicer tools for the segmentation and the analysis of the lung. In addition, we correlated the value of the score to values of DLCO (Alveolar-capillary diffusion Carbon Monoxide) and FVC (Forced vital capacity).

**RESULTS**

74 patients were divided into two groups and for each we calculated the CT score as well as the FVC and DLCO. 75% were men with average age of 73 ± 7 years. The CT score ranged from 19 to 0 with an average of 6 ± 4 in both groups. We found a not statistically significant difference in terms of DLCO, FVC, radiological visual score and AI analysis to one year in patients on Nintedabib therapy indicating disease stability (DLCO p= 0.7917, Score p = 0.7941, FVC p = 0.4133). On the contrary we found a statistically significant difference to one year in patients on Esbriet therapy indicating a worsening of the radiological picture and DLCO (DLCO p=0.0225, SCORE p=0.005) no difference was found in terms of FVC (p=0.0883). Another important result obtained with the use of AI tools were that the in patients treated with Esbriet had more infiltrates that the group treated with Nintedanib at one year control (P= 0.0429)

**CONCLUSION**

In our results we found that, in patients treated with Nintedanib, the values of DLCO, FVC and radiological scores remain stable one year after the start of treatment, and also the volume and the infiltrates calculated with AI, meanwhile in patients treated with Esbriet there is a deterioration in DLCO values and radiological score, and an increase of infiltrated, but a stability for FVC values.

**CLINICAL RELEVANCE/APPLICATION**

application in the current clinical and radiological practice

## M2-SPCH-9 CT FINDINGS OF ANTI-MELANOMA DIFFERENTIATION ASSOCIATED GENE 5 ANTIBODY POSITIVE DERMATOMYOSITIS ASSOCIATED INTERSTITIAL LUNG DISEASE: CORRELATION BETWEEN SHORT-TERM

## INTERVAL CHANGES AND PROGNOSIS

Takatoshi Aoki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoshiya Tanaka, MD (*Abstract Co-Author*) Nothing to Disclose
Yo Todoroki (*Abstract Co-Author*) Nothing to Disclose
Midori Ueno, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Anti-melanoma differentiation associated gene 5 antibody positive dermatomyositis (anti-MDA5-DM) associated interstitial lung disease (ILD) often show rapidly progressive course and resistance to treatment, but the clinical presentation and prognosis are varied. Although the CT findings of anti-MDA5-DM associated ILD were sporadically reported, to our knowledge, the relationship between short-term interval changes and prognosis has not been fully evaluated. This study aimed to evaluate the impact of the CT findings, including the short-term interval changes, on the prognosis in anti-MDA5-DM associated ILD patients.

### METHODS AND MATERIALS

A total of 24 anti-MDA5-DM associated ILD patients were included in this study. All 24 patients underwent follow-up CT scans an average of 24.5 days (range: 12-35 days) after baseline CT. Two thoracic radiologists assessed the CT findings at baseline CT before treatment for: consolidation, ground-glass opacities (GGO), reticulation, honeycomb, volume loss, perilobular opacities, crazy paving appearance, location and distribution, and the short-term interval changes of CT findings for: enlargement of consolidation/GGO/perilobular opacities, increased attenuation of GGO, progression of fibrosis, and whole lung abnormality changes (enlarge/stable/diminish). Kaplan-Meyer methods and log-rank test were used to identify the association between CT findings and death.

### RESULTS

Six patients died, and the mean time from baseline CT to death was 72.5 days (range: 28-124). Kaplan-Meyer methods and log-rank test revealed a higher mortality risk in cases with craniocaudal random distribution on baseline CT, progression of fibrosis and enlargement of total abnormal findings on short-term follow-up CT ($p=0.004$, 0.014, 0.020, respectively).

### CONCLUSION

In addition to craniocaudal random distribution at baseline, progression of fibrosis and enlargement of whole lung abnormality in short-term interval were the signs of poor prognosis of anti-MDA5-DM associated ILD patients.

### CLINICAL RELEVANCE/APPLICATION

Short-term interval changes of chest CT findings closely correlates with prognosis of anti-MDA5-DM associated ILD patients. Progression of fibrosis and enlargement of whole lung abnormality in short-term interval after baseline CT would require therapeutic changes.

## M2-SPER-1 OPTIMIZING EMERGENCY CARE: THE ROLE OF MULTI-ALGORITHM AI IN REDUCING IMAGING WAIT TIMES FOR CRITICAL CONDITIONS

Joseph H. Yacoub, MD, MD (*Abstract Co-Author*) Stockholder, NVIDIA Corporation
Pranay Krishnan, MD (*Abstract Co-Author*) Nothing to Disclose
Ross W. Filice, MD (*Abstract Co-Author*) Advisor, BunkerHill Health, Inc;Shareholder, BunkerHill Health, Inc;Speaker, General Electric Company;Speaker, Koios Medical;Researcher, Koios Medical
Luke Stoltzfus, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This study evaluates the efficacy of a multi-algorithm artificial intelligence (AI) platform in the emergency department (ED) for prioritizing imaging interpretation of patients with suspected critical conditions.

### METHODS AND MATERIALS

From November 2023 to March 2024, data was gathered from ED CTs processed by the AI platform in a major health system. The AI system issued prioritization notifications to radiologists for AI positive (AI+) findings in cases of suspected CT head angiography brain aneurysms (BA), non-contrast CT head intracranial hemorrhages (ICH), pulmonary angiography and contrast chest CT pulmonary embolisms (PE and iPE, respectively), and all vessel occlusions (all_VO). AI+ results were also displayed on the radiologist worklists. Median imaging interpretation wait times for AI-flagged cases (AI+) were compared to those not flagged by the AI (AI-). Imaging interpretation wait time is defined as the total time from scan acquisition to beginning of report dictation by the radiologist.

### RESULTS

A total of 43,977 ED cases were collected (BA 7.3%, ICH 48.1%, IPE 25.1%, PE 14.1%, all_VO 5.4%). AI+ cases were 3.52% (1,547/42,430) of the ED cases. The median wait time for all AI+ cases (ICH, BA, PE, IPE, and all_VO) was 14.3 minutes (IQR: 26.5 minutes) compared to 18.0 minutes (IQR: 32.6 minutes) for the AI negative cases. The observed median wait time reduction for all ED cases was statistically significant (Mood's test p-value <0.05) at a 20.6% reduction (3.7 minutes). The largest median wait time reduction observed was for BA cases at 26.9% reduction (4.1 minutes) and the smallest median wait time reduction was for all_VO cases at 6.7% (0.9 minutes).

### CONCLUSION

The implementation of a multi-algorithm AI significantly enhanced the prioritization process of ED cases for a range of critical conditions, particularly in brain aneurysm cases. This AI system significantly reduced imaging wait times for suspected positive cases, demonstrating its potential to streamline emergency care.

### CLINICAL RELEVANCE/APPLICATION

The decrease in imaging wait times for AI-flagged cases indicates that AI can significantly enhance the efficiency of emergency departments by prioritizing positive cases and accelerating the diagnosis, which may improve high acuity patient outcomes.

## M2-SPER-2 PERFORMANCE AND RELIABILITY OF AN ARTIFICIAL INTELLIGENCE ALGORITHM FOR THE AUTOMATED DETECTION OF INCIDENTAL ABDOMINAL AORTIC ANEURYSM

Mark J. Krycia, MD (*Abstract Co-Author*) Nothing to Disclose
Joseph J. Cavallo, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Jerome H. Avondo, PhD (*Abstract Co-Author*) Employee, Aidoc Ltd
Danling Chen, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Abdominal aortic aneurysm (AAA) is a frequently encountered incidental finding on CT imaging performed in the acute care setting, with an estimated prevalence of 1.3 to 12.5% in the general population. Artificial intelligence (AI) algorithms have been developed to automatically measure maximal aortic lumen size with the goal of improving AAA detection and streamlining radiology workflow. However, few studies have evaluated the performance of these tools in a large clinical setting. To this purpose, we conducted a retrospective study evaluating the accuracy of an AI algorithm for the screening and triage of incidental AAA on non-optimized CT imaging.

## METHODS AND MATERIALS

A retrospective study was performed on CT examinations (inclusive of contrast enhanced and noncontrast protocols) of the abdomen and pelvis performed in the emergency setting of a tertiary academic center from July 31-December 31, 2020, and January 1-May 10, 2021. CT exam images were processed by an FDA-cleared AI algorithm, while a natural language processing program (NLP) was used to analyze the associated radiology report. Exams which were positive for the presence of AAA on imaging by AI processing, but negative by NLP analysis of their corresponding report, were designated as potential discrepancies, and independently reviewed by an ED radiologist.

## RESULTS

In total, 4,023 abdominal and pelvic CT examinations were analyzed. 3,955 (98.3%) cases were negative for presence of AAA by NLP assessment of their respective report, with 16 of these cases flagged by the AI algorithm as discrepancies potentially positive for AAA. 31% (n=5/16) of the discrepant cases were determined by secondary review to be truly positive for previously undocumented AAA. A greater number of AAA were detected with AI versus with imaging interpretation by radiologists alone demonstrating an enhanced detection rate of 7.4% (5/(4,023-3,955) = 5/68). When analyzing discrepant cases that were ultimately deemed negative for AAA on secondary review (69%, n=11), it was noted that AI overestimation of abdominal aortic diameter was often related to obliquity of the aortic lumen in the axial plane. When axial CT images were subsequently reformatted in multiplanar reconstruction to account for aortic tortuosity, accurate measurements were obtained.

## CONCLUSION

Artificial intelligence algorithms demonstrate the potential to improve detection rates of incidental abdominal aortic aneurysms on CT imaging.

## CLINICAL RELEVANCE/APPLICATION

Abdominal aortic aneurysm can pose life-threatening consequences in the event of rupture. Accurate detection of incidental AAA, particularly in high throughput workflows such as the emergency department, is essential for guiding surveillance strategies and management.

## M2-SPGI-1 AUTOMATED HEPATIC STEATOSIS QUANTIFICATION IN PATIENTS WITH CHRONIC LIVER DISEASE ON CT: VOLUME OF INTEREST-BASED ATTENUATION MEASUREMENT

Seo Yeon Youn, MD (*Abstract Co-Author*) Nothing to Disclose
Yu Ri Shin (*Abstract Co-Author*) Nothing to Disclose
Sung Eun Rha, MD (*Abstract Co-Author*) Nothing to Disclose
Soon Nam Oh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Joon-Il Choi, MD, PhD (*Abstract Co-Author*) Research Grant, Guerbet SA;Research Grant, Samsung Electronics Co, Ltd
Hokun Kim, MD (*Abstract Co-Author*) Research Grant, TAEJOON Pharmaceutical Co, Ltd
Bohyun Kim, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The validity of an automated quantification of hepatic steatosis on computed tomography (CT) has been demonstrated in a screening cohort and in a healthy population, but not in a cohort of patients with known chronic liver disease (CLD). We investigated the feasibility of a CT-based automated hepatic steatosis quantification in patients with CLD on noncontrast CT images using magnetic resonance spectroscopy proton density fat fraction (MRS-PDFF) as a reference standard.

### METHODS AND MATERIALS

This retrospective study included patients with CLD who underwent liver CT including noncontrast images and liver MRI with MRS-PDFF within a 6-month period from Oct 2023 to Mar 2024. A commercially available CT-based liver fat assessment program (ClariHepato, Clarip Inc.) used automated volume of interest (VOI) to quantify the liver attenuation (density_L), the attenuation difference between the liver and spleen (diff_LS), the attenuation ratio of the liver and spleen (ratio_LS), and CT-derived fat fraction (CDFF). Averaged attenuation values (density_ROI) were obtained within three manually drawn regions of interest (ROIs) in the liver. Agreement between density_ROI and density_L was evaluated using intraclass correlation coefficient (ICC) and Bland-Altman analysis. Pearson's correlation analysis was performed for all subjects and a subgroup of patients with liver cirrhosis (LC), comparing MRS-PDFF with the following parameters: CDFF, density_L, diff_LS, and ratio_LS.

### RESULTS

: A total of 68 patients (mean age, 62.0±11.2 years, 42 men) with 101 pairs of CT and MRI were included. Of them, 33 patients had LC. Technical failure occurred in 2 cases (2.0%). Good agreement was observed between density_L and density_ROI with an ICC of 0.869 (95% confidence interval 0.812-0.910). All CT parameters showed a significant correlation with MRS-PDFF (ps<0.001), with correlation coefficients for CDFF, density_L, diff_LS, ratio_LS, and density_ROI of 0.572, -0.519, -0.523, -0.503, and -0.567, respectively. In patients with LC, a significant correlation was likewise found (ps<0.001), with correlation coefficients for CDFF, density_L, diff_LS, ratio_LS, and density_ROI of 0.654, -0.622, -0.636, -0.755, and -0.627, respectively.

### CONCLUSION

CT-based automated steatosis quantification using VOI showed significant correlations with manual ROI-based attenuation and MRS-PDFF values in patient with CLD, regardless of the presence of LC.

### CLINICAL RELEVANCE/APPLICATION

CT-based automated steatosis quantification is a feasible method for hepatic steatosis evaluation in patients with chronic liver disease.

## M2-SPGI-12 INTEGRATED CLINICAL AND CONTRAST-ENHANCED CT PARAMETERS FOR PREDICTING THERAPEUTIC RESPONSE IN COLORECTAL CANCER LIVER METASTASIS TREATED WITH CHEMOTHERAPY AND BEVACIZUMAB

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Long Yuan (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to investigate the predictive value of clinical and pre- and post-treatment contrast-enhanced computed tomography (CT) parameters for the early therapeutic response of colorectal liver metastasis (CRLM) treated with chemotherapy and bevacizumab.

### METHODS AND MATERIALS

A retrospective analysis was conducted on patients with CRLM who received first-line chemotherapy combined with bevacizumab treatment in our hospital from January 2018 to January 2023, including clinical and contrast-enhanced CT images. The morphological features of CRLM after four treatment cycles

were assessed using contrast-enhanced CT images. CT values at baseline and after four treatment cycles in different phases (PS, AP, VP, and DP), and density change values (?CT values) before and after treatment were calculated. According to RECIST 1.1, CRLM after 12 treatment cycles was categorized into responsive (PR, SD, and CR) and non-responsive groups (PD). Differences between the two groups were searched for using the T-test, Mann-Whitney U, or chi-square test, and diagnostic performances of the different variables were evaluated using the receiver operating characteristic (ROC) curve.

**RESULTS**

Forty-six patients (mean age: 58±11.37 years) with 121 CRLM (83 and 38 in the responsive and non-responsive groups) were included. RAS mutant-type CRLM was more prevalent in the responsive group than in the wild-type group, with a significant difference (P<0.001). CRLM with a lobulated shape and heterogeneous texture after four treatment cycles showed a poorer treatment response than those with a round shape and homogeneous texture, with a significant difference (P<0.05). Additionally, CT values of AP-pre, VP-pre, DP-pre, VP-post, and ?AP were higher in the responsive group than in the non-responsive group. The combined use of clinical and contrast-enhanced CT parameters demonstrated better efficacy (AUC >0.7) than single parameters. Parameters such as RAS, texture-post, and AP-pre combined showed higher predictive efficacy. Conclusion: The combination of clinical parameters and contrast-enhanced CT parameters before and after treatment can effectively predict the early therapeutic response in patients with CRLM.

**CONCLUSION**

The combination of clinical parameters and contrast-enhanced CT parameters before and after treatment can effectively predict the early therapeutic response in patients with CRLM.

**CLINICAL RELEVANCE/APPLICATION**

The findings underscore the utility of integrated parameters in facilitating the early detection of liver metastases with a more favorable treatment response. These results lay the groundwork for devising personalized treatment strategies in clinical settings and highlight their promising clinical relevance.

## M2-SPGI-13 DYNAMIC CHANGES IN IVIM PARAMETERS AND LIVER PATHOLOGICAL CHARACTERISTICS DURING LIVER REGENERATION IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD): AN EXPERIMENTAL STUDY

Wen Shen, MD (*Abstract Co-Author*) Nothing to Disclose
Shuangshuang Xie (*Abstract Co-Author*) Nothing to Disclose
Caixin Qiu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Hepatic steatosis will affect the regenerative capacity of the liver, and MASLD patients have a high complication rate and mortality after partial hepatectomy (PH) [1-3]. The mechanism of liver regeneration after hepatectomy in patients with MASLD is unclear. We aimed to explore the pathological changes that occur during regeneration of the residual liver after PH in rats with MASLD and to determine the value of using voxel-incoherent motion (IVIM) to monitor liver regeneration.

**METHODS AND MATERIALS**

Seventy male Sprague-Dawley rats were randomly divided into two groups: 1) Control group: underwent 70% PH (n=35); 2) MASLD group: underwent 70% PH after a high-fat diet for 10 weeks (n=35); Five rats from each group were randomly selected for IVIM longitudinal follow-up scans at baseline, postoperative day 1, day 2, day 3, day 5, day 7, and day 14. And then sacrificed for pathological analysis. Liver parenchyma D, D*, PF were measured, and hepatocyte KI-67 proliferation index, cell size, and cell hypertrophy rate were calculated. Two-way analysis of variance was used to compare differences in MR imaging parameters between the MASLD group and the control group. One-way analysis of variance was used to compare differences in MR imaging parameters at different time points among the control group and MASLD group. Pearson correlation analysis was used to assess the correlation between MR parameters and pathological indicators. A significance level of P<0.05 was considered statistically significant.

**RESULTS**

Compared to the control group, the trend of changes in D, D*, and PF values in the MASLD group was generally consistent (see Fig.1 for details). Compared to the control group, the MASLD group exhibited lower levels of KI-67 proliferation on post-PH days 1, and 2 (all P < 0.05), with peak levels observed on days 3, followed by a gradual decline (P > 0.05). Additionally, the hepatocytes in the MASLD group were overall larger than those in the control group (all P < 0.05). Both groups showed a trend of increased hepatocyte size followed by a decrease postoperatively, with the maximum hepatocyte size observed on day 2 in the MASLD group and on day 1 in the control group (Fig.2). D* value had a good negative correlation with hepatocyte size and KI-67 (r=-0.799, -0.815, respectively) (table 1).

**CONCLUSION**

The regeneration mechanism in MASLD liver following PH parallels that of a normal liver, involving hepatocyte hypertrophy and proliferation. However, MASLD liver regeneration is hindered. IVIM can reflect the pathological changes of liver regeneration after PH and can be used as a tool to monitor liver regeneration in MASLD.

**CLINICAL RELEVANCE/APPLICATION**

IVIM can serve as a non-invasive imaging technique to monitor liver regeneration in MASLD.

## M2-SPGI-3 INTRACELLULAR ENHANCED TECHNIQUE FOR GADOXETIC ACID-ENHANCED HEPATOBILIARY-PHASE MAGNETIC RESONANCE IMAGES: UTILITY FOR EVALUATING HEPATIC FUNCTION

Ryo Higashino (*Abstract Co-Author*) Nothing to Disclose
Yuko Nakamura, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Hepatic parenchymal enhancement on gadoxetic acid-enhanced hepatobiliary phase (HBP) magnetic resonance images decreases as the hepatic function decreases. However, simple signal measurements on HBP images may be affected not only by hepatocyte specific- but also by extracellular space enhancement. This results in the inaccurate estimation of liver function. To improve hepatocyte-specific gadoxetic acid enhancement, we developed an intracellular enhancement (ICE) technique that suppresses signals from the extracellular space using a motion-sensitized driven equilibrium pulse. To investigate the utility of this technique for the evaluation of hepatic function we compared HBP images acquired with and without our ICE technique.

**METHODS AND MATERIALS**

We subjected 67 patients with suspected neoplastic hepatic lesions to gadoxetic acid-enhanced HBP imaging with and without ICE (i+HBP, i-HBP). The images were acquired 20 min after the injection of gadoxetic acid. A radiologist calculated the liver-spleen ratio (LSC) [LSC = region of interest (ROI)LIVER/ROIS], where ROILIVER is the mean signal intensity (SI) of the hepatic parenchyma and ROIS the mean SI of the spleen. To explore factors related to outcomes (Child-Pugh classification), we performed uni- and multivariate logistic regression analysis. Receiver operating analysis (ROC) was used to evaluate the diagnostic performance of LSC on i+HBP and i-HBP (i+LSC and i-LSC) to differentiate between Child-Pugh class A and B.

**RESULTS**

Of the 67 patients, 57 patients were in Child-Pugh class A and 10 patients were in class B. Univariate logistic analysis identified both i+LSC ($p < 0.01$) and i-LSC ($p = 0.03$) as significant factors in determining the Child-Pugh classification. Multivariate logistic analysis identified i+LSC but not i-LSC as a significant factor for the Child-Pugh classification ($p < 0.01$ vs $p = 0.49$). For the differentiation between Child-Pugh A and B, the value of i+LSC [area under the curve (AUC) 0.81; cutoff 2.12, sensitivity 80.0%, specificity 66.7%] was higher than of i-LSC (AUC 0.68; cutoff 1.12, sensitivity 40.0%, specificity 96.3%).

**CONCLUSION**

On gadoxetic acid-enhanced MRI scans acquired in the HBP, hepatic function can be estimated accurately with our ICE technique.

**CLINICAL RELEVANCE/APPLICATION**

Hepatocyte-specific enhancement with our ICE technique may be an imaging biomarker for the evaluation of hepatic function.

## M2-SPGI-4 INTEGRATED CLINICAL AND CONTRAST-ENHANCED CT PARAMETERS FOR PREDICTING THERAPEUTIC RESPONSE IN COLORECTAL CANCER LIVER METASTASIS TREATED WITH CHEMOTHERAPY AND BEVACIZUMAB

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Long Yuan (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to investigate the predictive value of clinical and pre- and post-treatment contrast-enhanced computed tomography (CT) parameters for the early therapeutic response of colorectal liver metastasis (CRLM) treated with chemotherapy and bevacizumab.

**METHODS AND MATERIALS**

A retrospective analysis was conducted on patients with CRLM who received first-line chemotherapy combined with bevacizumab treatment in our hospital from January 2018 to January 2023, including clinical and contrast-enhanced CT images. The morphological features of CRLM after four treatment cycles were assessed using contrast-enhanced CT images. CT values at baseline and after four treatment cycles in different phases (PS, AP, VP, and DP), and density change values (?CT values) before and after treatment were calculated. According to RECIST 1.1, CRLM after 12 treatment cycles was categorized into responsive (PR, SD, and CR) and non-responsive groups (PD). Differences between the two groups were searched for using the T-test, Mann-Whitney U, or chi-square test, and diagnostic performances of the different variables were evaluated using the receiver operating characteristic (ROC) curve.

**RESULTS**

Forty-six patients (mean age: 58±11.37 years) with 121 CRLM (83 and 38 in the responsive and non-responsive groups) were included. RAS mutant-type CRLM was more prevalent in the responsive group than in the wild-type group, with a significant difference ($P<0.001$). CRLM with a lobulated shape and heterogeneous texture after four treatment cycles showed a poorer treatment response than those with a round shape and homogeneous texture, with a significant difference ($P<0.05$). Additionally, CT values of AP-pre, VP-pre, DP-pre, VP-post, and ?AP were higher in the responsive group than in the non-responsive group. The combined use of clinical and contrast-enhanced CT parameters demonstrated better efficacy (AUC >0.7) than single parameters. Parameters such as RAS, texture-post, and AP-pre combined showed higher predictive efficacy. Conclusion: The combination of clinical parameters and contrast-enhanced CT parameters before and after treatment can effectively predict the early therapeutic response in patients with CRLM.

**CONCLUSION**

The combination of clinical parameters and contrast-enhanced CT parameters before and after treatment can effectively predict the early therapeutic response in patients with CRLM.

**CLINICAL RELEVANCE/APPLICATION**

The findings underscore the utility of integrated parameters in facilitating the early detection of liver metastases with a more favorable treatment response. These results lay the groundwork for devising personalized treatment strategies in clinical settings and highlight their promising clinical relevance.

## M2-SPGI-5 PREDICTIONS OF LIVER FUNCTIONAL RESERVE USING IODINE-UPTAKE PARAMETERS AND HEPATOSPLENIC VOLUMETRIC INDICES FROM MULTIPHASE HEPATIC CT: COMPARISONS WITH INDOCYANINE GREEN RETENSION TEST AND 99MTC-GSA SCINTIGRAPHY

**PURPOSE**

To investigate whether extracellular volume fraction (ECV), iodine washout rate (IWR), and hepatosplenic volume indices on multiphase hepatic CT allow estimation of liver functional reserve measured with the indocyanine-green retention test (ICG-R15) and identification of patients with contraindications to major hepatectomy (ICG-R15=20%) compared to technetium-99m galactosyl human serum albumin (99mTc-GSA) scintigraphy.

**METHODS AND MATERIALS**

This retrospective study included 118 patients (84 men, mean age 69.4±11.3 years) who underwent ICG-R15 test, 99mTc-GSA scintigraphy, and multiphase hepatic CT including early portal venous phase (PVP) and 3-min delayed phase (DP) for the planning of hepatectomy. Hepatic ECV, IWR, and liver and spleen volumes normalized by body surface area (LV/BSA and SpV/BSA, respectively) were quantified with multiphase CT. For 99mTc-GSA, the hepatic uptake ratio at 15 minutes (HH15) and the receptor index (LHL15) were quantified. Associations between imaging parameters and ICG-R15 were evaluated using Spearman's correlation coefficient. Parameters were compared between patients with and without contraindications to major hepatectomy (ICG-R15=20% [n=22] and <20% [n=96], respectively). Diagnostic performance for identifying patients with ICG-R15=20% was evaluated using areas under the receiver operating characteristic curves (AUC). Multivariable logistic regression was used to identify independent CT predictors for ICG-R15>20%, and combined performance was determined.

**RESULTS**

IWR, LV/BSA, and LHL15 were lower, while ECV, SpV/BSA, and HH15 were higher in patients with ICG-R15=20% than in those with ICG-R15<20% (all p<0.001). ICG-R15 showed moderate correlations with IWR (r=-0.523) and LHL15 (r=-0.504), but weak or very weak correlations with ECV (r=0.355), LV/BSA (r=-0.123), SpV/BSA (r=0.248), and HH15 (r=0.385). AUCs of ECV, IWR, LV/BSA, SpV/BSA, HH15, and LHL15 for predicting ICG-R15=20% were 0.719, 0.845, 0.653, 0.694, 0.844, and 0.878, respectively. IWR, SpV/BSA, and LV/BSA were identified as independent CT predictors, with a combined AUC of 0.924.

**CONCLUSION**

IWR from multiphase hepatic CT provided better prediction of liver functional reserve compared to ECV and hepatosplenic volume indices. Combined IWR, liver, and spleen volume indices may be used as substitutes for 99mTc-GSA scintigraphy in identifying patients with contraindications to major hepatectomy.

**CLINICAL RELEVANCE/APPLICATION**

Multiphase hepatic CT for hepatic tumor assessments could enable estimation of hepatic functional reserves by quantifying IWR and hepatosplenic volume, potentially serving as simple, cost-effective, and reliable imaging approach to optimize treatment planning.

## M2-SPGI-6 QUANTITATIVE ASSESSMENT OF THE MICROSTRUCTURE AROUND THE RECTAL CANCER TO PREDICT N STAGE BY INTRAVOXLE INCOHERENT MOTION DIFFUSION WEIGHED MAGNETIC RESONANCE IMAGING

Anna Mou (*Presenter*) Nothing to Disclose

**PURPOSE**

The study is to determine whether the microstructural features around the tumor could predict lymph node(LN) staging in patients with rectal cancer by intravoxle incoherent motion diffusion-weighed magnetic resonance imaging(IVIM).

**METHODS AND MATERIALS**

74 patients with pathologically proven rectal adenocarcinoma underwent routine rectal MRI and IVIM(b values=0,20,50,100,200,400,600,800,1000,2000s/mm2) sequences were included. 45 patients had no lymph node metastasis(N0), 29 patients had positive lymph node metastasis(N+). ROIs were placed adjacent to (MAT,with 5mm of the outline of the largest cross-section of tumor) and distant from (MDT,at least 10mm from the tumor) the tumor to measure the IVIM parameters to predict LN. Unpaired t test and receiver operating characteristic (ROC) curve analysis were analyzed.

**RESULTS**

The positive lymph node(N+) demonstrated higher f values in MAT(0.331±0.110 vs 0,431±0.153, p=0.004) and higher D values in MDT(4.017 ±4.763 vs 8.351±1.348(10-3·mm2/s,p=0.003) than lymph node(N-). f values in MAT and D values in MDT had good diagnostic efficiency to predict N+ (AUC= 0.693,0.709,P=0.005,0.003).

**CONCLUSION**

f values in MAT and D values could noninvasive predict N stage in patients with rectal cancer based on IVIM.

**CLINICAL RELEVANCE/APPLICATION**

The microstructural features around the tumor could predict lymph node in patients with rectal cancer based on IVIM.

## M2-SPGI-7 DETECTION OF INFLAMMATORY BOWEL DISEASES IN MRE IMAGES WITH SPATIALLY CONTEXT-AWARE YOLOV4

Seohyun Lee (*Abstract Co-Author*) Nothing to Disclose
Joonseok Lim, MD (*Abstract Co-Author*) Nothing to Disclose
Nieun Seo, MD (*Abstract Co-Author*) Nothing to Disclose
Hansang Lee, PhD (*Abstract Co-Author*) Nothing to Disclose
Helen Hong, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Utilizing deep learning to detect inflammatory sites in single 2D slice images of magnetic resonance enterography (MRE) from patients with inflammatory bowel disease, e.g. Crohn’s disease, has limitations due to the lack of spatial context information, which can lead to numerous false positive detections. To improve the precision of inflammation detection, we propose a spatially context-aware YOLOv4 method that incorporate spatial context information with spatially-stacked multi-channel images.

## METHODS AND MATERIALS

The dataset consists of MRE images from 222 patients collected between March 2016 and December 2018. Initially, we utilized three-slice sequences of {m-s,m,m+s}-th slices mapped to three channels to incorporate spatial contextual information across slices, where s={1,2,3,4,5} refers to the distance between slices to control the spatial context. Subsequently, the YOLOv4 model based on the Darknet-53 framework was fine-tuned to detect inflammation from multi-channel images. Model training and evaluation were conducted in the Google Colab environment using Python and Darknet framework.

## RESULTS

The experimental results demonstrated that the proposed method significantly improves the consistency of inflammatory disease detection across multiple slices while reducing false positives compared to traditional single-slice detection methods. The baseline method employing single-slice imaging showed inconsistency in detection and higher rates of false positives. Conversely, the proposed method, utilizing the three-channel images, achieved higher consistency and precision in detecting inflammatory areas, as evidenced by the quantitative evaluations using mean Average Precision and recall scores. Additionally, the detection performance improved the most when the spatial context distance s was set to 1.

## CONCLUSION

Our method confirmed that leveraging spatial information from consecutive slices in MRE images through YOLOv4 significantly improves the accuracy and consistency of detecting inflammatory disease sites. By integrating a broader contextual understanding of the disease's manifestation across adjacent slices, our proposed method effectively addresses the variability and detection challenges posed by single-slice approaches. (This research was supported by a grant of the Korea Health Technology RD Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health Welfare, Republic of Korea (grant number : HI22C1496))

## CLINICAL RELEVANCE/APPLICATION

By improving inflammation detection with high accuracy and reduced false positives, the proposed method can be used to automatically estimate the activity of inflammatory bowel diseases.

# M2-SPGI-9 EARLY EXPLORATORY ANALYSIS OF IMAGE QUALITY AND DOSE SAVINGS IN DOUBLE LOW-DOSE ABDOMINAL CT FOR SUSPECTED ACUTE APPENDICITIS

Hokun Kim, MD (*Abstract Co-Author*) Research Grant, TAEJOON Pharmaceutical Co, Ltd
Seo Yeon Youn, MD (*Abstract Co-Author*) Nothing to Disclose
Soon Nam Oh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Bohyun Kim, MD (*Presenter*) Nothing to Disclose

## PURPOSE

In CT, lower kVp increases the attenuation of iodine, allowing for reduced contrast media (CM) doses. However, a standardized low-dose CM protocol for low-kVp abdominopelvic CT is lacking. Institutions, including ours, performed these scans using either standard dose CM (approximately 0.521 g I/kg) suited for 120 kVp (single low-dose CT, SLCT) or anecdotal reduced doses. Lowering both kVp and CM dose (double low-dose CT, DLCT) could benefit young adults suspected of acute appendicitis. We present an early exploratory analysis of image quality and dose savings from an ongoing prospective single arm study aiming to establish a tailored DLCT protocol (NCT05878665).

## METHODS AND MATERIALS

From Dec 2023 to Feb 2024, patients aged 18-44 years with BMI < 30 kg/m2 and clinical suspicion of acute appendicitis were enrolled. They underwent DLCT with a CM dose reduction targeted at 10% per 10 kVp decrease from the 0.521g I/kg and 120 kVp. Image quality, dose reduction, and positive predictive value (PPV) for appendicitis were compared between DLCT and SLCT. All images were acquired using a 128-slice CT scanner with automatic exposure control, automatic kV selection, and iterative reconstruction. For the statistical analysis, t-test and Mann-Whitney test were used with P values < 0.05 indicate significance.

## RESULTS

The DLCT group included 52 patients (age, 33.5 ± 7 years; 30 females), and SLCT group included 53 patients (age, 33.3 ± 6.5 years, 35 females) retrospectively collected from Nov 2023 to Dec 2023, with no enrollment period overlap. The BMI, body weight, effective diameters, and number of CT scans under 80kVp were comparable between groups (Ps = 0.06). While image noise levels were comparable, the SNR and CNR measured from the solid organs, portal vein, and psoas muscle were all significantly higher in SLCT group (Ps = 0.001). Subjective assessments of noise score was comparable in groups (P = 0.52), but organ enhancement and diagnostic image quality scored higher in SLCT (Ps < 0.001). Appendiceal visibility, diagnostic confidence, and PPV for diagnosing appendicitis (70% [7/10 cases] vs. 80% [8/10 cases]) were comparable (Ps = 0.62). The dose of the CM (0.383 ± 0.048 gI /kg vs. 0.589 ± 0.085 gI/kg) and effective dose (3.8 ± 1.9 mSv vs. 5.0 ± 2.3 mSv) was reduced by 35% and 22% in DLCT, respectively, compared to SLCT.

## CONCLUSION

DLCT reduced the iodide dose and effective dose by 35% and 22% compared to SLCT, while showing comparable appendiceal visibility, diagnostic confidence, and PPV for appendicitis despite lower SNR and CNR. Thus, the suggested DLCT protocol may be a feasible option for young adults with suspected acute appendicitis.

## CLINICAL RELEVANCE/APPLICATION

The DLCT protocol, reducing CM dose by 10% for every 10 kVp decrease, is viable for suspected acute appendicitis.

## M2-SPGU-1 CLINICAL VALIDATION OF DEEP LEARNING-EMPOWERED PRE-OPERATIVE AUXILIARY PLANNING SYSTEM FOR KIDNEY CANCER: A MULTICENTER STUDY

Fule Wu (*Abstract Co-Author*) Employee, Infervision
Shaokang Wang (*Abstract Co-Author*) Nothing to Disclose
Bing Zhong (*Abstract Co-Author*) Nothing to Disclose
Gongcheng Wang (*Abstract Co-Author*) Nothing to Disclose
Chen Xia (*Abstract Co-Author*) Nothing to Disclose
Ji Qi (*Abstract Co-Author*) Nothing to Disclose
Dawei Wang, PhD (*Presenter*) Employee, Infervision

### PURPOSE

Since the segmentation performance determines the three-dimensional reconstruction accuracy, in turn, affects the precision of surgery planning, we explore the reliability of deep learning (DL)-based pre-operative auxiliary planning system in aiding renal cancer surgery planning by examining its segmentation performance on renal lesions and vessels.

### METHODS AND MATERIALS

One hundred and eighty pre-operative abdominal contrast-enhanced CT examinations (slice thickness < 2mm) were retrospectively collected from patients who underwent renal cancer surgery in 8 medical centers. Two experienced surgeons established the gold standard annotations of renal lesions, kidneys, renal vessels, and other urological organs via consensus. Eligible samples for each segmentation task were included for validation. The DL-based pre-operative auxiliary planning system for kidney cancer (InferOperate Urology Planning, Infervision) which generates the three-dimensional reconstruction of renal structures based on automated structural segmentations was employed and validated in this study. The DICE index was calculated to evaluate the performance of segmentation algorithms underlying the auxiliary surgery planning system.

### RESULTS

The DICE index of the validated DL system reached 0.963 (95%: 0.964,0.962), 0.880 (95%CI: 0.885, 0.876), 0.860 (95%CI: 0.866, 0.855), and 0.909 (95%CI: 0.899, 0.920) for segmentations of kidney, renal artery, renal vein, and renal lesions, respectively. Subgroup analyses for CT manufacturers, slice thickness, reconstruction kernels, and tube voltages showed no significant difference, indicating the robustness of the underlying algorithms. Besides, the DICE indexes for segmenting adrenal glands and ureters were 0.816 (95%CI: 0.804, 0.828), and 0.757 (95%CI: 0.746, 0.763), respectively.

### CONCLUSION

The employed auxiliary planning system demonstrates robust performance in the segmentation of renal lesions, vessels, kidneys, and other urological organs and tissues, guaranteeing the accuracy of the 3D reconstruction and favoring precise renal cancer surgery planning.

### CLINICAL RELEVANCE/APPLICATION

Compared with 2D images, 3D reconstruction results can more accurately present the anatomical structure of the kidney, show the relationship between lesions and their adjacency, and assist in precise surgical implementation. The system validated in this study can efficiently and automatically complete the three-dimensional reconstruction of kidney lesions and anatomical structures and allow the surgical resection simulation based on 3D results, effectively assisting preoperative planning, and helping achieve precise surgery.

## M2-SPGU-2 BIPARAMETRIC PROSTATE MRI WITH SUPER-RESOLUTION DEEP LEARNING RECONSTRUCTION: COMPARISON WITH CONVENTIONAL RECONSTRUCTION TECHNIQUE

Hiromitsu Onishi, MD, PhD (*Abstract Co-Author*) Research Grant, General Electric Company;Speakers Bureau, General Electric Company

Atsushi Nakamoto, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Super-resolution deep learning reconstruction (SR-DLR) can simultaneously reduce image noise and improve spatial resolution. The purpose of this study was to compare image quality and diagnostic performance between biparametric prostate MRI with and without SR-DLR.

**METHODS AND MATERIALS**

This retrospective study included 38 patients who underwent prostate MRI including T2-weighted imaging (T2WI) and diffusion-weighted imaging (DWI) using a 3-Tesla scanner, followed by prostatectomy or MR/US fusion-guided prostate biopsy. T2WI and DWI were reconstructed using both conventional reconstruction and SR-DLR. The signal-to-noise ratio (SNR) of the prostate was measured as a quantitative analysis. Two radiologists independently evaluated the image quality of T2WI and DWI in terms of visibility of prostate anatomy, image noise, sharpness (T2WI), distortion (DWI), and overall image quality using a 5-point rating scale. They also assessed the likelihood of the presence of prostate cancer using PI-RADS version 2.1. Diagnostic performance was compared between two image sets (conventional T2WI+DWI and SR-DLR T2WI+DWI) using the jackknife free-response receiver operating characteristic (JAFROC) analysis.

**RESULTS**

The SNR of SR-DLR images was significantly higher than that of conventional images for both T2WI and DWI ($P < .001$). Mean visual scores of SR-DLR images were significantly higher than those of conventional images for both readers for all assessments ($P < .05$). The JAFROC1 figure of merit of SR-DLR images for prostate cancer detection was higher than that of conventional images for both readers, although the differences were not statistically significant (0.85 vs. 0.78, $P = 0.19$, and 0.70 vs. 0.69, $P = 0.86$, respectively).

**CONCLUSION**

SR-DLR resulted in higher image quality in prostate MRI compared to the conventional reconstruction technique. Diagnostic performance tended to be higher in SR-DLR images, although no significant differences were observed.

**CLINICAL RELEVANCE/APPLICATION**

SR-DLR can significantly improve the image quality of biparametric MRI by reducing noise and increasing spatial resolution. Some prostate cancers could only be detected by SR-DLR images, which may have the potential to improve the diagnostic performance.

## M2-SPGU-3 COMPARISON BETWEEN CONVENTIONAL CYSTOURETHROGRAPHY AND MRI WITH VOIDING MR-CYSTOURETHROGRAPHY IN THE EVALUATION OF MALE ANTERIOR URETHRAL STRICTURES

Marco Di Girolamo, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the accuracy of conventional retrograde and voiding cystourethrography and MRI together with voiding MR-cystourethrography in the evaluation of male urethral strictures.

**METHODS AND MATERIALS**

We evaluated 39 male patients with anterior urethral strictures diagnosed with urine flow velocity recording and conventional retrograde and voiding cystourethrography. All these patients underwent MRI and voiding MR-cystourethrography using a 1.5T superconductive magnet. The patients had urine-filled bladders and high-resolution sagittal TSE T2-weighted scans were performed (TR:6250ms; TE:90ms;sl.thick.:3mm; acq.time:3'38"). Voiding MR-cystourethrography was performed with T1-weighted spoiled 3D gradient-echo acquisitions on sagittal plane (TR:12ms; TE:2,7ms; flip-angle:40°; sl.thickness: 2mm; acq.time:12s) after the filling of bladder lumen with contrast-material-enhanced urine obtainded by the i.v administration 20 mg of furosemide followed by ¾ of the normal dose of a paramagnetic contrast agent (Magnevist, Bayer Pharma, Germany). After micturition high-resolution coronal TSE T2-weighted scans were performed at the level of the stenosis. Two radiologists in consensus evaluated the morphology and length of the urethral stenosis with the two modalities and with MRI the entity and the site of spongio-fibrosis was assessed.

**RESULTS**

6 patients were not able to perform voiding MR-cystourethrography. In 33 patients evaluated with two imaging modalities 42 urethral strictures were detected. The measurement of the stenosis length was equal or superior with voiding MR cystourethrography and the analysis of 3D sagittal scans allowed a better evaluation of the morphology of the urethral strictures in comparison with conventional cystourethrography. 32 strictures with Spongio-fibrosis were found (76%). The site of spongio-fibrosis was always assessed with MRI (dorsal, ventral, dorsal and ventral and circular fibrosis).

**CONCLUSION**

MRI with voiding MR-cystourethrography shows the morphology and the length of the urethral strictures better than conventional cystourethrography and allows the detection and site of spongio-fibrosis, avoiding radiation exposure to the gonads and urinary catheterization.

**CLINICAL RELEVANCE/APPLICATION**

MRI could be proposed as all-in-one technique for the evaluation of urethral stenosis, allowing their detection and length assessment and determining the presence and site of spongiofibrosis.

## M2-SPGU-4 CARDIOVASCULAR RISK AND METABOLIC SYNDROME IN MILD AUTONOMOUS CORTISOL SECRETION (MACS) PATIENTS: A COMPARATIVE STUDY WITH PRIMARY ALDOSTERONISM (PA)

Emilio Quaia, MD (*Abstract Co-Author*) Speakers Bureau, Bracco Group
Francesco Bigolin, MD (*Abstract Co-Author*) Nothing to Disclose
Filippo Crimi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Carlo D'Alessandro, MD (*Abstract Co-Author*) Nothing to Disclose
Giovanni Sussan, MD (*Abstract Co-Author*) Nothing to Disclose
Elvis Vassallo, MD (*Abstract Co-Author*) Nothing to Disclose
Chiara Zerbato (*Presenter*) Nothing to Disclose

**PURPOSE**

The incidence of incidentalomas has increased tenfold over the past two decades. Primary aldosteronism (PA) and Mild autonomous cortisol secretion (MACS), previously referred to as subclinical Cushing’s syndrome, are common hormonal abnormalities in benign adrenal tumors. The aim of the study

was to analyze the CT body composition parameters of patients with MACS and PA and to compare them to evaluate which population shows a higher cardiovascular risk and metabolic syndrome.

**METHODS AND MATERIALS**

We retrospectively included 90 patients, of whom 36 were diagnosed with PA and 54 with MACS. CT scans were performed at the diagnosis of PA and MACS.We evaluated total body circumferences and body surface, total fat area, visceral and parietal areas, visceral-total and visceral-parietal ratios, the area of muscular mass and the total body composition.Additionally, were also collected the attenuation value of the liver, spleen and cortical bone of the 3rd lumbar vertebra.Measurements were performed at the 3rd lumbar spine level with a semi-automated quantification by ImageJ, an open-source image processing program derived from NIH Image for the Macintosh platform. Using this program, we could adjust the image thresholds to obtain specific elements for our study.The data between the two cohorts were compared using Mann-Whitney or Student's t test, as appropriate.

**RESULTS**

The ratio visceral/total is significantly higher in MACS patients compared to PA (median 0,49, IQR 0,39-0,59 vs median 0,17, IQR 0,11-0,26; p<0,0001).The ratio visceral/parietal was different in the two cohorts, with a trend toward significance (median 0,94, IQR 0,64-1,46 vs median 0,79, IQR 0,71-0,86; p=0,060).Additionally, there was a higher visceral fat mass, which is more prominently represented in absolute terms in patients with MACS compared to those with PA (median 174cm2, IQR 114-279 vs median 133cm2, IQR 59-211 p< 0.03). Moreover, there was a significant reduction of the attenuation value of 3rd lumbar vertebra in MACS patients compared to those with PA (median 106HU, IQR 85-140 vs median 171HU, IQR 133-209; p<0,0001).Moreover, there was a reduction of the muscle mass in patients with MACS compared to those with PA (median 121cm2, IQR 99-151 vs median 288cm2, IQR 263-318; p<0,0001).

**CONCLUSION**

MACS patients have greater reduction in muscle mass and bone mass than PA patients, in addition they have greater fat mass.

**CLINICAL RELEVANCE/APPLICATION**

MACS patients have a higher cardiovascular risk and metabolic syndrome as PA patients, although guidelines do not recommend any specific medical or surgical treatment for these patients.

## M2-SPGU-6 COMPARING PSMA PET/CT AND MULTIPARAMETRIC MPMRI FOR SELECTING ELIGIBILITY FOR FOCAL THERAPY IN PROSTATE CANCER

Vahid Yaghmai, MD, MS (*Abstract Co-Author*) Nothing to Disclose
James Shi, MD (*Abstract Co-Author*) Nothing to Disclose
Maryam Rahmani, MD (*Abstract Co-Author*) Nothing to Disclose
Garrett G. Ward, MD (*Abstract Co-Author*) Nothing to Disclose
Seyedeh Niloufar Rafiei Alavi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Current guidelines recommend focal therapy for prostate cancer patients with unifocal, unilateral lesions and no extra-prostatic disease. This study aimed to compare the diagnostic accuracy of 18F-PSMA-PET/CT and multiparametric mpMRI in identifying bilateral or multifocal unilateral disease from unifocal hemi-lateral involvement of the prostate.

**METHODS AND MATERIALS**

We reviewed records for 140 prostate cancer patients using 18F-PSMA-PET/CT and mpMRI. Lesion lateralization was categorized as bilateral or unilateral. Unilateral involvement was further classified as unifocal if it involved adjacent sextants and multifocal if distant sextants (e.g., base and apex) were involved. Diagnostic accuracy and agreement were assessed using Cohen's kappa and ROC curve analyses.

**RESULTS**

36/140 (25.7%) of the patients had multifocal disease. Detection rates were 53.8% for both modalities, 19.4% only by PSMA PET/CT, and 2.7% only by mpMRI. 22.2%. of cases were missed by both modalities. The agreement on multifocal versus unifocal disease detection was moderate (kappa=0.549). 18F-PSMA-PET/CT showed higher sensitivity (72.9% [55.8-86.2]), specificity (88% [79.7-94.7]), PPV (75% [61.1-85.1]), and NPV (87.7% [80.6-92.4]) than mpMRI, which had a sensitivity of 63.6% [45.1-79.6], specificity of 82.2% [79.7-94.7], PPV of 58.3% [45.3-70.3], and NPV of 85.2% [78.4-90.1]. ROC analysis confirmed superior diagnostic accuracy of 18F-PSMA-PET/CT (AUC = 0.813 [0.720-0.906]) compared to mpMRI (AUC = 0.718 [0.610-0.826]).

**CONCLUSION**

18F-PSMA-PET/CT demonstrates superior accuracy in identifying multifocal versus unifocal disease, suggesting its preference in evaluating prostate cancer patients for focal therapy eligibility.

**CLINICAL RELEVANCE/APPLICATION**

18F-PSMA-PET/CT is recommended over mpMRI for assessing eligibility for focal therapy in prostate cancer due to its higher diagnostic precision.

## M2-SPGU-7 COMPARING IMAGE QUALITY CATEGORIZATION USING PI-QUAL VERSIONS 1 AND 2

Dimitri A. Kessler, PhD (*Abstract Co-Author*) GlaxoSmithKline, Funding of PhD Studentship
Iztok Caglic, MD (*Abstract Co-Author*) Nothing to Disclose
Tristan Barrett, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Kang-Lung Lee, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The diagnostic efficacy of prostate MRI for detecting lesions in prostate cancer is heavily reliant on image quality. Prostate Imaging Quality (PI-QUAL) seeks to standardize this evaluation and has recently been updated to version 2 in April 2024. This study aims to assess inter-reader agreement for PI-QUAL v1 and v2 scores from prostate multiparametric MRI (mpMRI) scans.

**METHODS AND MATERIALS**

Conducted retrospectively at an academic medical center, this study analyzed 350 mpMRI scans performed in biopsy-naļve patients using five different MR systems (1.5T or 3T) between 2018 and 2022. Two expert uroradiologists with 15 and 7 years of experience, respectively and independently evaluated mpMRI quality using PI-QUAL v1 and v2 guidelines. PI-QUAL v1 scores (out of 5) were grouped into inadequate (1-2), acceptable (3), or optimal quality (4-5). Additionally, following the v2 system, biparametric MRI categorization (v2 bpMRI) using T2WI and DWI was computed alongside

mpMRI categorization (v2 mpMRI). Inter-reader agreement was assessed using Cohen's weighted kappa. A chi-square test was employed to ascertain whether significant differences exist among quality scores from different criteria, with a significance level (a) set at 0.05.

**RESULTS**

Substantial inter-reader agreement was observed for the overall PI-QUAL v1 score (? = 0.64) and moderate agreement for v2 mpMRI (? = 0.54) and v2 bpMRI scores (? = 0.57). Predominant quality levels shifted from optimal in v1 (65%) to acceptable in v2 mpMRI categorization (55%) ($p < 0.001$). With the application of v2, the addition of DCE increased the proportion of cases of at least adequate quality from 30% (bpMRI) to 64% (mpMRI) ($p < 0.001$). Inter-reader agreements on individual sequences were similar between v1 and v2 on T2WI (? = 0.46 and 0.49 for v1 and v2, respectively), DWI (? = 0.66 and 0.70, respectively), and DCE (? = 0.71 and 0.61, respectively).

**CONCLUSION**

This study demonstrates substantial agreement for PI-QUAL v1 and moderate agreement for v2 mpMRI and v2 bpMRI scores. A notable shift from optimal to acceptable quality levels was observed from v1 to v2 mpMRI categorization. Furthermore, a significant shift occurred from inadequate to acceptable categorization between v2 bpMRI and v2 mpMRI. Inter-reader agreements on individual sequences remained comparable between the versions.

**CLINICAL RELEVANCE/APPLICATION**

PI-QUAL v2 enhances image quality evaluation for both bpMRI and mpMRI. Shifting from inadequate to acceptable, between v2 bpMRI and v2 mpMRI, confirms the role of DCE as an image quality “safety net”. Understanding inter-reader agreement between PI-QUAL versions 1 and 2 is crucial for ensuring reliable interpretation of prostate MRI findings, thereby improving diagnostic workflows in clinical practice.

## M2-SPGU-8 COMPARATIVE STUDY ON THE DIAGNOSTIC VALUE OF DIRECT LYMPHANGIOGRAPHY AND CT LYMPHANGIOGRAPHY IN PRIMARY CHYLURIA

Qi Hao (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the diagnostic value of direct lymphangiography (DLG) and CT lymphangiography (CTL) in primary chyluria.

**METHODS AND MATERIALS**

Thirty-seven patients diagnosed as primary chyluria were recruited in this retrospective study. All patients were examined by DLG and CTL. All images were reviewed by 2 radiologists separately and reached decisions by consensus.For DLG and CTL, the indexs were?Lymphatic morphology and lymphatic reflux of bilateral iliac lymphatic, lumbar trunk and thoracic duct; ?Distribution of abnormal lymphatic vessels in the urinary system,thorax and abdomen.The results of CTL and DLG were statistically analyzed. The Mcnemar test in the paired ?2 test was used to analyze indexs of CTL compared with DLG, and the difference was statistically significant at P& 4;0.05, and the Kappa test was also used to evaluate the concordance between the two methods of CTL and DLG for the diagnosis of primary chyluria.

**RESULTS**

The difference between CTL and DLG for showing contralateral iliac, contralateral lumbar trunk and bronchial mediastinal trunk lymphatic reflux was statistically significant ($P < 0.05$),and the detection rate of CTL was higher than that of DLG.CTL and DLG were highly consistent in showing ipsilateral and contralateral renal lymphatic reflux (Kappa > 0.800),CTL (34/37) had a higher detection rate for renal lymphatic reflux than DLG (30/37),and CTL could further reveal the distribution of abnormal lymphatic vessels in the kidney and perirenal area. The difference between DLG and CTL for showing lymphatic reflux in the cervical trunk and subclavian trunk was statistically significant ($P < 0.05$),and the detection rate of CTL was lower than that of DLG.

**CONCLUSION**

CTL can show the distribution, extent and severity of abnormal dilated lymphatic vessels in primary chyluria, it is especially valuable for the assessment of renal lymphatic reflux,the distribution of abnormal lymphatic vessels in the perinephric region, contralateral iliac and lumbar trunk lymphatic reflux. And DLG is more advantageous for showing thoracic duct dysfunction and terminal lymphatic reflux. The detection rate of DLG for primary chyluria was 81.1%, and the combined application of DLG and CTL was able to improve the detection rate to 91.9%.

**CLINICAL RELEVANCE/APPLICATION**

The DLG and CTL complement each other, this can provide an important imaging basis for the diagnosis and preoperative evaluation of primary chyluria.

### PURPOSE

To assess the capability of subtraction iodine maps (SIM) combined with deep learning reconstruction (DLR) to evaluate temporal bone tumors, compared with conventional temporal bone enhanced CT images.

### METHODS AND MATERIALS

This prospective study continuously recruited twenty-one patients with temporal bone tumors who underwent temporal bone enhanced CT scans. All acquisitions were performed with a 320 row-detector CT scanner (Aquilion ONE Genesis Edition). Pre-contrast and enhanced images were both reconstructed using HIR (Adaptive Iterative Dose Reduction [AIDR] 3D) and DLR (Advanced Intelligent Clear-IQ Engine [AiCE]). Afterward, these two groups of images processed with a dedicated software (SURESubtraction) to generate SIM images. Therefore, three groups of images were produced for analysis: Enhanced-HIR, SIM-HIR, SIM-DLR. Qualitative parameters, including overall image quality, confidence index of lesion detection, ability of lesion contour visualization, and temporal bone involvement display ability, were rated by two radiologists independently according to a five-point scale. Quantitative parameters, including contrast-to-noise ratio (CNR) between the temporal bone tumor and muscle, were computed and compared.

### RESULTS

For overall image quality, SIM-HIR was equivalent to Enhanced-HIR, and SIM-DLR was superior to SIM-HIR (all $p<0.05$). For ability of lesion contour visualization, the three groups had comparable scores, with the SIM-DLR being the highest. For ability of lesion contour visualization and temporal bone involvement display, SIM-HIR was superior to Enhanced-HIR (all $p<0.05$). And SIM-DLR was equivalent to SIM-HIR with higher scores. For qualitative evaluation, two raters showed good agreement, with kappa values of 0.707. For quantitative evaluation, the CNR of SIM-HIR was equivalent to that of Enhanced-HIR ($7.59\pm4.07$ vs $8.13\pm4.68$, $p=0.58$). And the CNR of SIM-DLR was significantly higher than that of SIM-HIR ($11.67\pm6.34$ vs $7.59\pm4.07$, $p<0.001$).

### CONCLUSION

Compared with conventional enhanced CT, subtraction iodine maps combined with deep learning reconstruction can improve the image quality of CT images of temporal bone tumor. With equivalent capability to detect temporal bone lesions, SIM-DLR can notably enhance the visualization of lesion contour and bone involvement.

### CLINICAL RELEVANCE/APPLICATION

SIM-DLR can enhance the visualization of the extent of tumor invasion in the temporal bone, facilitating the formulation of surgical strategies.

## M2-SPHN-4 INFLUENCE OF IMAGING PARAMETERS ON COCHLEA DUCT LENGTH AND OPERATIVE PLANING DECISIONS IN MULTISLICE CT

Philipp Feldle, MD (*Abstract Co-Author*) Nothing to Disclose
Jan P. Grunz, MD (*Abstract Co-Author*) Research Consultant, Siemens AG
Henner Huflage, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In CI surgery, precise Cochlear Duct Length (CDL) measurement is pivotal for individualized electrode carrier selection and postoperative anatomical fitting. The detail in preoperative temporal bone CT scans significantly impacts CDL measurement and CI electrode contact determination. This study aims to assess how radiation dose and reconstruction field of view (FOV) in multi-slice CT affect preoperative CDL measurement and electrode contact determination.

## METHODS AND MATERIALS

20 human petrous bone specimens were examined with multislice spiral CT with three radiation doses (CTDIvol 40, 20, 10 mGy). Each data set was reconstructed with three different FOV settings (250, 125, 50 mm). Preoperative measurement of the CDL was performed with an otological planning software. Ultra high-resolution images with outmaxed radiation dose (CTDIvol 250 mGy) served as a reference standard.

## RESULTS

Regardless of FOV reconstructions and cross all tested scan modes, including high, standard, and low dose there were no significant differences compared to the reference scans (all $p>0.05$) regarding cochlear duct length measurement and angular insertion depth. Preoperative simulation of the hearing frequency distribution showed no dependency on radiation dose or field of view (all $p>0.05$).

## CONCLUSION

For pre-operative evaluation of cochlear implant surgery in multi slice CT a significant reduction in radiation dose is feasible. Planning parameters do not benefit from reduced pixel size by dedicated small field of views.

## CLINICAL RELEVANCE/APPLICATION

Pre-operative evaluation for cochlear implant surgery is feasible with substantially reduced radiation dose and does not benefit by reduced pixel size.

## M2-SPIN-1 GENERATION OF LOW KEV MONOCHROMATIC LIKE IMAGE FROM SINGLE ENERGY CT USING DEEP LEARNING BASED TRANSFORMATION

Bipul Das, PhD (*Abstract Co-Author*) Nothing to Disclose
Risa Shigemasa (*Abstract Co-Author*) Nothing to Disclose
Kok Yen Tham (*Abstract Co-Author*) Nothing to Disclose
Utkarsh Agrawal (*Abstract Co-Author*) Nothing to Disclose
Rajesh Langoju (*Abstract Co-Author*) Nothing to Disclose
Yasuhiro Imai, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Monochromatic images play a crucial role in Dual Energy CT (DECT), where lower keV images offer enhanced contrast detectability. However, single energy CT (SECT) lacks the ability to generate these Monochromatic lower keV images. We propose a deep learning algorithm to generate lower keV images from single energy CT scans across various contrast phases and organs in body imaging. Our AI-based framework learns the attenuation transformation from a given kVp image to the desired low keV target image. Notably, the generated images exhibit higher contrast without additional artifacts compared to those acquired at the target energy (kVp/keV). This work holds promise for improving diagnostic accuracy and enhancing clinical workflows in body oncology and vascular studies.

### METHODS AND MATERIALS

We propose a supervised learning with a cyclic consistency check for high kVp to low keV target image transformation. Since SECT does not have the corresponding image, 70 keV (as comparable to 120 kVp [1,2]) and 50 keV monochromatic image pairs generated from GE HealthCare Gemstone Spectral Imaging (GSI), fast kV switching dual energy acquisition on Revolution and Revolution Apex CT systems are used in the supervised training. A cyclic consistency is used in the network to avoid degenerate solution arising from possible many-to-many mapping due to the attenuation properties of tissues across different energies between the input-target pairs. The cyclic part of the network generates the reverse transform from 50 keV to 70 keV image. MAE loss is used in the network balanced between the forward-reverse transformation. The proposed network is trained on more than 40000 of monochromatic image pairs acquired at different contrast levels, including arterial, portal/venous, and delayed cases. Inferencing is done on monochromatic images for quantitative evaluation and on single energy images for qualitative assessment.

### RESULTS

Fig. 2 shows comparison with prediction output from 70 keV portal abdomen images and true 50 keV and shows low deviation in the error map in range [-25,25]. While a sample 50keV image generated from a SECT 120 kVp image is illustrated in Fig. 3.

### CONCLUSION

We demonstrate a deep learning-based Monochromatic low keV image generation from single energy scan for improved contrast visibility across different contrast phases and evaluation across 70keV and single energy images.

### CLINICAL RELEVANCE/APPLICATION

A low keV image along with the primary standard single kVp image is helpful in oncology studies for vasculature analysis in contrast scans. Similar to GSI systems, this methodology opens the option of low keV like image along with primary image in single energy CT systems.

## M2-SPIN-2 DEVELOPING IMPROVED METRICS FOR DESCRIBING BRAIN INVOLVEMENT IN SYMPTOMS AFTER MILD TRAUMATIC BRAIN INJURY

Travis H. Snyder, DO (*Abstract Co-Author*) Nothing to Disclose
Jeffrey Lewine, PhD (*Abstract Co-Author*) Nothing to Disclose
Jose Martinez (*Abstract Co-Author*) Nothing to Disclose
Tzvi Crystal (*Abstract Co-Author*) Nothing to Disclose
Priya Santhanam, PhD (*Abstract Co-Author*) Nothing to Disclose
Alexeis Ong (*Abstract Co-Author*) Nothing to Disclose
Cheryl E. Vanier, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Relate laterality analysis approaches to functional models of brain hemispheric involvement in symptomatology after mild traumatic brain injury (mTBI). We approached this question using simulations based on parameters from empirical data.

### METHODS AND MATERIALS

The correlation between right and left side volumes for the primary motor cortex (PMC; NeuroQuant 3.0) was estimated from MRI-based volumetrics (n=520) mTBI patients. A subset (n=53) with neuropsychological testing were used to estimate empirical correlations between right and left PMC volumes and Beck Anxiety Index (BAI) score. Using the observed correlations, datasets with right and left PMC volume and BAI scores were simulated based on three known and one novel model of lateral brain influence on symptoms (Models A-D). Laterality metrics included separate analysis of right and left regions, a laterality index (LI=Right-Left)/(Right+Left), a different LI based on principal components (PC) analysis, and an asymmetry index (|LI-Median(LI)|. Simulated datasets with sample size of 100 were used to relate BAI to volume and laterality metrics in simple linear regressions, with subsequent Benjamini-Hochberg p-value adjustment.

### RESULTS

For Model A, where symptoms correlated only with right PMC volume, BAI unsurprisingly had relationships with right PMC volume (100% of simulations) and asymmetry index (3%); 56% of simulations incorrectly related BAI to left PMC volume and only 2% related BAI to the traditional LI. In 13% of simulations, BAI was related to the PC-based LI. Metrics performed as anticipated in Model B, where PMC had no lateralization relative to BAI. The same was true for Model C, where right and left PMC made partially overlapping contributions to BAI; however, the PC-based laterality inconsistently indicated laterality in some simulations (17%). Based on the novel Model D (BAI and side-independent asymmetry of PMC right and left sides were related), as expected, the anxiety related to the asymmetry index (100%), but not PMC volumes (2%-3%) nor the PC-based laterality (3%); however, LI did not behave as expected in Model D (51%).

### CONCLUSION

The most frequently used strategies for examining lateralization are analyzing right and left sides separately or the use of laterality indices. These results suggest both strategies can be misleading when trying to determine the underlying structure of lateralization in the brain relative to symptoms. Side-independent asymmetry deserves more study, as it was observed only when an appropriate metric was incorporated into the analysis.

### CLINICAL RELEVANCE/APPLICATION

Novel metrics of hemispheric brain laterality show promise in accurately reflecting the underlying brain involvement in mTBI symptoms.

## M2-SPIN-3 EYESEE: REAL RADIOLOGY ROOM EXPERIENCE WITH EYE TRACKING AND DEEP LEARNING

Elif Keles, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Bin Wang, BEng (*Presenter*) Nothing to Disclose

### PURPOSE

To record the eye movements of radiologists with eye-tracking technology in real radiology room experience with PACS system, allowing full functionality of real-time decision support system by going beyond lab experiments and test deep learning frameworks to assist auto-segmentation of organs and tumors.

### METHODS AND MATERIALS

We developed a new eye-tracking-based medical viewer system with automatic diagnostic capabilities supported by deep learning. The EyeSee allows us to capture the eye gaze data of radiologists during scan reading and input it into the trained deep learning algorithms. For diagnostic enhancement, EyeSee automatically crops the images into patches and extracts the deep image features of each patch. Meanwhile, we apply the proposed time-aggregation method to calculate each patch's eye gaze time duration feature. Then, EyeSee combines two features to conduct medical image classification or segmentation. EyeSee supports both 2D and 3D scans (ultrasound, X-ray, CT, PET, MRI, etc.). For demonstration purposes, a public Chest X-ray dataset with eye gaze was used in the experiments, which included 1083 cases with three different labels (Normal, Congestive Heart Failure, and Pneumonia). We also used CT, MRI, and X-Ray for real-time segmentation purposes.

### RESULTS

We employed 10-fold cross-validation to validate our diagnostic results in X-Ray disease classification, achieving an accuracy of 83.18% with an inference time of just 0.353 seconds per patient. This demonstrates that our method not only boosts diagnostic accuracy but also minimizes time consumption, enhancing the efficiency of integrating eye tracking into diagnostic readings. Furthermore, we evaluated various deep learning algorithms and found that graph neural networks outperform both convolutional neural networks and transformer-based models in this application. Our segmentation strategy is based on a combination of gaze prompts with SAM for real-time segmentation of objects; videos are attached for visual examples.

### CONCLUSION

In this study, we built the EyeSee system, which integrates eye-tracking technology into real-time medical image analysis in real radiology room settings. By utilizing the expert knowledge hidden in the eye gaze collected, our system enhances diagnostic accuracy with impressive efficiency. The strong application of eye tracking shows the combination of human and deep learning strengths.

### CLINICAL RELEVANCE/APPLICATION

There is an unmet need for decision-support systems in radiology rooms. Deep learning methods may fall short in many cases where radiologists' gaze patterns can fill this gap. EyeSee improves computer-aided diagnostic systems and helps with radiologists' busy work pace.

## M2-SPIN-4 MRI INTENSITY STANDARDIZATION VIA PROTOTYPE LEARNING FOR IMPROVED ONCOLOGICAL ANALYSIS OF HETEROGENOUS DATASETS

**PURPOSE**

Oncological MRI datasets exhibit significant heterogeneity due to variations in scanners, imaging protocols, and imaging of different anatomical regions. This limits the use of raw MRI scans for quantitative analysis and AI research. We propose a novel, prototype-learning-based approach to address MRI intensity standardization for such heterogeneous datasets.

**METHODS AND MATERIALS**

This study proposes a novel MRI intensity standardization model based on prototype learning. First, we use unsupervised clustering techniques to identify natural groups within the images by analyzing voxel-wise intensity metrics computed from raw MRI scans. These clusters are expected to group images from similar anatomical regions and acquired with similar protocols. Prototype learning selects a representative scan ("prototype") within each cluster. Cluster-specific intensity standardization (e.g., Nyul) is then applied, utilizing the corresponding prototype as the reference instead of a single image representing the entire dataset. We evaluate our method on brain, musculoskeletal, and abdominopelvic MRI datasets using cross-correlation (CC), mutual information (MI), and mean structure similarity (MSSIM).

**RESULTS**

The prototype learning approach achieved high efficacy in producing uniform intensity distributions across different anatomical regions, markedly improving upon traditional methods. For example, in the musculoskeletal MRI dataset, we observed enhancements of 4.9% in CC, 11% in MI, and 15% in MSSIM. For abdominopelvic MRI dataset, the increments were 0.4% in CC, 0.9% in MI, and 17% in MSSIM, indicating substantial enhancement in image quality and diagnostic reliability across varied anatomical regions. In MRI brain dataset, both CC and MSSIM showed similar improvements, with an increase of 0.66% in MSSIM. This likely be due to the inherently homogeneous nature of brain dataset compared to other datasets.

**CONCLUSION**

This study proposes methods that identify sources of heterogeneity within the MRI datasets and then apply intensity standardization within each group, providing scalable and efficient alternatives to conventional methods. By eliminating the need for labeled data, these techniques become more generalized across different anatomical regions and conditions, thus improving the robustness and reliability of quantitative MRI analyses.

**CLINICAL RELEVANCE/APPLICATION**

Standardized MRI data facilitates diverse oncological applications, including quantitative imaging and AI, potentially leading to improved cancer detection, staging, and diagnosis.

## M2-SPIN-5 LABEL-FREE LIVER TUMOR SEGMENTATION FOR AI DEVELOPMENT AND VALIDATION

Xiaoxi Chen, MD (*Abstract Co-Author*) Nothing to Disclose
Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Qixin Hu (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To relieve the need for time-consuming per-voxel annotation, we investigate whether training on synthetic tumors in abdominal CT scans can enable AI models to detect and segment real tumors in the liver.

**METHODS AND MATERIALS**

The Liver Tumor Segmentation Benchmark (LiTS) was used in this study. We followed the official split of LiTS using 5-fold cross-validation. The volume of liver tumors ranges from 38mm^3 to 349 cm^3, and the types of liver lesions include HCC and secondary liver tumors and metastasis derived from colorectal, breast, and lung cancer. For comparison, a dataset of 116 CT scans with healthy livers was assembled from CHAOS (20 CT scans), BTCV (47 CT scans), Pancreas-CT (38 CT scans), and health subjects in LiTS (11 CT scans). We then generated tumors in these scans on the fly, resulting in enormous image-label pairs of synthetic tumors for training the AI model. We designed a modeling-based method to synthesize liver tumors, consisting of shape generation and texture generation. First, we applied ellipse generation, elastic deformation, and mask blur to customize the shape. Second, we applied salt-noise generation, gaussian filter, scaling, and clipping to generate a texture mask, which was then subtracted by the original intensity of the healthy liver. We also considered the mass effect and cirrhosis in the healthy part of the liver. For quality assessment, we developed Visual Turing Test on synthetic vs. liver tumors (illustrated in Figure A). DSC and NSD scores were used to quantify segmentation performance, and Sensitivity was used to quantify small tumor detection (volume < 125mm^3) performance.

**RESULTS**

Medical professionals with 6-year and 35-year experience obtained an accuracy of 26.5% and 71.0% in distinguishing synthetic tumors from real ones in CT scans. AI trained with synthetic tumors could achieve a sensitivity of 61.8% in detecting small tumors. AI can also segment liver tumors with a DSC and NSD score of 59.8% and 61.3%. In contrast, AI trained with per-voxel annotations held a sensitivity of 52.0%, with a DSC and NSD score of 57.5% and 58.0%.

**CONCLUSION**

AI algorithms can segment liver cancer at high sensitivity, DSC, and NSD without manual annotation by radiologists. AI trained with synthetic lesions performed similarly to that trained with 100 per-voxel annotated CTs of liver cancer (which took months to create).

**CLINICAL RELEVANCE/APPLICATION**

Tumor synthesis showed promise to help AI algorithms segment and detect liver cancer in CT scans by creating sufficiently diverse training examples. Tumor synthesis also enabled us to conduct larger studies to rigorously examine AI performance in detecting liver cancer of different locations, sizes,

shapes, textures, and stages, which are not limited to a fixed finite-size test set.

## M2-SPIN-6 VALIDATION OF AN ARTIFICIAL INTELLIGENCE ALGORITHM FOR EARLY PANCREATIC CANCER DETECTION

Cindy Neuzillet (*Abstract Co-Author*) Nothing to Disclose
Mostafa El Hajjam, MD,MSc (*Abstract Co-Author*) Nothing to Disclose
Alexandre Bone (*Abstract Co-Author*) Employee, Guerbet SA
Clement Abi Nader (*Abstract Co-Author*) Nothing to Disclose
Abed Rhmari Tlemcani, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Pancreatic cancer (PC) has a poor prognosis, largely due to late diagnosis in 80% of patients, limiting therapeutic options. Late diagnosis results from the lack of specific early symptoms and screening methods. PC screening could detect early cases, enabling timely surgery and improving patient survival rates. However, the sensitivity of current imaging modalities prevents the development of PC screening approaches. Therefore, the goal of this work is to evaluate an artificial intelligence (AI) algorithm to detect Stage IA PC on portal venous phase CT scans.

### METHODS AND MATERIALS

An AI algorithm for PC detection on portal CT scans was trained on a private cohort of 2134 patients (Abi Nader et al., Invest Radiol, 2023). The algorithm was re-calibrated on an external test set of 882 patients (429 PC, 453 controls) and reached a 90% sensitivity and a 90% specificity. This algorithm was evaluated on an external cohort of 28 pre-operative CT scans of patients from the Ambroise Paré hospital who underwent PC resection. Patients were diagnosed at stage IA (T1, N0, M0). A radiologist with more than 25 years of experience reviewed both the portal and arterial CT scans of the patients for PC identification. The sensitivity of the algorithm, the radiologist, and a combination of both the algorithm and the radiologist were computed with respect to the histopathological gold-standard. Bootstrapping was performed to compare the sensitivity distributions of the different approaches.

### RESULTS

Lesions were small (mean ± sd lesion diameter: 16.5 ± 3.7 mm), resectable with 60% classified R0 after surgery (healthy margin > 1mm) according to NCCN guidelines and 57% lesions were isodense on the portal CT scan. The sensitivity of the algorithm, radiologist and combination of both were, 85.7%, [71.4, 96.4] (median [95% CI]), 89.2% [78.5, 100] and 92.8% [82.1, 100], respectively. Associated p-values were 0.65, 0.27 and 0.53 for the comparisons between algorithm/radiologist, algorithm/combination and radiologist/combination, respectively.

### CONCLUSION

The algorithm showed promise for detecting small and resectable PC using solely portal venous scans. The difference between the algorithm and an experienced radiologist which used both the portal and arterial phases was not statistically significant. The combination of both the AI algorithm and the expert radiologist showed a high sensitivity on this early-stage cohort. The addition of an AI system within the radiologist workflow could be clinically relevant for incidental early-stage PC detection, especially for non-expert radiologists.

### CLINICAL RELEVANCE/APPLICATION

This pilot study suggests that our AI algorithm could be a valuable tool for detecting early PC, motivating further validation on larger cohorts.

## M2-SPIN-7 MAKING YOUR FIRST CHOICE: TO ADDRESS COLD START PROBLEM IN MEDICAL ACTIVE LEARNING

Alan Yuille, PhD (*Abstract Co-Author*) Nothing to Disclose
Liangyu Chen (*Abstract Co-Author*) Nothing to Disclose
Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to reduce the manual annotation workload for radiologists in developing large, annotated datasets and advancing high-performance AI algorithms for computer-aided diagnosis.

### METHODS AND MATERIALS

We employed three medical imaging datasets: Cohort 1 (107,180 histopathological images of colorectal cancer tissue), Cohort 2 (58,850 CT scans of various abdominal organs), and Cohort 3 (17,092 microscopic images of peripheral blood cells). Each dataset was divided into an 85% training set and a 15% test set. To determine which data points should be annotated first by expert radiologists, we examined two data sampling strategies: active sampling and random sampling. Active sampling involved selecting data points based on their typicality and diversity, determined by entropy in AI predictions and similarity to already annotated data. We introduced a novel querying strategy named HaCon (Hard-to-Contrast), which involves feature extraction through contrastive learning, cluster assignment using K-means for label diversity, and selection of hard-to-contrast data points. In contrast, random sampling involved non-selective data point annotation. AI diagnostic performance was measured using the Area Under the ROC Curve (AUC) scores.

### RESULTS

Active sampling significantly outperformed random sampling, with AUC improvements of 1.8% on Cohort 1, 2.6% on Cohort 2, and 5.2% on Cohort 3. In summary, our active sampling can reduce annotation costs by over 60% while maintaining high-performance AI algorithms.

### CONCLUSION

Data are not created equal; intelligently selecting critical data points (i.e., typical and diverse) to be annotated first can substantially reduce labeling efforts for clinicians, and these data are more crucial for the development of high-performance AI algorithms. AI performance can be improved through the active learning process, wherein we identify the algorithm's failures and successes, pinpoint the most important data points, provide manual annotations for them, and retrain the algorithms.

### CLINICAL RELEVANCE/APPLICATION

The study supports the application of active learning in medical imaging, which minimizes radiologists' annotation efforts by focusing on areas where AI is less accurate. Our approach facilitated the creation of a comprehensive dataset of 9,262 fully annotated CT scans, cutting annotation efforts by 60% and maintaining high diagnostic accuracy in computer-aided diagnosis.

## M2-SPIN-8 MACHINE LEARNING AND CT RADIOMICS TO PREDICT DISEASE PROGRESSION AND TREATMENT RESPONSE TO 1ST-LINE PEMBROLIZUMAB MONOTHERAPY IN ADVANCED NON SMALL CELL LUNG CANCER (NSCLC)

Ren Yuan, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Qian Ye (*Abstract Co-Author*) Nothing to Disclose
Stephen Lam, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Ian Janzen, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

The 5-year survival rate of lung cancer (LC) is among the lowest for cancer survival largely due to majority diagnosed at late or advanced stages. Immunotherapy has fulfilled their promise for LC treatment. Health Canada approved single agent pembrolizumab (Pem) in the first line setting for stage IIIB/IV NSCLC with PD-L1=50%, no EGFR/ALK aberrations. In this cohort, despite 45% of patients would benefit the best from single agent Pem, the other 55% do not respond and may require an alternative first line regimen. The clinical dilemma is that are no consensus clinicopathological features that can be used to distinguish the two subgroups. We propose a Machine Learning (ML) model using pre-treatment CT radiomic features can predict treatment response to pembrolizumab in this high PD-L1 cohort.

### METHODS AND MATERIALS

Two retrospective cohorts of patients with stage IIIB/IV NSCLC, PD-L1=50%, with no EGFR/ALK mutations were studied, including a training set (Tr-set: N=97, 56F:41M, 73±6yo) and an external validation set (X-set: N=17, 9F:8M, 65±10yo). All patients had CT scans at baseline and additional follow-up (FU) CTs 9-12 weeks after receiving Pem. Response was determined using RECIST v1.1: "Disease Control" (DC) vs "Progressive Disease" (PD) (Tr-set: 60 DC vs. 37 PD; X-set: 9 DC vs. 8 PD). An in-house radiomic feature extraction pipeline was used to extract 2D radiomic texture and intensity features of lung lesions. A five-fold cross-validated Logistic Regression (LR) model was developed to classify DC vs. PD, and the best-fit LR was used to calculate the predicted "risk of PD" for each patient and to separate patients into "high-" vs. "low-risk of PD" groups by comparing their calculated "risk-of-PD" of the best-fit LR model. Three prediction models were trained on discrete feature sets: patient demographics and clinical features alone, baseline CT radiomic features alone, and the combination of both.

### RESULTS

ROC analysis indicates excellent performance in discriminating DC vs. PD of the best-fit LR model that incorporates a combination of baseline CT radiomics and clinical description features in both training and external validation cohorts (Tr-set: AUC=0.91±0.06; X-set: AUC=0.88, CI 95%: 0.72-0.99). The Kaplan-Meier plots showed that the "predicted high-risk of PD" group had worse OS compared to the "predicted low-risk of PD" group (in X-set, log rank $p<0.01$).

### CONCLUSION

The preliminary data showed that a ML model that integrates both clinical descriptors and CT radiomics can identify NSCLC patients who are likely to develop progressive disease while receiving upfront Pem monotherapy.

### CLINICAL RELEVANCE/APPLICATION

This ML model has a potential to assist decision-making for the optimal first line treatment in advanced NSCLC patients with PD-L1=50%.

## M2-SPIR-1 CLINICAL APPLICATION OF DEEP LEARNING-BASED TECHNIQUES FOR RADIATION DOSE REDUCTION IN CT-GUIDED LUNG BIOPSIES

Hai-Feng Duan, MMed (*Abstract Co-Author*) Nothing to Disclose
Long Xu (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the clinical application value of different noise indices (NI) for radiation dose reduction in CT-guided percutaneous lung puncture biopsy (PTNB) based on deep learning image reconstruction (DLIR) technique.

### METHODS AND MATERIALS

Thirty-two patients with PTNB were selected, and three sets of images were obtained after adjusting the puncture needle using a small range (40 mm), 100 KV, automatic tube current modulation (ATCM), and NI 15, 30, and 45 scans sequentially. Group A was scanned with NI 15, with 50% weight of adaptive statistical iterative reconstruction-V, and the DLIR-H reconstructed images with NI 30 and 45 were in group B and C respectively. The CT and SD values of paraspinal muscles, subcutaneous fat, and arterial vessels were measured at the center of the puncture point and its upper and lower 10-mm levels, respectively, and the signal-to-noise ratio (SNR) and the contrast-to-noise ratio (CNR) were calculated. Then the images were subjectively scored by two physicians while comparing the radiation dose (ED) among the three groups.

### RESULTS

By subjective evaluation, the image quality of group A, B, and C all meet clinical requirements for puncturing. The SD and SNR values of group B images were better than those of groups A and C. The SD and SNR at muscle and fat of group A and group B were significantly different, and the difference also existed in group B and group C ($P < 0.05$); the differences of the SD and SNR values of the images of groups A and C at paraspinal muscle and subcutaneous fat were not statistically significant. The differences in effective radiation dose (ED) among the three groups were all statistically significant ($P < 0.05$). Compared with Group A, the ED in Group B and C were reduced by 82.86% and 93.90% respectively; the ED in Group C was reduced by 64.44% compared with that in Group B.

### CONCLUSION

Increasing the noise index combined with the DLIR technique can significantly reduce the patient radiation dose during CT-guided PTNB.

### CLINICAL RELEVANCE/APPLICATION

The use of a low-dose CT scanning protocol combined with deep learning reconstruction (DLIR) reconstruction techniques can improve image quality and thus significantly reduce the dose of reduced radiation in CT-guided percutaneous lung puncture biopsy (PTNB).

## M2-SPIR-2 ULTRA-LOW RADIATION DOSE SCANNING COMBINED WITH DEEP LEARNING RECONSTRUCTION ALGORITHM IN CT-GUIDED LUNG ASPIRATION BIOPSY

Hai-Feng Duan, MMed (*Abstract Co-Author*) Nothing to Disclose
Long Xu (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the feasibility and clinical value of ultra-low radiation dose scanning combined with deep learning reconstruction (DLIR) algorithm in CT-guided lung puncture biopsy (PTNB).

### METHODS AND MATERIALS

According to the different scanning protocols, 60 patients with lung puncture biopsy were divided into conventional dose group (Group A) and ultra-low dose group (Group B).Group A was 100KV, noise (NI) was 15, Group B NI was 45, and the rest of the scanning parameters were the same. The first and last whole-lung scans in the conventional dose group were scanned using the conditions of groups A and B, respectively, for evaluating the image quality improvement potential of the deep learning reconstruction algorithm (DLR).The first whole-lung scan was reconstructed using filtered back projection (FBP) and adaptive statistical iterative reconstruction-V (50%-ASIR-V) with weights of 50%, and the last whole-lung scan was reconstructed using three intensities of the deep learning reconstruction algorithm (DLIR-L, DLIR-M, DLIR-H) reconstructed images. The CT and SD values of paraspinal muscles, subcutaneous fat, and aortic vessels were measured, the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. The baseline characteristics of the patients, total radiation dose during puncture, pathologic positivity rate and complication rate were compared between groups A and B.

### RESULTS

The differences in CT values at muscle, subcutaneous fat and aortic vessels in the reconstructed images under the five different conditions were not statistically significant (P>0.05), but the differences in SD, SNR and CNR values were statistically significant, and two-by-two comparative analyses between the groups showed that there were no statistically significant differences between the DLIR-H images and the 50% ASIR-V images in muscle, fat, vascular SD and SNR (both P> 0.05); the differences in CNR values between FBP vs DLIR-H and DLIR-L vs DLIR-H groups were statistically significant (both P < 0.05). Compared with group A, the total radiation dose of group B was reduced by about 93.6%, and the image quality of both groups could meet the needs of clinical puncture, and the differences in baseline characteristics, pathologic positivity rate, and complication rate of patients in the two groups were not statistically significant (P all > 0.05).

### CONCLUSION

Ultra-low-dose CT scanning combined with DLIR reconstruction can significantly reduce image noise and improve image quality without affecting the safety of puncture and the pathologic positive rate.

### CLINICAL RELEVANCE/APPLICATION

Ultra-low radiation dose scanning combined with deep learning reconstruction algorithms can reduce the radiation dose to the patient.

## M2-SPIR-3 DIAGNOSTIC PERFORMANCE OF AI BASED DE-NOISING ALGORITHM FOR LOW RADIATION DOSE CT GUIDED BIOPSIES AND COMPARISON WITH ITERATIVE RECONSTRUCTION TECHNIQUES

SUYASH KULKARNI (*Abstract Co-Author*) Nothing to Disclose
Aniruddha Nene (*Abstract Co-Author*) Nothing to Disclose
Akshay D. Baheti, MD, MD (*Abstract Co-Author*) Nothing to Disclose

Girish Chinnaswamy, MD (*Abstract Co-Author*) Nothing to Disclose
Vasundhara Smriti, MD (*Presenter*) Nothing to Disclose

### PURPOSE

CT radiation is a potential concern for radiation induced carcinogenesis. Iterative reconstruction techniques (IR) reduce the image noise and enables dose reduction, compared to conventional filtered back projection (FBP). However, IR is vendor specific, requires raw data, is computationally intense and only available in latest scanners. The study aimed to assess the image quality of a vendor neutral, AI based de-noising algorithm for CT guided biopsies and compare with IR.

### METHODS AND MATERIALS

We evaluated consecutive (January 1st, 2022 - September 1st, 2023) patients who underwent CT guided biopsies in an IRB-approved, HIPPA compliant, retrospective study. CT guided biopsy protocols are performed in 3 phases; planning, targeting and post procedure. Planning phase are diagnostic scans, performed at standard dose (100%) {SDp}. as targeting phase focuses on needle guidance, lower doses were selected, at 70%, 50% 33% reduced mA (kVp constant). Low dose targeting {LDt} phase was reconstructed with AI based de-noising algorithm (PixelShine®, AlgoMedica, CA, USA) (PS), FBP IR. Two readers (20 4 years of experience) subjectively evaluated the noise, edge sharpness, artifacts and overall diagnostic quality of the images, on 5-point Likert scale. Objective measurements for Hounsfield Units (HU), standard deviation of HU values, SNR CNR were calculated. Statistical analysis was performed to obtain p-values, paired T test, Wilcoxon Signed-Rank test.

### RESULTS

Out of 660 CT guided biopsies, 85 cases were identified with SDp LDt phases, 53 cases were performed on 128 slice scanners with IR (Incisive CT, Philips Healthcare) (35 cases with SDp + 50% LDt, 18 cases with SDp + 33% LDt) and 32 cases on 16 slice scanners with no IR (Sensation CT, Siemens Healthineers) (SDp + upto 50% LDt). Subjective assessment showed lower image noise in LDt-PS compared to LDt-FBP at both 50% and 33% low dose, whereas LDt-PS was almost equivalent to LDt-IR at 50% dose and slightly better at 33% dose. Similar edge sharpness was seen in LDt-PS and SDp-IR, artifacts were less on LDt-PS, with overall score of LDt-PS higher than SDp-IR. Image noise at 33% with LDt-PS was similar to SDp (12.3±3.2, 10.3±3.5) and lowered by 58% compared to LDt-FBP, and higher CNR and SNR than LDt-IR.

### CONCLUSION

Low dose (50% 33%) CT images processed with AI based de-noising algorithm showed lower image noise and artifacts compared to FBP, as well as IR post-processing. Furthermore, this vendor neutral algorithm showed similar image quality as vendor specific IR.

### CLINICAL RELEVANCE/APPLICATION

Vendor neutral AI based de-noising algorithm have the potential to lower CT radiation dose by 33% and provides similar image quality as IR and for the older CT machines this provides a viable option for drastic reduction in dose.

## M2-SPIR-4 FEASIBILITY OF MRI GUIDED IN-BORE BIOPSIES AT 0.55T

Hero K. Hussain, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Nicole Seiberlich, PhD (*Abstract Co-Author*) Royalties, Siemens AG;Research support, Siemens AG
Elaine M. Caoili, MD, MS (*Abstract Co-Author*) Steering Committee, ProKidney, LLC
Vikas Gulani, MD, PhD (*Abstract Co-Author*) Research support, Siemens AG;Consulting, Cook Group Incorporated
Yun Jiang, PhD (*Abstract Co-Author*) Nothing to Disclose
Shane A. Wells, MD (*Abstract Co-Author*) Consultant, Johnson & Johnson
Tejinder Kaur, MD, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate feasibility of lesion identification and in-bore MRI-guided prostate biopsies using a large-bore 0.55T scanner.

### METHODS AND MATERIALS

9 participants with a mean age of 67 ± 7.3 years prospectively participated in this IRB-approved study between May 2023 and March 2024. 8 participants underwent in-bore MRI-guided prostate biopsy at 0.55T MRI scanner(Magnetom Free.Max,Siemens Healthineers, Erlangen,Germany). 1 participant was unable to undergo the procedure due to chronic contractures. Imaging protocol included axial T2wTSE (pre-biopsy), single shot T2wTSE (HASTE) and balanced steady-state free precession (bSSFP) sequences used intraprocedurally. Four biopsies were carried out using a transrectal approach, employing a robot-controlled manipulator and intrarectal directing device (Soteria Medical, Arnhem, Netherlands). Participants who did not have a rectum underwent

percutaneous targeting via transgluteal route. 2-3 cores were obtained in each case. Lesion sizes, cancer detection rates, positive percentage volume, disease grade change, duration to first core, and the overall procedure were reported.

**RESULTS**

9 lesions (size 1.8 ± 0.9 cm) were biopsied. Lesions positive for malignancy showed one Grade Group 1 (GG 1) cancer, four GG 2 cancers, one GG 3 cancer, and one GG 5 cancer. Two lesions turned out to be benign. Two participants had Gleason score (GS) upgraded, one had a marked increase in the positive percentage volume of core from 5 % to 80%, and four had a new cancer diagnosis. One new cancer was identified in a patient with left hip arthroplasty ipsilateral to the prosthesis, due to improved susceptibility artifact at lower field. Average time for procedure and time to first core in transrectal approach was 1 hour 14 minutes and 33 minutes respectively. For percutaneous route average time for procedure was 1 hour 10 minutes and time to first core was 54 minutes.

**CONCLUSION**

The work shows that lesion identification and accurate targeting is possible in suspicious prostate cancers at low performance gradient 0.55T MRI. Both procedures currently take approximately 75 minutes, though time to first core is faster for the percutaneous route. Increased experience with the procedure/imaging is expected to decrease required times.

**CLINICAL RELEVANCE/APPLICATION**

MRI-guided interventions using lower-field 0.55T systems have the potential for accurate lesion identification and targeting. This capability can help alleviate undue pressure on higher-field scanners in terms of patient load. Additionally, it offers added benefits for patients with hip implants.

## M2-SPIR-5 NEXT-GENERATION SEQUENCING ANALYSIS OF IMAGE-GUIDED BIOPSY SAMPLES IN EARLY-STAGE NON-SMALL CELL LUNG CANCER: A REAL-WORLD FEASIBILITY STUDY

David F. Yankelevitz, MD (*Abstract Co-Author*) Consultant, Accumetra LLC;Stockholder, Accumetra LLC;Medical Advisory Board, Carestream Health, Inc;Royalties, General Electric Company;Consultant, AstraZeneca PLC;Consultant, Pfizer Inc;Consultant, F. Hoffmann-La Roche Ltd

Rowena Yip, PhD, MPH (*Abstract Co-Author*) Nothing to Disclose
Claudia I. Henschke, MD,PhD (*Abstract Co-Author*) Advisory Board, LungLifeAI, Inc;Board Member, Early Diagnosis and Treatment Research Foundation Inc
Louis Gros, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Next-generation sequencing (NGS) of tumor cell-derived DNA/RNA is crucial for early-stage Non-Small Cell Lung Cancer (NSCLC) care. This study examines NGS success rates, i.e., the feasibility of DNA and RNA sequencing, and the quality of DNA sequencing on early-stage NSCLC biopsies.

**METHODS AND MATERIALS**

We analyzed data from a multi-institutional study focusing on stage I NSCLC treatments. We included patients with NGS-tested biopsies of =30 mm nodules confirmed as stage I NSCLC by surgery. Our assessment covered biopsy types, NGS success rates (DNA and RNA sequencing feasibility and quality), tumor cellularity, radiological characteristics, and patient outcomes. Biopsy methods consisted of CT-guided fine needle aspiration biopsy (FNAB), CT-guided core needle biopsy (CNB) and endobronchial ultrasound-guided transbronchial fine needle aspiration (EBUS-TBNA). DNA sequencing meeting quality standards was assessed based on required coverage criteria. NGS assays' detection limits for genomic alterations vary and low tumor cell content can yield false negatives. We utilized the Sema4 assay (Stamford, CT), targeting 161 genes with a minimum sequencing depth of 200x and computed descriptive statistics.

**RESULTS**

77 patients were included (39 females), mostly white (57%) and smokers (75%), median age 68.6. Nodule types: 60 solid, 11 part-solid, 6 non-solid. Mean diameter: 19.6 mm, solid component: 13.6 mm. Biopsy methods: 57/77 FNAB, 12/77 CNB, and 8/77 EBUS-TBNA. No post-biopsy complications occurred. DNA sequencing was successful in 75 of 77 biopsies (97.4%). In 2 patients, tumor cellularity was too low. Quality standards were met in 88% of biopsies, with no significant differences among methods. Biopsies not meeting standards came from nodules with smaller solid components (8.4mm vs. 14.2mm, Welch Two Sample t-test p: 0.0481) and more part-solid/nonsolid nodules (44.4% vs. 19.1%). Tumor cellularity was lower in these samples (25.7% vs. 46.0%, Wilcoxon rank sum test, p=0.0443). RNA sequencing was feasible in 51/77 (66.2%), notably lower in samples from FNABs (59.6%) compared to CNBs (91.7%) and EBUS-TBNAs (75%) (Pearson's Chi-squared test, p=0.04). Nodule size was lower in the non-analyzable samples but not significantly, as was tumor cellularity (35.9% vs. 47.9%, p=0.053). Nodule consistency was comparable.

**CONCLUSION**

DNA sequencing succeeded in 97.4% of biopsies of nodules = 30 mm. Nodule solid component size and tumor cellularity correlated with DNA sequencing quality. RNA-based NGS feasibility was lower, especially in FNAB samples.

**CLINICAL RELEVANCE/APPLICATION**

NGS is feasible on small lung tumor biopsies with a high success rate. Quality depends on both the size of the solid component of the nodule and the tumor cellularity in the sample.

## M2-SPIR-6 CLINICAL FEASIBILITY OF AN INSTRUMENT-CONTROLLING MASTER-SLAVE CT FLUOROSCOPY-GUIDED INTERVENTIONAL ROBOT FOR PERCUTANEOUS PUNCTURE

Wenge Xing (*Abstract Co-Author*) Nothing to Disclose
Zhi Guo, MD (*Abstract Co-Author*) Nothing to Disclose
Yong Li (*Abstract Co-Author*) Nothing to Disclose
Xueling Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Nan Wang (*Abstract Co-Author*) Nothing to Disclose

Haipeng Yu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This work aims to introduce a novel master-slave interventional surgical robotic system using CT fluoroscopy guidance. The manipulator and end-effector of this system can be deployed in separate room to overcome the limitation of radiation dose to radiologists that existing in traditional CT-guided puncture approach. This system integrates fluoroscopy imaging and master-slave control technologies to enhance procedural feasibility and patient safety.

### METHODS AND MATERIALS

A prospective study was conducted on 83 participants (Age: 62.1±10.6yrs, F: 39, M: 44) for lung and liver percutaneous puncture surgery utilizing the robotic system. The primary aim was the one-time puncture success rate, the secondary aims included the number of needle adjustments, the time taken for successful puncture and the entire procedure, and user evaluation of device performance. Additionally, the radiation dose for the whole surgical procedure (including radiation dose in pre-operation scan, intra-operation and post-operation scan) was recorded and the safety of the system was evaluated.

### RESULTS

78 patients of Per Protocol Set were statistic evaluated. The system achieved a one-attempt puncture success rate of 96.2% among 78 participants. The average number of needle adjustments per procedure was 1.1. The mean time for a successful puncture was 1.61 minutes. Approximately 100% of clinicians rated the system's functionality, stability, and portability as "satisfactory". Regarding safety, 12.3% of participants experienced puncture-related complications (including pneumothorax, hemoptysis and bleeding), with no device defects occurring during the clinical trial. Moreover, the average effective radiation dose for the whole surgical procedure was 5.35 mSv under the usual CT dose for the thoracic-abdominal regions (6.1-7.7 mSv).

### CONCLUSION

This study demonstrates the feasibility and safety of the novel robotic system for percutaneous lung puncture. This system achieved a puncture time of less than 2 minutes and favorable clinician ratings, thereby highlighting its potential for widespread clinical adoption.

### CLINICAL RELEVANCE/APPLICATION

Traditional CT-guided percutaneous puncture techniques and existing navigation systems suffered from repeated radiation exposure, procedural complications, and the lack of real-time imaging. The master-slave interventional robot enhances one-time puncture success rate and safety to patients, significantly reducing puncture time, and is endorsed by clinicians for broader clinical application.

## M2-SPIR-7 COMPARATIVE RANDOMIZED CLINICAL TRIAL OF A MASTER-SLAVE INTERVENTIONAL ROBOT FOR ABDOMINAL PERCUTANEOUS PUNCTURE

Zi Wang, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

CT-guided percutaneous puncture is critical for diagnosing and treating abdominal malignancies. To improve clinical outcomes and avoid radiation to radiologists, a novel CT fluoroscopy image guided master-slave robotic system was developed, the manipulator and end-effector of this system can be deployed in separate room. This study aims to validate the feasibility and safety of the developed system of abdominal percutaneous punctures against traditional CT-guided techniques.

### METHODS AND MATERIALS

We conducted a prospective, randomized, controlled trial involving patients undergoing abdominal percutaneous puncture. 30 patients (M: 15, F: 15; mean lesion size 7.04cm) were enrolled in this study. 15 participants (mean lesion size 7.39cm) were divided in the study group. 15 participants (mean lesion size 6.71cm) experienced the conventional CT-guided freehand puncture to serve as the control group. The primary endpoint was the one-time puncture success rate. Secondary endpoints included patient radiation dose of whole procedure, total procedure time and complication rate. The procedure time analysis of each step (including preoperative planning, sterilization and anesthesia, preparation, puncture and target confirmation) was also evaluated.

### RESULTS

29 patients (M: 14, F: 15) of Per Protocol Set were statistically analyzed. The study group demonstrated a 100% (14/14) one-time puncture success rate compared to 40% (6/15) in the control group, with a statistically significant difference ($p<0.01$). The trial group also showed superiority in secondary endpoints, notably reduced puncture time (median 0.56min vs 2.05min, $p<0.01$), and less radiation dose (median 5.19mSv vs 17.49mSv, $p<0.001$) than the control group. These results indicate the enhanced feasibility and safety to patient of the robotic system. The median of total procedure time was 14.84 minutes vs 9.02 minutes with the procedure time analysis shown in Figure 1. No complication was observed in both groups.

### CONCLUSION

The developed system significantly improves the success rate of abdominal percutaneous punctures and reduces the puncture time and radiation dose, as well as eliminates all radiation to radiologists, demonstrating superior efficiency and safety compared to traditional CT-guided methods. Its successful application in abdominal punctures highlights the potential for broader clinical adoption, enhancing procedural outcomes and patient care.

### CLINICAL RELEVANCE/APPLICATION

The new interventional robot boosts surgical feasibility in abdominal puncture over traditional methods. These findings suggest the system's potential for widespread clinical adoption and mark a significant advancement in the minimally invasive treatment of abdominal malignancies.

## M2-SPIR-9 THE EFFECTS OF OPERATOR SPECIALTY ON DIAGNOSTIC YIELD AND BLEEDING COMPLICATIONS FOR PERCUTANEOUS RENAL PARENCHYMAL BIOPSY

Atul B. Shinagare, MD (*Abstract Co-Author*) Consultant, VirtualScopics, Inc;Consultant, Imaging Endpoints
Daniel I. Glazer, MD (*Abstract Co-Author*) Nothing to Disclose
Matthew P. Schenker, MD (*Abstract Co-Author*) Nothing to Disclose
Agatha Stanek, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the safety and efficacy of percutaneous renal parenchymal biopsy and compare outcomes when performed by radiologists and nephrologists

## METHODS AND MATERIALS

This IRB-approved single institution retrospective cohort study included all patients undergoing percutaneous renal parenchymal biopsies performed by radiologists (1/1/22-12/31/23) and nephrologists (1/1/22-12/31/22). Basic demographic data (age, sex, weight), guidance modality, needle gauge, biopsy technique, number of core samples, adverse events, and number of glomeruli obtained were all collected from the electronic health record. Biopsies of both native and transplant kidneys were included. Procedures performed by radiologists utilized 18-gauge side cutting needles and co-axial technique and procedures performed by nephrologists utilized 16-gauge side cutting needles and non-coaxial technique. Adverse events were graded according to SIR criteria. Categorical variables were compared with a Fisher exact test and continuous variables were compared with a t-test.

## RESULTS

A total of 324 biopsies were performed during the study period, 124 by radiologists (16 transplant, 108 native) and 200 by nephrologists (79 transplant, 121 native). Mean patient age was similar (53.1 years vs 55.5 years, $p=0.21$) with patient weight greater for biopsies performed by radiologists (92.8 kg vs 76.03 kg, $p<0.001$). Diagnostic rate was 100% [124/124] for radiologists and 98.5% [197/200] for nephrologists ($p=0.29$). Number of core samples (2.6 vs 2.0; $p<0.001$) and glomeruli obtained per procedure (36.9 vs 31.0; $p<0.001$) were higher for biopsies performed by radiologists. Bleeding events were more common following biopsies performed by nephrologists (55/200, 27.5%) compared to biopsies performed by radiologists (4/124, 3.2%) ($p<0.001$), although almost all were minor. Two major bleeding events occurred. One major bleeding event was a radiologist performed biopsy of a native kidney that requiring overnight observation but no intervention. The other major bleeding event was a nephrologist performed native kidney biopsy that resulted in hypotension due to active arterial bleeding and required urgent transarterial embolization.

## CONCLUSION

Percutaneous renal parenchymal biopsies performed by radiologists resulted in fewer bleeding events and had similar diagnostic yield compared to procedures performed by nephrologists despite the greater average weight of patients biopsied by radiologists.

## CLINICAL RELEVANCE/APPLICATION

Kidney parenchymal biopsies should be performed with 18-gauge needles and coaxial technique as this has equivalent diagnostic yield to larger core needle samples with fewer adverse events.

## M2-SPMK-1 REFORMULATING IMAGE TRANSITION AS IMAGE SELF-INPAINTING: SYNTHESIZING HIGH-FIDELITY MRI IMAGES

Enhao Gong, PhD (*Abstract Co-Author*) Employee, Subtle Medical, Inc;Stockholder, Subtle Medical, Inc
Long Wang (*Abstract Co-Author*) Nothing to Disclose
Lei Xiang, MS (*Abstract Co-Author*) Nothing to Disclose
Zhihao Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

Synthesizing required sequences from the acquired ones of MRI protocol can make the entire process more efficient. We developed an inpainting-based deep learning (DL) network (IBSNet) for MRI sequence high-fidelity synthesis and assessed its image quality.

### METHODS AND MATERIALS

Ten clinical knee MRI cases from multiple institutions and scanners were retrospectively identified with sagittal T2 FS sequence as the source and sagittal PD sequence as the target. A total of 3200 slices were used for training and 800 slices were used for testing. We ingeniously reformulated the problem of image transition as a self-restoration task, wherein during training, random rectangular regions of arbitrary sizes were cropped from the target image as missing patches, which were then filled with content from the corresponding regions of the source image to construct the source image. We generated over ten thousand source-target image pairs and trained a DL model to learn the nonlinear mapping between them. During inference, the source image was directly utilized as input, with missing patches set to areas equal to their own size. To assess the image quality, the SNR and CNR on four pathological tissues, i.e, muscle, cartilage, fluid, and menisci were calculated for both synthetic images and SOC images. Additionally, the Signal-to-Noise Ratio (PSNR) and Structural Similarity (SSIM) were used to measure the similarity between the synthetic images and SOC images. Wilcoxon signed-rank tests was utilized for intergroup comparisons. $p<0.05$ indicated a statistically significant difference. Additionally, we performed ablation experiments to compare our method quantitatively and qualitatively with other state-of-the-art DL methods.

### RESULTS

The median SNR of all tissues of synthetic sequences were higher than that of SOC sequences (muscle:137.06 vs. 49.47, cartilage:126.14 vs. 41.68, fluid: 361.39 vs. 128.57, menisci: 30.07 vs. 11.24), $p<0.05$. The median CNR of cartilage-to-fluid, fluid-to-menisci, and menisci-to-cartilage of synthetic sequences were 0.34, 12.01, and 0.08, respectively equal to or higher on that of SOC sequences (0.32, 11.44, 0.08), with no statistically significant difference. Synthetic sequences exhibited excellent similarity to SOC sequences, with a PSNR of 31.81±1.91db and SSIM of 99.76±0.03. Compared to five other DL methods, ours outperformed them by 1.88 to 3.94 in PSNR and exhibiting more realistic visual results.

### CONCLUSION

MRI synthesized by the inpainting-based method exhibit higher image quality and visual fidelity compared to SOC images.

### CLINICAL RELEVANCE/APPLICATION

Our inpainting-based method has the ability to synthesize high-fidelity target MRI sequences, reducing the scanning time and improving patient experience.

## M2-SPMK-2 DEEP LEARNING MODELS FOR LUMBAR SPINAL STENOSIS ON MRI: COMPARISON WITH GENERAL RADIOLOGISTS AND ORTHOPEDISTS

### PURPOSE

To develop deep learning models to automate detection and stenosis classification on lumbar spine MRI, and evaluate performance compared to General Radiologists and Orthopedists.

### METHODS AND MATERIALS

Lumbar spine MRI studies from Sep 2015 to Sep 2019 were obtained retrospectively. Exclusion criteria were spinal instrumentation, suboptimal image quality, post-gadolinium studies, and severe scoliosis. Axial T2w and sagittal T1w images were used. Studies were split into training, validation and test sets. A local external test set of 100 studies was available. Training data were labelled by 4 Radiologists using predefined gradings (normal, mild, moderate, severe) for the central canal, lateral recesses and neural foramina. A 2-component model using convolutional neural networks (CNN) for region of interest (ROI) detection and classification, and a transformer model utilizing a CNN to extract latent features first and a transformer architecture for ROI detection and classification were developed. Consensus labelling by 2 Musculoskeletal Radiologists (10 and 12 years of experience) served as the reference standard. Test sets were separately labelled by 8 participants (2 General Radiologists, 2 Radiology Trainees, 2 Orthopedic Surgeons, and 2 Orthopedic Trainees). Detection recall (%), interrater agreement (Gwet ?), sensitivity, and specificity were evaluated for the models and participants.

### RESULTS

Overall, 564 MRI lumbar spine studies were included (mean age ± SD, 52 ± 19; 302 women), with 464 used for training (74%), validation (8%), and 100 (18%) for the internal test set. Both models showed high recall values for all ROIs in both test sets (central canal >99%; lateral recess 95-98%; neural foramina 94-95%; p<0.001), similar to the participants. Dichotomous classification (normal/mild vs moderate/severe) by the CNN model, transformer model and participants showed respective ? values for central canal 0.99, 0.99, 0.97-0.98, lateral recess 0.98, 0.94, 0.81-0.94, and neural foramina 0.98, 0.95, 0.91-0.95 on internal testing (p<0.001); for central canal 0.99, 0.97, 0.92-0.97, lateral recess 0.97, 0.90, 0.61-0.91, and neural foramina 0.99, 0.94, 0.87-0.93 on external testing (p<0.001).

### CONCLUSION

Compared to a range of clinicians, the CNN model showed superior performance and the transformer model showed similar to superior performance for classification of central canal, lateral recess and neural foraminal stenosis.

### CLINICAL RELEVANCE/APPLICATION

These models could assist radiologists in lumbar spine MRI assessment, improving efficiency through semi-automated reporting and providing guidance to radiologists in-training. In the clinic, the model predictions could assist orthopedists in surgical planning and patient education.

## M2-SPMK-4 AUTONOMOUS MEASUREMENT OF ANATOMIC MALROTATION OF EXTREMITIES ON CT IMAGING IN PEDIATRICS

Heidi Kecskemethy, MS (*Abstract Co-Author*) Nothing to Disclose
Md Sanzid Bin Hossain (*Abstract Co-Author*) Nothing to Disclose
Patrick Yang (*Abstract Co-Author*) Nothing to Disclose
Chandra Teja Tiriveedhi (*Abstract Co-Author*) Nothing to Disclose

Harry Lee (*Abstract Co-Author*) Nothing to Disclose
Andrew Sanford (*Presenter*) Nothing to Disclose

### PURPOSE

Malrotation of lower extremities manifests as in/out-toeing that requires meticulous CT evaluation of torsional angles for corrective surgical planning in patients 8 years and older. Manual measurement of these angles is both tedious and labor-intensive and requires training by an expert radiologist to perform accurately. We develop novel artificial intelligence/machine learning (AI/ML) models to automate accurate measurement of these torsional angles on CT in a pediatric clinical population.

### METHODS AND MATERIALS

We analyzed two dimensional DICOM images from CT scans acquired from patients seen by Nemours Radiology from 2019 to 2022. To make precise angular measurements, we selected the correct DICOM slice for each of up to 8 angles at the femur and tibia that maximizes specific landmark anatomy per clinical guidelines. To develop our algorithm, we focused on only the proximal femur at the hip using femoral head and neck as anatomical landmarks. To identify these landmarks, we leveraged “template matching” which depends on a set of rigid visual patterns to discriminate the femoral head from neck, ResNet50 which is classic pretrained deep learning model for classification using bounding boxes, and the pretrained state-of-the art “Segment Anything Model” (SAM) for most precise auto-segmentation of the femoral structures. We then leveraged OpenCV methods to calculate precise angles about the segmented landmarks.

### RESULTS

We downloaded 141,805 DICOM files from 190 pediatric patients (41% male; average age = 12.7y [2y-22y]). We made 956 annotations of up to 8 angles on 167 patients. We developed a custom SAM-Med2D instance fine-tuned on 2D medical images to generate auto-segment masks for a ResNet50 classifier that discriminates anatomic landmarks. Our novel SAM-Med2D-Resnet50 model could both learn to identify the optimal slice that maximizes the surface area of anatomical landmarks and accurately measure the angle at the selected slice. Initial validation in 22 patients shows accurate performance for both slice selection and angle measurement when landmarks were distinct.

### CONCLUSION

We developed state-of-the art AI/ML to jointly identify the correct slice of the CT that maximized femoral head and neck anatomical landmarks on CT and curate the angle between them as precisely as the gold standard human expert measurements in most cases.

### CLINICAL RELEVANCE/APPLICATION

Integrating precise AI/ML algorithms into radiology workflows may optimize orthopedic surgical planning, enhance diagnostic precision, and streamline decision-making for pediatric patients to impact their entire lives. Ongoing work will model all 8 angles of the lower extremities and special cases to allow for fully autonomous assessment of malrotation of clinical patients on CT.

## M2-SPMK-6 POTENTIAL OF ENHANCING GPT-4 IN MRI REPORT SUMMARIZATION WITH VISUAL CONTENTS: A QUANTITATIVE ANALYSIS

Kang Wang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Yang Yang, PhD (*Abstract Co-Author*) Nothing to Disclose
Jin Liu (*Abstract Co-Author*) Nothing to Disclose
Zheren Zhu, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

The advancements in large language models (LLM) have shown great promise in radiological text generation. Recently, multimodal LLMs, especially those incorporating image inputs, emerged and offered great potential beyond language-only systems. In this study, we want to evaluate whether and how the quality of related supplementary visual contents can enhance GPT's performance in radiology through MRI report summarization from finding to impression.

## METHODS AND MATERIALS

We acquired 20 de-identified clinical sagittal MSK MRI studies carried out on a 0.55T low-field (LF) scanner (Siemens Free.Max, UCSF Health) from 19 patients. All these studies include image series using 4- or 5-times-repeated scanning. Radiology reports were used as text contents, where the 'Finding' and 'Impression' parts were used for summarization and the ground-truth outputs. One middle slice of an image series was selected as related supplementary visual content for each study, considering the maximum images the GPT model can take and the centered region of interest in MSK studies. We used the single repetitions and the averages of multi-repeated images as low signal-to-noise ratio (SNR) and high-SNR pairs. We evaluated the three approaches: text only, text plus the low-SNR (noisy) image, and text plus the high-SNR (clean) image as contents fed to the LLM to generate the impressions. We utilized OpenAI's GPT-4 vision (gpt-4-turbo-2024-04-09) API and modified the concept of few-shot prompt engineering by contextually supplying 50 impression text examples from 50 unseen reports. Our prompts were structured by following best practices. We set 'Impression:' as an initiation and the temperature parameter to 0.1 to help focus the model's response. Machine translation metrics Rouge-1, Rouge-L, and BLEU were employed to evaluate word overlap, common subsequence, and quality of short sequences.

## RESULTS

Applying an additional clean image (Rouge-L 32.1, 95% CI: 26.9, 37.4) significantly outperformed (paired t-test, $p=0.05$) the addition of a noisy image (Rouge-L 27.8, 95% CI: 25.2-30.4) in generating sequences close to those of radiologists. It also surpassed text-only inputs (Rouge-L 29.4, 95% CI: 26.2-32.6), though not significantly ($p=0.22$).

## CONCLUSION

This study shows that the quality of visual content is crucial for aiding LLMs in radiological text generation, as high-quality content showed the potential to enhance GPT in MRI report summarization, while low-quality visuals hindered performance.

## CLINICAL RELEVANCE/APPLICATION

Incorporating visual data into LLMs has the potential to better streamline radiologists' workflows, leading to more efficient and accurate radiology report generation.

## M2-SPMS-1 ACUTE EFFECTS OF SMOKING AND VAPING ON MARKERS OF VASCULAR FUNCTION VIA QUANTITATIVE MRI, AN EXPANDED COHORT

Christiana Cottrell (*Abstract Co-Author*) Nothing to Disclose
Felix W. Wehrli, PhD (*Abstract Co-Author*) Nothing to Disclose
Michael Langham (*Abstract Co-Author*) Nothing to Disclose
Rasleen Grewal (*Abstract Co-Author*) Nothing to Disclose
Marianne Nabbout, MD, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This work aims to evaluate the acute effects of tobacco smoking, nicotinized- and non-nicotinized e-cigarette vaping challenges on vascular function in healthy smokers and vapers via quantitative MRI. Pre-inhalation challenge markers are compared to baseline data from non-smokers/non-vapers.

### METHODS AND MATERIALS

Participants undergo three study visits involving two suites of MRI scans separated by inhalation challenges: (1) tobacco cigarette smoke, (2) nicotinized e-cigarette aerosol, (3) non-nicotinized e-cigarette aerosol. Thirty-one healthy smokers and vapers (17 males), ages 21-49 years, have been studied to date. Twenty-two participants completed all three visits, eight participants completed one visit, and one participant completed two visits. Ten non-smokers/non-vapers (two males), ages 21-33 years, also underwent a baseline scan protocol only. Most elements of the protocol have been described in previous literature published by our laboratory. In brief, a cuff occlusion was applied at the proximal thigh to assess flow-mediated dilation (FMD). Following deflation, femoral artery flow velocity and venous oxygen saturation (SvO2) were quantified. Aortic arch pulse wave velocity was evaluated with complex difference signals from velocity-encoded projections. Phase-contrast MR at the superior sagittal sinus (SSS) during a breath-hold challenge yielded a measure of cerebrovascular reactivity. Cerebral metabolic rate of oxygen was derived from the SSS flow velocity and SvO2. Finally, neurovascular compliance of the brain's arterial tree was measured from time-resolved carotid flow rates. Pre- versus post-inhalation markers from each of the three interventions were then compared using unpaired t-tests.

### RESULTS

The study is ongoing and double-blinded. Therefore, data from all three interventions were combined. Following inhalation there were significant decreases in the superficial femoral artery baseline velocity and time of forward flow, suggesting impaired vascular reactivity (both $p<0.05$). At the femoral vein, baseline SvO2 was reduced ($p = 0.01$). The comparison of biomarkers from smokers/vapers pre-inhalation to non-smokers/non-vapers (no inhalation) showed NVC was greater (+37%; $p<0.005$) and FMD lower (-42%; $p<0.05$) in smokers/vapers.

### CONCLUSION

This MRI protocol was able to detect acute effects of smoking and vaping on markers of vascular function.

### CLINICAL RELEVANCE/APPLICATION

The data highlight the deleterious effects of smoking and vaping.

## M2-SPMS-2 XENON-129 MRI PULMONARY GAS EXCHANGE IN LONG COVID IS ASSOCIATED WITH COGNITIVE FUNCTION AND BRAIN MRI

## PURPOSE

Assess associations between pulmonary MRI gas exchange, structural and functional brain MRI, and cognition in long COVID patients.

## METHODS AND MATERIALS

Subjects with persistent dyspnea and/or fatigue following the resolution of acute COVID-19 infection (long COVID) were recruited from a post-COVID-19 clinic. Hyperpolarized 129Xe pulmonary MRI, structural and functional brain MRI, pulmonary function (forced expiratory volume in 1 second [FEV1]) and cognitive tests were acquired at the same study visit. Images of pulmonary gas exchange were obtained spectroscopically using a 1-point Dixon technique to estimate the xenon uptake in alveolar-capillary membrane (mem:gas) and red blood cell (RBC:gas) compartments and gas transfer ratio (RBC:mem). 3D MPRAGE anatomical and T1 weighted ASL functional brain MRI were processed using BRAINSAutoWorkup to quantify cerebral gray (GM) and white matter (WM) volumes and cerebral blood flow (CBF). Perceived cognitive difficulties were measured using Patient-Reported Outcomes Measurement Information System (PROMIS Cognitive Function) and objective cognitive performance was assessed using National Institute of Health Toolbox V3 Cognition Battery with normatively adjust t-scores grouped as follows: total cognition composite (TCC), executive function (EF), processing speed (PS), memory (Mem) and language (Lang). Univariate relationships were evaluated using Spearman correlations.

## RESULTS

11 subjects (10 female, age=52±12 yrs. [min-max=28-63], BMI=30±8 kg/m3 [min-max=21-42]) approximately 31 months from acute infection (min-max=24-40 months) were evaluated. Subjects self-reported cognitive difficulties (PROMIS mean t-score=34.4); cognitive performance was within normal limits (TCC mean t-score=55.5). Pulmonary-cognition relationships were observed for EF with RBC:mem (?=0.76, p=0.02) and RBC:gas (?=0.60, p=0.05). Percent predicted FEV1 was not significantly related to cognition, but trended toward a relationship with PS (?=0.54, p=0.08). Pulmonary-brain MRI relationships were observed for RBC:mem with cerebral WM (?=0.65, p=0.04), frontal lobe GM (?=0.66, p=0.04), parietal lobe WM (?=0.77, p=0.01), parietal lobe WM (?=0.71, p=0.02) volumes, and CBF (?=-0.74, p=0.04). RBC:gas was also correlated with CBF (?=-0.79, p=0.02).

## CONCLUSION

In long COVID, lower pulmonary gas exchange may be associated with cognitive dysfunction, as well as lower GM and WM volumes and higher CBF.

## CLINICAL RELEVANCE/APPLICATION

Gas exchange abnormalities sensitively detected using 129Xe MRI may help identify long COVID patients who require additional treatment or long-term management.

Oliver S. Zhao (*Abstract Co-Author*) Nothing to Disclose
Timothy Hohman (*Abstract Co-Author*) Nothing to Disclose
T. Bryan Jackson (*Abstract Co-Author*) Nothing to Disclose
Sydney Nelson (*Presenter*) Nothing to Disclose

### PURPOSE

Chimeric Antigen Receptor (CAR) T-cell therapy represents a novel and effective method of treating many malignancies. In CAR T-cell therapy, normal T-lymphocytes are removed from the body, re-engineered to attack specific cancer cells, and returned to the patient. Though CAR T-cell therapy has improved survival in hematologic malignancies, it is associated with neurotoxicities in up to 70% of patients as measured by immune cell-associated neurotoxicity scores (ICANS). We do not yet know what areas of the brain are most susceptible. 2-[18F]-fluoro-2-deoxy-glucose (FDG) PET represents a noninvasive method of assessing early changes in neuronal and synaptic function. Here, we evaluate the changes in FDG PET of the brain before and after CAR T-cell treatment.

### METHODS AND MATERIALS

22 patients treated with CAR T-cell therapy who had a pre-treatment and post-treatment FDG PET scan were identified through the Institution's Cancer Center's Cancer registry. Standardized uptake value ratio (SUVR) was calculated, and each FDG PET image was co-registered and nonlinearly warped to a standardized coordinate system. Voxel-wise linear mixed-effect models were used to assess for changes in SUVR after CAR T-cell therapy. A conservative two-sided voxel-level threshold of $p<0.001$ uncorrected and gaussian random field theory for cluster correction with a family-wise error rate (FWER) of $pFWER < .05$ was used.

### RESULTS

Compared to baseline, multiple large clusters met conservative significance thresholds with decreases in glucose metabolism following CAR T-cell therapy. These included large regions in the frontal and temporal lobes and in the white matter, throughout nearly the entire corpus collosum and part of the occipital tract ($pFWER=<0.001$). 14 of these patients had at least one ICANS =1 indicating neurological symptoms after treatment with dis-orientation and word finding difficulty symptoms present in 5 of these patients. Analyses stratifying and covarying by ICANS are ongoing.

### CONCLUSION

This is the first study to evaluate the effects of CAR T-cell therapy on the brain using FDG PET, a highly sensitive biomarker of neuronal health. Consistent with multiple published MR studies, the white matter appears particularly vulnerable to the effects of CAR T-cell therapy. Though the neurotoxic effects from CAR T-cell therapy can vary widely, many of our patients had word-finding difficulty which has also been previously associated with white matter changes.

### CLINICAL RELEVANCE/APPLICATION

This is the first study to evaluate which regions of the brain are most susceptible to the effects of CAR T-cell therapy using images of the brain extracted from routine whole body FDG PET.

## M2-SPNMMI-2 UV-LIGHT ANTIBACTERIAL PHOTODYNAMIC THERAPY THROUGH ELECTROMAGNETIC TRACKING TECHNOLOGY IN PROSTHETIC JOINT INFECTIONS

Anthony O. Osifuye, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Periprosthetic joint infection (PJI) is associated with high patient morbidity. Despite improvements in infection prevention, diagnostic approaches, surgical and antimicrobial treatment, more individuals are being diagnosed with PJIs each year. Antimicrobial photodynamic therapy (aPDT), an emerging clinical

application of theranostics, is specifically designed to identify and destroy microorganisms causing local infection. APDT uses multi-functional molecules called photosensitizers (PSs), which can be excited by light of a specific wavelength to transfer energy to surrounding oxygen and produce reactive oxygen species (ROS), which in turn damage and/or eradicate the bacteria. Several metal-based photosensitizers conjugated with radioisotopes used in PET and SPECT nuclear imaging preclinical research studies demonstrate differentiation between sterile inflammation and infection. Consequently, PJIs can be identified and therapeutic effects monitored in real time. Using emerging next-generation electromagnetic tracking technology to access difficult-to-reach areas of the body circumvents limitations associated with UV/visible light, which has a limited penetration depth in biological tissues (< 3 mm). The hypothesis is decreased bacterial presence in a prosthetic joint space model through use of UV-light photodynamic therapy through electromagnetic tracking technology.

## METHODS AND MATERIALS

A model is developed to mimic prosthetic joint infection by introducing manufacturer-cultured bacterial strains into the prosthetic joint space. To track and treat the infection, Radwave's GPS electromagnetic tracking technology is used along with ultraviolet type-C diode application. Furthermore, counter-on-chip bacterial cultures are employed for precise quantification and analysis of bacterial cells.

## RESULTS

Results in process

## CONCLUSION

Based on the findings of this study, the goal is to show a reduction in treated bacterial cultures measured with counter-on-chip technology and a decrease in standard value units in the region of interest on SPECT and PET scans. This will enable quantification analysis of bacterial cell destruction using UV-light photodynamic therapy facilitated by electromagnetic tracking technology.

## CLINICAL RELEVANCE/APPLICATION

This underexplored alternative therapy has the potential to serve a critical role in PJI treatment.

## M2-SPNPM-1 PROGRAM SIGNAL UTILIZATION AND IMPACT ON RADIOLOGY RESIDENCY MATCH: SURVEY OF APPLICANTS

Jeffery Hogg, MD (*Abstract Co-Author*) Nothing to Disclose
Francis Deng, MD (*Abstract Co-Author*) Nothing to Disclose
Arun Murugesan, MD (*Abstract Co-Author*) Nothing to Disclose
Mahla Radmard, MD (*Abstract Co-Author*) Nothing to Disclose
Sahil Patel, MD (*Abstract Co-Author*) Nothing to Disclose
David M. Yousem, MD, MBA (*Abstract Co-Author*) Royalties, RELX;Speaker, MRI Online;Board Member, MRI Online;
Muhammad H. Malik, MD (*Abstract Co-Author*) Nothing to Disclose
Dhairya Lakhani, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Despite an incremental increase in residency slots, the surge in DR residency applicants has intensified the competitiveness of the radiology match. In response to these challenges, compounded by the shift to virtual interviewing, the NRMP introduced the signaling system in 2022. This system is designed to aid applicants in effectively conveying their program preferences, thereby enhancing the likelihood of securing interview invitations from desired programs. This study evaluates the effectiveness of the ERAS signaling system for DR candidates.

### METHODS AND MATERIALS

This survey-based study was approved by our Institutional Review Board and conducted after the Match results of March 2024 using the Qualtrics Research Suite. The survey targeted 728 radiology residency applicants registered with TheRadRoom platform, achieving a completion rate of 75% (n=202). We collected detailed demographic data, information on applications and interview invitations both with and without the use of program signals, and respondents' strategic use of signals. Statistical analyses were performed using IBM SPSS, focusing on interview conversion rates for different signal categories and stratifications. independent samples t-tests were conducted for two-group comparisons and one-way ANOVA was used for multiple group comparisons. chi-square test was utilized for categorical data analysis.

### RESULTS

202 applicants completed the survey. 176 (87.1%) were first-time applicants. 98.5% utilized the ERAS signaling system. Programs targeted with signals showed significantly higher interview invitation rates compared to those not targeted. The interview conversion rate for programs targeted with gold signals was 59.8% (±27.4%) and 51.8% (±31.3%) for silver signals. In contrast, the interview conversion rate for programs that did not receive any signals was significantly lower, at 8.5% (±8.5%). Furthermore, 76% (n=146 out of 192 respondents) endorsed continued use of signaling for future DR match cycles

### CONCLUSION

The ERAS signaling system is perceived to be a beneficial tool in the radiology residency application process, enabling applicants to better convey their program preferences and increasing their chances of securing interviews. Future cycles may benefit from refining this system to accommodate the growing competitiveness of the match process

### CLINICAL RELEVANCE/APPLICATION

The ERAS signaling system enhances diagnostic radiology residency applicants' ability to secure interviews at preferred programs, addressing the increased competition in the match process. Its strategic use and potential refinement could improve match outcomes, benefiting applicants and programs alike

## M2-SPNPM-2 ENHANCING EARLY RADIOLOGY EDUCATION AND INTEREST THROUGH RESIDENT-LED WORKSHOPS

Latifa L. Sanhaji, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Quach, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In many medical schools, radiology is introduced late, typically during clinical years, often leading students to struggle with image interpretation and not grasp its relevance early in their training. This delay can affect their performance in clinical rotations and standardized tests like USMLE Steps 1 and 2CK, which include many image-based questions. Recognizing the growing interest among students in radiology as a potential specialty, we started targeted, resident-led workshops aligned with preclinical modules to bridge this gap early in their educational journey.

## METHODS AND MATERIALS

We enlisted volunteer radiology residents to conduct monthly, high-yield lectures aligned with preclinical organ modules. Over two years (2022-2024), 152 students participated in 10 comprehensive sessions. The curriculum was designed around popular STEP review resources, emphasizing case-based scenarios that contrast normal and pathological images. Each lecture featured 3-5 questions to measure understanding and track progress, with added queries about confidence in image interpretation and interest in radiology careers to better gauge effectiveness of the workshops in those domains.

## RESULTS

The workshops led to substantial improvements in various categories: 1. Scores on pre- and post-tests improved markedly from 64% to 82%. 2. Confidence in interpreting radiological images increased by 50%, with average scores rising from below four to six out of ten. 3. 88% of survey respondents found the lectures beneficial for future scenarios in clinical rotations. 4. Notably, 83% of survey respondents reported a heightened interest in pursuing radiology residencies (DR/IR).

## CONCLUSION

Developing a coherent preclinical radiology curriculum can be challenging but rewarding. Our workshops, integrated with the institutional curriculum and supported by the Radiology Interest Group, significantly boosted student engagement and preparedness for clinical roles and exams. This proactive approach not only aids in mastering the imaging sections of standardized tests and better preparing students for interpreting images during clinicals, but also fosters early interest in radiology, positioning students better for residency applications.

## M2-SPNR-1 ASSESSING THE VISIBILITY OF NIGROSOME-1 IN LOWER RESOLUTION MCTFI QSM IMAGING: IMPLICATIONS FOR PARKINSON'S DISEASE AND DEMENTIA WITH LEWY BODIES

Salil Soman, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Bulent Aslan, MD (*Abstract Co-Author*) Nothing to Disclose
Youssef Masmoudi, MD (*Abstract Co-Author*) Nothing to Disclose
Yi Wang, PhD (*Abstract Co-Author*) Nothing to Disclose
Yan Wen, PhD (*Abstract Co-Author*) Nothing to Disclose
Pascal Spincemaille, PhD (*Abstract Co-Author*) Nothing to Disclose
Shreyas Balaji (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to identify the presence of Nigrosome-1 (N1) in mcTFI QSM images. N1 is a dopamine rich region of the substantia nigra (SN) which contains the largest portion of neurons affected in Parkinson's disease (PD). During Dementia with Lewy Bodies (DLB) and PD, iron is deposited in N1, leading to loss of visibility of N1. Previous studies have shown that N1 has a strong negative predictive value (close to 100%) for PD., and that N1 is visible in QSM images with a minimum voxel resolution of 0.6 x0.67x1.34mm. Our work aims to confirm the visibility of N1 on QSM images with a lower voxel resolution of 0.8x1x2mm.

### METHODS AND MATERIALS

A total of 29 mcTFI QSM images were collected with a 3T MRI scanner on healthy patients with no known diagnosis of DLB or PD. These images were reviewed to confirm the presence or absence of N1, specifically through the presence of the "Swallow Tail Sign" (STS) that has been shown to indicate the presence of N1. Two images were excluded due to artifacts, resulting in a total count of 27 subjects. Images where more than half of the reviewers agreed that N1 was present, and images where all reviewers agreed that N1 was present were counted.

### RESULTS

In all 27 subjects, the SN was visible bilaterally. Out of the 27 cases, in 8 cases all reviewers agreed the STS was visible, in 2 cases a majority agreed the STS was visible, and in 9 cases at least 1 reviewer stated that STS was visible. This corresponded to 29.6% of cases where all reviewers agreed N1 was present, 37.0% of cases where more than half suggested N1 was present, and 70.3% of cases where at least 1 reviewer stated that N1 was present. In addition, in 3 cases where the STS was present, it was only present unilaterally.

### CONCLUSION

In select scans, N1 appears to be visible on mcTFI QSM images with a resolution of 0.8x1x2mm. Future work is necessary to examine why N1 is more visible on some QSM images than others at this resolution, as well as quantification of the size/presence of N1.

### CLINICAL RELEVANCE/APPLICATION

The appearance of N1 at a lower resolution potentially indicates the usefulness of N1 imaging through mcTFI QSM imaging in MRI scanners that are more widely available. Based on previous research, given the near 100% negative predictive value for PD of the STS, this may allow PD to be ruled out in a wider range of clinical settings. However, absence of the STS in a scan at this resolution cannot confirm PD.

## M2-SPNR-10 GENETIC MECHANISMS UNDERLYING GRAY MATTER ATROPHY IN PARKINSON'S DISEASE:A TRANSCRIPTOME AND NEUROIMAGING STUDY

Xiangminh Fang, MD (*Abstract Co-Author*) Nothing to Disclose
Ji Yi (*Presenter*) Nothing to Disclose

### PURPOSE

Extensive research has shown prominent gray matter atrophy (GMA) in patients with Parkinson's disease (PD), yet its genetic mechanisms are largely unknown. The purpose of our study was to explore the genetic mechanisms underlying GMV alterations in PD.

### METHODS AND MATERIALS

To achieve this goal, we first conducted a neuroimaging meta-analysis as well as a VBM study in an independent dataset to investigate GMV changes. We carried out the meta-analysis and recruited 48 PD patients and 26 healthy controls (HC) to acquire magnetic resonance images using a 3.0T MRI scanner (Magnetom 3T Siemens, Prisma, Germany). Furthermore, we combined the AHBA to perform a transcriptome-neuroimaging spatial association analysis to

identify genes whose expression levels were related to gray matter atrophy in PD. Finally, an array of post hoc analyses were conducted to investigate the functional features of the identified genes.

**RESULTS**

Following the extensive literature review and selection process, 1,831 PD patients and 1,378 HC from 44 studies were included, with prominent gray matter atrophy in PD patients ($p < 0.05$, FWE corrected). Our data showed that PD patients consistently showed significant gray matter atrophy in the superior temporal gyrus. Furthermore, a spatial correlation study between the transcriptome data and neuroimaging indicated that these gray matter reductions were spatially related to the expression of 1952 overlap genes. In addition, the genes were exclusively expressed in the brain tissue, specifically among dopamine receptor cells, throughout almost the entire developmental stage. Likewise, these genes showed the potential for creating a PPI network supported by 16 putative hub genes of functional significance. In addition, we delineated the spatial temporal expression trajectory of three hub genes with the highest degree values (i.e., CTNNB1, MAPK3, and CALM3). We discovered that the genes were correlated with an array of behavioral terms, including vision motion, spatial cognition, execution, and intensity emotion, by correlating gene expression with behavioral domains using BrainMap along with behavioral domains including early visual, motion, and regulation via Neurosynth.

**CONCLUSION**

Overall, our findings indicate that gray matter atrophy in PD could potentially be a consequence of intricate interactions between a complex set of genes, confirming the polygenic nature of this neurological condition.

**CLINICAL RELEVANCE/APPLICATION**

Our findings may not only offer unique insight into the genetic mechanisms of gray matter atrophy in PD but also inform novel treatment approaches targeting the molecular substrates underlying brain morphological abnormalities.

## M2-SPNR-12 INTEGRATED EVALUATION OF NIGROSOME 1 SIGN, NEUROMELANIN-SENSITIVE MR AND IRON DEPOSITION

Atsushi Shima (*Abstract Co-Author*) Nothing to Disclose
Kiarash Ghassaban (*Abstract Co-Author*) Nothing to Disclose
Yasutaka Fushimi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Although the deformation of the substantia nigra pars compacta (SNpc) (i.e. loss of swallow tail sign), signal loss on neuromelanin-sensitive MRI, and iron deposition in the deep gray matter (DGM) structures are important findings in Parkinson's disease (PD), an integrated analysis including these biomarkers has not been performed well. The aim of this study was to differentiate between PD and healthy controls by using integrated analysis of PD-specific MR findings.

**METHODS AND MATERIALS**

Patients with PD and healthy controls were recruited between August 2022 and December 2023. All subjects gave written consent to this prospective study. All subjects underwent 3T MRI (MAGNETOM Skyra, Siemens Healthineers) including a magnetization transfer contrast (MTC) and a double flip angle multi-echo protocol as part of Strategically Acquired Gradient Echo (STAGE) (SpinTech Inc., Bingham Farms, MI, USA). The data analysis included detecting the presence of Nigrosom-1 (N1) sign in the SNpc, signal intensity and volume of neuromelanin (NM) content and iron quantification through quantitative susceptibility mapping (QSM) in DGM including caudate nucleus (CN), globus pallidus (GP), putamen (Pt), thalamus (TH), pulvinar thalamus (Pul), substantia nigra (SN), red nucleus (RN), and dentate nucleus (DN). The 3D regions of interest were manually demarcated on QSM maps. Mean susceptibility values from global analysis (i.e. from the whole structure) as well as regional high iron analysis (extracted from thresholding susceptibility values higher than the upper 95% prediction intervals at a given age) were extracted for each individual structure. Univariate and multivariate analyses were performed using these parameters.

**RESULTS**

Nineteen patients with PD (68.0 ± 8.0 years, 10 males, Hoehn and Yahr scale 1 (n=1), 2 (n=13), 3 (n=4), 4 (n=1)) and 21 healthy controls (68.3 ± 8.6 years, 12 males) were enrolled. Discriminating PD from controls was successful using each method: N1 sign ($P<0.001$), NM volume($P<0.001$), susceptibility values of global analysis (CN, $P<0.001$; Pt, $P<0.001$; Pul, $P=0.006$), regional analysis (Pt, $P<0.001$; Pul, $P=0.009$, TH, $P=0.008$). Stepwise logistic regression analyses were performed and the best model was created using N1 sign, NM volume, Pt, RN and TH (area under the curve of 0.99).

**CONCLUSION**

Integrated analysis of PD specific MR findings including N1 sign, NM volume, and iron content in the DGM structures robustly discriminates between PD and healthy controls.

**CLINICAL RELEVANCE/APPLICATION**

Integrated analysis of N1 sign, NM volume, and QSM is clinically feasible and has diagnostic potential in the evaluation of PD. Our results show NM volume decrease potentially precedes iron increase in the nigral regions of early PD patients.

## M2-SPNR-14 ALTERED NEUROVASCULAR COUPLING IN CHILDREN WITH SPASTIC CEREBRAL PALSY

**PURPOSE**

This study aimed to investigate the possible neurovascular decoupling (NVC) and its clinical implications in childhood spastic CP using resting-state functional magnetic resonance imaging (rs-fMRI) and arterial spin labeling (ASL).

**METHODS AND MATERIALS**

Spastic CP patients and healthy participants underwent rs-fMRI and ASL to calculate regional homogeneity (ReHo), fractional amplitude of low-frequency fluctuation (fALFF) and cerebral blood flow (CBF), respectively. Two types of NVC metrics (CBF/ ReHo, CBF/fALFF) were compared between spastic CP and healthy controls (HCs), and the inner association between altered NVC metrics and clinical variables in spastic CP group was further analyzed.

**RESULTS**

The study included 20 children with spastic CP and 22 sex- and age-matched HCs. Compared to HCs, among regional level (all PGRF<0.05), spastic CP showed significantly higher CBF/ReHo coupling in left fusiform, right lingual, bilateral thalamus, left calcarine, left caudate, and increased CBF/fALFF coupling in left lingual, left middle temporal, right middle occipital, bilateral caudate, left angular, left middle cingulum. Furthermore, increased CBF/fALFF coupling was found in the left middle temporal, left angular and negatively correlated with the Communication Function Classification System level of spastic CP.

**CONCLUSION**

Children with spastic CP present altered NVC, associated with Communication Function level. The study shed a new insight into the pathophysiology of spastic CP.

**CLINICAL RELEVANCE/APPLICATION**

Spastic CP has been showed perfusion and neural activity alteration; however, the coupling changes is still unknown. Rs-fMRI study provides neuroimaging evidence of neuronal injury and cerebral perfusion changes in CP. However, these studies on CP mainly used a single imaging modality, and this method cannot comprehensively reflect the altered regional CBF and neuronal activity caused by CP. In contrast, NVC combined with rs-fMRI and ASL can comprehensively reflect the relationship between neural activity changes and regional CBF. However, it is presently unclear how the balance between cerebral perfusion and neural activity changes in spastic CP. Thus, we sought to explore relationships between perfusion and neural activity organization on regional basis and to determine how proxies of NVC change during the pathophysiology of spastic CP.

## M2-SPNR-16 VULNERABILITY OF NEUROMELANIN IN SUBSTANTIA NIGRA IN HEALTHY CONTROLS AND EARLY-STAGE PARKINSON'S DISEASE: LEFT HEMISPHERIC AND SENSORIMOTOR PREDOMINANCE

Na Wang (*Abstract Co-Author*) Nothing to Disclose
Pu-Yeh Wu (*Abstract Co-Author*) Nothing to Disclose
Liqin Yang (*Abstract Co-Author*) Nothing to Disclose
Yuxin Li (*Abstract Co-Author*) Nothing to Disclose
Xueling Liu, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the hemispheric and spatial asymmetries of neuromoelanin in substantial nigra in healthy controls (HCs) and early-stage Parkinson's Disease (EPD) patients by setMag images reconstructed from quantitative susceptibility mapping (QSM).

**METHODS AND MATERIALS**

We recruited right-handed 57 EPD and 34 HC aged over 50 years. Quantitative susceptibility mapping were acquired, from which short-echo-time magnitude (setMag) images and study-specific neuromelanin-sensitive template was generated. Then neuromelanin contrast ratio (CR) were calculated in the sensorimotor, associative and limbic subregions of substantia nigra pars compacta (SNc). We analysed hemispheric and spatial asymmetry of the CR in HC and EPD groups using two-way ANOVA, respectively. An unpaired-t test was used to compare the group differences in neuromelanin CRs. Receiver operating characteristic (ROC) curves were performed for the diagnosis of EPD in different hemispheres and locations of SNc, and Delong test was used to assess the discriminative diagnostic efficacy for EPD.

**RESULTS**

There were significant hemisphere × location interactions in HC [$F(1, 66) = 21.630$, $p < 0.001$] and EPD [$F(1.758, 98.435) = 24.613$, $p < 0.001$] groups. According to the simple effect analysis, neuromelanin CR of the left hemisphere was lower than that of the right hemisphere only in the sensorimotor territory of SNc, but no hemispheric difference was found in associative or limbic territory in both HC and EPD groups. Meanwhile, in the left hemisphere, the CR value of SNc was found lowest in sensorimotor territory of SNc in both HC and EPD groups. The area of under curves (AUCs) of the neuromelanin CR between the HC and EPD subjects in different hemispheres and locations were from 0.705 to 0.869, and Delong test showed the highest discrimination value was found in the left sensorimotor territory of SNc.

**CONCLUSION**

This template-based neuromelanin measurement detects the left sensorimotor territory of SNc as the predominant vulnerable region for neuromelanin degeneration inn both HC and EPD.

**CLINICAL RELEVANCE/APPLICATION**

This finding suggests that the left sensorimotor territory of SNc maybe the first neuromelanin degeneration area in both HC and EPD subjects, focusing on this specific region may enhance early detection for PD and potentially guiding targeted therapeutic interventions.

## M2-SPNR-18 NEUROIMAGING EVIDENCE OF GLYMPHATIC SYSTEM DYSFUNCTION IN PARKINSON'S DISEASE WITH SLEEP DISORDERS

Zhuofeng Liang (*Abstract Co-Author*) Nothing to Disclose
Wen Zhibo, BA (*Abstract Co-Author*) Nothing to Disclose
Xinzi Liu (*Abstract Co-Author*) Nothing to Disclose
Yongzhou Xu (*Abstract Co-Author*) Nothing to Disclose
Ni Zeng (*Abstract Co-Author*) Nothing to Disclose
Xinran Yan (*Abstract Co-Author*) Nothing to Disclose
Anyi Lin (*Abstract Co-Author*) Nothing to Disclose
Jingyue Xue (*Presenter*) Nothing to Disclose

### PURPOSE

In Parkinson's disease (PD), the glymphatic system, responsible for clearing a-synuclein, may be linked to sleep disorders. We're exploring this association using a noninvasive and visualized technique, called diffusion tensor image analysis along the perivascular space (DTI-ALPS) to compare glymphatic activity in PD patients with sleep disorders (PD-s) ,without sleep disorders (PD-ns) and healthy controls (HC). We aim to explore whether early sleep intervention can benefit those at high risk for PD, whether improving sleep in PD patients can alleviate motor symptoms and enhance quality of life.

### METHODS AND MATERIALS

This study prospectively enrolled 104 PD patients and 28 HC from March 2023 to March 2024. PD patients were categorized into two groups based on the Pittsburgh sleep quality index (PSQI): PD-s group (n = 58) and PD-ns group (n =46). DTI sequence was acquired. Image processing and index calculation were conducted using the FSL platform. An in-house bash script integarating FSL and MRtrix3 commands was developed for image preprocessing, generating FA and DTI-ALPS images. After co-registeration with standard templates, specific brain regions were identified using the marker atlas and the ALPS-index was calculated based on these regions showing in Fig. 1.

### RESULTS

Table 1 and Table 2 present the basic characteristics of three groups, including the ALPS index. Fig. 2 illustrates significant differences in the ALPS index across three groups ($P < 0.05$). Post-hoc tests revealed a higher ALPS index in the HC group compared to the PD-s ($P = 0.001$) and a high ALPS index in the PD-ns group compared to the PD-s group ($P = 0.040$). The correlations between the ALPS index and these clinical features with significant differences in two PD groups were showed in Fig. 3.

### CONCLUSION

We employed a non-invasive approach to unveil glymphatic system dysfunction in PD patients. The ALPS index emerges as a pivotal marker of cerebral glymphatic system alterations, particularly in PD patients with sleep disorders, suggesting that targeting sleep disorders could be a novel intervention strategy. Moreover, we propose the ALPS index as a valuable follow-up indicator. Our DTI-ALPS pipeline, which yields rapid and stable results, holds promise for future clinical applications.

### CLINICAL RELEVANCE/APPLICATION

We propose a new framework regarding 'a-syn-glymphatic system-sleep disorder-motor disturbance-PD', which may enhance our understanding of the pathophysiology of PD. We think DTI-ALPS-index is a follow-up indicator and an assessment after interventions.

## M2-SPNR-4 EFFECTS OF PERIPHERAL ACTH LEVELS ON BRAIN NETWORK TOPOLOGY IN PATIENTS WITH MAJOR DISORDER DEPRESSION

Yanwei Miao (*Abstract Co-Author*) Nothing to Disclose
Chun Yang (*Abstract Co-Author*) Nothing to Disclose
Shiyun Tian, MD (*Presenter*) Nothing to Disclose

### PURPOSE

A subgroup of major depressive disorder (MDD) is associated with elevated hypothalamic-pituitary-adrenal (HPA) axis hormone levels. In this study, we aimed to explore the differences in resting-state brain network topology in depressed patients with different ACTH levels, and to evaluate their relationship with peripheral blood ACTH levels to understand the neuroendocrine axis mechanism of hormone-related depression.

### METHODS AND MATERIALS

This study collected resting-state functional magnetic resonance imaging (fMRI) data and peripheral blood hypothalamic-pituitary-adrenal (HPA) axis-related hormones (adrenocorticotropic hormone; ACTH, cortisol; CORT) from N=49 patients with depression, further stratified into high ACTH cases (High ACTH MDD; >65 pg/mL; N=20) and normal ACTH cases (Normal ACTH MDD; 7 pg/mL 65 pg/mL; N=29). Additionally, fMRI scans were conducted on N=21 healthy control(HC) subjects. In this analysis, topological global and local metrics were used to identify indices that differed between MDD and HC, and the correlation between different brain network metrics and ACTH was analyzed.

### RESULTS

1. The outcomes of the global network indicators reveal a substantial reduction in the AUC of Cp ($t=-2.729, P=0.008$) and Eloc ($t=-2.744, P=0.008$) AUC values for all MDD patients when compared to HCs (Fig. 1A, B). Similarly, the AUC values for Cp ($t=-2.637$, $p=0.012$) and Eloc ($t=-2.834$, $p=0.007$) in High-ACTH MDD exhibit a significant decrease compared to HC (Fig. 1C, D). 2. The local indicators demonstrate that the nodal Eloc of all MDD compared to HC in the cingulo-opercular network right temporal lobe has increased ($pBonferroni=0.00014$). For Normal-ACTH MDD compared to HC, the nodal Eloc in the cingulo-opercular network has increased (right temporal lobe, $pBonferroni = 0.00001$), while for High-ACTH MDD compared to HC, the nodal Cp of the cingulo-opercular network has decreased (left ventral frontal cortex, $pBonferroni = 0.00002$) (Fig. 1E). 3. Correlation analysis was conducted between meaningful network node indices and ACTH, with age and gender as covariates. The partial correlation analysis showed a significant correlation with the node Cp vFC.L ($p=0.030$, $r=-0.317$) and node Eloc ($p=0.676$, $r=-0.063$) (Fig. 1F).

### CONCLUSION

The ACTH level in patients with depression is related to the topological structure of the brain network. As the ACTH level increases, the functional separation disorder in the cognitive control processing system area becomes more serious.

### CLINICAL RELEVANCE/APPLICATION

The brain topology of patients with depression at different levels of the HPA axis is different, which is related to the pathogenesis of neuroendocrine-related depression and has guiding significance for subsequent treatment.

## M2-SPNR-5 EVALUATION OF CORRELATIONS BETWEEN TRACE ELEMENTS AND SPINOCEREBELLAR ATAXIA TYPE 3: A MULTI-ELEMENTAL ANALYSIS

Lihua Deng (*Abstract Co-Author*) Nothing to Disclose
Chen Liu (*Presenter*) Nothing to Disclose

### PURPOSE

Spinocerebellar ataxia type 3 (SCA3), a neurodegenerative disorder resulting from excess CAG repeats in the ATXN3 gene, leads to progressive cerebellar ataxia and other symptoms. The results of previous studies suggest that trace element dysregulation can contribute to neurodegenerative disorder

onset.Here, we explored the relationships of trace element dysregulation with CAG repeat length in the ATXN3 gene, as well as structural and functional connectivity in the brain,and reveals the extent and location of trace element-induced neurodegeneration in the brains of patients with SCA3.

**METHODS AND MATERIALS**

We enrolled 45 patients with genetically confirmed SCA3 and 44 healthy controls (HCs), assessing them with inductively coupled plasma mass spectrometry to measure blood levels of essential trace elements. Neuroimaging assessments included high-resolution Diffusion Tensor Imaging (DTI) and resting-state functional MRI (rs-fMRI) to evaluate brain structural integrity and functional connectivity. Statistical analysis correlated trace element levels with imaging findings and clinical data.

**RESULTS**

We found that the blood concentrations of lithium (Li), selenium (Se), and copper (Cu) were significantly lower in patients with SCA3 than in HCs; there were negative correlations of Li and Se levels with CAG repeat length, especially in the manifest subgroup. Through DTI combined with rs-fMRI, we revealed that Li levels were negatively correlated with fractional anisotropy in the bilateral superior longitudinal fasciculus(SLF), and positively correlated with bidirectional causal connectivity between the right inferior parietal lobule (IPL) and left cerebellum for SCA3 patients.The tractography map traced from the SLF showed reduced structural connectivity of nerve fibre paths in patients with SCA3(mostly distributed in the cerebellar, brainstem, and thalamus),and reduced dorsal premotor cortex (PMd)/IPL and cerebellum functional connectivity in patients with SCA3.

**CONCLUSION**

The study confirmed that trace element dysregulation is significantly associated with genes, clinical manifestation and neurodegenerative changes in SCA3. The findings suggest that specific trace elements might play roles in disease progression and could potentially serve as biomarkers for SCA3 severity and progression.

**CLINICAL RELEVANCE/APPLICATION**

Understanding the relationship between trace elements and SCA3 pathophysiology not only provides insights into the underlying mechanisms of the disease but also opens potential therapeutic avenues. Modulating levels of specific trace elements such as lithium might offer novel approaches to mitigating clinical symptoms and neurodegenerative progression in SCA3.

## M2-SPNR-7 GLYMPHATIC SYSTEM DYSFUNCTION AND RISK OF CLINICAL MILESTONES IN PATIENTS WITH PARKINSON'S DISEASE

Minming Zhang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Cheng Zhou (*Presenter*) Nothing to Disclose

**PURPOSE**

Glymphatic dysfunction may play a significant role in the development and progression of neurodegenerative diseases. We aimed to evaluate the association between glymphatic dysfunction and the risk of malignant event/clinical milestones in Parkinson's disease (PD).

**METHODS AND MATERIALS**

This retrospective cohort study was conducted at the Second Affiliated Hospital of Zhejiang University. Baseline data were collected from August, 2014, to December, 2020. A convenience sample of 236 patients with PD was recruited by the movement disorder specialists, and need routine visits to the hospital's movement disorder clinic. Diffusion Tensor Imaging analysis along the perivascular space (DTI-ALPS) index was calculated as an approximate measure of glymphatic function. The primary outcomes were four clinical milestones including recurrent falls, wheelchair dependence, dementia, and placement in residential or nursing home care. First, the associations of DTI-ALPS with the risk of clinical milestones were examined using multivariate Cox proportional hazards regression models. Second, logistic regression was repeated using clinical variables and DTI-ALPS index individually and in combination with the two to explore the ability to distinguish patients who reached clinical milestones within a five-year period.

**RESULTS**

A total of 175 PD patients (age 59.7 ± 9.6, 42% female) with baseline DTI-ALPS index and follow-up clinical assessments were included. A lower DTI-ALPS was independently associated with increased risk of recurrent falls (HR 0.09; 95% CI 0.02-0.41; P = .002), wheelchair dependence (HR 0.05; 95% CI 0.01-0.39; P = .004), and dementia (HR 0.04; 95% CI 0.00-0.74; P = .030). Additionally, in 103 patients (age 60.7 ± 8.9, 42% female) monitored over 5-years, logistic regression model combining clinical variables and DTI-ALPS index showed better performance for predicting recurrent falls within 5 years than model using clinical variables or DTI-ALPS index alone (AUC, 0.82 vs. 0.72, and 0.82 vs. 0.72; P = .040 and .020, respectively).

**CONCLUSION**

Glymphatic dysfunction, as measured by the DTI-ALPS index, was associated with increased risk of clinical milestones in patients with PD. This finding implies that therapy targeting glymphatic system may serve as a viable strategy for slowing down the progression of PD.

**CLINICAL RELEVANCE/APPLICATION**

These findings suggest that therapeutic strategies targeting the glymphatic system could potentially improve outcomes for patients with Parkinson disease.

Aviad Rabinowich, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The American Academy of Pediatrics (AAP) advises that the nutrition of preterm infants should target a body composition similar to that of a fetus in utero. Still, reference charts for intrauterine body composition are missing. Moreover, data on sexual differences in intrauterine body composition during pregnancy are limited. Additionally, conditions such as fetal growth restriction and gestational diabetes can alter fetal body composition, suggesting the need for charts for risk stratification. The purpose of this study was to create reference charts for intrauterine body composition from 30 to 36+6 weeks post-conception and evaluate differences between sexes.

### METHODS AND MATERIALS

In this single-center retrospective study, data from 225 normal developing fetuses acquired at 3T magnetic resonance imaging (MRI) scans, including True Fast Imaging with Steady State Free Precession (TruFISP) and T1-weighted 2-point Dixon sequences covering the entire fetus, were included. Deep Convolutional Neural Networks were utilized to segment the fetal body and subcutaneous adipose tissue automatically. The fetus's body mass (BM), fat signal fraction (FSF), fat mass (FM), FM percentage (FM%), fat-free mass (FFM), and FFM percentage (FFM%) were calculated. Using the Generalized Additive Models for Location, Scale, and Shape (GAMLSS) method, reference charts were created, and sexual dimorphism was examined using analysis of covariance (ANCOVA). A P-value below 0.05 is deemed significant.

### RESULTS

Throughout late gestation, there was an increase in BM, FSF, FM, FM%, and FFM, while the FFM% decreased. Reference charts and gestational age and sex-specific percentiles are provided. Males exhibited significantly higher BM, FFM, and FFM% and lower FSF and FM% ($P<0.001$) compared with females, with no significant difference in FM between sexes ($P=0.126$).

### CONCLUSION

MRI-derived intrauterine body composition growth charts are valuable for tracking growth in preterm infants, adhering to the AAP guidelines, and risk stratification in pregnancies complicated with fetal malnutrition. This study demonstrated that sexual differences in body composition are already present in the intrauterine phase.

### CLINICAL RELEVANCE/APPLICATION

MRI-based fetal body composition reference charts may be used to monitor preterm infant growth.

## M2-SPPD-3 PREDICTING PERINATAL OUTCOMES OF FETAL GROWTH RESTRICTION COMPLICATED PREGNANCIES WITH MULTI-MODALITY FETAL SONOGRAPHIC AND MRI APPROACH

Aviad Rabinowich, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Predict perinatal outcomes of fetal growth restriction (FGR)-complicated pregnancies using multi-modality multi-parametric data including fetal MRI, US, and clinical data with supervised machine learning (ML).

**METHODS AND MATERIALS**

Participants with FGR-complicated and appropriate for gestational age (AGA) pregnancies were prospectively recruited and followed until the infant was discharged. Two primary outcomes were recorded - intervention due to non-reassuring fetal status (NRFS) and a composite of adverse neonatal outcomes (CANO), which included any of the following: necrotizing enterocolitis, intraventricular hemorrhage, respiratory interventions, =10 days in the neonatal intensive care unit or >7 days for complete enteral nutrition. Participants underwent fetal MRI and US within a 7-day interval. MRI scans were acquired with 3T scanners employing True Fast Imaging with Steady State Free Precession (TruFISP) and T1-weighted 2-point Dixon covering the entire womb. The fetal body, subcutaneous adipose tissue, and placenta were automatically segmented from MRI using Deep Convolutional Neural Networks. Nine supervised ML classifiers were evaluated using 3-fold cross-validation to predict primary outcomes, and key predictive features were computed using the Shapley Additive Explanation tool. We further compared the multi-modality approach with the US-only approach (routine fetal biometrics and Doppler studies).

**RESULTS**

46 participants with FGR-complicated pregnancies and 26 participants with AGA pregnancies were enrolled. An eXtreme Gradient Boosting (XGBosst) with a logistic objective yielded the best results for predicting CANO, resulting in an area under the receiver operating characteristics curve (AUC-ROC) of 0.87, accuracy of 0.87, and F1-score of 0.69. Key predictive features included placental volume, MRI-estimated fetal weight, fat mass, and abdominal circumference. The US-alone approach reached an AUC-ROC of 0.76, accuracy of 0.83, and F1-score of 0.5 using the same algorithm. A support vector machine (SVM) with a linear kernel model yielded the best results for predicting interventions for NRFS with an AUC-ROC of 0.9, accuracy of 0.87, and F1-score of 0.53, with similar results using the sonographic-alone approach.

**CONCLUSION**

Multi-modality approach coupled with supervised ML algorithms may improve adverse neonatal prognostication of FGR-complicated pregnancies. However, predictions for interventions due to NRFS were less effective across both models.

**CLINICAL RELEVANCE/APPLICATION**

Employing multi-modal data can potentially enhance the prediction of adverse neonatal outcomes in pregnancies complicated by FGR.

## M2-SPPH-1 OPTIMIZATION OF PHOTON COUNTING CT FOR CARDIAC IMAGING IN PATIENTS WITH LEFT VENTRICULAR ASSIST DEVICES; AN IN-DEPTH ASSESSMENT OF METAL ARTIFACTS

Lilian Henriksson (*Abstract Co-Author*) Nothing to Disclose
Tino Ebbers, PhD (*Abstract Co-Author*) Nothing to Disclose
Marten Sandstedt, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Linus Ohlsson, MD (*Abstract Co-Author*) Nothing to Disclose
Anders Persson, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Bente Konst (*Presenter*) Nothing to Disclose

### PURPOSE

Photon counting CT (PCCT) holds promise for mitigating metal artifacts and can produce virtual mono-energetic images, while maintaining temporal resolution, making it a valuable tool for characterizing the heart. This study aimed to evaluate and optimize PCCT for cardiac imaging in patients during LVAD therapy by conducting an in-depth objective assessment of metal artifacts and visual grading.

### METHODS AND MATERIALS

Various scan and reconstruction settings were tested on a phantom and further evaluated on a patient acquisition to identify the optimal protocol settings. The phantom comprised an empty thoracic cavity, supplemented with heart and lungs from a cadaver lamb. The heart was implanted with an LVAD and iodine contrast. Scans were performed on a PCCT. Metal artifacts were assessed by three objective methods: HU/SD measurements (DiffHU , SDARTIFACT), Fourier analysis (AmplitudeLowFreq) and depicted LVAD volume in the images (BloomVol). 6 radiologists graded metal artifacts and the diagnostic interpretability in the LVAD lumen, cardiac tissue, lung tissue, and spinal cord using a 5-point rating scale. Regression and correlation analysis were conducted to determine the assessment method most closely associated with acquisition and reconstruction parameters, and the objective method demonstrating the highest correlation with visual grading

### RESULTS

Imaging the lamb heart with 90 kVp results in more streaks and areas with loss of information than imaging with 120/140 kVp. Due to blooming artifact, the LVAD volume varied from 42.3 to 92.7 cm3. This variation is dependent on factors in descending order of impact: kVp, kernel, keV, and iMAR. The qualitative assessment showed that radiologists found images acquired at 120 kVp and IQ 80, reconstructed with110 keV, kernel Qr40 and iMAR preset pacemaker to have fewest metal artifacts. For diagnostic interpretability of cardiac tissue T3D and kernel Bv56 are preferred.

### CONCLUSION

In our study, we identified acquisition and reconstructions parameters that produced image quality preferred by the radiologist, while minimizing metal artifacts. The volume of LVAD to measure blooming was shown to be the best objective method to assess metal artifacts, while the Fourier method for assessing streak artifacts was also shown to be effective. Overall, PCCT has the potential to revolutionize the evaluation of patients with left ventricular assist devices by offering improved image quality and thereby augmented device assessment.

### CLINICAL RELEVANCE/APPLICATION

Left ventricular assist devices (LVADs) of today are placed above the diaphragm which increases CT artifacts on the heart. Photon counting CT (PCCT) is shown to reduce metal artifacts and an optimal protocol may enable a wider use of PCCT during the therapy.

## M2-SPPH-10 VISUAL DISCRIMINATION OF IODINATED- AND GADOLINATED- CONTRAST AGENTS USING PROTOTYPE PHOTON COUNTING DETECTOR CT

Toshinori Hirai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoshinori Funama, PhD (*Abstract Co-Author*) Nothing to Disclose
Shinichi Kojima (*Abstract Co-Author*) Employee, FUJIFILM Holdings Corporation
Kazuma Yokoi (*Abstract Co-Author*) Employee, FUJIFILM Holdings Corporation
Isao Takahashi, PhD (*Abstract Co-Author*) Employee, FUJIFILM Holdings Corporation
Seitaro Oda, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Photon counting detector CT (PCD-CT) uses energy-resolving detectors that can simultaneously sample the energy spectrum at multiple regions. This allows a higher spectral resolution, enabling the identification of material-specific spectral characteristics, such as the K-edge signature of the contrast agent. This study aimed to investigate the visual discrimination ability of iodinated- and gadolinated- contrast agents in prototype PCD-CT.

### METHODS AND MATERIALS

Phantom containing tubes with water, five different gadolinated contrast concentrations (0.39-3.15 mgGd/mL), and two different iodinated contrast concentrations (1.5 and 3.0 mgI/mL) was used. The phantom was scanned 10 times each using the tube voltage at 120 kVp and three types of milliampere-seconds (105mAs, 150mAs, 300mAs) with the prototype PCD-CT developed by FUJIFILM Healthcare Corporation. Iodine-gadolinium discrimination color images (red for iodine, green for gadolinium) for each scan were generated. Two radiologists rated their confidence in visual discrimination of iodine and gadolinium in the color images using a 4-point scale (0, not distinguishable - 3, definitely distinguishable). We compared the visual confidence scores for each tube current setting.

### RESULTS

Iodine and gadolinium can be distinguished by using the spectral information, while lower concentrations of both iodine and gadolinium resulted in lower visual confidence scores. For visual identification of gadolinium below 2.36mgGd/mL, the lower the tube current setting, the lower the visual confidence score. For visual identification of iodine at 3.0 mgI/mL, visual confidence scores were significantly lower at lower tube current settings. At 1.5 mgI/mL, there was no significant difference in visual confidence scores depending on tube current. Regarding visual scores, there was excellent interobserver agreement (kappa, 0.85; 95% confidence interval: 0.80, 0.90).

### CONCLUSION

Iodinated- and gadolinated-contrast agents can be visually discriminated by using the prototype PCD-CT, and observers' confidence tended to decrease, especially at low concentrations and at low tube current settings. Visual observation of material decomposition images can require appropriate imaging settings depending on the concentration of the target materials.

### CLINICAL RELEVANCE/APPLICATION

Sufficient visual discrimination can be possible in material decomposition images using PCD-CT under appropriate imaging settings.

## M2-SPPH-11 UTILIZING MATERIAL DECOMPOSITION TECHNOLOGY BASED ON DUAL-ENERGY CT FOR STRATIFICATION OF LIVER IRON DEPOSITS IN THALASSEMIA PATIENTS

Lina Li (*Abstract Co-Author*) Nothing to Disclose
Peng Peng, MD (*Abstract Co-Author*) Nothing to Disclose
Minggui Wei (*Presenter*) Nothing to Disclose

### PURPOSE

This study investigated the utility of dual-energy CT (DECT) using a material decomposition (MD) algorithm to quantify hepatic iron deposition. The objective was to determine an optimal DECT-derived virtual iron concentration (VIC) threshold that stratifies hepatic iron levels, with MRI T2* serving as the reference standard.

### METHODS AND MATERIALS

125 thalassemia patients who underwent both DECT and MRI scans. VIC measurements were derived from iron (water) and iron (Fat) material images reconstructed using the MD algorithm. Five regions of interest (ROIs) were defined on the largest cross-sectional area of the liver parenchyma in VIC [iron (water)], VIC [iron (Fat)], and T2* (MRI) images, with two on the left lobe and three on the right. The average of these ROIs represented the final VIC and T2* values. Spearman statistics evaluated the correlation between VIC values and T2*. Patients were categorized into four groups based on MRI T2* grading: none (T2* > 6.3 ms, grade 0), mild (T2*, 2.7-6.3 ms, grade 1), moderate (T2*, 1.4-2.7 ms, grade 2), and severe (T2* < 1.4 ms, grade 3). Receiver operating characteristic (ROC) curves were generated to assess the diagnostic accuracy of VIC [iron (water)] and VIC [iron (Fat)] for detecting liver iron deposition, with area under the curve (AUC) calculated. Optimal Youden index-based cutoff points for VIC [iron (water)] and VIC [iron (Fat)] were determined to diagnose hepatic iron deposition and to differentiate between severity grades.

### RESULTS

VIC [iron (water)] demonstrated a strong negative correlation with T2* (r = -0.937), with AUCs of 0.964, 0.977, and 0.973 for identifying mild, moderate, and severe hepatic iron deposition, respectively. Cutoff values for VIC [iron (water)] were 3.04 for diagnosing grade 1 or higher (sensitivity 84.3%, specificity 100%), 3.93 for grades 2 or 3 (sensitivity 93.1%, specificity 96.4%), and 6.24 for grade 3 (sensitivity 96.3%, specificity 94.3%). Similarly, VIC [iron (Fat)] correlated strongly negatively with T2* (r = -0.938, 95% CI: -0.957 to -0.910), with AUCs of 0.964, 0.973, and 0.970 for the respective grades. Cutoffs for VIC [iron (Fat)] were 12.032 for grade 1 or higher (sensitivity 84.3%, specificity 100%), 13.116 for grades 2 or 3 (sensitivity 91.4%, specificity 94.6%), and 15.326 for grade 3 (sensitivity 93.6%, specificity 95.4%).

### CONCLUSION

DECT employing the MD algorithm effectively correlated with T2* MRI, enabling accurate quantification and grading of liver iron concentrations in thalassemia patients.

### CLINICAL RELEVANCE/APPLICATION

Implementing DECT for quantitative analysis of hepatic iron deposition enhanced detection efficacy, providing a reliable and convenient diagnostic tool for assessing hepatic iron levels.

## M2-SPPH-2 A COMPARATIVE ANALYSIS OF A PHOTON-COUNTING CT SYSTEM AND PREMIUM DUAL-ENERGY CT PLATFORMS: A PHANTOM STUDY

Steven A. Rothenberg, MD (*Abstract Co-Author*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC

### PURPOSE

Variations in spectral CT systems may lead to significant differences in image quality and radiation dose. The purpose of this study was to evaluate the performance of a clinical photon counting CT (PCCT) platform and various premium dual-energy CT (DECT) scanners using a multi-energy CT phantom.

### METHODS AND MATERIALS

The multi-energy CT phantom (Model 1472, Gammex Inc.) with 26 different inserts was initially scanned at standard dose (16 mGy), low dose (8 mGy) and extra-low dose (4 mGy) settings with a clinical PCCT system (NAEOTOM Alpha, Siemens Healthineers). For comparison, a fast-kVp-switching DECT (Discovery 750 HD, GE Medical Systems) and a dual-source DECT (Somatom FORCE, Siemens Healthineers) were also utilized to scan the phantom. Similar acquisition parameters were used for the different scanners. Quantitative accuracy of attenuation, measured in Hounsfield Units (HU), and noise, measured as the standard deviation of HU, were assessed by drawing circular regions of interest placed in the center of the insert rods. The center was determined when the four localization markers were present in the images. Mean signal-to noise ratio (SNR) and contrast-to-noise ratio (CNR) values were calculated and compared for acquisitions at the same dose or those at different doses. The Friedman test with Dunnett's multiple comparisons test was used to assess differences between related samples.

### RESULTS

The highest mean SNR and CNR values for the PCCT were 7.85 and 4.65, respectively, which were significantly better than those of the other scanners ($p<0.0001$). The extra-low dose scan of the PCCT demonstrated a better SNR value overall compared to the standard and low dose scans of the fast-kVp-switching DECT scanner ($p<0.05$) and had similar results with the standard and low dose scans of the dual-source DECT scanner. Mean SNR values were progressively increased with the dosage and best SNR yielded at the standard dose. The SNR values for all three doses differed significantly from each other ($p<0.05$). The best mean CNR was achieved at the standard dose, which was not statistically significant compared to the mean CNR of the low dose but was statistically different compared to the extra-low dose ($p<0.05$). Mean HU values were not significantly different between the scanners.

### CONCLUSION

PCCT enables high-quality exams even at extra-low dose CT scanning settings. When using equivalent doses, the PCCT significantly enhances overall image quality, or permits radiation dose reduction in comparison to the latest-generation DECT scanners.

### CLINICAL RELEVANCE/APPLICATION

PCCT scanners provide better overall image quality and contrast compared to DECT scanners, potentially enabling a superior diagnostic assessment at a lower radiation dose to the patient.

## M2-SPPH-6 A NOVEL UCP-1 QUANTITATIVEMETHOD: EXPLORATORY ON THE SPECTRAL CT MATERIAL DECOMPOSITION TECHNIQUE OF THE IDENTIFICATION OF ANIMAL ADIPOSE TISSUE TYPES

Bo Duan (*Abstract Co-Author*) Nothing to Disclose

Qingyu Ji (*Presenter*) Nothing to Disclose

### PURPOSE

To explore and validate the feasibility of quantitative measurement of Uncoupling Protein 1 (UCP-1) in rat brown adipose tissue and white adipose tissue using spectral CT substance separation technique.

### METHODS AND MATERIALS

In this study, we performed spectral CT scanning on 81 SD rats (2 months old) at room temperature for quantitative measurement of UCP-1 in brown and white adipose tissue. We obtained the UCP-1 virtual values of brown adipose tissue located in the interscapular region (BAT), subcutaneous white adipose tissue in the abdomen (WAT- subcutaneous), and abdominal visceral white adipose tissue (WAT-visceral) for the UCP-1 using self-prepared UCP-1 (Fat) matrix pairs. T-test and one-way ANOVA were applied to compare the difference in UCP-1 content in the adipose tissue of the three sites (including BAT, WAT-subcutaneous, and WAT-visceral), and $p<0.001$ was considered statistically significant.

### RESULTS

T-test showed that the difference in UCP-1 values between BAT and WAT-subcutaneous were statistically significant ($p<0.001$), and the values in the two groups of BAT and WAT-visceral were also statistically significance ($p<0.001$). However, p was 0.0018 between WAT-subcutaneous and WAT-visceral ($p>0.001$). The mean±standard of UCP-1 of BAT, WAT-subcutaneous, and WAT-visceral were: 1028.9±98.1, 135.9±13.7 and -50.7±9.4, One-ANOVA test showed there was statistically significance ($F=231.098$, $p=0.000$).

### CONCLUSION

The feasibility of the spectral CT technique in quantifying the difference in UCP-1 content between brown and white adipose tissue in rats was successfully validated in this study. It provided important methods to explore novel clinical diagnoses and therapeutic strategies in lipid metabolic diseases.

### CLINICAL RELEVANCE/APPLICATION

UCP-1 is a protein found in mitochondria, mainly distributed in the mitochondria of brown adipose tissue. It plays a significant role in the regulation of energy metabolism and thermogenesis. UCP-1 can actively promote the metabolism and burning of fatty acids to produce ATP for cellular use in energy metabolism and antioxidant activity. The mechanism helps to prevent the growth and spread of tumor cells. The UCP-1 in brown adipose tissue assists reduce oxidative stress and keeps cells from oxygen radical damage to prevent the risk of tumor. Therefore it is important to conduct a quantitative study on UCP-1 in tumor prevention and therapy. This validation study will advance the development of non-invasive diagnostic techniques by measuring UCP-1 in brown adipose tissue and white adipose tissue of experimental rats, which will make it possible to quantify UCP-1 in vivo by spectral CT substance separation techniques.

## M2-SPPH-8 ENHANCING METAL OBJECT IMAGING: EXPLORING THE POTENTIAL OF SPECTRAL PHOTON-COUNTING CT

Ting Y. Tao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Adrian A. Sanchez, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Christopher D. Abraham, MD (*Abstract Co-Author*) Nothing to Disclose
Krystle Barhaghi, MD (*Abstract Co-Author*) Nothing to Disclose
Yao Hao, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhongwei Zhang, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

In clinical settings, the population of patients with metal objects is steadily increasing. These objects range from biomedical implants for organ support, body function monitoring, and targeted medication delivery, to foreign bodies resulting from trauma. The appearance of metal artifacts manifests as prominent bright and dark streaks across the reconstructed images, thereby compromising the image quality. Despite advances in metal artifact reduction techniques, CT scans still struggle to accurately assess tissues neighboring metal objects. In this study, we aimed to investigate the potential of virtual monoenergetic imaging via photon-counting CT (PCD-CT) to improve the imaging of metal objects through phantom studies.

**METHODS AND MATERIALS**

Spectrum estimation: to model the photons that remain detectable post-attenuation through various metallic materials, including C (Z=6), Mg (Z=12), Al (Z=13), Ti (Z=22), Fe (Z=26), Co (Z=27), Ni (Z=28), and Pb(Z=82).Phantom Study: A torso phantom (icotec Medical Inc.) with 4 types of spine configurations was used: I) normal/native spine without hardware insert; II) Titanium screw and rod spine insert; III) hybrid spine insert with CFR-PEEK screw and Titanium tulip head; and IV) CFR-PEEK spine insert with CFR-PEEK screw and rod. Each respective insert was scanned using Siemens NAEOTOM Alpha PCD-CT. Monoenergetic keV image reconstruction at variable levels was applied. The phantom was also scanned using both kV and MV CBCT for comparison purposes.

**RESULTS**

Spectrum estimation study not only illustrate the differential attenuation of low-energy and high-energy photons compared to the original x-ray spectrum but also delineate the crucial keV threshold necessary for monogenic keV image reconstruction. Lower-energy photons experience more significant attenuation, causing a shift in the original photon-energy spectrum towards higher energies. Additionally, higher Z elements correspond to higher keV thresholds.The phantom study showed that increasing the keV level reduces metal artifacts, albeit at the cost of lower tissue contrast. The optimized keV should ideally surpass, yet remain proximal to, the detectable keV threshold for optimal image quality.

**CONCLUSION**

By reconstructing images at specific energy levels, PCD-CT offers a unique approach to imaging, particularly advantageous for patients with metal objects within the body, where traditional CT imaging often faces challenges such as beam hardening artifacts and reduced image quality.

**CLINICAL RELEVANCE/APPLICATION**

PCD-CT improves imaging with metallic objects through monoenergetic image reconstruction, rendering it an appealing choice for clinical settings aiming to enhance image quality in cases involving metallic objects.

## M2-SPPH-9 LIVER FAT QUANTIFICATION WITH SILICON-BASED PHOTON-COUNTING CT: AN IN-SILICO IMAGING STUDY

Ehsan Samei, PHD (*Abstract Co-Author*) Research Grant, General Electric Company;Advisory Board, General Electric Company;Research Grant, Siemens AG;Advisory Board, Siemens AG;Advisory Board, medInt Holdings, LLC;Advisory Board, Metis Health Analytics;Research Consultant, Nanox Imaging Ltd;Royalties, General Electric Company;Royalties, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Mirion Technologies, Inc;Royalties, Cambridge University Press;Royalties, John Wiley & Sons, Inc

Raj Kumar Panta, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the clinical utility of silicon-based photon-counting CT (Si-PCCT) to quantify liver fat content (LFC) on material-decomposed images.

**METHODS AND MATERIALS**

Si-PCCT is a new PCCT technology with multiple prototype systems currently available for investigation but not ready for clinical application. To evaluate such eventual utility, we developed a simulator of the system and benchmarked against the prototype. The simulator was used to image a computational Gammex phantom (in-plane dimension of 40cm x 30cm) and XCAT virtual human phantoms (VHPs) with different levels of LFC (1-100%) using a standard abdominal CT protocol. Spectral sinograms were processed using a maximum-likelihood based material decomposition technique. The estimated LFCs in the reconstructed material-decomposed images were compared against the digitally defined ground-truth values.

**RESULTS**

A linear relationship (R2 = 0.987) was observed between the estimated LFC and the ground-truth LFC on both the Gammex phantom and VHP datasets. Statistical analysis indicated statistical similarity in the LFC quantification accuracy between the Gammex phantom and the VHPs (p-value = 0.674). The root mean square error for both datasets was 3.65%. The Bland-Altman plot showed an excellent agreement between the estimated and the ground-truth LFC, with lower discrepancy (< ± 2%) at higher LFC and higher discrepancy (< ± 6 to 8%) at lower LFC.

**CONCLUSION**

Si-PCCT offers accurate fat quantification across a wide range of LFC as evidenced by in-silico evaluation conducted on both a geometrical and anthropomorphic phantom.

**CLINICAL RELEVANCE/APPLICATION**

The study highlights the potential of Si-PCCT to accurately quantify LFC in individuals with fatty liver disease. This technique has important clinical implications in liver fat assessment, offering promising prospects for opportunistic screening in clinical settings.

## M2-SPVA-1 DEVELOPMENT AND CLINICAL APPLICATION OF KEY TECHNOLOGIES FOR RECOGNIZING AND DIAGNOSING LOWER EXTREMITY ARTERIAL CTA IMAGING USING ARTIFICIAL INTELLIGENCE

Qingyu Ji (*Abstract Co-Author*) Nothing to Disclose
Hao Zhi (*Abstract Co-Author*) Nothing to Disclose
Jiahuan Xu (*Abstract Co-Author*) Nothing to Disclose
Bo Duan (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the accuracy of artificial intelligence (AI) -based diagnostic system in the analysis of lower extremity arterial stenosis and plaque, and to explore its clinical application value in the diagnosis and treatment of lower extremity arterial diseases.

### METHODS AND MATERIALS

A total of 180 patients who underwent CT angiography (CTA) of lower extremity arteries and digital subtraction angiography (DSA) of lower extremity arteries were retrospectively collected. The DSA results were used as the gold standard to evaluate the accuracy of lower extremity artery CTA and artificial intelligence in the diagnosis of lower extremity artery stenosis, and the segmentation analysis was performed, with the results of lower extremity artery CTA as the gold standard. The accuracy of artificial intelligence in the diagnosis of lower extremity arterial plaque attributes was evaluated, and its specificity, sensitivity and accuracy were calculated. The ROC curve was drawn to evaluate the efficiency of the artificial intelligence diagnosis system. At the same time, the report release time and non-AI post-processing were compared.

### RESULTS

Finally, 4180 vessels and 6270 vessel segments were analyzed in this study. The accuracy, sensitivity and specificity of artificial intelligence in the diagnosis of calcified plaque and non-calcified plaque were 92.76% and 93.88%, 73.93% and 74.37%, 94.15% and 97.55%, respectively. The accuracy, sensitivity and specificity of artificial intelligence in the diagnosis of significant stenosis of cranial and carotid arteries were 92.64%, 78.46% and 94.67%, respectively. Compared with conventional non-artificial intelligence post-processing, the time of vascular report production was saved by 29.0±4.5 minutes after AI-assisted diagnosis.

### CONCLUSION

The CTA system based on artificial intelligence is reliable in the diagnosis of lower extremity arterial plaque characteristics and vascular stenosis, which significantly improves the work efficiency of radiologists.

### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence (AI) is highly accurate and efficient in analyzing lower extremity arterial narrowing and plaque formation, aiding in the early detection and precise diagnosis of peripheral artery disease (PAD). This technology can streamline the workflow of healthcare professionals, leading to faster assessments and improved treatment planning for patients. AI also assists in risk prediction and personalized care strategies for better patient outcomes. Overall, AI plays a significant role in enhancing the diagnosis, management, and outcomes of PAD patients.

## M2-SPVA-2 CT IMAGING USING VARIABLE HELICAL PITCH (VHP) SCANNING FOR LOWER EXTREMITY ARTERIAL DISEASE (LEAD): REDUCED CONTRAST MEDIUM DOSE, IMPROVED IMAGE QUALITY AND DIAGNOSTIC ACCURACY

Wanli Yang (*Abstract Co-Author*) Nothing to Disclose
Bei Bei DU (*Abstract Co-Author*) Nothing to Disclose
Yadi Yang (*Abstract Co-Author*) Nothing to Disclose
Xin Li (*Abstract Co-Author*) Nothing to Disclose
Xiaoshi Li (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the clinical value of VHP in lower extremity CTA scanning for LEAD patients.

### METHODS AND MATERIALS

Eighty Patients with suspected LEAD underwent lower extremity CTA were prospectively enrolled between October 2022 and October 2023. Patients were divided evenly into two groups: VHP group (n=40) and conventional group (n=40). In the VHP group, test bolus injection method was used to obtain the variable helical pitch. The scanning range was divided into two parts, above the knee and below the knee. Two helical pitches can be determined based on

the time to peak of contrast arrival at the knee joint and the scanning range of the two parts. The contrast medium (CM) volume for the VHP group was 15 mL (test bolus) + subsequent CTA examination (scan time * injection rate 4 mL/s). The conventional group uses bolus tracking and scans are conducted with a standard pitch of 0.828. If the arteries below the knee joint level are not clearly displayed, an additional small range re-scan is performed, ranging from the toes to the lower edge of the knee joint. The CM volume of conventional group was determined according to the body weight (=60 kg, 80 mL; 60-90 kg, 100 mL; >90 kg, 120 mL). The standard deviation (SD), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) were calculated. The subjective image quality was independently evaluated by two radiologists. Radiation dose and CM volume were also recorded. The diagnostic accuracy was calculated.

**RESULTS**

The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) on small distal lower extremity vessels in the VHP group, such as the anterior tibial artery and dorsalis pedis artery, were superior to the conventional group (all $p<0.05$). The subjective image quality score in the VHP group was better than the conventional group ($p<0.05$). There was no statistically significant difference in radiation dose between the two groups (VHP: 1.67 ± 0.64 mSv, conventional group: 1.65 ± 0.39 mSv, $p=0.87$). The CM volume in the VHP group (64.55 ± 11.87 mL) was lower than the conventional group (89.63 ± 10.03 mL), with a decrease of approximately 33.0%. VHP group had higher sensitivity (100% vs. 87.5%) and accuracy (100% vs. 97.35%) than the conventional group.

**CONCLUSION**

In lower extremity arterial CTA scans, the use of VHP technology can significantly reduce the CM dose, improve subjective image quality, and enhance the objective image quality of distal small vessels.

**CLINICAL RELEVANCE/APPLICATION**

It has the potential to replace conventional scans in clinical practice and become the standard technique for lower extremity arterial CT scans.

## M2-SPVA-3 DESCENDING THORACIC AORTIC ELONGATION PREDICTS TYPE B AORTIC DISSECTION IN MARFAN SYNDROME

Nicholas S. Burris, MD (*Abstract Co-Author*) Royalties, ImBio, LLC
Heather A. Knauer, PhD (*Abstract Co-Author*) Nothing to Disclose
Prabhvir S. Marway, BA, MBBChir (*Abstract Co-Author*) Nothing to Disclose
Nic Tjahjadi (*Abstract Co-Author*) Nothing to Disclose
Himanshu J. Patel, MD (*Abstract Co-Author*) Research Consultant, W. L. Gore & Associates, IncResearch Consultant, Medtronic plcResearch Consultant, Terumo CorporationResearch Consultant, Edwards Lifesciences Corporation
Carlos Alberto Campello Jorge, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Marfan syndrome (MFS) patients are at high risk of type B dissection (TBAD) after prophylactic repair of the root/ascending aorta, commonly occurring at normal or mildly dilated diameters. Alternative anatomic predictors such as arch angle acuity, increased descending thoracic aortic length and tortuosity have been suggested as potential biomarkers, but longitudinal data to corroborate their prognostic value is sparse. The purpose of this study was to evaluate changes in aortic geometric features in MFS patients -beyond diameter measurements- in an attempt to identify novel predictors of TBAD development.

**METHODS AND MATERIALS**

In this single-center, retrospective study, computed tomography angiography scans from adult MFS patients (2004-2023) without prior descending thoracic aortic repair were included, with a minimal inter-scan interval of 2 years. Aortic diameter at multiple standard levels, centerline length (left subclavian to celiac artery) and tortuosity index (centerline length/linear height) were measured in descending thoracic aorta and were normalized by the time interval (per year). Arch angle was measured between the apex of the arch and the ascending and descending aorta at the level of the main pulmonary artery. Aortic growth rate was assessed by vascular deformation mapping technique, a validated 3-dimensional image analysis technique for aortic growth measurement.

**RESULTS**

Of the 105 patients included, the majority (63.8%) were male, 70.5% with prior ascending root replacement, a mean age of 40 ± 15 years, and an imaging interval of 6.1 ± 3.6 years. During imaging surveillance, 12 (11.4%) patients developed acute TBAD. There were increased rates of female sex, dural ectasia, warfarin usage, and mechanical aortic valve replacement in the TBAD group. Patients with TBAD had significantly larger diameters at follow-up CTs, higher elongation rate (2.4 vs. 0.5 mm/y; $p < 0.001$), and increasing acuity of arch angle over follow-up (-5.2° vs. +2.1°, $p = 0.03$). Multivariable logistic regression revealed an increased risk of TBAD with a higher elongation rate (OR 2.16, 95% CI 1.28-3.65; $p=0.004$) and aortic growth rate (OR 9.78, 95% CI 1.11-86.08; $p = 0.04$), but not with age, female sex, and pre-dissection proximal descending aortic diameter.

**CONCLUSION**

Descending aortic elongation rate independently predicts the development of type B dissection in MFS, whereas diameter, age, and sex do not. These findings suggest that centerline-derived elongation rate is a valuable parameter to be considered in the risk-stratification of MFS patients.

**CLINICAL RELEVANCE/APPLICATION**

Monitoring aortic elongation presents as a key instrument in the surveillance of MFS patients and may help identify patients at high risk for TBAD.

## M5A-SPBR-1 MULTIPARAMETRIC MRI MODEL WITH DYNAMIC CONTRAST-ENHANCED AND APPARENT DIFFUSION COEFFICIENT ENABLES ACCURATE PREDICTION OF BENIGN AND MALIGNANT BREAST LESIONS

Huanhuan Liu (*Abstract Co-Author*) Nothing to Disclose
Ran Luo, MD (*Abstract Co-Author*) Nothing to Disclose
Lijun Wang (*Abstract Co-Author*) Nothing to Disclose
Dengbin Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Yanhong Chen (*Presenter*) Nothing to Disclose

### PURPOSE

The study aims to investigate the value of a convolutional neural network (CNN) based on multiparametric magnetic resonance imaging in predicting malignancy of breast lesions.

### METHODS AND MATERIALS

We developed a CNN model based on the dynamic contrast-enhanced imaging (DCE) and Diffusion-Weighted Imaging(DWI) with apparent diffusion coefficient(ADC) mapping to characterize breast lesions. Between November 2018 and October 2019, 556 lesions (307 malignant, 249 benign) in 556 patients were pooled in the training/ validation set. Lesions were semi-automatically segmented by two breast radiologists using ITK-SNAP software. The standard of reference was histologic consequences. Algorithm performance was evaluated in an independent testing set of 243 lesions in 243 patients using weighted sums of the area under the curve (AUC) scores.

### RESULTS

In the Testing set, the model of DCE-ADC achieved the highest diagnostic efficiency with an area under the receiver operating characteristic (ROC) curve(AUC) of 0.889 and the accuracy, sensitivity, and specificity were 82.5%, 80.7% and 84.1%, respectively, surpassing the other models including DCE-DWI-ADC, DCE-DWI, and other single-parameter model.

### CONCLUSION

Multiparametric MRI using DCE-MRI and DWI-ADC maintains high sensitivity, improves specificity, and maximizes diagnostic accuracy, which can prevent unnecessary breast biopsy.

### CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI model enables accurate prediction of benign and malignant breast lesions guiding clinical decision-making.

## M5A-SPBR-10 COMPARISON OF THE RISK SCORE FOR CANCER DETECTION ON SCREENING MAMMOGRAMS GIVEN BY AN AI ALGORITHM AND THE RADIOLOGISTS

Solveig S. Hofvind (*Abstract Co-Author*) Nothing to Disclose
Jonas Gjesvik (*Abstract Co-Author*) Nothing to Disclose
Tone Hovda, PhD, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To explore association of an artificial intelligence (AI) algorithm's risk score for cancer detection and the radiologists' interpretation scores in a population-based mammographic screening program using independent double reading and consensus.

### METHODS AND MATERIALS

The study sample included 602,134 screening mammography examinations performed 2004-2018, including 3439 screen-detected breast cancer cases, all independently read by two radiologists and assigned a score on a scale 1-5 (1: normal/benign, 2: probably benign, 3: intermediate suspicious, 4: probably malignant, 5: malignant). All examinations were analyzed by a commercially available AI-algorithm, scoring each examination on a continuous scale from 0.0-1.0, with 1.0 representing highest likelihood of cancer. We defined score sum as the sum of interpretation scores by both radiologists, ranging from 3 (score 1+2) to 10 (score 5+5), sums 8-10 were collapsed into one category. We analyzed algorithm sensitivity and association with score sum at three different thresholds: At T1, the 3.0% highest AI-scores were considered positive (corresponding to the actual recall rate in the study population). At T2, the 8.7% highest AI-scores were considered positive (corresponding to the actual consensus rate), and at T3, the 50% highest AI-scores were considered positive. We performed descriptive analyses and one-way ANOVA for trend, $p<0.05$ statistically significant.

### RESULTS

AI scored 83.3% (2864/3439) of the screen-detected cancers positive at T1, ranging from 57.4% (264/460, score sum 3) to 98.9% (717/725, score sum 8-10). At T2, AI scored 93.5% (3216/3439) of the cancers positive, range 82.2% (378/460, score sum 3) to 99.9% (724/725, score sum 8-10). At T3, AI scored 99.7% (3427/3439) of the cancers positive, ranging from 98.9% (455/460, score sum 3) to 100.0% (725/725, score sum 8-10). P<0.01 for trend for sum of scores for T1, T2 and T3.

### CONCLUSION

We observed a statistically significant positive association between AI risk score and radiologists' interpretation scores.

### CLINICAL RELEVANCE/APPLICATION

Agreement between AI risk score and radiologists' interpretation scores indicates that it is safe to further test AI as a stand-alone reader in prospective studies; however, screen-detected cancers with less suspicious characteristics remain a challenge to both AI and radiologists.

## M5A-SPBR-2 AUTOMATED IDENTIFICATION OF CHALLENGING MAMMOGRAPHIC CASES USING ARTIFICIAL INTELLIGENCE: A NOVEL APPROACH FOR EDUCATIONAL TEST SET CURATION

Mary T. Rickard, MBBS, FRANZCR (*Abstract Co-Author*) Nothing to Disclose
Ziba Gandomkar (*Abstract Co-Author*) Nothing to Disclose
Patrick C. Brennan, BS, PhD (*Abstract Co-Author*) Director, DetectED-X
Moayyad E. Suleiman, PhD (*Presenter*) CTO, DetectED-X

### PURPOSE

Traditional methods of assessing the interpretative difficulty of mammographic cases for educational purposes may not always accurately reflect their true difficulty. To address this, we propose a novel approach utilizing artificial intelligence (AI) to classify normal mammograms as either easy or challenging. This would facilitate the rapid identification of difficult cases within large archives of mammographic images to streamline educational test set curation process.

### METHODS AND MATERIALS

A dataset of 441 cancer-free screening mammograms, confirmed through a two-year follow-up, was utilized. Each mammogram was independently assessed by numerous radiologists or trainees. Regions of interest (ROIs) containing false positives (FPs) were identified and categorized as challenging-to-interpret if marked by over 10% of interpreters; otherwise, they were deemed easy-to-interpret. Concurrently, three publicly available AI-based models were employed to generate ROIs. These outputs were then used as input to train and validate an EfficientNet B3 model, aimed at distinguishing between challenging and easy-to-interpret FP ROIs. Performance was evaluated using ten-fold cross-validation.

### RESULTS

Among 11,410 FPs annotated by readers, 1,142 were identified as challenging-to-interpret. Combining outputs from the AI-based models yielded 14,112 ROIs, effectively encompassing 99.56% of radiologists'-identified challenging FPs and 98.00% of easy-to-interpret FPs. The cross-validated EfficientNet model achieved an area under the receiver operating characteristics curve (AUC) of 0.85 (95% CI: 0.84-0.86) for identifying challenging-to-interpret FP ROIs.

### CONCLUSION

Our study demonstrates that combining AI-generated ROIs with a finely tuned EfficientNet model can accurately predict challenging-to-interpret normal mammograms. This approach has the potential to streamline the curation of educational test sets and guide AI development towards cases where it is most beneficial.

### CLINICAL RELEVANCE/APPLICATION

The findings highlight the potential of AI in rapidly identifying difficult cases within large archives of mammographic images. This has implications for improving the quality and relevance of educational materials for radiologists and trainees, thereby enhancing their diagnostic skills and proficiency.

## M5A-SPBR-3 DUAL-DOMAIN MTANN FOR VIRTUAL HIGH-DOSE IMAGING IN DIGITAL BREAST TOMOSYNTHESIS (DBT)

ZHIPENG DENG (*Abstract Co-Author*) Nothing to Disclose
Kenji Suzuki, PhD (*Abstract Co-Author*) Nothing to Disclose
Ze Jin, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Digital breast tomosynthesis (DBT) is an advanced imaging technique that enhances early breast cancer detection by providing three-dimensional (3D) representations. Although DBT increases diagnostic precision, it exposes patients to a higher radiation dose compared with traditional 2D mammography. With the goal of substantial reduction in the radiation exposure in DBT, we developed a novel dual-domain radiation dose reduction technology that involves denoising in both raw projection and reconstructed domains.

### METHODS AND MATERIALS

Our dual-domain massive-training artificial neural network (MTANN) approach consists of applying 2D-MTANN to raw DBT projections, followed by a reconstruction process, and then utilizing a 3D-MTANN on reconstructed slices. During training, our MTANN learned the relationship between low-dose (LD) images and high-dose (HD) images. In the testing phase, this approach was able to convert LD raw projections into virtual high-dose (VHD) reconstructed slices, which significantly reduced noise and artifacts while preserving image quality. VHD images retained fine details, such as microcalcifications (MCs), which are vital for accurate breast cancer diagnosis.

### RESULTS

Our dual-domain radiation dose reduction technology was capable of converting LD images into VHD images, the image quality of which was similar to real HD images. To assess the effectiveness of dose reduction, we evaluated the image quality by measuring the contrast-to-noise ratio (CNR). Our method achieved the highest CNR among all methods with statistically significant differences (paired t-test: $P < 0.05$). Small MCs, measuring approximately 0.45 mm and 0.3 mm, lost the contrast to various extents in the output images from BM3D, K-SVD, RED-CNN, DnCNN, and DnGAN, unlike our method which effectively preserved the contrast.

### CONCLUSION

We developed a dual-domain radiation dose reduction technology based on MTANN, which converts LD DBT images into VHD DBT images, equivalent to full-dose DBT images, as evaluated in 51 non-training clinical cases. We showed that the integration of denoising in both the raw projection domain and the reconstructed domain of DBT images was effective, with each compensating for the other. This novel technology effectively reduced noise in half-dose images while preserving calcifications and breast tissue structures.

### CLINICAL RELEVANCE/APPLICATION

Our method was able to reduce radiation dose to patients by generating virtual high-dose images from low-dose input images.

## M5A-SPBR-4 FORECAST OF GENETIC ASSESSMENTS FOR TUMOR RESPONSE TO CHEMOTHERAPY ONLY WITH PRETHERAPEUTIC BREAST MRI BY MEANS OF RADIOGENOMIC IMAGING BIOMARKER SCHEME

Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ze Jin, PhD (*Abstract Co-Author*) Nothing to Disclose
Taiguang Yuan (*Abstract Co-Author*) Nothing to Disclose
Yukiko Tokuda, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yasuto Naoi, MD,PhD (*Abstract Co-Author*) Research Grant, Sysmex CorporationSpeaker, Sysmex Corporation
Kenji Suzuki, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Genetic assessment is frequently used to predict chemotherapy responses and the recurrence risk for breast cancer patients. However, the genetic test is costly, invasive, and not feasible for every patient. Our study aims to develop a non-invasive scheme that uses only pretherapeutic MRI to predict the genetic assessments for tumor response to chemotherapy (immune-related 23-gene signature: IRSN-23) and risk of cancer recurrence (95-gene classifier: 95-GC). This was achieved by integrating machine-learning techniques with an optimal biomarker selection method.

### METHODS AND MATERIALS

Our database contained 118 breast MRI studies from 118 patients, all of which had IRSN-23 results; 76 patients of which had 95-GC results. The proposed scheme encompasses a systematic three-step process: feature extraction from a segmented tumors in pretherapeutic MR images, discovering imaging biomarkers by our original biomarker selection method under the maximal area-under-the-curve (MaxAUC) criterion, and prediction of genetic assessment with the imaging biomarkers. Our MaxAUC biomarker selection method was applied to 318 features to discover the most effective imaging biomarkers for forecasting genetic assessments. A prediction model was established with a support vector machine classifier with the most effective combination of imaging biomarkers. The comparative study evaluated the proposed method's performance against the latest state-of-the-art (SOTA) deep-learning models, including ResNet, DenseNet, and the Vision Transformer (ViT) models.

### RESULTS

In five-fold cross-validation tests, our proposed scheme achieved AUC values of 0.93 and 0.95 in predicting genetic test results of 95-GC and IRSN-23, respectively, which significantly outperformed 0.77 and 0.62 ($P << 0.05$), respectively, by the best-performing SOTA model.

### CONCLUSION

Our results demonstrated that our proposed scheme forecasted the genetic assessments for the risks of recurrence (by 95-GC) and responses to chemotherapy (by IRSN-23) for breast cancer accurately only with pretherapeutic MRI before chemotherapy.

### CLINICAL RELEVANCE/APPLICATION

Our scheme is able to forecast recurrence risks and tumor responses to chemotherapy for breast cancer solely from pretherapeutic MRI data before the commencement of chemotherapy, which offers novel personalized and non-invasive diagnosis in breast cancer treatment.

## M5A-SPBR-5 COMPREHENSIVE SUPPORT FOR BREAST MAMMOGRAM INTERPRETATION: EVALUATION OF A MULTI-INSTANT MULTI-MODAL AI SYSTEM SUPPORTING INTERPRETIVE AND NONINTERPRETIVE FUNCTIONS

Svati S. Long, MD (*Abstract Co-Author*) Nothing to Disclose
Pierre Fillard, PhD (*Abstract Co-Author*) Employee, Therapixel SA;Stockholder, Therapixel SA
Pauline Germaine, DO (*Abstract Co-Author*) Nothing to Disclose
Caroline Sclafert (*Abstract Co-Author*) Nothing to Disclose
Thomas Bertinotti (*Abstract Co-Author*) Nothing to Disclose
Serena Pacile, PhD (*Presenter*) Employee, Therapixel SA

### PURPOSE

Artificial intelligence (AI) has been proven to hold promising potential for revolutionizing breast cancer screening, offering advanced capabilities to enhance diagnostic accuracy and efficiency. In this study, we aimed to evaluate the impact of a multi-modal multi-instant AI-based system on the diagnostic performance of radiologists in interpreting mammograms.

### METHODS AND MATERIALS

We designed a multi-reader multi-case study taking into account the evaluation of both interpretive and non-interpretive tasks. The overall diagnostic performance was compared between the unaided versus aided reading condition using the Area Under the Receiver Operator Characteristic (AUC). Intra-class correlation coefficient (ICC), Fleiss Kappa and accuracy were used to analyze agreement and performance on non-interpretive tasks. Reading time and perceived fatigue were used as comprehensive metrics to assess the efficiency of readers.

### RESULTS

The average diagnostic performance significantly increased by 7.4% [95% CI: 4.5% - 10%] with the concurrent assistance of the AI system with a p-value<0.001. All readers experienced an augmented AUC with AI support, with improvements ranging from 0.02 to 0.18. On average, readers found 8% more cancers in assisted reading condition compared to the unassisted reading conditions. The intra-class correlation coefficient, used to quantify the agreement between readers when interpreting a case, went from 0.6 [95% CI: 0.55 - 0.65] in unassisted condition to 0.74 [95% CI: 0.70 - 0.78] for readings done with the concurrent assistance of AI. An overall decrease of 24% in reading time and a markedly reduced perceived fatigue were also found.

**CONCLUSION**

The incorporation of this AI system, capable of handling multiple image type, prior mammograms, and multiple outputs, notably improved the diagnostic proficiency of radiologists in identifying breast cancer when analyzing both DBT and 2D mammography images together, while also reducing the time required for combined interpretive and non-interpretive tasks.

**CLINICAL RELEVANCE/APPLICATION**

The application of such AI-based system could offer a comprehensive solution to support breast cancer screening practice and improve its effectiveness.

## M5A-SPBR-6 ARTIFICIAL INTELLIGENCE (AI)-BASED MAMMOGRAPHY SCORES FOR PREDICTING LYMPH NODE METASTASIS IN EARLY-STAGE BREAST CANCER

Jalim Koo (*Abstract Co-Author*) Nothing to Disclose
Na Lae Eun, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to develop and validate nomograms based on an Artificial Intelligence (AI)-based scores for mammography, combined with clinicopathologic features, to predict lymph node (LN) metastasis in early-stage breast cancer.

**METHODS AND MATERIALS**

A retrospective cohort of patients with clinical T1 or T2 and N0 breast cancers who underwent definitive breast and axillary surgery between January 2013 and December 2015 was included. Patients were randomly allocated into traning and validation sets (7:3 ratio). Clinicopathologic features and the AI score for mammography (Lunit Insight MMG) were analyzed using logistic regression to develop nomograms for LN metastasis prediction. The area under the receiver operating characteristic curve (AUC) was used to evaluate nomogram performance.

**RESULTS**

A total of 516 women were included (mean age ± standard deviation, 50 years ± 10.5). Multivariable analysis identified the AI score for mammography, lymphovascular invasion, HER2-positive status, and total mastectomy surgery type as significantly associated with LN metastasis (all $P < .05$). The developed prediction model achieved an AUC of 0.750 in the training set and 0.773 in the validation set for predicting LN metastasis, respectively.

**CONCLUSION**

The AI score for mammography, in combination with lymphovascular invasion, HER2-positive status, and total mastectomy surgery type, demonstrates significant utility in predicting LN metastasis in early-stage breast cancer.

**CLINICAL RELEVANCE/APPLICATION**

The integration of AI-based scores for mammography, alongside traditional clinicopathologic factors, may offer a valuable tool for predicting LN metastasis in early-stage breast cancer.

## M5A-SPBR-7 FEATURE ANALYSIS OF SCREENING DETECTED CANCER AND MISSED CANCER OF ARTIFICIAL INTELLIGENCE-BASED COMPUTER-ASSISTED DIAGNOSIS (AI-CAD) ON AI-STREAM STUDY

Jin Kyung An, MD (*Abstract Co-Author*) Nothing to Disclose
Nami Choi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyunghee Ko, MD (*Abstract Co-Author*) Nothing to Disclose
Jung Kyu Ryu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yeong Mi Park, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yun Woo Chang, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This presentation aims to investigate the characteristics of screening-detected cancer and missed cancer by applying AI-CAD to the prospective, multicenter study populations of the AI-STREAM study.

**METHODS AND MATERIALS**

From 2021.02 to 2022.12., 24,545 cases of 24,543 participants enrolled in the AI-STREAM study were analyzed as AI-CAD (Lunit INSIGHT mammography). Positive AI results were defined as scores > 10%. Negative AI results were observed in 23,010 cases, while positive results were found in 1,535 cases. Breast density, provided by AI-CAD, was recorded in four groups. A total of 131 cases of screening-detected cancer were diagnosed based on pathological diagnosis within 6 months, with AI-CAD detecting 118 cases. Breasts were subdivided into nine groups (10-99, 10 units each) based on their abnormality scores, and positive predictive value (PPV) was calculated for each subgroup. AI-abnormal scores were compared to mammographic and pathological findings.

**RESULTS**

The overall PPV of AI-CAD was 7.69. The PPVs ranged from 0.8% to 6.3% in groups 1 to 6 and increased sequentially from groups 7 to 9, reaching 19.6%, 31.7%, and 74.4, respectively. The median AI scores of malignant in fatty breasts [median, 98.8] appeared higher than those in dense breasts (88.4). In mammography findings of malignancy, the highest AI score was for mass with microcalcification (96.4), and the lowest was for asymmetry (58.6). When comparing pathological findings, the median AI score was higher in IDC (90.6) than in DCIS (75.6). The AI score was lower in malignant tumors<1 cm, those without LN metastasis, and those classified as Luminal A type ($p < 0.05$). 13 cases of AI-CAD missed cancer included DCIS (n=5), IDC (n=7), and medullary cancer (n=1). The size ranged from 0.7 to 8cm, and all of which were classified as luminal A. Mammography of missed cancer predominantly showed dense breasts (n=10) compared to fatty breasts (n=3), including asymmetry (n=5), mass (n=4), distortion(n=1), and microcalcification (n=1). None of the mass with microcalcification. Two cases exhibited negative mammographic features and dense breasts.

**CONCLUSION**

AI-CAD demonstrates significant promise in detecting breast cancer within screening populations, with AI abnormal scores showing an acceptable correlation with pathologic and mammographic features. Understanding the characteristics of AI-CAD detected or missed cancers could aid in the application of AI-CAD systems.

### CLINICAL RELEVANCE/APPLICATION

1. The overall PPV of AI-CAD was 7.69, falling within the recommended PPV1 range of 3-8%. 2. The PPV of AI-CAD increased sequentially, depending on the abnormal score. 3. AI-CAD demonstrated acceptable performance and correlation with pathological and mammographic features.

## M5A-SPBR-8 EXTERNAL MULTI-CENTER MULTI-MANUFACTURER VALIDATION OF A MAMMOGRAPHY-BASED AI SCORE TO SELECT PATIENTS FOR SUPPLEMENTAL BREAST CANCER SCREENING

Fredrik Strand, MD, PhD (*Abstract Co-Author*) Speaker, Lunit Inc

### PURPOSE

AISmartDensity is an AI-based score for selecting women for supplemental screening. It integrates risk, masking, and cancer signs, which also takes as input the score of one commercial AI CADe system. It has been validated in a single-center setting with AI CADe from Lunit and Hologic images. This retrospective study extended the evaluation to images from GE, Phillips, and Siemens.

### METHODS AND MATERIALS

We used a subset of the VAIB dataset which was created by sampling 5763 four-view FFDM examinations of women from 3 regions in Sweden during 2014-2019. Weighted random sampling ensured representivity for equipment manufacturer, patient age, and density. Cancer or healthy status was confirmed within 3 years of the exam. We included exams between 60 days and 3 years before diagnosis to avoid screen-detected cancer. Exams diagnosed within 2 months to 2 years were considered Interval Cancers (IC), and within 2 to 3 years, Next Round Detected Cancer (NRDC). The healthy and NRDC exams were upsampled to resemble a real-world incidence of 0.2% IC and 0.5% NRDC.The AUC, sensitivity, and PPV were measured for the exams belonging to the top 8% AISmartDensity scores.

### RESULTS

The AUC of AISmartDensity was for GE (n=161641): 0.62 (95%CI=[0.60, 0.63]), for Phillips (n=161641): 0.73 (95%CI=[0.71, 0.74]) and for Siemens (n=57553): 0.74 ( 95%CI=[0.68,0.80]) with p-value < 0.001 for each comparison. The sensitivity, for the top 8% of scores, showed that for GE 22% of cancers were included, for Philips 25% and for Siemens 30%.

### CONCLUSION

AISmartDensity generalised well to images acquired with Philips and Siemens equipment but not GE. This highlights the importance of validating on images from the same manufacturer as the algorithm will be applied to before clinical implementation. The overall results were lower than the ones previously reported on Hologic images.

### CLINICAL RELEVANCE/APPLICATION

Selecting patients for further work-up based on the scores created by AISmartDensity proved to reduce the number of IC and NRDC by detecting up to 32% more cancers than standard double reading screening.

## M5A-SPBR-9 AN AI-GUIDED REVIEW PROCESS LOWERS RECALL RATES WHILE MAINTAINING CANCER DETECTION RATES

Benjamin Reece (*Abstract Co-Author*) Employee, RadNet, Inc
A. Gregory Sorensen, MD (*Abstract Co-Author*) Employee, RadNet, Inc;Board member, IMRIS Inc;Board member, Siemens AG;Board member, DFB Healthcare Acquisitions Corp;Board member, inviCRO, LLC;;;;
Jacqueline S. Holt, MD (*Abstract Co-Author*) Nothing to Disclose
Bryan Haslam, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Jiye G. Kim, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Leeann Louis, BS, PhD (*Presenter*) Researcher, RadNet, Inc

### PURPOSE

Optimal mammography screening maintains adequately high cancer detection rates (CDR) while keeping recall rates (RR) low. We tested the hypothesis that an AI-guided review process could be used to lower recalls, the most common harm of screening, while maintaining high cancer detection rates by performing an additional review on a subset of exams where cancer likelihood is very low, but the patient was recalled by the interpreting radiologist.

### METHODS AND MATERIALS

An FDA-cleared CADe/x device was run on all eligible screening mammograms (N=292,692) at 3 outpatient screening mammography practices (including 64, 2, and 17 facilities that performed 180,529 screens, 12,889 screens and 99,274 screens at Practices 1, 2, and 3 respectively) from 07/2022-10/2023. Starting 03/2023 for Practices 1 and 2, and 04/2023 for Practice 3, a recall-focused AI-guided review process (AIRP) was implemented, where exams in the least suspicious 75% of AI scores recalled by the interpreting radiologist underwent a second review by an expert breast imaging specialist. The second reviewer decided whether to consult with the interpreting radiologist to reconsider their recall decision. To determine whether implementing AIRP lowered RR without negatively impacting CDR, we measured RR and CDR before and after the process was implemented and compared them using a Chi-squared test. In addition, to determine whether the impact of AIRP varied by radiologist's baseline RR, we plotted each radiologist's change in RR with AIRP as a function of their RR without AIRP and fit an ordinary least squares regression.

### RESULTS

Recall rates dropped significantly with AIRP for Practice 1 (from 12.0% to 10.4%, $p < 0.01$) and 3 (from 9.9% to 9.1%, $p < 0.01$) but not for Practice 2 (10.4% to 10.5%, $p = 0.84$), likely due to the low number of screens performed there. The cancer detection rate did not change significantly at any practice as a result of AIRP ($p > 0.05$). The change in RR with AIRP was significantly and negatively correlated with RR without AIRP ($p = 0.001$), meaning radiologists who had higher RR without AIRP had the biggest drop in RR with AIRP.

### CONCLUSION

Use of an AI-guided review process successfully lowered RR at 2 out of 3 outpatient screening mammography practices without compromising CDRs. This was driven primarily by a decrease in the RR of radiologists whose average RR was higher during baseline, indicating the process was most effective for

the radiologists who needed it the most.

**CLINICAL RELEVANCE/APPLICATION**

An AI-guided review process has the potential to lower RR without compromising CDR, reducing the most common harm identified by the USPSTF associated with screening mammography.

### PURPOSE

Artificial intelligence-powered coronary artery calcium scan (AI-CAC) provides more actionable information than currently reported. In this study we compared left ventricular (LV) volume measured by AI-CAC versus cardiac magnetic resonance imaging (CMR) and NT-proBNP for predicting heart failure (HF). Additionally, we compared AI-CAC vs. NT-proBNP for detection of left ventricular hypertrophy (LVH) defined by CMR.

### METHODS AND MATERIALS

We used 15-year outcomes data for incident heart failure (HF) from 3078 asymptomatic MESA participants (52.3% women, age 62.2±10.3 years) who underwent both CAC scans and CMR at the baseline examination. Data on CMR semi-manual LV volume, NT-proBNP, and Agatston CAC score were obtained from MESA. Discrimination was assessed using the time-dependent area under the curve (AUC) for incident HF.

### RESULTS

Over 15 years of follow up, 133 cases of HF were diagnosed. The AUC for AI-CAC (0.789) and CMR (0.793) were not significantly different (p=0.67) but were significantly higher than NT-proBNP (0.719) and Agatston score (0.664) (p<.0001) for prediction of incident HF. AI-CAC and CMR significantly improved the continuous Net Reclassification Index of NT-proBNP (0.37) and Agatston score (0.45) for HF prediction (p<0.001 for all). The AUC for AI-CAC vs. NT-proBNP for LVH was 0.871 vs. 0.600 for males and 0.854 vs. 0.600 for females.

### CONCLUSION

In MESA, AI-CAC automated LV volumetry and CMR semi-automated LV volumetry equally predicted incident HF over 15 years and outperformed NT-proBNP. AI-CAC significantly outperformed NT-proBNP for detection of LVH. Both AI-CAC and CMR significantly improved on NT-proBNP and Agatston CAC score for predicting incident HF.

### CLINICAL RELEVANCE/APPLICATION

Radiologists and cardiologists are currently unable to detect enlarged cardiac chambers in non-contrast chest CT scans without the AI, therefore these patients go undetected and untreated. Opportunistic screening of enlarged cardiac chambers in non-contrast CT scans enables detection of asymptomatic patients at high risk for HF.

## M5A-SPCA-10 EVALUATION OF AN ARTIFICIAL INTELLIGENCE-BASED AUTOMATIC POSITIONING METHOD FOR SETTING THE RANGE OF CORONARY CT ANGIOGRAPHY: A RETROSPECTIVE STUDY

Kai Zhao, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate and compare the performance of the conventional manual positioning method and the artificial intelligence (AI)-based automatic positioning method in setting the range of coronary CT angiography (CCTA).

### METHODS AND MATERIALS

In this retrospective study, 52 patients who underwent CCTA were included and analyzed. All patients underwent a localization scan before the CCTA scan to determine the appropriate scan range. The scan range for CCTA was then determined using the conventional manual positioning method, based on analyzing anterior-posterior (AP) scout images derived from the localization scan. The artificial intelligence automatic positioning method was retrospectively used to calculate the range for CCTA scan based on AP scout images. The actual location and range of the coronary arteries were retrospectively determined by examining CCTA axial images. The performance of conventional manual positioning and AI-based automatic positioning in setting the range of coronary artery scanning were compared using the actual location and range of the coronary arteries as the reference standard.

### RESULTS

The scan length determined by AI-based automatic positioning was significantly shorter than that determined by manual positioning (123.85±10.85 mm vs. 148.46±11.40, $p < 0.00$). Moreover, the actual position and range of the coronary artery were both within the scan length range determined by AI automatic positioning and manual positioning for all included patients. The AI-based automatic positioning method showed significantly lower absolute error compared to the conventional manual method for both superior (29.34±8.60 mm vs. 36.96±9.11 mm, $p < 0.001$) and inferior boundaries (12.98±7.98mm vs. 29.91±10.72mm, $p < 0.001$) of coronary arteries. Mean absolute and relative measurement errors with AI were also significantly lower than those with manual positioning for determining CCTA scan range (42.26±9.68 mm vs. 66.87±11.88 mm; 52.63%±14.18% vs. 83.33% ±19.19%; all p <0 .001).

### CONCLUSION

The AI-based automatic positioning method is superior to the conventional manual positioning method for setting the scan range in CCTA.

### CLINICAL RELEVANCE/APPLICATION

AI-based scan range determination in CCTA can provide improved accuracy, reduced radiation dose, and optimized scanning workflow.

## M5A-SPCA-2 CORONARY ARTERY CALCIUM SCANS POWERED BY ARTIFICIAL INTELLIGENCE (AI-CAC) PREDICTS ATRIAL FIBRILLATION AND STROKE COMPARABLY TO CARDIAC MAGNETIC RESONANCE IMAGING: THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS (MESA)

Matthew J. Budoff, MD (*Abstract Co-Author*) Nothing to Disclose
Morteza Naghavi (*Presenter*) Nothing to Disclose

### PURPOSE

AI-CAC provides more actionable information than the Agatston coronary artery calcium (CAC) score. We have recently shown in the Multi-Ethnic Study of Atherosclerosis (MESA) that AI-CAC automated left atrial (LA) volumetry enabled prediction of atrial fibrillation (AF) as early as one year. In this study we evaluated the performance of AI-CAC LA volumetry versus LA measured by human experts using cardiac magnetic resonance imaging (CMRI) for predicting AF and stroke, and compared them with CHARGE-AF risk score, Agatston score, and NT-proBNP.

### METHODS AND MATERIALS

We used 15-year outcomes data from 3552 asymptomatic individuals (52.2% women, age 61.7±10.2 years) who underwent both CAC scans and CMRI in the MESA baseline examination. CMRI LA volume was previously measured by human experts. Data on BNP, CHARGE-AF risk score and the Agatston score were obtained from MESA. Discrimination was assessed using the time-dependent area under the curve (AUC).

### RESULTS

Over 15 years follow-up, 562 cases of AF and 140 cases of stroke accrued. The AUC for AI-CAC versus CMRI for AF and stroke were not significantly different (0.802 vs. 0.798 and 0.762 vs. 0.751 respectively, $p=0.60$). AI-CAC significantly improved the continuous Net Reclassification Index (NRI) for prediction of AF and stroke when added to CHARGE-AF risk score (0.28, 0.21), NT-proBNP (0.43, 0.37), and Agatston score (0.69, 0.41) respectively (p for all<0.0001).

### CONCLUSION

AI-CAC automated LA volumetry and CMRI LA volume measured by human experts similarly predicted incident AF and stroke over 15 years. Further studies to investigate the clinical utility of AI-CAC for AF and stroke prediction are warranted.

### CLINICAL RELEVANCE/APPLICATION

Opportunistic screening of enlarged cardiac chambers in non-contrast CT scans enables detection of asymptomatic patients at high risk for AF and stroke.

## M5A-SPCA-3 AI-ENABLED AUTOMATED BONE MINERAL DENSITY MEASUREMENT IN CORONARY ARTERY CALCIUM SCANS (AUTOBMD) IS ASSOCIATED WITH HIGH CORONARY ARTERY CALCIUM SCORE INDEPENDENTLY OF CONVENTIONAL RISK FACTORS: MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS (MESA)

David F. Yankelevitz, MD (*Abstract Co-Author*) Consultant, Accumetra LLC;Stockholder, Accumetra LLC;Medical Advisory Board, Carestream Health, Inc;Royalties, General Electric Company;Consultant, AstraZeneca PLC;Consultant, Pfizer Inc;Consultant, F. Hoffmann-La Roche Ltd

Kyle Atlas (*Abstract Co-Author*) Nothing to Disclose
Matthew J. Budoff, MD (*Abstract Co-Author*) Nothing to Disclose
Claudia I. Henschke, MD,PhD (*Abstract Co-Author*) Advisory Board, LungLifeAI, Inc;Board Member, Early Diagnosis and Treatment Research Foundation Inc
Morteza Naghavi (*Presenter*) Nothing to Disclose

**PURPOSE**

The association between low bone mineral density (BMD) and coronary artery calcium (CAC) has been reported before using manual measurement of thoracic BMD. Such manual measurements are time-consuming and subject to operator errors. We therefore used an AI-enabled BMD measurement tool to explore the relationship between CAC and BMD independent of traditional risk factors.

**METHODS AND MATERIALS**

The validation of AutoBMDTM (HeartLung.AI, Houston TX) has been reported previously. We applied AutoBMD to CAC scans of 6043 individuals (53.3% female, age 61.9±10.2 years) from the baseline examination (2000-2002) of MESA. Thoracic BMD was measured in T7-T9 vertebrae. Osteoporosis was defined as a T-Score below -2.5. Cox proportional hazards regression was used to calculate hazard ratios (HR) per unit change for 10-year coronary heart disease (CHD) prediction.

**RESULTS**

Average BMD in men and women were 164.4 ± 45.1 and 163.1 ± 50.0 g/cm3 respectively (P=0.3467). Average CAC score for men and women were 223.4±544.0 and 76.2± 241.3 cm3 respectively (P<0.0001). A total of 1672 cases were classified as osteoporotic, which included 986 (58.0%) men and 714 (42.0%) women. After adjusting for age, gender and conventional CVD risk factors, average CAC score in osteoporotic cases versus normal BMD was 170.1 ± 531.1 vs. 130.4+272.8 respectively (P = 0.004). Decreased BMD was associated with CHD independently of CAC and CVD risk factors (HR=0.997, p=0.0143).

**CONCLUSION**

Low BMD and high CAC are associated independently of age, gender, and traditional risk factors of cardiovascular diseases.

**CLINICAL RELEVANCE/APPLICATION**

Further studies are warranted to evaluate the potential added value of automated BMD to CAC for prediction of adverse events.

## M5A-SPCA-5 APPLICATION OF ONE-BEAT ACQUISITION WITH MOTION CORRECTION ALGORITHM (SSF1) IN CORONARY ARTERY CT ANGIOGRAPHY OF PATIENTS WITH ATRIAL FIBRILLATION: EVALUATION OF CORONARY ARTERY USING ARTIFICIAL INTELLIGENCE ASSISTED DIAGNOSTIC SYSTEM

Shumeng Zhu (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the impact of one-beat acquisition with motion correction algorithm (SSF1) on image quality of coronary CT angiography (CCTA) in patients with atrial fibrillation, and its diagnostic efficiency using an artificial intelligence aided diagnosis system (AI-ADS).

**METHODS AND MATERIALS**

A total of 91 consecutive patients with atrial fibrillation (56 males, 67.32±11.45y), who underwent one-beat CCTA were analyzed. Images were reconstructed with SSF1. The subjective and objective image quality of the coronary arteries were evaluated. Using the invasive coronary catheter angiography as the gold standard, the diagnostic efficacy of AI-ADS and AI-ADS + radiologist for stenoses above moderate and severe degrees were calculated.

**RESULTS**

Effective radiation dose was 2.54±0.86 mSv. The average CT values of all major coronary arteries and branches were greater than 400HU. The two radiologists rated vessels as good or above 96.70% (350/364) and 96.15% (352/364), respectively, and the diagnosable rate reached 100% (subjective score =3 points). The diagnostic efficacy of AI-ADS vs. AI-ADS + radiologist for above moderate stenoses: diagnostic accuracy (85.71% vs 91.21%), sensitivity (90.91% vs 98.70%), and specificity (57.14% vs 50.00%) on patient level; (84.07% vs 86.54%), (74.22% vs 84.78%), and specificity (89.41% vs 87.61%) on vascular level; (90.99% vs 93.11%), (67.14% vs 79.05%) and (95.49% vs 95.84%) on segment level. For above severe stenoses: diagnostic accuracy (60.44% vs 69.23%), sensitivity (55.93% vs 83.05%), and specificity (68.75% vs 43.75%) on patient level; (80.84% vs 84.62%), (43.21% vs 66.67%), and (91.17% vs 89.75%) on vessel level; (91.94% vs 94.91%), (34.21% vs 64.91%) and (97.36% vs 96.96%) on segment level.

**CONCLUSION**

One-beat acquisition with SSF1 can obtain high-quality coronary images in patients with atrial fibrillation. AI-ADS can automatically distinguish coronary images with different stenosis degrees, but the sensitivity of AI-ADS is low, especially for the diagnosis of severe stenosis. AI-ADS + radiologist can improve the diagnostic efficiency.

**CLINICAL RELEVANCE/APPLICATION**

One-beat acquisition with SSF1 can obtain high-quality coronary images in patients with atrial fibrillation. AI-ADS can automatically distinguish coronary images with different stenosis degrees, and AI-ADS + radiologist can improve the diagnostic efficiency.

## M5A-SPCA-6 DIRECT ESTIMATION OF CARDIAC EJECTION FRACTION WITHOUT LEFT VENTRICULAR CONTOUR TRACING USING DEEP LEARNING

Tim Leiner, MD, PhD (*Abstract Co-Author*) Research support, Pie Medical Imaging BV;Advisory Board, Cart-Tech BV;Advisory Board, AI4MedImaging;Advisor, Quantib BV;Consultant, Guerbet SA
Jacinta Browne, PhD (*Abstract Co-Author*) Nothing to Disclose
Enas Ahmed (*Abstract Co-Author*) Nothing to Disclose
Tzu Cheng Chao (*Abstract Co-Author*) Nothing to Disclose
Nichol He, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study was to train a deep learning model to predict normal or abnormal LVEF from end-diastolic (EDV) and end-systolic (ESV) cardiac MR volumes.

**METHODS AND MATERIALS**

MR cine images from 373 patients were used to train several ResNet model variations. LVEF was calculated from EDV and ESV segmentations by expert radiologists. Sample size was expanded through augmentations and fed into ResNet models as EDV/ESV pairs. A 3-bin output model was trained to

predict overt cardiac dysfunction (LVEF < 40%), mild systolic LV dysfunction (LVEF between 40-50%), and normal (LVEF > 50%). A 4-bin output model was trained to detect hyperdynamic LV function (LVEF > 65%) as well. To balance input data, 400 volumes per bin and 250 volumes per bin were used to train the 3-output model and 4-output model respectively. Testing was performed on remaining volumes, and confusion-matrix metrics were calculated. ResNet models were built using MONAI's library.

**RESULTS**

Of the ResNet variations tested, a simple 4-layer ResNet with in-plane sizes (16, 32, 64, 128) was found to have the best performance on both 3-output and 4-output configurations. Processing time was 0.62 s/sample. The 3-output model demonstrated greater classification performance (F1: 0.73, 0.60, 0.90, AUC: 0.88, 0.86, 086). Other variations on the ResNet architecture were tested as well, such as integrating multi-layer perceptron's to encode EDV/ESV separately and utilizing autoencoders to encode input volumes. However, neither method provided any improvements to predictive power.

**CONCLUSION**

A simple ResNet architecture enables high accuracy classification of LVEF into categories of overt dysfunction, mild dysfunction and normal systolic LV function in < 1 second without the need for human expert or AI-based LV contouring.

**CLINICAL RELEVANCE/APPLICATION**

Left ventricular ejection fraction (LVEF) serves as a fundamental measure of cardiac function. However, quantitative measurement of LVEF requires human-supervised segmentation while qualitative measurements are subjective1. While recent literature focuses on cardiac segmentation2,3, qualitative LVEF prediction is simpler and more efficient for clinical application.

## M5A-SPCA-7 ARTIFICIAL INTELLIGENCE BASED CORONARY ARTERY CALCIUM SCORING REDUCES TIME TO INTERPRETATION AND MAINTAINS EXPERT-LEVEL ACCURACY

Ismail M. Kabakus, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
James Munford (*Abstract Co-Author*) Nothing to Disclose
Sameer Abrol, MD (*Abstract Co-Author*) Nothing to Disclose
Jordan H. Chamberlin, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Coronary artery calcium (CAC) score is an important metric for cardiac risk stratification; However, manual segmentation is notably time consuming and tedious to perform. Artificial intelligence (AI) has been suggested as a possible solution, but successful implementation requires demonstration of both expert level accuracy and improved efficiency.

**METHODS AND MATERIALS**

148 patients who underwent routine low dose gated non-contrast cardiac computed tomography ("Calcium scoring protocol") were retrospectively identified and prospectively evaluated. Two raters performed a timed assessment with both manual (expert alone) and semi-automatic (manual review and as-needed modification of AI segmentation) quantification of CAC in addition to a fully automatic and previously validated deep learning CAC quantification (AI-RAD Companion, Siemens Healthineers). Metrics of inter-rater reliability, accuracy, and efficiency were calculated. Assessment of change in the multi-ethnic study of atherosclerosis (MESA) score was also performed with the different CAC scores.

**RESULTS**

AI-Expert inter-rater reliability for CAC score was considered excellent; Two-way ICC = 0.951 (0.933 - 0.964). AI was significantly faster to measure CAC score alone than with manual or with semiautomatic scoring (15 ± 2s vs 38 ± 13s vs 45 ± 24s, P < 0.001 for both comparisons) across all brackets of CAC severity. Semiautomatic (AI + Expert review) demonstrated a significant reduction in time for patients with at least mild calcium burden. (Pmild = 0.004, Pmoderate = 0.001, Psevere < 0.001). Regarding MESA scores, the mean bias for the whole cohort was 2.1 ± 12.1%, and 95% of the differences in percentiles between AI and expert score fell within ± 10% of the gold standard.

**CONCLUSION**

A deep learning algorithm to perform CAC scoring demonstrated inter-expert reliability of results and was significantly faster than manual segmentation, especially for patients with higher burden of CAC.

**CLINICAL RELEVANCE/APPLICATION**

AI can help expedite calculation of clinically meaningful risk statistics and reduce burden of post-processing on cardiac imagers.

## M5A-SPCA-8 CLINICAL UTILITY OF FRACTIONAL FLOW RESERVE-COMPUTED TOMOGRAPHY (FFR-CT) FOR PATIENT WITH SUSPECTED VASOSPASTIC ANGINA: PRELIMINARY REPORT

Si-Hyuck Kang, MD (*Abstract Co-Author*) Nothing to Disclose
Ki Yeol Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Eun Ju Chun, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Dowon Yoon, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Vasospastic angina (VA) is diffuse or segmental coronary spasm of coronary arteries, one of the causes of myocardial infarction with nonobstructive coronary artery but requires invasive coronary angiography with ergonovine provocation tests (ICA-EPT). Recently, fractional flow reserve computed tomography (FFR-CT) has been shown to have good performance in detecting lesion-specific ischemia noninvasively. Therefore, we aimed to determine whether changes in FFR-CT values during the cardiac cycle have diagnostic utility in patients with suspected VA.

**METHODS AND MATERIALS**

Among patients who presented to the emergency department with acute chest pain and underwent coronary CT angiography (CCTA) for excluding obstructive stenosis, 58 patients (56±11 years, 53.4% male) with VA confirmed by ICA-EPT were retrospectively collected. In all patients, FFR values were obtained from systolic and diastolic images on retrospective ECG-gating CCTA using a commercially available automated program (HeartMedi+; AI Medic Inc., Korea). We evaluated the change of FFR value of three coronary arteries during systolic and diastolic phases as follows: 1) fixed ischemia (FFR = 0.75 on both phases), 2) Spastic ischemia (FFR = 0.75 on any phase), 3) No ischemia (FFR > 0.75 on both phases). In addition, we compared the location of ischemic coronary arteries between FFR-CT and spastic arteries by ICA-EPT.

**RESULTS**

A total of 162 vessels of FFR-CT from 58 patients with VA were analyzed and matched with ICA-EPT. On the analysis of the changes of FFR values, 10 vessels (6.2%) showed fixed ischemia and 29 vessels (21.0%) showed spastic ischemia in 27 patients (45.6%) with VA. Of 39 vessels showing fixed or spastic ischemia on FFR-CT, 25 vessels (64.1%) form 16 patients with VA were well matched to vessels causing vasospastic angina on ICA-EPT.

**CONCLUSION**

FFR-CT may be helpful for diagnosing the VA when considering the changes of FFR values during cardiac cycle.

**CLINICAL RELEVANCE/APPLICATION**

FFR-CT, which can noninvasively detect lesion-specific ischemia, may be used for dynamic ischemic change when considering the changes of FFR values during cardiac cycle, therefore, it may be helpful for diagnosing the VA.

## M5A-SPCA-9 EFFECT OF INCREASED SPATIAL RESOLUTION OF PHOTON-COUNTING DETECTOR CORONARY COMPUTED TOMOGRAPHY ANGIOGRAPHIES ON ARTIFICIAL INTELLIGENCE BASED CAD-RADS ASSESSMENT

Moritz Halfmann, MD (*Abstract Co-Author*) Nothing to Disclose
Tilman S. Emrich, MD (*Abstract Co-Author*) Speaker, Siemens AG;Travel support, Siemens AG;Advisory Board, Siemens AG
Philipp Locherer (*Abstract Co-Author*) Nothing to Disclose
Anton Kilburg (*Presenter*) Nothing to Disclose

**PURPOSE**

Recent studies have shown that an increased in-plane resolution of coronary computed tomography angiographies (CCTA) provided by a photon-counting detector (PCD) CT can significantly influence the classification of patients within the Coronary Artery Disease Reporting and Data System (CAD-RADS). However, the higher resolution typically comes with an increase in image noise and little is known whether fully automatic reporting tools can equally benefit from the increased resolution as a human reader can. Thus, the purpose of this study was to compare CAD-RADS classification between a commercially available automatic classification tool and cardiovascular radiologists as a reference standard.

**METHODS AND MATERIALS**

A total of 26 patients with coronary artery disease who underwent PCD-CCTA with an acquired in-plane resolution of 0.11 mm were retrospectively identified. Curved multiplanar reconstructions consisting of 9 images per main coronary artery (right coronary artery, left anterior descending and left circumflex) were reconstructed from reconstructions with 0.2 mm and 0.6 mm slice thicknesses and sent to an artificial intelligence (AI) based, CE-marked CAD-RADS classification tool (CorEx, Spimed AI). As a reference standard, two specifically trained radiologists, who were blinded to each other's results, assessed the CCTA images at both slice thicknesses according to CAD-RADS. Differences were assessed on a per-patient basis by Wilcoxon signed rank tests.

**RESULTS**

Prior to final analysis, 4/26 (15.4%) patients with stair-step artifacts had to be excluded due to erroneous processing in the AI-tool. From the remaining 22 patients, the higher spatial resolution led to significantly lower median CAD-RADS scores per patient (2 [IQR, 1-5] vs. 3 [IQR, 1-5], P=.015), with a reclassification of 7/22 (32 %) patients to a lower score. There was no evidence of a difference in median CAD-RADS scores compared to the expert reference (3 [IQR, 1-5] vs. 2 [IQR, 2-3], P=0.061 for 0.6 mm slice thickness reconstructions and 2 [IQR, 1-5] vs. 2 [IQR, 1-3], P=.081 for 0.2 mm slice thickness reconstructions, respectively).

**CONCLUSION**

Fully automated, artificial intelligence aided assessment of coronary artery computed tomography angiographies significantly improves with increasing spatial resolution, leading to reclassification of one third of patients into lower disease categories according to the Coronary Artery Disease Reporting and Data System.

**CLINICAL RELEVANCE/APPLICATION**

Existing AI-based tools for automated assessment of CAD-RADS categories be used on increased spatial resolution PCD-CCTA.

## M5A-SPCH-1 ENHANCING RADIOLOGICAL ASSESSMENT OF DUST DISEASES: EVALUATING THE IMPACT OF ONLINE SELF-ASSESSMENT EDUCATIONAL MODULES AND FEEDBACK INTERVENTIONS

Patrick C. Brennan, BS, PhD (*Abstract Co-Author*) Director, DetectED-X
Ziba Gandomkar (*Abstract Co-Author*) Nothing to Disclose
Moayyad E. Suleiman, PhD (*Presenter*) CTO, DetectED-X

### PURPOSE

This study evaluates the efficacy of online self-assessment test sets and feedback interventions in enhancing radiological skills for dust diseases in chest X-ray and lung CT cases.

### METHODS AND MATERIALS

In this longitudinal study, 11 radiologists and trainees participated. Baseline and post-intervention performance (measured by sensitivity, specificity, and Cohen's Kappa) were evaluated using curated test sets for CT images and chest X-rays with similar difficulty. Additional educational cases were provided in two self-assessment test sets, allowing immediate feedback and comparison to ground truth. In the interventions, they received feedback on 45 CT cases and 90 chest X-rays, covering a total of 47 dust disease cases. Paired Wilcoxon signed rank tests evaluated significant improvements in performance metrics between baseline and final test sets, with further exploration of associations between performance improvement and participant characteristics using the Kruskal-Wallis test.

### RESULTS

Results showed significant improvements in Kappa values post-intervention for CT ($p=.03$), and a marginal improvement in chest X-ray specificity ($p=.07$). Participant characteristics such as familiarity with the B Reader Self-Study Syllabus ($p=.04$) and B-reader certification status ($p=.03$) significantly influenced performance improvement in CT. In chest X-ray, specialty interest in lung diseases ($p=.006$) and workload (<20 vs =20 cases per week; $p=.023$) were associated with higher specificity improvement. For CT feature assessment, a substantial increase in agreement between observers was observed for "Diffuse well-rounded opacities" ($p=.02$), "Grading of diffuse well-rounded opacities" ($p=.047$), and "Identifying the type of predominant parenchymal abnormality" ($p=.02$). For chest x-ray, significant improvement was observed in assessing the presence of interstitial lung disease ($p=.014$).

### CONCLUSION

Self-guided educational interventions with feedback mechanism effectively enhance radiological assessment skills for dust diseases. Participant characteristics such as familiarity with study materials and certification status could play role in in the degree of improvement.

### CLINICAL RELEVANCE/APPLICATION

Online self-assessment enhances radiologists' dust disease diagnosis skills on chest X-ray and lung CT. For CT, familiarity with ILO classification boosts post-intervention improvement in performance.

## M5A-SPCH-2 PRELIMINARY CLINICAL EVALUATION OF LUNG ADENOCARCINOMAS USING A CADMIUM ZINC TELLURIDE-BASED PHOTON-COUNTING DETECTOR COMPUTED TOMOGRAPHY

### PURPOSE

This study aimed to evaluate image quality and diagnostic confidence in lung adenocarcinomas using a cadmium zinc telluride (CZT)-based photon-counting detector computed tomography (PCD-CT).

**METHODS AND MATERIALS**

This prospective study was approved by our institutional review board, and informed consent was obtained from all participants. Twenty-five patients were examined using a CZT-based PCD-CT (TSX-501R, Canon Medical Systems, Otawara, Japan). Eighteen of them (median age 74.5 years, IQR 65-77 years; 13 men; total twenty lesions) were suspected or confirmed as adenocarcinoma in situ, minimally invasive adenocarcinoma, or invasive adenocarcinoma. Two different collimation mode images with adaptive iterative dose reduction 3D (AIDR 3D) were reconstructed; 512 x 512 matrix named as normal resolution (NR) mode, 1024 x 1024 matrix named as super high resolution (SHR) mode. Furthermore, deep learning reconstruction (DLR) was added for SHR mode instead of using AIDR 3D. For qualitative image analysis by the two readers, kappa coefficients of the image findings for lung adenocarcinomas, 5-point Likert scales for image quality, and diagnostic confidence were evaluated. For quantitative image analysis, signal-to-noise ratio (SNR) and tilts of the air abronchiologram after the correction were compared.

**RESULTS**

There were 3 pure ground glass nodules, 10 part-solid nodules, and 7 solid nodules. For qualitative analysis, there were good interobserver agreements in the most features (kappa coefficients > 0.6). Compared to the NR, the SHR with AIDR 3D had significantly higher diagnostic confidence for almost all imaging findings ($P < 0.01$), but significantly lower image noise ($P < 0.01$). In addition, SHR with DLR showed significantly higher image quality and diagnostic confidence than SHR with AIDR 3D. For quantitative analysis, SNR, the minimum and maximum tilts of air bronchiolograms were significantly difference among the three groups ($P = 0.024$, $P < 0.001$, and $P < 0.001$, respectively [Friedman tests]).

**CONCLUSION**

SHR modes showed improved diagnostic confidence for most imaging findings of lung adenocarcinomas. Furthermore, DLR added further improvement of diagnostic confidence and significant reduction of image noise.

**CLINICAL RELEVANCE/APPLICATION**

SHR with DLR can depict the details of lung adenocarcinomas with higher diagnostic confidence with significant reduction of image noise.

## M5A-SPCH-3 PREDICTING HIGH-GRADE PATTERN IN IASLC GRADING SYSTEM OF LUNG ADENOCARCINOMA USING $^{18}$F-FDG PET/CT IMAGING COMBINED WITH CLINICAL FEATURES: A NOMOGRAM APPROACH

Jinju Sun (*Abstract Co-Author*) Nothing to Disclose
Shuangqi Fu (*Presenter*) Nothing to Disclose

**PURPOSE**

The new International Association for the Study of Lung Cancer (IASLC) grading system for invasive lung adenocarcinoma has demonstrated significant prognostic efficacy, benefiting many patients with adjuvant chemotherapy.We aimed to develop a nomogram that integrates PET/CT imaging and clinical features for preoperative prediction of IASLC grading.

**METHODS AND MATERIALS**

This study included 1327 lung adenocarcinoma patients who underwent preoperative 18F-FDG PET/CT and were confirmed by surgical pathology,with retrospective analysis conducted on their images and clinical data.Univariate and multivariate analyses identified independent clinical and imaging variables.Finally,a predictive model and a nomogram were established using multivariable logistic regression analysis.Model performance was evaluated using receiver operating characteristic (ROC) curves and accuracy assessments. Decision curve analysis (DCA) and calibration curves assessed clinical utility.

**RESULTS**

In the training cohort, the PET/CT imaging-clinical combined model effectively predicted patients with high-grade pattern(AUC=0.837),outperforming the PET(AUC=0.789, DeLong, $p<0.05$) or CT (AUC=0.780, DeLong, $p<0.05$) models.Similar superiority was observed in the test cohort (AUC = 0.834),with improved performance over standalone PET (AUC = 0.780, DeLong test, $p < 0.05$) and CT (AUC = 0.767, DeLong test, $p < 0.05$) models.Good calibration and decision curve analysis demonstrated the clinical usefulness of the nomogram.

**CONCLUSION**

The 18F-FDG PET/CT imaging-clinical combined model is effective in predicting high-grade patterns in patients.The derived nomogram aids in identifying patients who would benefit from adjuvant therapy.

**CLINICAL RELEVANCE/APPLICATION**

Utilizing 18F-FDG PET/CT imaging combined with clinical features provides a robust predictive tool for high-grade patterns in lung adenocarcinoma,which helps predict patient prognosis and select individuals to benefit from adjuvant treatment.

## M5A-SPCH-4 BLIND SPOTS FOR RADIOLOGISTS AND LUNG-RADS: ANALYSIS OF CTS OF PATIENTS WHO DIED OF LUNG CANCER DESPITE LUNG CANCER SCREENING

James Brown (*Abstract Co-Author*) Nothing to Disclose
Alexander Beagle (*Abstract Co-Author*) Nothing to Disclose
Masha Bondarenko (*Abstract Co-Author*) Nothing to Disclose
Maya Vella, MD (*Abstract Co-Author*) Nothing to Disclose
Jae Ho Sohn, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hannah Ahn, MD (*Abstract Co-Author*) Nothing to Disclose
Sayedomid Ebrahimzadeh, MD (*Abstract Co-Author*) Nothing to Disclose
Tician Schnitzler, MD (*Abstract Co-Author*) Nothing to Disclose
Adam Yala, PhD (*Abstract Co-Author*) Nothing to Disclose
Ashita Tanwar (*Presenter*) Nothing to Disclose

**PURPOSE**

Lung cancer screening is associated with 20% reduction in lung cancer mortality, but an unanswered question is why many still die of lung cancer despite adherence to screening. Improved understanding of such cases can elucidate potential gaps in screening practices at the individual radiologist and/or the Lung-RADS guideline level.

**METHODS AND MATERIALS**

We retrospectively reviewed National Lung Screening Trial (NLST) data to identify participants who died of lung cancer within 7 years of their first CT, determined by the study's end-point verification process, and whose first CT did not raise suspicion for lung cancer ("negative"). For CTs that had nodule(s) visible in negative scans which eventually became suspicious for lung cancer (determined by a thoracic radiologist), 4 board-certified, thoracic fellowship trained, radiologists individually determined if the nodule was suspicious in the negative scan based on Lung-RADS v2022; for cases with disagreement, adjudication was performed by group consensus discussion.

**RESULTS**

Of NLST's 26,722 patients who received annual CTs, 173 died of lung cancer from 2002-2009 and did not have cancer identified on the baseline CT. We excluded 25 for missing scans, 28 for cancer between screening CTs, and 29 who had 3 negative screens and died more than 2 years after their final screen; 91 NLST participants met inclusion criteria. Upon the radiologists' review and discussion of the cases: 22 (24%) had "missed," retrospectively visible nodules rated Lung-RADS v2022 3/4 (on negative screens) that developed into lung cancer. 18 (20%) had retrospectively visible nodules (on negative screens) that did not meet Lung-RADS criteria ("not callable") and later developed into cancer. 48 (53%) had no nodule visible in retrospect or aggressive cancers that appeared between the 1 year screening interval, and 3 (3.3%) cases were uncategorized due to group disagreement. 45% of missed nodules were peribronchovascular, 14% were juxtapleural, and 18% were obscured by abnormality and many had spiculated morphology. 10 (56%) of not callable nodules were small (<6mm), 6 (33%) were obscured by abnormality, and 4 (22%) were subsolid.

**CONCLUSION**

Commonly "missed" nodules were often juxtapleural, peribronchovascular, or obscured by abnormality, but often with spiculated morphology. Nodules "not callable" as suspicious by Lung-RADS v2022 were often small (<6mm), obscured by abnormality, or subsolid.

**CLINICAL RELEVANCE/APPLICATION**

Retrospective review of lung nodules in screening associated with lung cancer death revealed blind spots for radiologists and/or guidelines, illustrating ways to elevate individual radiologists' diagnostic accuracy and providing valuable data for Lung-RADS improvement.

## M5A-SPCH-6 VOLUMETRIC BODY COMPOSITION METRICS EXTRACTED FROM PET/CT PREDICT CLINICAL OUTCOMES IN NON-SMALL CELL LUNG CANCER PATIENTS

Govind Mattay, MD, MBA (*Presenter*) Nothing to Disclose

**PURPOSE**

Determine whether whole body volumetric body composition metrics extracted from PET/CT predict progression free survival (PFS) and overall survival (OS) in Non-Small Cell Lung Cancer (NSCLC) patients.

**METHODS AND MATERIALS**

206 patients (median age 65 years; 116 females and 90 males) with treatment-naive lung adenocarcinoma (T1-T4, N0-N3, M0-M1) were included in this retrospective analysis. PFS and OS were defined as time from initial pathologic diagnosis to progression and death respectively. Body composition metrics from T1 to the hips were extracted from initial staging FDG PET/CT through automated volumetric CT segmentation (Voronoi Health Analytics Inc). Extracted metrics included total volume, % total body composition, and Hounsfield unit density of different anatomical compartments (adipose tissue, skeletal muscle, bones, and visceral organs). The optimal cutoff value for each metric to predict survival was calculated via biomarker threshold optimization. A Cox proportional hazards univariate regression model was used to determine which variables predicted survival in all patients and males and females separately, with hazard ratios (HR) > 1 indicating a negative impact on survival. The Benjamini-Hochberg procedure was used to control for false discovery rate.

**RESULTS**

Body composition metrics had different effects on PFS and OS. Increased fractional intramuscular fat was associated with worse OS (HR=2.39, p=0.03). Increased fractional subcutaneous fat was associated with worse PFS (HR=1.83,p=0.02), an effect driven by the female sex (female HR=2.10, p=0.01; male HR =2.09, p=0.11). Increased fat attenuation across most compartments were associated with worse PFS and OS. Although higher iliopsoas volume was associated with better PFS in all patients (HR=0.54, p=0.048), total body skeletal muscle had no effect (HR=0.81,p=0.14). Increased trabecular bone density was associated with better OS (HR=0.42, p=0.03). Although increased abdominal aortic calcifications were associated with worse OS in all patients (HR=2.68, p=0.03), cardiac calcifications had no effect (HR=0.65, p=0.06).

**CONCLUSION**

Several body composition metrics were significant predictors of survival in treatment-naive NSCLC patients, however metrics had different effects on PFS and OS and between men and women.

**CLINICAL RELEVANCE/APPLICATION**

Volumetric body composition metrics extracted from PET/CT can aid in prognostication in NSCLC patients. These biomarkers may be useful to tailor lifestyle modifications that improve overall survival and potentially alter tumor biology.

## M5A-SPCH-7 PREDICTION OF SHORT-TERM PULMONARY COMPLICATIONS FOLLOWING LOBECTOMY OR SUB-LOBECTOMY FOR LUNG CANCER USING PREOPERATIVE CHEST QUANTITATIVE COMPUTED TOMOGRAPHY

Wanyi Zheng (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of the predicted postoperative pulmonary function values derived from preoperative chest quantitative computed tomography (QCT) in predicting short-term pulmonary complications (PC) after lobectomy or sub-lobectomy for lung cancer.

**METHODS AND MATERIALS**

Seventy-nine consecutive patients with lung cancer who underwent thoracoscopic lobectomy or sub-lobectomy were enrolled in the study. A chest CT scan and pulmonary function test (PFT) were performed one week before the surgery. Patients were divided into PC+ group (n=16) and PC- group (n= 63) according to the one-week hospitalization. The total functional lung volume (TFLV) and the resection functional lung volume (RFLV) were calculated by QCT method. The predicted postoperative pulmonary function indexes, including preoperative total lung capacity (TLC), forced expiratory volume in the first second (FEV1), forced vital capacity (FVC), and diffusion capacity for carbon monoxide (DLCO), were calculated using the QCT method and the anatomical segmentation (AS) method. PC-related factors were screened by univariable analysis to construct clinical, clinical-PFT, clinical-AS, and clinical-

QCT models. A combined model was constructed using all PC-related parameters. Multivariable logistic regression was used to find independent predictors of PC. Receiver operating characteristic (ROC) analysis was conducted to evaluate the predictive performance.

**RESULTS**

Age, removed number of lung segments, RFLV, RFLV/TFLV in the PC+ group were higher than those in the PC- group (P<0.05); FEV1, FVCQCT, FEV1QCT, FVCAS, and FEV1AS in PC+ group were lower than those in PC- group (P <0.05). FEV1QCT (OR: 0.043, P=0.001) and FVCAS (OR: 12.314, P = 0.048) were independent predictors. Comparison of the areas under the curve: Clinical-QCT (0.851) > Clinical-AS (0.823) > Clinical-PFT (0.803) > Clinical (0.718) model. When all PC-related factors were combined, the area under the curve (AUC) of combined model was the highest of 0.871, with a sensitivity of 75% and a specificity of 88.5% under the optimal cut-off value.

**CONCLUSION**

FEV1QCT is an independent predictor of short-term PC after lung lobectomy or sub-lobectomy, and QCT-based model had high predictive performance.

**CLINICAL RELEVANCE/APPLICATION**

Chest QCT provides quantitative parameters to predict postoperative early complications, providing valuable insights for treatment selection and prognosis assessment.

## M5A-SPCH-8 VALUE OF THE PREDICTED POSTOPERATIVE PULMONARY FUNCTION VALUES CALCULATED FROM PREOPERATIVE CHEST QUANTITATIVE COMPUTED TOMOGRAPHY IN PREDICTING SHORT-TERM PULMONARY COMPLICATIONS AFTER LOBECTOMY OR SUB-LOBECTOMY FOR LUNG CANCER

Wanyi Zheng (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of the predicted postoperative pulmonary function values derived from preoperative chest quantitative computed tomography (QCT) in predicting short-term pulmonary complications (PC) after lobectomy or sub-lobectomy for lung cancer.

**METHODS AND MATERIALS**

Seventy-nine consecutive patients with lung cancer who underwent thoracoscopic lobectomy or sub-lobectomy were enrolled in the study. A chest CT scan and pulmonary function test (PFT) were performed one week before the surgery. Patients were divided into PC+ group (n=16) and PC- group (n= 63) according to the one-week hospitalization. The total functional lung volume (TFLV) and the resection functional lung volume (RFLV) were calculated by QCT. Furthermore, the predicted postoperative pulmonary function indexes, including preoperative total lung capacity (TLC), forced expiratory volume in the first second (FEV1), forced vital capacity (FVC), and diffusion capacity for carbon monoxide (DLCO), were calculated using the QCT method and the anatomical segmentation (AS) method. Univariable analysis was used to screen PC-related parameters which were utilized to construct clinical, clinical-PFT, clinical-AS, and clinical-QCT models. Multivariable logistic regression was used to find independent predictors of PC. Receiver operating characteristic (ROC) analysis was conducted to evaluate the predictive performance.

**RESULTS**

Age, removed number of lung segments, RFLV, RFLV/TFLV in the PC+ group were higher than those in the PC- group (P<0.05); FEV1, FVCQCT, FEV1QCT, FVCAS, and FEV1AS in PC+ group were lower than those in PC- group (P <0.05). FEV1QCT (OR: 0.043, P=0.001) and FVCAS (OR:12.314, P=0.048) were independent predictors. Comparison of the area under the curve: Clinical-QCT (0.851) > Clinical-AS (0.823) > Clinical-PFT (0.803) > Clinical (0.718) model. The sensitivity and specificity of the Clinical-QCT model under the optimal cutoff were 75% and 83.6%, respectively.

**CONCLUSION**

FEV1QCT is an independent predictor of short-term PC after lung lobectomy or sub-lobectomy. The Clinical-QCT model had higher predicting performance than the Clinical-AS and the Clinical-PFT models.

**CLINICAL RELEVANCE/APPLICATION**

Chest QCT provides quantitative parameters to predict postoperative early complications, which can be very important for the selection of treatment strategy and prognosis assessment.

## M5A-SPCH-9 COMPARATIVE ANALYSIS OF SHORT-TERM EFFICACY OF CT-GUIDED PERCUTANEOUS AND NAVIGATION BRONCHOSCOPY-GUIDED ABLATION FOR LUNG CANCER

Weiqing Huang (*Abstract Co-Author*) Nothing to Disclose
Yingying Chen (*Abstract Co-Author*) Nothing to Disclose
Yun Liu (*Abstract Co-Author*) Nothing to Disclose
Chen Huai, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the safety and short-term effect of local control of CT-guided percutaneous ablation and navigation bronchoscopy-guided ablation in the treatment of lung cancer.

**METHODS AND MATERIALS**

A retrospective study was conducted on 65 patients with lung cancer who underwent CT-guided percutaneous ablation and navigation bronchoscopy-guided ablation in our hospital from 2016 to 2023. The percutaneous ablation group comprised 31 patients, while the bronchoscopic ablation group had 34 patients. The basic information, therapeutic information and postoperative follow-up information were collected for the two groups. The local control rate was assessed by analyzing post-operative CT results, and postoperative complications were compared to evaluate the safety. We used SPSS 26.0 for statistical analysis.

**RESULTS**

The results indicate that there was no statistically significant difference in gender, age, tumor origin, tumor size and composition, tumor location, and the distance from the parietal pleura between the two groups (p>0.05). There was also no significant difference in the size of the ablation zone of one month and three months post-procedure,as well as in 3-month complete ablation rate (p>0.05). In terms of complications, the percutaneous ablation group had a higher incidence of pneumothorax (35.5% vs 0.0%, p<0.001) and pleural effusion (25.8% vs 2.9%, p<0.05) as compared to the bronchoscopic ablation group. Nevertheless, the two groups had no significant difference in the incidence rates of post-operative complications such as fever, hemoptysis, and chest pain (all p>0.05).

## CONCLUSION

Based on the current results, percutaneous ablation and bronchoscopic ablation are similar in early local control of lung cancer, while bronchoscopic ablation has a lower complication rate of pneumothorax and pleural effusion.

## CLINICAL RELEVANCE/APPLICATION

The results have important clinical implications as they highlight the need for careful consideration of the potential risks associated with each ablation technique. By understanding the advantages and disadvantages of each ablation technique, clinicians can tailor the treatment approach to individual patients. These findings could assist in clinical decision-making and personalized treatment planning for lung cancer patients, ultimately leading to improved outcomes and quality of life.

Min-Keun (Kevin) Song (*Abstract Co-Author*) Nothing to Disclose
Christiana Cottrell (*Abstract Co-Author*) Nothing to Disclose
Rashad Madi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Gun violence is a public health issue in the US, with over 48,000 deaths per year from related injuries. For patients with gunshot wounds (GSW), CT scans are crucial for identifying injuries sustained from ballistic trauma, including organ injuries, hemorrhage, penetrating fractures, and retained bullet fragments. However, a rapid assessment of multiple GSWs in emergency settings is clinically difficult and risks treatment delays and complications. This work aims to build and assess the capabilities of machine learning pipelines to identify bullet fragments in CT scans quickly, accurately, and precisely for initial emergency care.

### METHODS AND MATERIALS

Using CT scout view images and manual annotations from 1335 patients treated for GSW injuries at an urban Level 1 trauma center from 2019 to 2022, three pipelines built upon pre-existing architectures were trained for bullet detection and segmentation. Pipeline 1 employed a Mask R-CNN model trained on bullet fragment annotations to detect and segment bullet fragments. Pipeline 2 employed a Mask R-CNN model trained on high-density annotations to detect high-density ROIs and then classify and segment bullet fragments. Pipeline 3 used a Faster R-CNN model to detect high-density ROIs, two ResNet50 models to classify images as coronal or sagittal and determine if they contain the patient's head, three ResNet50 models to classify ROIs as bullet fragments, and an FCN model for segmentation.

### RESULTS

Pipeline 3 identified the most bullet fragments at 89-91% prediction intersection of bullet annotations across varying non-maximum suppression intersection over union thresholds (76-79% for pipeline 1, 62-66% for pipeline 2), yielded 88-91% accuracy in ROI classification (63%-71% for pipeline 1, 48-59% for pipeline 2), and also provided the greatest overlap of predicted masks and annotations with a Dice coefficient of 0.488 (0.336 for pipeline 1, 0.247 for pipeline 2). Intermediate models in pipeline 3 classified images as coronal vs sagittal with 98.8% accuracy and containing the head or not with 99.3% accuracy.

### CONCLUSION

Our study demonstrates the potential of deep learning pipelines in rapidly and accurately identifying bullet fragments in CT scans of patients with GSW. Further fine-tuning could enhance bullet fragment detection, potentially matching the performance of radiologists and facilitating the calculation of additional metrics, such as bullet movement over time, to improve clinical decision-making and expedite treatment in emergency settings.

### CLINICAL RELEVANCE/APPLICATION

Deep learning pipelines help clinicians quickly and accurately identify bullet fragments in CT scans of patients with GSW, potentially enhancing treatment efficacy and expediting care in emergency settings.

## M5A-SPER-2 LATENT DIFFUSION MODEL APPROACH FOR DETECTION OF PANCREATIC ABNORMALITIES IN ABDOMINAL CT OF EMERGENCY PATIENTS

Jingyo Jeong (*Abstract Co-Author*) Nothing to Disclose
Jhii Hyun Ahn, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop and to validate a latent diffusion model able to detect pancreatic abnormalities at CT

## METHODS AND MATERIALS

To generate normal abdominal CT images using latent diffusion model, we retrospectively collected contrast-enhanced abdominal CT images obtained from 368 patients (mean age, 53 years ± 12 [SD], 177 women) with a normal pancreas who visited the emergency room. For testing, we used contrast-enhanced abdominal CT images obtained from 8 patients (mean age, 51 years ± 14 [SD], 3 women) with pancreatic abnormality who visited the emergency room. We applied a window level setting (width=350, level=50) before using abdominal CT images for learning to remove unnecessary organs and improve contrast. The proposed latent diffusion model for anomaly detection only trains normal data. The input data converts into Encoded Latent Z using the encoder of a pre-trained Variational Autoencoder (VAE). Noise is added to generate Noised Latent Z through the diffusion process. A Denoising U-Net produces Denoised Latent Z, and the decoder of VAE generates normal images. For the quantitative evaluation of the anomaly detection algorithm, an anomaly map was generated by comparing the differences between the original abdominal CT images of patients with pancreatic diseases and the generated images. The anomaly map was used to classify the images into normal and abnormal class. The proposed algorithm performance was evaluated on a slice-by-slice basis for true positives, true negatives, false positives, and false negatives. In addition, the metrics such as accuracy, sensitivity, specificity, and AUC (area under the receiver operating characteristic curve) were computed using established formulas.

## RESULTS

In the test set, there were 2 chronic pancreatitis, 2 acute pancreatitis, 1 accessory spleen in pancreas tail, 1 pancreas serous cystadenoma, 1 pancreatic duct dilatation, and 1 traumatic transection of pancreas. The latent diffusion model achieved 87.8% accuracy, 95.4% sensitivity, 87.2% specificity and 0.916 AUC for detecting pancreatic abnormalities.

## CONCLUSION

Deep learning model based on latent diffusion model, a generative approach designed to transform images with pancreatic diseases similar to normal data, can accurately detect pancreatic abnormalities on abdominal CT.

## CLINICAL RELEVANCE/APPLICATION

If this proposed model is implemented in the emergency room, it can accelerate the diagnostic process for pancreatic abnormalities and increase diagnostic accuracy, resulting in appropriate treatment and improved prognosis for patients.

## M5A-SPGI-10 DIAGNOSTIC PERFORMANCE OF DUAL ENERGY CT ANGIOGRAPHY (DECTA) FOR GASTROINTESTINAL BLEEDING (GIB)

Sung Yoon Park, MD (*Abstract Co-Author*) Nothing to Disclose
Dushyant Sahani, MD (*Abstract Co-Author*) Advisory Board, Koninklijke Philips NV;Advisory Board, Canon Medical Systems Corporation;Advisory Board, General Electric Company;
Sarabjeet Singh, MD, MBA (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Toshiba Corporation;Research Grant, General Electric Company;Research Grant, Koninklijke Philips NV
Karthika Devi D S, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

Gastrointestinal bleeding (GIB) is a potential life-threatening condition and accurate detection of the cause is crucial for timely management. The purpose of the study was to assess the role of DECTA in the evaluation of potential causes of GIB.

### METHODS AND MATERIALS

In an IRB-approved retrospective study (January 2023 - December 2023), 1744 consecutive DECTA exams for suspected GIB. DECTA were evaluated. CTA were performed on fast kV switching (Revolution Apex, GE) Dual source (Definition Force, Siemens). Images were acquired with NC, Art late venous phase after iodinated CM (Omnipaque 350 GE) at 3-5.5 cc/s. Images were reconstructed as axial, coronal, sagittal, MIPS (coronal) and MD-iodine. Two readers (30 15 years of experience) independently evaluated for active GIB or potential source of bleeding. Subjective image assessment was graded on 5-point Likert scale for image quality diagnostic confidence. MD-I images were evaluated after the initial assessment for the findings and readers confidence.

### RESULTS

A total of 59/1744 (3.3%) exams were rated CT positive for active GIB or potential source of bleeding. Active bleed as qualified by contrast extravasation was detected in 25/59 (42.3%) exams. Additional diagnostic/interventional procedures were performed in 17/25 (68%) patients. GIB sites were detected in stomach (n=5), duodenum (n=4), jejunal (n=3) colon (ascending n=1, transverse n=3, sigmoid n=3), rectal (n=2) and omental (n=1) region. In 34 patients with no active bleed on CTA, potential bleeding source was identified in 25 (73.5%). MDI images helped improve diagnostic confidence for detection in 39.5 % cases. In cases with reference standard verification (n=32) the calculated sensitivity and specificity for DECTA were 80.0% 81.8 % respectively.

### CONCLUSION

CTA is frequently ordered exam in patients with suspected GIB with overall low yield (3.3%) for positive findings. DECTA helps in accurate detection of active bleeding as well as in identifying a potential source of bleeding.

### CLINICAL RELEVANCE/APPLICATION

Imaging with dual-energy CT angiography helps fast accurate diagnosis of gastrointestinal bleeding and can show precise location or source, thereby guiding next steps in clinical management.

## M5A-SPGI-2 QUANTITATIVE ANALYSIS OF THE STAGING OFHEPATIC FIBROSIS INANIMALS USING SPECTRALCT MATERIAL DECOMPOSITION: FOCUSING ON THE EFFECT OF HYDROGEN PEROXIDE

Bo Duan (*Abstract Co-Author*) Nothing to Disclose
Qingyu Ji (*Abstract Co-Author*) Nothing to Disclose
Yan Gao (*Abstract Co-Author*) Nothing to Disclose
Hongliang Li (*Abstract Co-Author*) Nothing to Disclose
Runyu Miao (*Abstract Co-Author*) Nothing to Disclose
Lu Wang (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to explore the clinical value of hydrogen peroxide in the staging of hepatic fibrosis (HF) by means of spectral CT material decomposition technique.

**METHODS AND MATERIALS**

Twenty-five healthy New Zealand white rabbits were randomly divided into control group (n = 5) and experimental group (n = 20). The experimental group was injected with 10% carbon tetrachloride olive oil solution to establish the model of liver fibrosis. At 5, 7, 9 and 11weeks, 5 rabbits in the experimental group and 1 rabbit in the control group were randomly selected to undergo spectral CT unenhanced scan and arterial phase enhanced scan (80kVp-140kVp, 405 mA). All images were transferred into the AW 4.7 workstation and image post-processing was performed using the GSI Viewer software, and images containing only hydrogen peroxide were generated by the spectral CT material decomposition technique. Regions of interest (ROI) was placed on the lesion images, and to avoid individual differences, the same size ROI was placed within the aorta at the same level in order to calculate the normalized hydrogen peroxide concentration (NHPC). Liver tissue samples from all experimental rabbits were collected to assess the staging of HF using pathologic tests. The NHPC and the pathological staging of the liver were used as the evaluation indexes, and statistics were analyzed by analysis of variance (ANOVA) to compare the differences between groups, with $P < 0.05$ indicating a statistically significant difference.

**RESULTS**

To compare the difference of NHPC in arterial phase between the staging of HF, ANOVA was used in this study, and the results showed that NHPC in each fibrosis stage was F0 (0.89±0.07), F1 (0.99±0.08), F2 (0.96±0.15), F3 (1.08±0.50), and F4 (1.11±0.71), and the difference between the groups was statistically significant ($F=3.269$, $P<0.05$). The diagnostic efficacy of NHPC in differentiating the staging of HF in the arterial phase was well demonstrated, with an area under the curve of 0.082, $p<0.05$, and a 95% confidence interval of (0.676-0.998).

**CONCLUSION**

NHPC of liver at spectral CT material decomposition showed correlation with the stages of HF and has a good diagnostic performance.

**CLINICAL RELEVANCE/APPLICATION**

Quantitative measurement of hydrogen peroxide concentration using spectral CT material decomposition provides a noninvasive method for clinical diagnosis of HF stages compared with liver histopathological examination.

## M5A-SPGI-3 QUANTITATIVE ASSESSMENT OF SPLENIC HEMODYNAMICS BY LOW-DOSE MULTI-PARAMETER CT FOR PREDICTING HIGH-RISK ESOPHAGEAL VARICES IN CIRRHOSIS

Cheng Yan (*Abstract Co-Author*) Nothing to Disclose
Liqin Zhao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of splenic hemodynamic parameters from low-dose one-stop dual-energy and perfusion CT (LD-DEPCT) in non-invasively predicting high-risk esophageal varices (HREV) in cirrhotic patients.

**METHODS AND MATERIALS**

We retrospectively analyzed cirrhotic patients diagnosed with esophageal varices (EV) through clinical, laboratory, imaging, and endoscopic examinations from January 2019 to December 2023 in two hospitals. All patients underwent LD-DEPCT to acquire splenic iodine concentration and perfusion parameters. Radiation dose was recorded. Patients were classified into non-HREV and HREV groups based on endoscopy. Imaging parameter differences between groups were evaluated through independent sample t-tests and Mann-Whitney U tests. Predictive accuracy was determined by analyzing receiver operating characteristic curves and calculating the area under the curve (AUC) values. $P < 0.05$ was considered statistically significant.

**RESULTS**

The 89 patients were divided into the non-HREV (n=33) and the HREV groups (n=56). The total radiation dose was 20.66 ± 4.07 mSv. There were significant differences in portal iodine concentration (PIC), blood flow (BF), permeability surface (PS), spleen volume (V-S), total iodine concentration (TIC), and total blood volume of the spleen (BV-S). TIC showed the highest predictive efficacy (AUC=0.87), with 91.07% sensitivity and 81.82% specificity at a cutoff of 1283.41 mg.

**CONCLUSION**

Splenic hemodynamic parameters obtained from LD-DEPCT can non-invasively and accurately assess the hemodynamic status of the spleen in cirrhotic patients with EV and predict the occurrence of HREV.

**CLINICAL RELEVANCE/APPLICATION**

CT multi-parameter obtained using low-dose one-stop dual-energy and perfusion CT present significant clinical application value in noninvasively evaluate HREV.

## M5A-SPGI-7 IDENTIFICATION OF BENIGN OR MALIGNANT LIVER MASSES USING CORRECTED EFFECTIVE ATOMIC NUMBER

Mitsunari Maruyama (*Presenter*) Nothing to Disclose

**PURPOSE**

To examine whether hepatic hemangiomas and malignant liver masses (hepatocellular carcinomas/liver metastases) can be differentiated using corrected effective atomic numbers on plain CT images.

**METHODS AND MATERIALS**

Plain and contrast-enhanced Dual-energy CT was performed on 96 patients (132 liver masses) using the 256-row CT (Revolution Apex Elite, GE HealthCare, Waukesha, WI, USA) ) from October 2023 to March 2024. There were 49 hepatic hemangiomas (Hemangioma), 43 hepatocellular carcinomas (HCC), and 40 liver metastases (Meta). Of the 40 Meta, 17 were colon cancer metastases and 23 were pancreatic cancer metastases. AW Server3.2 Ext. 4.9 was used to establish and measure a 10 mm diameter region of interest (ROI) in the tumor on the plain CT images. The ROI was set in the area where there was no degeneration, referring to contrast-enhanced CT. Corrected effective atomic numbers (Zeff) were calculated from the actual measurement Zeff and the Liver fat value (%) on plain CT images using the following formula: Corrected Zeff=[Actual measurement Zeff - 6.27*Liver fat value (%)/100] / [1-Liver fat value (%)/100]. Mean Corrected Zeff was compared among the Hemangioma, HCC, and Meta groups.

**RESULTS**

The Mean Corrected Zeff was as follows: Hemangioma,7.618±0.114; HCC,7.771±0.123; Meta, 7.756±0.204. There was a significant difference between Corrected Zeff (Hemangioma vs. HCC, $p< 0.001$; Hemangioma vs. Meta, $p< 0.001$; Tukey's multiple comparison test). There was no significant difference

between HCC and Meta. When malignant liver mass was defined as HCC/meta, the corrected Zeff > 7.666 differentiated malignant liver mass and Hemangioma with a sensitivity of 80.7% and specificity of 71.4% (AUC = 0.771, p = 0.042).

## CONCLUSION

Corrected effective atomic numbers > 7.666 on plain CT could distinguish malignant liver masses (hepatocellular carcinomas/liver metastases) and hepatic hemangiomas with a sensitivity of 80.7% and specificity of 71.4% (AUC = 0.771, p = 0.042).

## CLINICAL RELEVANCE/APPLICATION

Corrected effective atomic numbers (Zeff) were calculated from the actual measurement Zeff and the Liver fat value (%) on plain CT using the following formula: Corrected Zeff=[Actual measurement Zeff - 6.27*Liver fat value (%)/100] / [1-Liver fat value (%)/100]. Corrected effective atomic numbers > 7.666 could distinguish malignant liver masses (hepatocellular carcinomas/liver metastases) and hepatic hemangiomas with a sensitivity of 80.7% and specificity of 71.4% (AUC = 0.771, p = 0.042).

Filippo Ceccato (*Abstract Co-Author*) Nothing to Disclose
Irene Tizianel (*Abstract Co-Author*) Nothing to Disclose
Alessandro Toniolo, MD (*Presenter*) Nothing to Disclose

### PURPOSE

We studied the application of CT texture analysis in adrenal incidentalomas with baseline characteristics of benignity highly suggestive for adenoma to find whether there is a correlation between the extracted features and the secretory and clinical data. Patients with non-functioning adrenal adenomas normally do not require any intervention, otherwise those with hormonal hypersecretion are worthy to be further clinically investigated, even if it does not cause any symptoms. This study utilizes CT and a radiomic-based machine-learning approach to predict mild autonomous cortisol secretion by adrenal incidentalomas.

### METHODS AND MATERIALS

A total of 206 patients (mean age 65.9 years; 113 female) between 2005 and 2020 affected by adrenal incidentaloma were retrospectively enrolled. On the basis of the biochemical and endocrinological evaluation the patients were divided into those with Non-Functioning Adrenal Adenomas (NFAI, n=115), and with Mild Autonomous Cortisol Secretion (MACS, n=91). After a resampling of all CT images, the adenomas were delineated using LifeX in the unenhanced phase and 136 texture parameters were extracted for each volume of interest (VOI). Highly correlated features were removed, and the entire group was then randomly divided in a training cohort of 143 patients and in a validation cohort of 63. Random Forest was used both in the training and validation cohorts to test the accuracy of CT textural features and cortisol-related comorbidities in identifying MACS patients.

### RESULTS

Twelve parameters were retained in the Random Forest radiomic model, that showed a 100% sensitivity and specificity in the training cohort. In the validation cohort, high specificity (81%) and positive predictive value (74%) were achieved by the model, however the sensitivity (39%) and negative predictive value (50%) obtained were relatively low. Noteworthy, if the data about presence or absence of comorbidities linked to cortisol hypersecretion, such as hypertension, diabetes, dyslipidemia and osteoporosis, were added in the model, the results did not differ, confirming a 100% sensitivity and specificity in the training cohort and an 81% specificity and a 39% sensitivity in the validation group.

### CONCLUSION

Radiomic analysis of adrenal incidentalomas with characteristics highly suggestive of benignity, in unenhanced CT scans, could screen with a good specificity those patients who will need a further endocrinological evaluation for mild autonomous cortisol secretion, regardless of the clinical information about the cortisol-related comorbidities.

### CLINICAL RELEVANCE/APPLICATION

Radiomic analysis performed at unenhanced CT scans could predict mild autonomous cortisol secretion by adrenal incidentalomas with a benign aspect.

## M5A-SPGU-2 CYSTITIS GLANDULARIS: MR IMAGING CHARACTERISTICS IN 27 PATIENTS

Haiyi Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Mengqiu Cui (*Abstract Co-Author*) Nothing to Disclose
Bai Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Honghao Xu (*Abstract Co-Author*) Nothing to Disclose
Liu Haili (*Abstract Co-Author*) Nothing to Disclose
Chen Yijian (*Abstract Co-Author*) Nothing to Disclose
Yuanhao Ma (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the diagnostic characteristics of Cystitis Glandularis (CG) using magnetic resonance imaging (MRI).

### METHODS AND MATERIALS

A retrospective consecutive study was conducted on patients who underwent bladder MRI examination at the First Medical Center of Chinese PLA General Hospital between January 2019 and November 2023, who also underwent pathological biopsy within one month. Image analysis was jointly conducted by two radiologists with 20 and 15 years of experience in imaging diagnosis of urologic diseases, respectively.

### RESULTS

A total of 27 patients were included in the study (median age 47 years, 24 males) (Table 1). CG lesions are commonly located in the bladder trigone area (18/27); in terms of morphology, they can be categorized as focal thickening (17/27), nodular (8/27), and diffuse thickening of the entire bladder (2/27). On T2-weighted imaging (T2WI), (15/17) patients appeared as slightly hyperintense thickened inner layer (comparing to obturator internus), and there was a higher signal in the central thickened inner layer, resembling a "sandwich sign" (Figure 1), and (6/8) patients presented with slightly hyperintense nodules. (19/27) patients showed slightly hypointense on T1-weighted imaging (T1WI) (lesion signal slightly lower than obturator internus signal), and lesions on DWI were mainly high (5/27) and slightly high signal (21/27), with an average ADC value of 2.171 ± 0.052 × 10-3mm2/s. Among the 23 patients who underwent dynamic contrast-enhanced scanning, (18/23) lesions showed mild enhancement in the arterial phase (average 1.7 times comparing to unenhanced phase), and the degree of enhancement gradually increased in the venous and delayed phases (average 2.2 and 2.3 times compared to the unenhanced phase, respectively), showing a "progressive" enhancement pattern (Figure 2).

### CONCLUSION

On MRI, the majority of CG manifest as focal thickening or nodules in the bladder trigone area, showing slightly hyperintense on T2WI, slightly hypointense on T1WI, a “progressive” enhancement pattern, without significant restriction on DWI. Focal thickening lesions may exhibit a special “sandwich sign”.

### CLINICAL RELEVANCE/APPLICATION

To clarify the MRI diagnostic features of Cystitis Glandularis.

## M5A-SPGU-3 CT TEXTURE ANALYSIS TO PREDICT RESPONSE TO EDP-M CHEMOTHERAPY IN PATIENTS WITH ADRENOCORTICAL CARCINOMA

Filippo Crimi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Francesca Turatto, MD (*Abstract Co-Author*) Nothing to Disclose
Maurizio Iacobone (*Abstract Co-Author*) Nothing to Disclose
Irene Tizianel (*Abstract Co-Author*) Nothing to Disclose

Filippo Ceccato (*Abstract Co-Author*) Nothing to Disclose
Emilio Quaia, MD (*Abstract Co-Author*) Speakers Bureau, Bracco Group
Cristina Campi, PhD (*Abstract Co-Author*) Nothing to Disclose
Carlo D'Alessandro, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Adrenocortical carcinoma (ACC) is a rare and highly aggressive malignancy, which typically has a poor prognosis. Locally advanced and metastatic ACC represent respectively 18%-26% and 21%-46% of ACC at diagnosis, and these patients usually undergo chemotherapy with etoposide, doxorubicin, cisplatin and mitotane (EDP-M). The value of image-based texture features as a powerful method to assist clinical management in cancer patients has been established recently. We aimed to analyze the association between response to EDP-M treatment and textural features in patients with locally advanced or metastatic ACC.

### METHODS AND MATERIALS

17 patients who underwent adequate pretreatment and post-treatment CT images were included. Response to treatment was assessed by using RECIST 1.1, Choi and volumetric criteria. A literature-based comprehensive approach, used as our gold standard, allowed us to binary classify responders and non-responders. Texture features were obtained from the largest tumoral lesion of each patient using LifeX freeware, and we compared the two groups to highlight features with significant differences. With the parameters selected, ROC curves were drawn to evaluate the accuracy in detecting responders to EDP-M therapy.

### RESULTS

The long-run high grey level emphasis (LRHGLE_GLRLM) and the intensity-histogram kurtosis features showed good ability to discriminate responders and non-responders (AUC of 0.8; 95%CI 0.55-1.0; 95%CI 0.55-1.0), with higher accuracy if considered together (AUC of 0.9; 95%CI 0.724-1.0).

### CONCLUSION

Texture parameters from routinely performed CT images could be used as an independent imaging tool for predicting response to chemotherapy with EDP-M regimen. We also conjecture that coarser and more heterogeneous texture features could represent more favorable behavior in these patients. However, further research is needed.

### CLINICAL RELEVANCE/APPLICATION

Radiomic features obtained from the texture analysis of primitive or metastatic lesions in CT performed routinely, may predict response to therapy with EDP -M in patients with advanced and/or metastatic adrenocortical carcinoma.If validated by further studies, this information could be used as an independent parameter to predict response to chemotherapy in patients with adrenocortical carcinoma.

## M5A-SPGU-4 CORRELATION OF PROSTATE WHOLE GLAND AND ZONAL VOLUMES AND RISK OF TRANSITION ZONE PROSTATE CANCER

Gu Mu Yang Zhang, MD (*Abstract Co-Author*) Nothing to Disclose

Lili Xu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the role of prostate whole gland volume (Vwg) and zonal volumes in prostate cancer pathogenesis by analyzing their correlation with transition zone clinically significant prostate cancer (csPCa).

**METHODS AND MATERIALS**

Patients who underwent prostate biopsy, radical prostatectomy, or follow-up diagnosed benign disease at our institution between January 2019 and December 2022 were retrospectively enrolled. A previously developed prostate zonal segmentation model was utilized to segment prostate zonal glands and calculate the Vwg, transition zone volume, and peripheral zone volume. Prostate zonal volumes and clinical risk factors were subjected to univariate analysis and multivariate analysis, with subgroup analyses based on significant clinical variables. Prostate volume was also evaluated concerning cancer aggressiveness. Receiver operating characteristic (ROC) curves were generated to evaluate and compare the diagnostic performance for csPCa.

**RESULTS**

The study included 821 patients (median age: 65 [59-71] years), with 120 diagnosed with csPCa. Univariate followed by multivariate analysis identified age, prostate-specific antigen (PSA), Prostate Imaging-Reporting and Data System (PI-RADS) score, and Vwg as independent csPCa risk factors (OR: 1.065, 1.088, 2.380, and 0.942, respectively, all $P < 0.05$). Subgroup analysis showed that in patients with different PI-RADS categories, PSA levels, and age groups, the non-csPCa group consistently exhibited significantly higher Vwg compared to the csPCa group, except those under 55 years. No statistical significance was noted between patients with different cancer aggressiveness. Diagnostic performance analysis revealed that incorporating Vwg into the model with age, PSA, and PI-RADS significantly improved diagnostic efficacy (area under the ROC curve: 0.909 vs 0.635—0.810, all $P < 0.05$).

**CONCLUSION**

Prostate whole gland volume is an important protective factor for transition zone csPCa but was not correlated with cancer aggressiveness. Integrating prostate whole gland volume with clinical factors enhances diagnostic accuracy for transition zone csPCa.

**CLINICAL RELEVANCE/APPLICATION**

This study underscores the significance of prostate whole gland volume in the pathogenesis of transition zone csPCa, which could improve diagnostic accuracy and inform decision-making in prostate cancer management.

## M5A-SPGU-5 COMPARISON OF MRI-DIRECTED TRANSRECTAL ULTRASOUND (TRUS)-GUIDED VERSUS MRI-DIRECTED TRANSPERINEAL (TP)-GUIDED FUSION PROSTATE BIOPSY FOR DIAGNOSIS OF PROSTATE CANCER: A PRAGMATIC RANDOMIZED CONTROL TRIAL

Nicola Schieda, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare any prostate cancer (PCa) and clinically significant (CS)-PCa detection rates for TP-guided and TRUS-guided fusion prostate biopsy.

**METHODS AND MATERIALS**

This IRB approved study is a pragmatic randomized control trial which was conducted at a single tertiary-care referral center for PCa from October 2022 to May 2024 (Trial# NCT03936127). Patients with abnormal (=1 lesion, PI-RADS score =3) prostate MRI performed within 6-months of planned targeted prostate biopsy were recruited. Men were randomized to undergo either TP-guided or TRUS-guided targeted fusion biopsy. Patients and biopsy-operators were unblinded to allocation. PCa and CS-PCa diagnosis by lesion was retrieved from histopathology reports and compared overall and stratified by PI-RADS, lesion location and clinical indication using mixed-effect logistic regression modelling. Procedure-related pain score (1-10) and complications (infection, sepsis, bleeding) were also compared.

**RESULTS**

Preliminary data analysis included 182 patients (45%; 81/182 TRUS, 55%; 101/182 TP) with 250 lesions. There were 73% (183/250) peripheral zone (PZ) and 27% (67/250) transition zone (TZ) lesions and 10% (24/250) lesions located at the prostate base, 32% (80/250) at the prostate apex and the remaining 58% (146/250) lesions encompassing the mid-gland. Overall, any-PCa and CS-PCa cancer detection were: 64% (52/81) TRUS and 76% (77/101) TP ($p=.08$) and 46% (37/81) TRUS and 53% (54/101) TP ($p=0.30$). There was no difference in CS-PCa stratified by PI-RADS score comparing TRUS and TP biopsy ($p>0.05$). In the TZ, for TRUS: 45% (14/31) any-PCa and 10% (3/31) CS-PCa; and, for TP: 53% (19/36) any-PCa and 28% (10/36) CS-PCa. Comparing biopsy techniques for the prostate base, for TRUS: 45% (5/11) any-PCa and 36% (4/11) CS-PCa; and, for TP 72% (13/18) any-PCa and 13% (1/8) CS-PCa. For the prostate apex, for TRUS: 71% (30/42) any-PCa and 52% (14/27) CS-PCa; and, for TP: 70% (38/54) any-PCa and 57% (17/30) CS-PCa. No difference was noted comparing TRUS to TP for any lesion location ($p>0.05$). Mean pain scores were: 3±2 (IQR 1-4) TRUS versus 3±2 (IQR 2-5), $p=0.20$. There was one case of urinary retention, 1 urinary tract infection and 1 case of urosepsis in the TRUS group only.

**CONCLUSION**

This pragmatic RCT shows no difference in any-PCa and clinically significant PCa diagnosis comparing TP-guided and TRUS-guided targeted prostate biopsy overall, stratified by PI-RADS score and lesion location.

**CLINICAL RELEVANCE/APPLICATION**

There is no difference in prostate cancer detection comparing TRUS and TP guided fusion biopsy.

## M5A-SPGU-6 CT-BASED RADIOMICS ANALYSIS CAN DIFFERENTIATE ADRENAL PHEOCHROMOCYTOMAS FROM ADENOMAS WITH HIGH ACCURACY: RESULTS IN 170 MASSES

William W. Mayo-Smith, MD (*Abstract Co-Author*) Nothing to Disclose
Oleg S. Pianykh, PhD (*Abstract Co-Author*) Nothing to Disclose
Justine A. Barletta, MD (*Abstract Co-Author*) Nothing to Disclose
Jay B. Patel, PhD (*Abstract Co-Author*) Nothing to Disclose

Melissa Viator, BS, MS (*Abstract Co-Author*) Nothing to Disclose
Christopher Bridge, DPhil (*Abstract Co-Author*) Institutional support, NVIDIA Corporation;Institutional support, General Electric Company;Institutional support, Nuance Communications, Inc
Daniel I. Glazer, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To identify optimal CT-based radiomics features that can differentiate adrenal pheochromocytomas from adenomas

**METHODS AND MATERIALS**

An institutional pathology database was queried to retrospectively identify unique patients with pathologically proven adrenal pheochromocytomas from 5/1/05-5/1/23. In addition to tissue confirmation of pheochromocytoma, patients needed to have a contrast-enhanced abdominal CT with an adrenal mass available in the electronic health record (n=95). The adrenal glands were segmented using a previously validated machine learning algorithm. To serve as a comparison, 75 adrenal adenomas were identified from a previously reported and segmented dataset of 991 consecutive portal venous phase CT examinations. Pheochromocytoma segmentations were reviewed and corrected if needed by a board-certified abdominal radiologist with 9 years post-fellowship experience. The final dataset consisted of 170 adrenal masses (95 pheochromocytomas and 75 incidental nodules) with 136 used in the development set and 34 in the test set. Following confirmation of accurate segmentation, 457 different radiomics features were evaluated and used to create a Boolean rule model. Performance of the Boolean rule model was cross-validated and reported using F1 score on the test set.

**RESULTS**

The study cohort included 65 males and 105 females with mean age 61 years. The Boolean rule-learning model determined that the single feature most predictive of pheochromocytoma was maximum pixel attenuation of > 137 HU, producing an F1 score of 0.85. For a two-feature model, adding grey scale non-uniformity of > 30 to the model achieved an F1 score of 0.94 (Figure). Increasing the model to three features produced only a minor increase in F1 score (0.97).

**CONCLUSION**

A two-feature machine learning model utilizing maximum pixel attenuation > 137 HU and non-grey scale uniformity > 30 is highly predictive of adrenal pheochromocytoma.

**CLINICAL RELEVANCE/APPLICATION**

Identifying adrenal lesions that require further management is challenging as etiologies other than adenomas are uncommon. CT-based radiomics may add value by diagnosing a nodule as a pheochromocytoma based on hyperenhancement and heterogeneity without additional testing.

## M5A-SPGU-7 CT UROGRAPHY FOR HEMATURIA: IMPACTS OF RISK-STRATIFICATION

Jody Riherd, MD (*Abstract Co-Author*) Nothing to Disclose
Ian P. Rumball, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

While recent guidelines support risk-stratified evaluation for hematuria, discrepancies remain between exact criteria for imaging use and selection, and engrained utilization patterns may lead to excess use of CT Urography (CTU) despite potential for adverse effects and poor diagnostic performance in certain populations. We investigated the prevalence of benign and malignant causes of hematuria found on CTU in patients of varying pre-test risk, evaluated diagnostic performance of CTU for urologic malignancy, and identified adherence to recent diagnostic guidelines.

**METHODS AND MATERIALS**

969 consecutive patients who underwent primary CTU for hematuria at a rural academic medical center between 1/1/2021 - 7/31/2023 were included. Cases were divided into microscopic and gross hematuria, and risk-stratified according to the 2020 American Urologic Association (AUA) and 2023 Dutch Association of Urology guidelines. CTU, cystoscopy, and pathology reports were reviewed to assess prevalence of benign and malignant hematuria etiologies on CTU and diagnostic performance of CTU for urologic malignancy.

**RESULTS**

658 cases (68%) had a potential cause for hematuria found on CTU, of which 466 (48%) were suggestive of benign hematuria etiologies and 192 (20%) were suggestive of malignant hematuria. When compared to cases in which AUA did not recommend CTU, the cohort of AUA-concordant CTUs (N=917) had improved CTU detection of all hematuria causes (70% vs 35%; $p<0.001$) and suspected malignancies (21% vs 3.8%; $p=0.003$). Similar trends were found for the Dutch criteria (N=687, 75% vs 50%; $p<0.001$, 23% vs 11%; $p<0.001$). For urologic malignancy, CTU had a diagnostic yield of 11.2% and a false referral rate of 1.5%. 94.6% of CTUs ordered were in concordance with AUA guidelines, compared to 70.1% for the Dutch guidelines.

**CONCLUSION**

Application of risk-stratifying guidelines improved the performance of CTU for detecting urologic abnormalities and malignancies that cause hematuria. Imaging obtained according to the 2020 AUA criteria detected malignancy at a comparable rate compared with the 2023 Dutch criteria (21% vs 23%), with a lower rate of suspected malignancy among cases where CTU was not suggested (3.8% vs 11%) at the expense of 230 more recommended studies. Our study displayed a strong diagnostic yield of CTU for urologic malignancy, perhaps related to high guideline adherence.

**CLINICAL RELEVANCE/APPLICATION**

Application of the 2020 AUA and 2023 Dutch criteria can improve diagnostic performance of CTU, though increased imaging utilization or a higher rate of missed malignancy, respectively, are trade-offs when comparing the two.

## M5A-SPGU-9 COMPREHENSIVE EVALUATION OF DEEP LEARNING RECONSTRUCTION IN ULTRA-LOW-DOSE CT FOR UROLITHIASIS: ASSESSING IMAGE QUALITY AND LESION DETECTION IN PHANTOM AND CLINICAL SCENARIOS

Min Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose
Lili Xu (*Abstract Co-Author*) Nothing to Disclose
Hao Sun, MD (*Abstract Co-Author*) Nothing to Disclose
Xin Bai III, MD (*Abstract Co-Author*) Nothing to Disclose
Gu Mu Yang Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaoxiao Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the efficacy of the Advanced Intelligent Clear-IQ Engine (AICE), a deep learning reconstruction algorithm, in enhancing image quality and lesion detection in ultra-low-dose-CT (ULDCT) for urolithiasis, comparing with various reconstruction algorithms across phantom and clinical images

## METHODS AND MATERIALS

A phantom containing high-contrast and low-contrast objects of 2 mm, 5 mm, and 8 mm sizes underwent scanning at low-dose and ultra-low dose radiation levels. Low-dose images were reconstructed with the Adaptive Iterative Dose Reduction 3D algorithm (LD-AIDR), while ultra-low-dose images were reconstructed using different methods including filtered back projection (ULD-FBP), Adaptive Iterative Dose Reduction 3D (ULD-AIDR), Forward-projected model-based Iterative Reconstruction SoluTion (ULD-FIRST), AICE (ULD-AICE), and sharp AICE (ULD-AICEs). Quantitative metrics such as noise power spectrum (NPS), task transfer function (TTF), and detectability were assessed. Clinical patients with suspected urolithiasis underwent LDCT and ULDCT, with images reconstructed similarly to the phantom. Radiation dose, stone characteristics, lesion detection and subjective image quality were evaluated.

## RESULTS

In phantom images, ULD-AICEs exhibited superior detectability of high-contrast and low-contrast objects across all sizes compared to LD-AIDR images and other ULD methods ($P < 0.01$). ULD-AICEs demonstrated significantly higher TTF10%, and TTF 50% for high-contrast objects, as well as higher TTF10% for low-contrast objects compared to LD-AIDR ($P < 0.01$). ULD-AICEs also showed significantly lower NPS than LD-AIDR. In clinical patients, the average effective radiation dose of ULDCT was significantly lower than that of LDCT ($1.34 \pm 0.37$ vs. $6.33 \pm 0.98$ mSv, $p < 0.01$). LD-AIDR detected 129 urinary stones and ULD-AICEs detected 123 out of 129 stones, achieving the highest detection rate of 95.34% compared to other reconstruction methods. Stone characteristics in ULD-AICEs were comparable to LD-AIDR. Moreover, ULD-AICEs exhibited the highest lesion detection rate (92.2%, 60/64) among all reconstructions, according to LD-AIDR, which serves as the gold standard. The ULD-AICEs demonstrated superior image quality with the lowest noise and highest SNR, except in fat, and achieved the highest average subjective score.

## CONCLUSION

The AICEs reconstruction algorithm demonstrates promise in optimizing ULDCT for urolithiasis, offering superior lesion detection and image quality enhancement across phantom and clinical studies.

## CLINICAL RELEVANCE/APPLICATION

AICE emerges as a preferred reconstruction algorithm for ULDCT in urolithiasis, potentially enhancing diagnostic accuracy and patient care in urological imaging.

## M5A-SPHN-2 EVALUATION OF FACIAL NERVE IMAGING USING CRANI IN PAROTID GLAND PATHOLOGIES: A PRELIMINARY EXPERIENCE

Ullas V. Acharya, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Uday D. Patil, MD (*Abstract Co-Author*) Research Consultant, General Electric Company
Georgina George, MD, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

The intracranial portions of cranial nerves are visualized using heavily T2-weighted 3D imaging; however, visualizing the extracranial portions of these nerves remains difficult due to their small diameters, tortuous courses, susceptibility artifacts, blood vessels, all of which can confound nerve visualization. Post-contrast 3D CRANI adequately suppresses signals from surrounding blood vessels and fat, enabling better visualization of extra foraminal cranial nerves. In this study, 3D CRANI was tested in its clinical application to view the extra-foraminal facial nerve and its branches, particularly in relation to parotid gland pathologies.

### METHODS AND MATERIALS

A post-contrast CRANI sequence was acquired in a 3T system scanner (Philips, Ingenia) with a 32-ch head coil to evaluate the extraforaminal course of the facial nerve in a total of 10 cases, 8 associated with parotid lesions, 1 with lymphomatous involvement of the nerve, and 1 with facial neuritis. The nerve was visualized and evaluated with multiplanar reformations and maximum intensity projections of post-gadolinium CRANI images with a thickness of 5mm and an overlapping slice gap of -0.5mm. Three radiologists—one with three years of experience, one with thirteen years as a neuroradiologist, and one with over thirty years as a senior radiologist—reviewed the pictures and reached a consensus.

### RESULTS

The extraforaminal segment of the facial nerve was well visualized in all cases up to its bifurcation, demonstrating its relationship with the parotid lesion. In a case of lymphoma, the extent of the lymphomatous involvement of the extraforaminal portions of both facial nerves was well visualized, which was seen as focal, segmental thickening as compared to diffuse, uniform thickening of the nerve seen in a case of facial neuritis, i.e. Bell's palsy. The visualization and tracing of distal branches of the facial nerve after its bifurcation in relation to the lesion were, however, poor.

### CONCLUSION

This study illustrated the ability of this unique MR neurography sequence to create nerve-selective imaging and detail the relationship of the facial nerve in parotid pathologies within clinically reasonable acquisition times.

### CLINICAL RELEVANCE/APPLICATION

Understanding the facial nerve and its relationship to a parotid gland lesion can allow surgeons to make better preoperative assessments. This enables surgeons to choose and perform extracapsular parotid dissections over superficial parotidectomies, significantly enhancing facial nerve preservation and function in selected cases. Although this is an early study demonstrating the effectiveness of this unique MR sequence, it is certain to spark interest in analyzing other cranial nerve courses and pathologies.

## M5A-SPHN-3 THE VALUE OF SYNTHETIC MRI IN DISCRIMINATING METASTATIC AND NON-METASTATIC LYMPH NODES IN HNSCC, COMPARED WITH DWI AND MULTI-RADIOLOGISTS

Fan Yang (*Abstract Co-Author*) Nothing to Disclose
Meng Lin (*Abstract Co-Author*) Nothing to Disclose
Xiaoduo Yu (*Abstract Co-Author*) Nothing to Disclose
Haoran Wei (*Presenter*) Nothing to Disclose

### PURPOSE

To explore whether the histogram parameters of synthetic MRI (SyMRI) are useful in differentiating metastatic from benign cervical lymph nodes in patients with HNSCC.

### METHODS AND MATERIALS

A total of 46 HNSCC patients with 149 pathologically confirmed lymph nodes (LNs) (metastatic LNs: 58, non-metastatic LNs: 91) were included in the study. The histogram parameters derived from SyMRI, ADC values, and short and long diameters for each LN were obtained. The LNs were randomly divided into a training set and an independent validation set by a ratio of 7:3. Significantly different parameters between metastatic and non-metastatic

LNs were selected in the training set, and logistic regression analysis was adopted to construct different models. ROC analysis and AUC were performed to assess the diagnostic performance of different models and multi-radiologists. The DeLong test was used to determine the best diagnostic model.

**RESULTS**

The AUCs of the three models were 0.806 (SyMRI_model), 0.783 (DWI), and 0.878 (Combined_model) in the validation set. The Combined_model (SyMRI+ADCvalue+size) had the highest diagnostic potency in differentiating metastatic LNs from non-metastatic LNs in both training and validation sets, with an accuracy of 0.875 and 0.867 in the two sets. The diagnostic performance of Combined_model was superior to multi-radiologists not only in all LNs but also in the cohort of sub-centimeter LNs.

**CONCLUSION**

SyMRI-derived histogram parameters manifested satisfactory diagnostic performance for the discrimination of cervical LNs in HNSCC.

**CLINICAL RELEVANCE/APPLICATION**

HNSCC is common malignancy worldwide, with up to 80% of patients having cervical (LNM) at the time of diagnosis. The presence of LNM serves as a significant adverse prognostic factor, contributing to disease progression, diminished long-term survival rates, and therapeutic complexities.Within a single acquisition, SyMRI generates multiple parameter maps, quantitative T1, T2, and PD values could be biomarkers that reflect the intrinsic magnetic properties of the tissue, establishing a relationship between MRI images and microstructural features.In the study, we observed notable differences in several histogram parameters obtained from SyMRI between metastatic and non-metastatic LNs in HNSCC. The Combined_model achieved high AUC. In addition, our model demonstrated superior diagnostic performance compared to the subjective analysis of multi-radiologists, especially in the sub-centimeter groups.

## M5A-SPHN-5 BASELINE VIRTUAL MR ELASTOGRAPHY AND RADIOLOGICAL DEPTH OF INVASION IN THE PREDICTION DISEASE-PROGRESSION IN NASOPHARYNGEAL CARCINOMA

Meng Lin (*Abstract Co-Author*) Nothing to Disclose
Xiaoduo Yu (*Abstract Co-Author*) Nothing to Disclose
Yueluan Jiang (*Abstract Co-Author*) Nothing to Disclose
Hongmei Zhang (*Abstract Co-Author*) Nothing to Disclose
Haoran Wei (*Abstract Co-Author*) Nothing to Disclose
Fan Yang (*Presenter*) Nothing to Disclose

**PURPOSE**

Nasopharyngeal carcinoma (NPC) is an aggressive head and neck cancer. Concurrent chemoradiotherapy is the mainstay of treatment for NPC. However, appropriately 10-30% of NPC patients would suffer treatment failure. Virtual MR elastography (vMRE) could be used to obtain tissue elasticity value. However, those studies are lacking in the head and neck field. NPC with high T stage have poorer prognosis than those with low T stage. Whether the radiological depth of invasion (rDOI), a quantitative factor, could serve as a prognostic factor in NPC has not been exploited. Therefore, based on the concept of quantitative and objective assessment, we explored the prognostic value of vMRE and rDOI in predicting disease progression in NPC.

**METHODS AND MATERIALS**

This study prospectively included 45 NPC patients. The mean and median value of shift ADC (sADC) at b value of 200/1000 and 200/1500 were obtained based on the largest slice of tumor. Besides, we measured the rDOI in both axial and coronal positions. At the axial CET1WI, a reference line connecting the front of lateral nasopharyngeal wall (or the front of tumor when it not extent beyond lateral nasopharyngeal wall) and the center of posterior nasopharyngeal wall on the largest slice of tumor was firstly drew. The length of inward invasion of the tumor perpendicular to the reference line was defined as axial rDOI (rDOI_aT1WI). At the coronal CET1WI, a reference line connecting the vertices of the pterygoid process on both sides was firstly drew. The distance of upward invasion of tumors perpendicular to the reference line was defined as coronal rDOI (rDOI_cT1WI). The X-tile software was used to obtain the optimal cut-off value and to categorize patients into low-risk (both < cut-off value) and high-risk groups (the rest). The clinical outcome is progression-free survival (PFS). All statistical analysis was conducted using R. Univariate and multivariate Cox analysis were used to construct models. The nomogram and calibration curves were plotted. The C-index was calculated.

**RESULTS**

18/45 (40.0%) patients were diagnosed with disease progression and the median follow-up duration was 56.5 (22.5, 58.2) months. Several parameters were significantly correlated with PFS and sADCmean (200/1000) and rDOI were the independent predictors. After multivariate analysis, sADCmean and rDOI were selected to construct vMRE+rDOI model. The C-index of vMRE+rDOI model were 0.753, which was significantly higher than TNM model (0.556). The nomogram, calibration curves and Kaplan-Meier curve were attached.

**CONCLUSION**

Our study is the first to find that sADC of vMRE and rDOI could predict disease progression in NPC.

**CLINICAL RELEVANCE/APPLICATION**

Patients with high sADCmean and high-risk rDOI need aggressive treatment and close follow-up.

## M5A-SPIN-1 SARCOPENIA DIAGNOSIS IN OPPORTUNISTIC CHEST CT SCREENING AMONG THE KOREAN POPULATION: ESTABLISHING THRESHOLDS AND CLINICAL APPLICATIONS

Jong H. Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Changmin Park (*Abstract Co-Author*) Nothing to Disclose
Sihwan Kim, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate optimal thresholds for skeletal muscle area (SMA) on different vertebra locations from 12th thoracic (T12) vertebra level to 2nd lumbar (L2) vertebra level using Korean population data; beyond the body composition assessment on 3rd lumber vertebra (L3) level.

### METHODS AND MATERIALS

The patients are consisted of 354 male (54.8%) and 291 female (45.2%). Average age of total patients (n = 645) is 63.7 yrs (64.3 for male and 63.1 for female). The sarcopenia is defined by the sex-specific L3 SMA threshold referenced as 117.04cm2 for male and 71.39cm2 for female. Based on the criteria, sarcopenia patients of the study were 72 (20.3%) for male and 22 (7.5%) for female. The vertebra body was localized by YOLO detection model and SMA value was calculated using automatic body composition analysis software (ClariMetabo, ClariPi, Seoul, Republic of Korea). For vertebra localization model, 120 contrast-enhanced abdominal CT scan data was used and it was augmented to 480 cases using CT contrast agent removing algorithm for mixing the synthetic non-contrast CT images. To find an optimal threshold, a receiver operating characteristic (ROC) curve analysis, sensitivity, specificity, and the area under ROC (AUROC) were calculated to evaluate diagnosis agreement at suggesting SMA thresholds.

### RESULTS

The optimal SMA threshold for sarcopenia detection at T12, L1, L2 vertebra levels were 91.5 cm2, 98.0 cm2, 113.8 cm2 in male, and 56.9 cm2, 62.4 cm2, 67.5 cm2 in female. The sensitivity for detecting sarcopenia using optimal SMA threshold at T12, L1, L2 vertebra levels were 0.79, 0.88 and 0.98 for male, and their specificity were 0.82, 0.82 and 0.55 for female, respectively. The AUROC for SMA threshold of each vertebra level (T12, L1 and L2) was 0.85, 0.90 and 0.90 for male, and 0.55, 0.57 and 0.66 for female. Through our study, it is possible to have an opportunistic screening for diagnosing sarcopenia on different CT scan protocols, not limited to the abdominal CT assessment using the L3 vertebra. To the best of our knowledge, this is the only reference standards using Korean population data to diagnose sarcopenia on different levels of the vertebra.

### CONCLUSION

We suggested cut-off values of SMA for substitutable vertebra bodies (e.g. L2, L1, T12) replacing the L3 level assessment when diagnosing sarcopenia. We hope the opportunistic screening chance to diagnose sarcopenia on different CT scan protocols be accomplished, and thresholds be applicated as more practical standards in Asia.

### CLINICAL RELEVANCE/APPLICATION

In CT-based sarcopenia diagnosis, a SMA measured at the L3 vertebra level is traditionally referenced using abdominal CT, but it is important to find alternative diagnosis criteria within a chest CT for a more universal diagnosis in terms of opportunistic screening.

## M5A-SPIN-2 AUTOMATED QUANTITATIVE ANALYSIS OF CARDIAC MR SHORT-AXIS CINE IMAGES IN THE NAKO HEALTH STUDY: SEGMENTATION PIPELINE AND QUALITY CONTROL

Maximilian Russe, MD (*Abstract Co-Author*) Nothing to Disclose
Fabian Isensee, MSc (*Abstract Co-Author*) Nothing to Disclose
Christopher Schuppert, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop an automated segmentation pipeline for short-axis cardiac magnetic resonance (CMR) cine images from the prospective multi-center NAKO Health Study and to perform an in-depth quality control of image and segmentation quality.

### METHODS AND MATERIALS

A deep learning algorithm based on the nnU-Net architecture was trained for semantic segmentation on an independent dataset of expert-annotated short-axis CMR cine images including standard contours for both ventricles. The trained model was applied to CMR data from the NAKO Health Study baseline cohort, comprising 29,491 examinations from individual participants. The model inference was used to calculate ventricular volumes at all time points and to subsequently determine parameters of left and right ventricular (LV, RV) morphofunction, including volumes at end-diastole and end-systole (EDV, ESV), and myocardial mass (LVM). A visual quality control for image and segmentation quality included cases exhibiting (1) outliers in standard morphofunctional parameters, (2) outliers in the difference between left and right ventricular stroke volumes, or (3) outliers in timepoint differences between EDV and ESV. Additionally, cases exhibiting (4) abnormal LV time-volume curves were considered. The ratings employed a five-point Likert scale with values ranging from 5 (good) and 4 (acceptable) to 3 (moderate), 2 (poor), and 1 (non-diagnostic).

### RESULTS

All 29,491 CMR examinations were processed. The outlier analysis identified 5,180 cases (17.6% of the total), of which 1,936 (6.6%) received a moderate or lower rating for image or segmentation quality. The majority of these cases were associated with outliers in morphofunctional parameters and abnormal time-volume curves. After excluding these cases, the mean values calculated from the automated segmentations for LVEDV, LVESV, and LVM were 141.5 ml, 52.3 ml, and 113.3 g, respectively. The excluded cases showed significantly higher means by 4.6 ml (3.3%) for LVEDV, 13.8 ml (26.4%) for LVESV, and 8.1 g (7.2%) for LVM compared to the included cases (all $p<0.001$).

### CONCLUSION

The presented pipeline enabled the automated segmentation of a large CMR dataset. It also served to facilitate quality control by identifying examinations with suboptimal image or segmentation quality, allowing subsequent quantitative analyses to be conducted with a reduced risk of introducing bias.

### CLINICAL RELEVANCE/APPLICATION

An accurately performing segmentation pipeline for short-axis CMR cine images is the gateway to any large-scale quantitative analyses of such datasets. Findings from the NAKO Health Study based on this dataset may provide new insights into cardiovascular risk factors and (sub)clinical disease.

## M5A-SPIN-3 MANUAL VERSUS AI-ASSISTED RECIST-BASED MEASUREMENT OF LYMPH NODE METASTASIS: A COMPARATIVE ANALYSIS OF MEASUREMENT VARIABILITY AND TIME

Chikako Tanaka (*Abstract Co-Author*) Nothing to Disclose
Motoo Nomura, MD (*Abstract Co-Author*) Nothing to Disclose
Ryo Sakamoto, MD, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Shigemi Matsumoto (*Abstract Co-Author*) Nothing to Disclose
Koji Fujimoto, MD, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation

### PURPOSE

In oncology clinical trials, tumor lesion assessment based on RECIST criteria is required, which places a great burden on radiologists or clinicians to accurately measure the size of targeted lesions while understanding the tumor morphology. Recently, AI-assisted measurement became possible for this task. We tested its effectiveness using cases with lymph node metastasis.

### METHODS AND MATERIALS

Metastatic lymph nodes reported in radiology reports for clinical trials in 2011-2023 were randomly included in this retrospective study. Sixteen lesions with well-defined margins in ten cases were eligible for evaluation. Two board-certified radiologists (DrA and DrB) independently measured these metastatic lymph nodes, using both manual (M) and AI-assisted (A) methods. One of them performed measurements twice. The coefficient of variation (CV) for the measured diameter and the measurement time were compared between the 1st and the 2nd measurement of one radiologist to evaluate intra-reader variability both for M (M1DrA vs M2DrA) and A (A1DrA vs A2DrA). Similarly, inter-reader variability was evaluated both for M (M1DrA vs M1DrB) and A (A1DrA vs A1DrB). Times required for the measurement were compared between M of DrA and DrB, A of DrA and DrB, M and A of DrA, and M and A of DrB. Statistical analyses were performed using Wilcoxon signed-rank tests. P-values after Bonferroni correction ($p < 0.05/4 = 0.0125$) were considered to indicate statistically significant differences.

### RESULTS

Sixteen lesions ranged 12-30 mm in the longest diameter in the short axis. Intra-reader CV of AI-assisted measurement was smaller than that of M, but the difference was not significant ($p=0.018$). Inter-reader CV of AI-assisted measurement was smaller than that of M, but the difference was not significant ($p=0.403$). There were no significant differences between intra-reader CV and inter-reader CV ($p=0.396$ for M, $p=0.092$ for A). Measurement times for AI-assisted measurement was shorter than that of M ($p=0.004$ for DrA, $p=0.0006$ for DrB). Measurement times by DrA was significantly longer than that by DrB ($p=0.000$ for M, $p=0.001$ for A).

### CONCLUSION

The required time for the measurement of metastatic lymph nodes were significantly reduced by the AI-assisted measurement compared with manual measurement.

### CLINICAL RELEVANCE/APPLICATION

An AI-assisted measurement for the metastatic lymph nodes for clinical trials may reduce the burden of radiologists.

## M5A-SPIN-4 CT SCAN COMPOSITE SCORE CAN IDENTIFY GLIOBLASTOMA PATIENTS WITH WORSE OUTCOMES

**PURPOSE**

Obesity is a risk factor for many cancer types including glioblastoma multiforme (GBM). Body mass index alone is an insufficient indicator of health risks associated with obesity. We used CT body composition analyses to construct a sex-specific composite score that would optimally predict overall survival in GBM.

**METHODS AND MATERIALS**

Using a retrospective institutional cohort, we performed single slice (L3) and volumetric (L1-L5) automated body segmentation analyses on abdominal and pelvic computed tomography (CT) scans performed within 1 month of diagnosis of GBM. Multivariable Cox proportional hazards models were then used to identify variables that were independently associated with GBM overall survival. Lastly, a learning-tree algorithm was implemented to identify the relative importance of body composition metrics using a XGBoost-powered learning model. These weights were used to create sex-specific composite CT scan scores of protective and predisposing factor with relation to GBM survival. A log-rank pairwise t-test was used to compared GBM survival across patient groups stratified based on these CT composite scores.

**RESULTS**

Higher relative inter/intramuscular adipose tissue volume (HR(95%CI):1.9(1.01-3.06), p=0.02), visceral adipose tissue volume (HR(95%CI):2.1(1.04-4.1), p=0.04) and aortic calcification volume (HR(95%CI):2.6(1.2-5.5), p<0.001) were associated with lower GBM overall survival, while higher subcutaneous adipose tissue volume (HR(95%CI):0.4(0.2-0.8), p=0.02), iliopsoas muscle volume (HR(95%CI):0.4(0.2-0.9), p<0.001), and trabecular bone density (HR(95%CI):0.4(0.1-0.8), p=0.003) were predictive of higher GBM OS (p-value of all tests <0.05). Using quartiles of the CT scan composite predisposing and protective scores, we were able to stratify male and female participants with significantly different outcomes with regards to GBM OS (Figure). Male and female participants with higher burden of predisposing factors had significantly lower chances of survival compared to those with lower cumulative burden of these factors (Figure, p-value Q4 vs. Q1 males< 0.01 and 0.001 in females).

**CONCLUSION**

Using automated body segmentation analysis and through an XGboost-powered learning algorithm, we optimized a CT scan composite score that was able to stratify GBM patients with worse overall survival.

**CLINICAL RELEVANCE/APPLICATION**

Metabolism measured with abdominal body composition provides an actionable advancement toward precision medicine in GBM management, as life-style and dietary regimens have the ability to alter body composition and metabolism and potentially GBM tumor biology.

## M5A-SPIN-5 DIFFERENTIATE ADRENAL LIPID-POOR ADENOMA FROM NODULAR HYPERPLASIA WITH CT QUANTITATIVE PARAMETERS: A FEASIBILITY STUDY

Hao Sun, MD (*Abstract Co-Author*) Nothing to Disclose
Gu Mu Yang Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Lili Xu (*Abstract Co-Author*) Nothing to Disclose
Li Chen (*Abstract Co-Author*) Nothing to Disclose
Erjia Guo, MS, BA (*Abstract Co-Author*) Nothing to Disclose
Jiahui Zhang (*Abstract Co-Author*) Nothing to Disclose
Xiaoxiao Zhang (*Abstract Co-Author*) Nothing to Disclose
Qianyu Peng (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose
Xin Bai III, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to explore the potential of CT quantitative parameters in differentiating adrenal lipid-poor adenoma (LPA) from nodular hyperplasia and evaluate diagnostic performance.

**METHODS AND MATERIALS**

Retrospective analysis was conducted on patients with LPA or nodular hyperplasia who underwent unenhanced and contrast-enhanced CT before adrenalectomy. Regions of interest were created to allow determination of each lesion's unenhanced (CTpre), portal-venous phase attenuation (CTp), and the portal-venous phase attenuation of the abdominal aorta. We subsequently calculated absolute enhancement (a lesion’s portal-venous phase attenuation minus unenhanced attenuation [in HUs]), relative enhancement (absolute enhancement divided by unenhanced attenuation), and the relative enhancement ratio ([absolute enhancement divided by abdominal aorta’s portal-venous phase attenuation] ×100%). We also measured lesion size and recorded lesion number. Volume was assessed by ITK-snap software and the ratio of lesion volume to ipsilateral adrenal volume (volume ratio) was determined. Intergroup differences were analyzed using Student’s t-test and chi-squared test. Binary and multivariate logistic regression models were developed, and receiver operating characteristic (ROC) curves were constructed to determine the area under the ROC curve (AUC), sensitivity, and specificity. The model’s performance was then compared against radiologists’ subjective assessments, and the inter- and intra-reader agreement values among radiologists were calculated.

**RESULTS**

The study enrolled 128 patients with pathologically confirmed LPA (n=83) and nodular hyperplasia (n=45). Portal-venous phase attenuation, volume ratio, and lesion number were independent predictors of LPA. The AUC for the multivariate logistic regression model incorporating CTp, volume ratio, and lesion number was 0.835 (95% CI, 0.764-0.907; with a sensitivity of 73.5% and specificity of 80%). The radiologists’ diagnostic specificity and accuracy appeared to be inferior to the model. The inter-reader agreement among radiologists ranged from 0.082 to 0.535, and the intra-reader agreement values of two radiologists were 0.734 and 0.583, respectively.

**CONCLUSION**

The portal-venous phase CT demonstrated significant potential in distinguishing LPA from nodular hyperplasia. The model integrating CTp, volume ratio, and lesion number exhibited superior diagnostic performance compared to radiologists in terms of variability and reproducibility.

**CLINICAL RELEVANCE/APPLICATION**

The proposed model based on CT quantitative parameters of the portal-venous phase can guide clinical treatment decisions and prevent unnecessary surgery in patients with nodular hyperplasia.

## M5A-SPIN-6 TOTALSEGMENTATOR V2 - BETTER, FASTER, AND MORE SUSTAINABLE

### PURPOSE

We introduce TotalSegmentator v2, an enhanced version of the CT image segmentation tool TotalSegmentator, designed to improve segmentation accuracy even on difficult cases, support a wider range of anatomical structures, run faster, and require less memory. These improvements enable even more large-scale radiology studies and sophisticated development of radiology deep learning algorithms.

### METHODS AND MATERIALS

The version 2 segments 137 classes, including 33 new anatomical structures compared to version 1 (supra-aortic vessels, appendicular bones, tissue types, thyroid, sternum, costal cartilages, pulmonary veins, superior vena cava, spinal cord, kidney cysts, vertebrae body). It uses a larger and more diverse training set of 1559 CT scans (v1: 1204 CT scans), with a focus on complex pathological cases (e.g. hemorrhage or ascites) and cases where TotalSegmentator v1 failed. The segmentation framework now relies on the newly released nnU-Net segmentation algorithms v2 with improved runtime. Performance was validated using a test set of 89 CT scans including various pathologies (test set 1). To demonstrate the improved accuracy on pathological cases, we additionally evaluated the segmentation performance on abdominal organs affected by hemorrhage or ascites (11 CT scans) (test set 2).

### RESULTS

TotalSegmentator v2 demonstrated robust segmentation on test set 1 with a Normalized Surface Distance (NSD) across all structures of 0.929 [CI 0.903 - 0.950] at 3mm resolution and 0.962 [CI 0.941 - 0.977] at 1.5mm resolution. Improvements were noted in abdominal organ segmentation among pathological cases (test set 2), with a NSD of 0.949 [CI: 0.916 - 0.980], surpassing TotalSegmentator v1 (0.931 [CI 0.879 - 0.973], p=0.416) and significantly outperforming a model trained on the open BTCV dataset (0.767 [CI 0.698 - 0.826], p=0.003). Compared to TotalSegmentator v1 runtime is up to 5x faster when running on GPU (v2: 44 s; v1 233 s) and 32x faster when running on CPU (v2: 49 s; v1 1560 s) while reducing memory consumption by 40%. This results in lower energy consumption and higher sustainability.

### CONCLUSION

TotalSegmentator v2 substantially enhances the utility and scalability of automated anatomical segmentation in CT imaging. It is (1) publicly available; (2) easy to use; and (3) works robustly amongst various clinical settings.

### CLINICAL RELEVANCE/APPLICATION

With its higher accuracy and faster runtime, TotalSegmentator v2 enables more precise and extensive segmentations of anatomical structures. This advancement supports a broader range of clinical and research applications, potentially improving diagnostic accuracy and therapeutic planning in diverse patient populations.

## M5A-SPIN-8 AUTOMATED SEGMENTATION AND QUANTIFICATION OF ADIPOSE TISSUE AND BONE MARROW ON WHOLE-BODY DIXON MRI USING CROSS-MODALITY TRANSFER LEARNING

Ge Hu (*Abstract Co-Author*) Nothing to Disclose
Huadan Xue, MD (*Abstract Co-Author*) Nothing to Disclose
Da-Ming Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose
Jiao Li, MS,MS (*Abstract Co-Author*) Nothing to Disclose
Shengqian Huang (*Presenter*) Nothing to Disclose

### PURPOSE

1) To develop a deep learning-based method for automated segmentation and quantification of adipose tissue (AT) and bone marrow (BM) on whole-body Dixon MRI images. 2) To evaluate a cross-modality transfer learning strategy via CT-to-Dixon MRI image synthesis for improving the performance of this segmentation task.

### METHODS AND MATERIALS

The real Dixon MRI dataset consisted of whole-body T1-weighted Dixon MRI scans in 26 patients. Subcutaneous AT (SAT), visceral AT (VAT), mediastinal AT (MAT), vertebral body BM, pelvic bone BM, and femur BM were manually annotated on fat-only images (553-688 slices per case). 20 cases were used for 5-fold cross-validation and 6 cases were used for testing. Extra 6 cases with MRI scans and 500 cases with labeled CT data from the TotalSegmentator dataset were collected for training a generative adversarial network (CycleGAN). CT-to-Dixon MRI conversion was achieved by introducing AT and BM reconstruction loss in CycleGAN. 3D nnU-Net was pre-trained on pseudo Dixon MRI dataset and fine-tuned on real Dixon MRI dataset. The predicted BM was used for localization to automatically determine the volumes of fat in different parts, the fat areas at each vertebral level, and the BM fat fraction (FF). The segmentation performance was evaluated using Dice similarity coefficient (DSC), and the quantitative results were assessed using Pearson correlation coefficient (r), intraclass correlation coefficient (ICC), and mean relative error (MRE).

### RESULTS

DSC are presented in order of SAT, VAT, MAT, vertebral body BM, pelvic bone BM, and femur BM. In cross-validation, DSC using the transfer learning strategy were 0.982, 0.980, 0.940, 0.890, 0.911, and 0.961, respectively, outperforming the model trained from scratch ($p < 0.05$, paired t-test). When training with 25% samples, the strategy achieved comparable performance to training with all samples for AT segmentation (mean DSC: 0.962 vs. 0.964). Notably, the pre-trained model itself enabled zero-shot segmentation of AT (DSC: 0.943, 0.924, 0.851). The predicted volumes of SAT/VAT/MAT, AT volumes in chest/abdomen/pelvis/thighs, AT areas at L3 level, and BMFF showed excellent consistency with the ground truth ($r > 0.98$, ICC > 0.97,

MRE < 5%). The model also demonstrated good segmentation (DSC: 0.987, 0.981, 0.942, 0.897, 0.911, 0.966) and quantification performance (r > 0.98, ICC > 0.97, MRE < 3%) on the test set.

**CONCLUSION**

Deep learning model can efficiently segment whole-body AT and BM, enabling precise quantification of fat in different body parts. The cross-modality transfer learning strategy enhances the segmentation performance.

**CLINICAL RELEVANCE/APPLICATION**

This method enables automated fat quantification, which can be applied in clinical assessments and scientific studies.

## M5A-SPIR-1 PREDICTORS OF DIAGNOSTIC SUCCESS IN PERCUTANEOUS BIOPSIES OF BONE LESIONS

Rush H. Chewning, MD (*Abstract Co-Author*) Nothing to Disclose
Ahmad I. Alomari, MD (*Abstract Co-Author*) Nothing to Disclose
Gulraiz A. Chaudry, MBChB (*Abstract Co-Author*) Nothing to Disclose
Raja Shaikh, MD (*Abstract Co-Author*) Nothing to Disclose
Usama Anwar, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

To determine the procedural and lesion-specific predictors that influence the diagnostic success of percutaneous biopsies for bone lesions.

### METHODS AND MATERIALS

This retrospective study evaluated 287 patients who underwent 313 image-guided PCNBs for bone lesions in interventional radiology at a tertiary care pediatric hospital, from February 2009 to September 2023. Procedural details like biopsy core numbers, needle specifications, and guidance methods were recorded alongside pre-procedural imaging (CT, MRI, radiographs, PET scans) data. Bivariate and multivariate analyses were performed using LOGISTIC and HPLOGISTIC procedures in SAS/STAT® 14.1.

### RESULTS

Of the 313 biopsies, 306 had sufficient data to analyze. In this subset, the average age was 11.6 years ± 4.5 (163 male). Of the 306 biopsies, 208 (68%) were diagnostic while 100 (32%) were non-diagnostic. The most common needles used were 14 and 16-gauge (76%). Single Predictor Models: Important predictors of the odds of diagnostic success included extracting = 5 cores (OR = 2.78, 95% CI: 1.69-4.57, P < 0.001), diffuse lesions (OR = 2.55, 95% CI: 1.14-5.69, P = 0.022), and the presence of a soft tissue component (OR = 2.79, 95% CI: 1.39-5.62, P = 0.004). Positive PET avidity increased the odds compared to presumed or known negative avidity (OR = 3.45, 95% CI: 1.30-9.14, P = 0.013). Larger lesion volumes increased the odds with an estimate on the log(volume) scale of 0.194 (95% CI: 0.097-0.290, P < 0.001). Multiple Predictor Model: The multivariable analysis of 306 procedures identified an optimal model with moderate accuracy (AUC = 0.71) using three predictors: number of cores = 5 (OR = 1.82, 95% CI: 1.06-3.15, P = 0.031), lesion volume (estimate = 0.156, 95% CI: 0.052-0.261, P = 0.003), and clinical suspicion (P = 0.053). For clinical suspicion, the OR for secondary vs recurrent lesion was 10.80 (95% CI: 1.54-75.68, P = 0.017), and for secondary vs primary lesion was 6.94 (95% CI: 1.61-33.33, P = 0.009).

### CONCLUSION

The study demonstrates that the number of extracted cores and specific lesion characteristics significantly influence the diagnostic success of image-guided PCNBs for bone lesions.

### CLINICAL RELEVANCE/APPLICATION

Based on the three-predictor model, the extracted number of cores and assessment of specific lesion characteristics can be optimized to increase the diagnostic yield of PCNBs for bone lesions.

## M5A-SPIR-2 SAFETY AND EFFICACY OF IMAGE GUIDED BONE BIOPSIES: INSIGHTS GAINED FROM THE REGISTRY OF THE GERMAN SOCIETY FOR INTERVENTIONAL RADIOLOGY AND MINIMALLY INVASIVE THERAPY (DEGIR) 2018-2023

Sebastian Zensen, MD (*Abstract Co-Author*) Nothing to Disclose
Johannes Haubold, MD (*Abstract Co-Author*) Speaker, Siemens AG
Michael Forsting, MD (*Abstract Co-Author*) Nothing to Disclose
Aleksandar Milosevic, MD (*Abstract Co-Author*) Nothing to Disclose
Benedikt M. Schaarschmidt, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In bone lesions, a histopathological analysis is essential prior to any further therapeutic approach. Here, percutaneous image guided biopsies have gradually replaced open biopsies because of their high diagnostic yield and low complication rate. However, improved diagnostic possibilities, most notably in the field of molecular diagnosis, have increased the demand considerably. Hence, historical data on these procedures have to be considered as outdated. The aim of the present evaluation was to use data from the prospectively managed multinational registry of the German Society for Interventional Radiology and Minimally Invasive Therapy (DeGIR, Deutsche Gesellschaft für Interventionelle Radiologie und minimal-invasive Therapie) to investigate procedural details, success and complication rate of percutaneous image guided bone biopsies.

### METHODS AND MATERIALS

During a five-year timespan from 2018 until 2022, 17,397 biopsies from 214 centers were analyzed (median patient age: 64 years, IQR 51-75 years; female: 52%, 9,046/17,397). Technical success was defined as the visually successful placement of the biopsy needle in the target lesion. Based on the recommendations of the Society of Interventional Radiology (SIR), complications were subsumed as minor (Grade A B) or major (C-F). Explorative data analysis was performed.

### RESULTS

Around one third of biopsies were performed as outpatient procedures (34%, 5,924/17,397). Most interventions were performed using local anesthesia only (86.6% (15,072/17,397). In most cases, CT-guidance was used (68.7%,11,952/17,397), followed by ultrasound (18.5%, 3214/17,397), fluoroscopy (12.1%, 2,099/17,397), MRI (0.6%, 121/17,397), and combined approaches (e.g., ultrasound + CT) in 0.7% (140/17,397).A technically successful biopsy was possible in 98.9% (17,201/17,397). In 11,073 cases with an available histopathological report, the biopsy sample was histologically representative in 93.2% (10,316/11,073). The reported complication rate was 0.62% (108/17,397) and only 23.1% (25/108) were considered as major complications according to the SIR classification.

### CONCLUSION

Percutaneous image guided bone biopsies are safe procedures with a low complication and a high technical success rate.

### CLINICAL RELEVANCE/APPLICATION

As percutaneous image guided bone biopsies have a low complication rate, it might be possible to perform this intervention mainly as an outpatient procedure.

## M5A-SPIR-3 TRANSVASCULAR TARGETED BIOPSIES WITH ANGIO CT IN HYBRID MODE

Philipp M. Paprottka (*Abstract Co-Author*) Nothing to Disclose
Tobias Geith (*Abstract Co-Author*) Nothing to Disclose
Jonathan Nadjiri, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study evaluated the feasibility and safety of transvascular targeted biopsies (TTB), a novel technique utilizing conventional endovascular biopsy sets guided by angio-CT. The primary goal was to enable precise tissue sampling, particularly in cases where percutaneous access was either unattainable or contraindicated.

### METHODS AND MATERIALS

The study spanned from 2021 to 2023 and included cases involving targeted biopsies of paravascular structures using conventional transvascular biopsy sets. These cases necessitated a non-percutaneous approach due to either infeasibility or contraindication resulting from coagulopathy. The procedures were conducted in an angio-CT hybrid suite. Initially, a contrast-enhanced or native CT scan was performed for pre-procedural planning. Post-processing techniques were employed to identify target locations, and this information was seamlessly integrated into fluoroscopy images. Fluoroscopy guided the placement of conventional transjugular biopsy sets, while CT-fluoroscopy was employed when necessary to precisely position the needle within the suspected lesion. Adverse events were monitored for a follow-up period of 7 days as an indicator of safety, with success inferred from pathology reports containing representative results.

### RESULTS

Transvascular targeted biopsies were successfully performed in six patients. Among these cases, two involved biopsies of tumours adhering to the outside of the superior vena cava with severe upper inflow congestion. Additionally, one paracaval lymph node near the inferior vena cava was biopsied. Other successful TTB procedures included biopsies of a circumscriptive liver metastasis, a transplanted and a non-transplanted kidney with kidney failure. Notably, no adverse events were reported, and the technical success rate, as confirmed by pathology reports, was 100%.

### CONCLUSION

Transvascular targeted biopsies conducted within an angio-CT environment utilizing conventional biopsy sets are feasible and helpful, achieving a seemingly high technical success rate with high safety.

### CLINICAL RELEVANCE/APPLICATION

Transvascular targeted biopsies (TTB) offer a breakthrough in tissue sampling, especially in cases where percutaneous access is challenging or contraindicated. This novel technique, utilizing conventional endovascular biopsy sets guided by angio-CT, enables precise sampling of paravascular structures, broadening diagnostic possibilities in complex clinical scenarios. With a 100% technical success rate and no reported adverse events, TTB demonstrates promising feasibility and safety, potentially transforming diagnostic approaches and guiding tailored treatment strategies for patients facing challenging biopsy scenarios.

## M5A-SPIR-4 NOVEL ENDOBILIARY RADIOFREQUENCY ABLATION SYSTEM USING STENT-BASED ELECTRODE IN THE PORCINE MODEL: A PRELIMINARY FEASIBILITY STUDY

Jung-Hoon Park, PhD (*Abstract Co-Author*) Nothing to Disclose
Yubeen Park (*Abstract Co-Author*) Nothing to Disclose
Dong-Sung Won, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Endobiliary radiofrequency ablation (RFA) has been developed as a promising palliative therapy to improve stent patency and patient survival in the malignant biliary obstruction (MBO). However, conventional catheter-based electrodes may be limited by insufficient tumor ablation due to inadequate contact with the tortuous bile duct wall. This study aimed to investigate the feasibility and possibility of the stent-based electrode (SBE)-RFA system in the porcine common bile duct (CBD).

### METHODS AND MATERIALS

An endobiliary RFA system composed of bipolar SBE with two electrodes using braided nitinol wires and a customized RFA generator with a polarity-switching system. Ex-vivo studies utilizing porcine livers were conducted to evaluate ablation area under various protocols, manipulating output power and ablation times as independent variables. Subsequently, endobiliary RFA was performed in nine male porcine using a protocol selected based on ex-vivo findings. Pre- and post-procedural evaluations, including cholangiography, endoscopy, and histological analysis were performed.

**RESULTS**

The SBE custom RFA generator exhibited accurate temperature feedback and power output, demonstrating high reproducibility. The ablation zone in pig liver was confirmed to increase as both power and time were increased. In the porcine CBD, endobiliary RFA was technically successful without ductal perforation, and led to luminal narrowing proportional to both output power and ablation time. The degree of mucosal damage, including hemorrhagic erosion and erythema, was increased with higher RFA-related parameters in the endoscopic examination. Histological examination demonstrated enhanced ablation area and circumferential shape with increased inflammatory cell infiltration, cellular necrosis, and heat shock proteins proportional to the ablation protocol.

**CONCLUSION**

This study demonstrates the technical feasibility and efficacy of endobiliary RFA utilizing a novel bipolar SBE-RFA system. Enhanced and uniformed ablation ranges were observed in the porcine CBD, suggesting its potential as a palliative therapeutic option for unresectable MBO.

**CLINICAL RELEVANCE/APPLICATION**

The SBE-RFA system represents a significant advancement in the management of MBO with uniform ablation zone and provides a minimally invasive alternative to improve survival in ineligible surgical patients.

## M5A-SPIR-5 INTERVENTIONAL MICRODEVICE IMPLANTATION AND RETRIEVAL FOR IN-VIVO DRUG RESPONSE ASSESSMENTS: PRECLINICAL SAFETY AND FEASIBILITY IN A RABBIT VX-2 SOFT TISSUE SARCOMA MODEL

**PURPOSE**

To evaluate the safety and feasibility of an interventional technique for placement and retrieval of a novel, implantable microdevice (IMD) in a rabbit VX-2 tumor model, with the overall goal of enabling rapid drug response assessments in solid tumors.

**METHODS AND MATERIALS**

IMDs are miniaturized devices that fit inside the tip of a percutaneous needle and contain multiple individual wells, each containing microdoses of drugs that diffuse locally into surrounding tumor tissue. This study utilized a rabbit hindlimb VX-2 tumor model with similar risk and technical complexity of a human soft tissue sarcoma. Under conscious sedation and using US guidance, 4-5 IMDs were placed into eight rabbit tumors. Each IMD released microdoses of fluorescent drugs (Doxorubicin, Topotecan, Sunitinib) into 18 spatially distinct microscopic tissue regions over a 1-day period. Under fluoroscopic guidance, a custom over-the-wire biopsy procedure was used to extract the IMD along with surrounding tumor tissue for drug-response analysis. Procedural adverse events were evaluated. The number of IMDs and drug release sites retrieved with sufficient intact tissue (at least 300um) per tumor were quantified using gross pathology and fluorescence imaging.

**RESULTS**

An average of 4.5 ± 0.5 IMDs were implanted containing 81.0 ± 9.0 drug release sites per tumor. Mean implantation procedure duration was 25.5 ± 2.5 minutes and retrieval procedure duration was 46.0 ± 0.5 minutes. No clinically significant complications were observed, including bleeding, infection, or inability to remove the IMD. The retrieval success rate, defined as retrieval of drug-containing tumor tissue, was 68.25% (57-76%), with an average of 55.25 ± 5.3 discrete drug sites retrieved per tumor.

**CONCLUSION**

This animal study supports that interventional IMD placement and retrieval in a superficial soft tissue tumor is safe and feasible. These findings suggest that translation to first-in-human trials in similar locations could be considered in the future.

**CLINICAL RELEVANCE/APPLICATION**

Percutaneous image-guided IMDs analyze drug effects of numerous individual cancer treatments simultaneously in-vivo and have the potential to personalize drug optimization and advance drug development. The ability to perform IMD implantation and retrieval without surgery may substantially expand patient eligibility and IMD utilization in cancer trials.

## M5A-SPIR-6 ASSESSING ABDOMINAL AORTIC ANEURYSM GROWTH BY USING RADIOMICS OF PERIVASCULAR ADIPOSE TISSUE AFTER ENDOVASCULAR REPAIR

Rui Lv (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the relationship between radiomic features of perivascular adipose tissue (PVAT) and abdominal aortic aneurysm (AAA) growth after endovascular aneurysm repair (EVAR).

**METHODS AND MATERIALS**

Patients with sub-renal AAA who underwent regular follow-up after EVAR from March 2014 to March 2024 were retrospectively collected. Two radiologists segmented the aneurysm and PVAT. By calculating the aneurysm volume from two follow-up CT scans, patients were divided into growing and non-growing groups. 107 radiomic features were automatically extracted from the PVAT region. Univariable and multivariable logistic regression was performed to analyze radiomic features and clinical characteristics. The performance of the integrated clinico-radiological model was compared with models using only radiomic features or clinical characteristics separately.

**RESULTS**

A total of 79 patients (68±9 years, 89% men) were enrolled in this study, 19 of whom had an growing aneurysm. Compared to the stable group, PVAT of growing AAA showed higher surface area to volume ratio (non-growing vs. growing, 0.63 vs. 0.70, P=0.04), and a trend of low dependence and high dispersion manifested by texture features (P<0.05). The area under the curve (AUC) of the integrated clinico-radiological model was 0.78 (95% CI 0.65-0.91), with a specificity of 87%. The integrated model outperformed models using only radiomic or clinical features separately(0.78 vs. 0.69 vs. 0.69).

**CONCLUSION**

Higher surface area to volume ratio and more heterogeneous texture presentation of PVAT were associated with aneurysm dilation after EVAR. Radiomic features of PVAT have the potential to predict AAA progression.

**CLINICAL RELEVANCE/APPLICATION**

Radiomic features of perivascular adipose tissue are associated with abdominal aortic aneurysm progression and can be an independent risk factor for aneurysm dilatation to assist clinicians in postoperative patient surveillance and management.

## M5A-SPIR-7 CT THERMOGRAPHY CAN PREDICT THE CHANGE IN TEMPERATURE DISTRIBUTION INSIDE ICE-BALL DURING CRYOABLATION?- VERIFICATION WITH PHANTOM EXPERIMENT

Hajime Sakuma, MD, PhD (*Abstract Co-Author*) Research Grant, Eisai Co, Ltd;Research Grant, FUJIFILM Holdings Corporation;Research Grant, Guerbet SA;
Katsutoshi Nakamori, RT (*Abstract Co-Author*) Nothing to Disclose
Yuki Omori (*Abstract Co-Author*) Nothing to Disclose
Hikari Fukui (*Abstract Co-Author*) Nothing to Disclose
Masashi Fujimori, MD,PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Cryoablation (CA) has become a widely used thermal treatment for tumors since the advent of argon (Ar) gas-based system. Reported tumor lethal zone is <-40°C and a margin of >6 mm is recommended. However, the ambient temperature around the tumor and Ar gas pressure during CA may affect the ice ball size and the temperature distribution inside the ice ball. This phantom study assessed the effects of ambient temperature and Ar gas pressure on the temperature distribution of the ice ball and verified the feasibility of computed tomography (CT) thermography.

**METHODS AND MATERIALS**

A 500ml of 5% agarose gel phantom was prepared using saline solution with embedding a multi-polar fine thermocouple and a cryoprobe. The phantom was settled in a thermostatic chamber placed in a CT. The chamber temperature was set at 24°C (low; LT) and 37°C (high; HT). Freezing was performed for 15 minutes, and the phantom temperature was recorded every 5 second. The entire phantom was scanned with CT just before and 15 minutes after starting freezing. The experiment was triplicated at different Ar gas pressure of 26.2~27.5MPa. The curvilinear temperature changes in the ice ball were modeled by the least-squares method. The distances from the cryoprobe to 0 and -40°C were estimated and compared for different chamber temperatures and gas pressures. Spherical regions of interest with a diameter of 2 mm were set at 2 mm intervals outward from the cryoprobe and CT values were measured before and 15 minutes after freezing, and the correlation between the change in CT values and the estimated temperatures was evaluated.

**RESULTS**

The mean central temperature significantly decreased in LT than HT (-64.2? v.s. -57.0?, P=0.01). The mean radius of the ice ball (18.5 mm v.s. 16.2 mm, p=0.002) and % of area <40? in ice ball (38.5% v.s. 35.2%, P=0.04) increased significantly in LT than HT. No significant difference was found in the size of area with 0?~-40? (LT: 11.4 mm v.s. HT: 10.5 mm, P=0.07). Single regression analysis showed that as Ar gas pressure at the start of freezing decreased, % of area <40? decreased regardless of the ambient temperature (coefficient of determination, R2=0.79). At lower temperatures, the decrease in CT values of ice ball tended to be greater compared to pre-freeze CT values, but the correlation was poor (R2=0.33).

**CONCLUSION**

The central temperature of the ice ball was lower and the overall ice ball size and % of area <40°C are larger in lower ambient temperature, but % of area <40°C became smaller as Ar gas pressure decreased, regardless of the ambient temperature. However, this temperature distribution was difficult to estimate from the CT images obtained during CA.

**CLINICAL RELEVANCE/APPLICATION**

Since CT thermography is diffiult, a larger margin should be secured under lower Ar gas pressure setting.

## M5A-SPIR-8 SPECTRUM AND GENOTYPE-PHENOTYPE CORRELATIONS OF EXTRACRANIAL VASCULAR ANOMALIES DRIVEN BY RAS/MAPK VARIANTS

Vanessa F. Schmidt, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We aimed to correlate alterations in the rat sarcoma virus (RAS)/mitogen-activated protein kinase pathway in vascular anomalies to the clinical phenotype for improved patient and treatment stratification.

**METHODS AND MATERIALS**

This retrospective multicenter cohort study included 29 patients with extracranial vascular anomalies containing mosaic pathogenic variants (PVs) in genes of the RAS/mitogen-activated protein kinase pathway. Tissue samples were collected during invasive treatment or clinically indicated biopsies. PVs were detected by the targeted sequencing of panels of genes known to be associated with vascular anomalies, performed using DNA from affected tissue. Subgroup analyses were performed according to the affected genes with regard to phenotypic characteristics in a descriptive manner.

**RESULTS**

Twenty-five vascular malformations, 3 vascular tumors, and 1 patient with both a vascular malformation and vascular tumor presented the following distribution of PVs in genes: Kirsten rat sarcoma viral oncogene (n=10), neuroblastoma ras viral oncogene homolog (n=1), Harvey rat sarcoma viral oncogene homolog (n=5), V-Raf murine sarcoma viral oncogene homolog B (n=8), and mitogen-activated protein kinase kinase 1 (n=5). Patients with RAS PVs had advanced disease stages according to the Schobinger classification (stage 3-4: RAS, 9/13 versus non-RAS, 3/11) and more frequent progression after treatment (RAS, 10/13 versus non-RAS, 2/11). Lesions with Kirsten rat sarcoma viral oncogene PVs infiltrated more tissue layers compared with the other PVs including other RAS PVs (multiple tissue layers: Kirsten rat sarcoma viral oncogene, 8/10 versus other PVs, 6/19).

**CONCLUSION**

This comparison of patients with various PVs in genes of the RAS/MAPK pathway provides potential associations with certain morphological and clinical phenotypes.

**CLINICAL RELEVANCE/APPLICATION**

RAS variants were associated with more aggressive phenotypes, generating preliminary data and hypothesis for future larger studies.

## M5A-SPIR-9 LIVER TUMOR RABBITS MODEL BUILD WITH A NEWLY DEVELOPED $VX_2$ RABBIT CARCINOMA CELL LINE

Shenbo Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the application of a newly established transplantable VX2 rabbit carcinoma cell line in building rabbit models of liver cancer.

**METHODS AND MATERIALS**

The Institute of Basic Medical Sciences of the Chinese Academy of Medical Sciences provided the cell line. The cell line originated from the VX2 tumor strain and has cultured 21 generations. A total of 2 ×108 VX2 cells <and> conventional VX2 tumor strains were injected into the hind limb muscle of 2 healthy New Zealand white rabbits respectively. Two weeks later the VX2 tumor was harvested and transplanted into the liver of 15 healthy Newzeland white rabbits (10 cell-line-derived tumors and 5 tumor-strain-derived tumors). To evaluate tumor growth, all of the rabbits underwent CT scanning 2 weeks after transplantation. The rabbits were sacrificed 3 weeks after transplantation to harvest the tumor for pathological examination (hematoxylin-eosin staining).

**RESULTS**

The tumor grew in both VX2-cell-line-injected <and> VX2-tumor-strains-injected rabbits. Tumor growth was observed in five of ten that underwent cell-line-derived tumor transplantation, <and> three of five rabbits that underwent tumor-strain-derived tumor transplantation. Pathological examination demonstrated similar microscopic construction between tumor-strain-derived tumors <and> cell-line-derived tumors.

**CONCLUSION**

This newly developed VX2 rabbit carcinoma cell line can generate tumors in healthy Newzeland White rabbits. The generated tumor has similar pathological characters under hematoxylin-eosin staining with conventional tumor-strains-derived tumors.

**CLINICAL RELEVANCE/APPLICATION**

This newly developed VX2 rabbit carcinoma cell line is promising to replace the conventional tumor strain in building rabbit models of liver cancer.

## M5A-SPMK-1 A Conditional GAN Approach for Artifact Removal: Preserving Pathological Patterns in Dual-energy CT Imaging

Ashok Kambaluru (*Abstract Co-Author*) Nothing to Disclose
Chankue Park, MD (*Abstract Co-Author*) Nothing to Disclose
Siyeoul Lee (*Abstract Co-Author*) Nothing to Disclose
Seonho Kim (*Abstract Co-Author*) Nothing to Disclose
Minwoo Kim (*Abstract Co-Author*) Nothing to Disclose
Dongeon Lee (*Abstract Co-Author*) Nothing to Disclose
Chunsu Park, MS, BA (*Presenter*) Nothing to Disclose

### PURPOSE

Artifacts in dual-energy CT (DECT) can obscure or simulate the pathological edema patterns, leading to incorrect interpretations if not properly recognized. Although conventional deep neural networks have been employed to eliminate artifacts in DECT, there is a risk of unintentionally changing the appearance of edema patterns because of the similarity to artifacts. We developed a novel framework to enhance networks maintaining bone structure integrity while selectively removing artifacts and ensuring that the generated images retain crucial patterns for disease diagnosis.

### METHODS AND MATERIALS

This retrospective study was approved by the institutional review board and the need for informed consent was waived. We collected DECT (80 and 140 kVp, Revolution CT; GEHealthcare) and corresponding MRI images from 70 patients meeting the conditions for accurate annotation and data integrity. Regions of interest were annotated, extracted, and resized to (256 × 256). We used 2,901 slices (n = 56, mean age: 57 ± 11years; 30 female) and 731 slices (n = 14, mean age: 63 ± 12years; 8 female), for training and testing, respectively. Our network's architecture comprises multiple neural networks that are strategically interconnected, enabling artifact removal to access a diverse set of artifact-corrupted bone images. This configuration directs the model to proficiently distinguish between artifacts and pathological edema patterns, facilitating effective isolation.

### RESULTS

We evaluated the efficacy of our proposed method by comparing it to various attribute-editing image reconstruction methods such as FaderNet, StarGAN, and CycleGAN. Our model, CAPTURE-GAN, demonstrated superior effectiveness in clearing a variety of artifact patterns (87.7%) while retaining edema characteristics (80.3%). At the same time, CAPTURE-GAN maintained the integrity of tissue structure and texture, crucial for identifying diseases. These results are supported by quantitative evaluation findings with high PSNR (39.52) and SSIM (0.986).

### CONCLUSION

Our study presents a new solution aimed at improving the interpretation of DECT images by preserving critical edema patterns while removing artifacts. This approach utilizes a classifier and masks during the training process, offering a simple yet impactful method for maintaining essential information about edema, which is vital and must not be compromised. Remarkably, our model outperforms existing networks in preserving edema features while effectively eliminating artifacts.

### CLINICAL RELEVANCE/APPLICATION

Our innovative artifact removal can enhance the diagnostic accuracy of medical professionals with limited experience in DECT, especially by minimizing misinterpretations of normal patterns as abnormal findings.

## M5A-SPMK-2 DEEP LEARNING MODEL DEVELOPMENT FOR SCREENING JOINT INFLAMMATION IN HAND RADIOGRAPH OF RHEUMATOID ARTHRITIS PATIENTS

Keum San Chun, PhD (*Abstract Co-Author*) Nothing to Disclose
Hyemin Park (*Abstract Co-Author*) Nothing to Disclose
Sungwon Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Joon-Yong Jung, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Seung Eun Lee, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Ultrasound is the standard imaging modality to evaluate the inflammatory changes in hand joints of rheumatoid arthritis (RA) patients. However, it is operator-dependent and takes a long time to examine. In this study, we developed the deep learning (DL) model to automatically detect the joint location and inflammation in the hand radiographs of RA patients.

## METHODS AND MATERIALS

The two-step model consisted of a joint localization model (model 1) and an inflammation detection model (model 2). Two datasets of the anteroposterior (AP) view plain radiographs of both hands from two institutions (D1, n=330; D2, n=289) were used for model development. In model 1, D1 and D2 were used as training and test sets, respectively. DeepLabCuts algorithm was implemented to localize each hand and wrist joint as a radiocarpal, ulnocarpal, CMC, MCP, PIP, and DIP joint. The mean squared error (MSE) was calculated for model 1 evaluation. In model 2, D2 included the RA patients satisfying the ACR/EULAR RA classification criteria with the result of ultrasound exam of hand joints. Radiographs with severe joint deformity and artifact were excluded. Each hand and wrist joint were labeled positive or negative on plain radiographs based on the result of the ultrasound exam. A positive label was assigned in two conditions: 1) both synovitis and increased effusion were observed, 2) either synovitis or increased effusion was present in the ultrasound image accompanied by the steroid injection. We grouped 36 joints on both hands and wrists into three categories based on their anatomical shapes. Each joint group was assigned an instance of model 2, a pre-trained ResNet50. The input images were pre-processed using contrast limited adaptive histogram equalization (CLAHE) and resized into 224-by-224 image prior to getting input to model 2. The classification performance for each group was reported separately with the precision, recall, and F1 score.

## RESULTS

In model 1, the test error of all joint was 3.06 ± 0.30 pixels and MSE was 0.098. In model 2, 418 finger joints (n=4,984), 152 radiocarpal joint (n=302) and 133 ulnocarpal joints (n=300) were labelled as positive after the curation of D2. The precision, recall, and F1 scores were in 65%, 88%, 75% in finger joint, 71%, 97%, 82% in radiocarpal joint, and 47%, 91%, 62% in ulnocarpal joint, respectively.

## CONCLUSION

Our developed DL model for joint localization and inflammation detection demonstrated high recall values, indicating its feasibility in identifying the disease affected joints and screening target joints for ultrasound examination in RA patients.

## CLINICAL RELEVANCE/APPLICATION

We can screen the inflammatory change on the hand radiograph with the DL model assistance and offer the information about target joint for ultrasound examination.

# M5A-SPMK-4 BENCHMARKABLE EXTERNAL VALIDATION FOR SEQUENTIAL ADOPTION OF AN AI SOLUTION AT FOUR HOSPITALS IN VESTRE-VIKEN HOSPITAL TRUST (VV), NORWAY

Jonas Vardal, MD (*Abstract Co-Author*) Nothing to Disclose
Ramprabananth Sivanandan, MD, MBBS (*Presenter*) Nothing to Disclose

## PURPOSE

Being the first to implement a commercially CE approved AI solution in a clinical workflow setting in Norway, a benchmarkable external validation was conducted in one of the hospitals to evaluate a bone fracture algorithm. Subsequent mini validations were carried out on other hospitals within VV to ensure consistency and reliability across multiple locations.

## METHODS AND MATERIALS

This AI algorithm was used to detect fractures on X-rays with patient history of recent trauma. Validation occurred in three phases involving 1,601 examinations (fig.1). Phase 1, a double-blinded retrospective study was conducted over a seven-month period that included 634 examinations with a balanced distribution of positive and negative cases among different age groups, and fracture locations (fig.2). Additional findings included various fracture types and related findings such as casts, prostheses, effusions, or bone lesions. Phase 2 was also a retrospective double-blinded study over a two-week period with 465 examinations. Phase 3 was a prospective study allowing radiologist access to AI results, covering 504 examinations over another two-week period. Validation was conducted by three board-certified radiologists and two radiology residents, with ground truth established via radiologist reports, relevant CT and MRI related to the history. Mini validations at other hospitals were based on Phase 2, with outcomes compared to benchmarked results.

## RESULTS

In Phase 1, AI detection accuracy was 91.3%, compared to 95.2% for radiologists' reports. Phase 3 showed an increase in sensitivity from 93% to 98% with AI assistance, although specificity marginally decreased from 99.3% to 98.8%. Mini validation results across hospitals showed slight variations but remained consistent with benchmarked outcomes (fig.3).

## CONCLUSION

The study effectively mitigated bias related to fracture location in Phase 1 and assessed real-world applicability in Phase 2 through mini validations at other hospitals. Phase 3 evaluated the enhanced diagnostic outcomes with AI assistance. Overall, the AI application demonstrated good accuracy, slightly lower than that of radiologists but significantly improved sensitivity and accuracy with AI support.

## CLINICAL RELEVANCE/APPLICATION

The multiphasic external validation helped in secure and successful adoption of this AI algorithm and sequential implementation across multiple hospitals at VV through mini validation. Also, incorporation of this AI algorithm enhanced the diagnostic process in clinical settings.

## M5A-SPMS-1 PREDICTION OF METASTATIC AND NON-METASTATIC PELVIC AND RETROPERITONEAL LYMPH NODES BASED ON RADIOMICS ON CT IMAGES

Yaofeng Zhang (*Abstract Co-Author*) Nothing to Disclose
Kexin Wang (*Abstract Co-Author*) Nothing to Disclose
Xiaodong Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Jinpeng Li (*Presenter*) Nothing to Disclose

### PURPOSE

To establish a model by radiomics to predict pelvic and retroperitoneal metastatic/non-metastatic lymph nodes in patients with malignant tumors.

### METHODS AND MATERIALS

A total of 215 preoperative abdominal and pelvic enhanced CT scans of the patients who underwent lymph node related pathological examinations at our center and were confirmed to have pelvic and retroperitoneal lymph node metastases were retrospective collected to construct the model. Another 38 preoperative enhanced CT scans of the patients under the same conditions (different time periods) were retrospective collected as hold-out test set, and the two datasets were mutually exclusive. The ground truth was determined after a doctor marked metastatic/non-metastatic lymph nodes according to the the region and size of the metastatic/non-metastatic lymph nodes in the corresponding pathological report and CT image features, and examined by another doctor. Using CT portal vein phase thin-layer images as input, a predictive model was established using radiomics and deep learning radiomics. AUC was used to evaluate the classification performance of each combination method in the test set of the model construction data and hold-out test set. Four combination methods, radiomics and deep learning radiomics, were selected with the highest AUC in the test set and hold-out test set, respectively. The model performance was evaluated by sensitivity, specificity, accuracy, PPV, NPV, and AUCs of ROC curves in the test set of the model construction data and hold-out test set. Comparing the AUCs of radiomics models with different combinations by Delong test.

### RESULTS

For the test set of model construction data, the sensitivity, specificity, accuracy, PPV, NPV, and AUC of the four different combinations of radiomics models were the highest at 0.818 (0.746,0.890), 0.910 (0.847,0.974), 0.830 (0.828,0.831), 0.908 (0.843,0.973), 0.767 (0.678,0.857), and 0.899 (0.856,0.942). For the hold-out test set, the sensitivity, specificity, accuracy, PPV, NPV, and AUC of the four different combinations of omics models were the highest at 0.828 (0.736,0.921), 0.907 (0.830,0.985), 0.856 (0.854,0.858), 0.906 (0.827,0.984), 0.814 (0.714,0.913), and 0.885 (0.823,0.946). There was no statistically significant difference in AUCs among the four different combinations of radiomics models in the test set for model construction data or hold-out test set.

### CONCLUSION

Based on radiomics, it is great to predict pelvic and retroperitoneal lymph node metastasis or non-metastasis in patients with malignant tumors.

### CLINICAL RELEVANCE/APPLICATION

Radiomics and deep learning radiomics models were developed to predict pelvic and retroperitoneal metastatic/non-metastatic lymph nodes in patients with malignant tumors.

## M5A-SPMS-2 MRI-BASED PREDICTION OF TOTAL AND REGIONAL BRAIN VOLUME LOSS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS, INDEPENDENT OF THE VISCERAL FAT DISTRIBUTION

Soojin Lee (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to investigate the link between Type 2 Diabetes Mellitus (T2DM) and brain volume, while controlling for age, gender, and visceral fat distribution.

## METHODS AND MATERIALS

The study analyzed whole-body MRIs (WB-MRI) acquired at 1.5 T from 341 patients with T2DM and compared with 338 non-diabetics matching for age, gender and visceral fat distribution. Brain volumes were segmented into 96 regions using FastSurfer, with normalization by intracranial volume. Visceral fat (vfat) volume was segmented using 3D nnU-Net model. T-tests were used to compare mean total brain volumes, including gray and white matter zones, lobes (frontal, temporal, parietal, and occipital), and Alzheimer's prone regions (i.e., hippocampus, posterior cingulate, and precuneus).

## RESULTS

No statistically significant differences were observed in the mean ages of the T2DM group (63.03 ± 10.82) and the normal group (mean age 62.86 ± 10.64).The mean BMI and vfat distributions were 29.84 kg/m2 and 4835.38 ml in the T2DM group as compared to 29.80 kg/m2 and 4831.20 ml in the non-diabetic group. T2DM was associated with lower total brain volume ($p = 0.024$) and white matter volume ($p = 0.007$). There were no statistically significant reductions in gray matter ($p = 0.062$) or hippocampal volume ($p = 0.290$) within the T2DM group. T2DM-related white matter loss was most pronounced in the occipital lobe ($p = 0.034$). While lower volumes were also observed in the frontal lobe ($p = 0.066$), left caudate ($p = 0.059$) and right caudate ($p = 0.069$) regions, the results did not reach statistical significance.

## CONCLUSION

Lower total brain and white matter volumes suggest a structural impact of the metabolic disorder on the brain. These findings suggest a direct association between T2DM and brain morphology, suggesting potential pathways through which T2DM may contribute to neurological changes. Interestingly, T2DM has shown to be a risk factor for Lewy body and Parkinson's disease dementia, which has been associated with an abnormal appearance of the occipito-parietal region on brain MRIs.

## CLINICAL RELEVANCE/APPLICATION

This study uncovers a significant link between T2DM and reduced brain volume, particularly in white matter, independent of obesity. These findings emphasize the structural impact of diabetes on the brain, which may explain the cognitive decline seen in T2DM patients.

## M5A-SPNMMI-1 ASSOCIATION BETWEEN PRETREATMENT C-11 METHIONINE PET METRICS, HISTOLOGY, AND PROGNOSIS IN 125 NEWLY DIAGNOSED ADULT-TYPE DIFFUSE GLIOMA PATIENTS BASED ON THE WHO 2021 CLASSIFICATION

Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Michinobu Nagao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shuji Sakai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Koichiro Kaneko, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To clarify the relationships between 11C-methionine (MET) positron emission tomography (PET) metrics and the histology, genetics, and prognosis of adult-type diffuse glioma (ADG) based on the World Health Organization (WHO) 2021 classification.

### METHODS AND MATERIALS

A total of 125 newly diagnosed ADG patients were enrolled. We compared the maximum standardized uptake value (SUVmax), tumor-to-normal ratio (TNR), metabolic tumor volume (MTV), and total lesion methionine uptake (TLMU) to the histology and genetics of the ADG patients. We also evaluated the prognoses of the 93 surgically treated patients.

### RESULTS

The isocitrate dehydrogenase (IDH) wild (w) ADG patients showed significantly higher MET-PET metrics ($p<0.05$ for all parameters), significantly shorter overall survival (OS) and progression-free survival (PFS) ($p<0.0001$ for both) than those of the IDH mutant (m) ADG patients. Among the parameters, the TNR showed the highest area under the curve (0.77) (0.63-0.74) for differentiating these patient groups. In the IDHm ADG group, the SUVmax, MTV, and TLMU values were significantly higher in IDHm grade (G) 4 astrocytoma patients than IDHm G2/3 astrocytoma patients ($p<0.05$ for all), but not than G2-3 oligodendroglioma patients. The PFS was significantly shorter in the G4 astrocytoma patients versus the G2/3 astrocytoma and G3 oligodendroglioma patients ($p<0.05$ for both). The SUVmax and TNR values were significantly higher in recurrent patients than non-recurrent patients ($p<0.01$ for both), but no significant differences were found in MTV or TLMU values.

### CONCLUSION

MET-PET metrics well reflect the histological subtype, WHO grade and prognosis of ADG based on the 2021 WHO classification, with the exception of oligodendroglial tumors. Volumetric parameters were not significantly associated with recurrence, unlike the SUVmax and TNR.

### CLINICAL RELEVANCE/APPLICATION

1) MET-PET metrics well reflect the histological subtype of ADG based on the new WHO 2021 classification, but oligodendroglial tumors shows high MET-PET metrics regardless of their favorable prognosis.2) TNR is the best parameter for distinguish IDH wild ADGs from IDH mutant ADGs.3) Preoperative TNR and SUVmax values are significantly associated with prognosis.of ADG patients. However, volumetric parameters such as MTV and TLMU are not associated with prognosis unlike those of FDG-PET in other malignancies.

## M5A-SPNMMI-2 EXTRACELLULAR VOLUME FRACTION (ECV) VALUE IN LUNG CANCER CALCULATED FROM PHOTON-COUNTING DETECTOR CT: CORRELATION OF ECV VALUES WITH [18-F] FAPI-PET/CT AND [18-F] FDG-PET/CT UPTAKE VALUES

## PURPOSE

[18-F]-labeled fibroblast activation protein inhibitor (FAPI)-PET/CT can visualize cancer stroma such as cancer-associated fibroblasts (CAF). Comprehensive spectral data using photon-counting detector (PCD)-CT may provide more accurate extracellular volume fraction (ECV) value associated with CAF. The aim of this study was to compare ECV values on PCD-CT between uptake values on [18-F] FAPI-PET/CT and [18-F] FDG (fluorodeoxyglucose)-PET/CT.

## METHODS AND MATERIALS

13 nodules with 12 lung cancer patients (5 women) were scanned by PCD-CT. Unenhanced and enhanced CT (3-minute-delayed scan) images were obtained with 1 mm slice thickness using a reconstruction kernel (Qr40) and quantum iterative reconstruction level 4 (QIR4). The dose of contrast material (300mgI) per patient was decided on the basis of 2 ml per weight. Two different ECV values (ECV-a and ECV-b) were calculated from CT values (Hounsfield Units, HU) and iodine density (mg/cc) respectively. Formulas using hematocrit values (Hct) of each patient were as follows: 1) ECV-a (%) = (100-Hct) x [enhancement value in cancer (HU)] / [enhancement value in blood pool (HU)]; and 2) ECV-b (%) = (100-Hct) x [Iodine density in cancer (mg/cc)] / [Iodine density in blood pool (mg/cc)]. In [18-F] FAPI-PET/CT and [18-F] FDG (fluorodeoxyglucose)-PET/CT close to the imaging date of PCD-CT, each uptake value was measured at a location corresponding to the ECV measurement part. Correlation between each ECV value and each uptake value were evaluated using regression analysis. P values < 0.05 were considered significant.

## RESULTS

Size of nodules (8 part-solid and 5 solid) showed 23.0mm±10.2mm (mean ± standard deviation [SD]). ECV-a was 32.5±56.4% (mean ± SD) and ECV-b was 41.3±9.64% (mean ± SD). FAPI uptake showed 5.16±4.63 (mean ± SD) and FDG uptake showed 5.57±5.30 (mean ± SD). There was a significant correlation between ECV-b (y) and FAPI uptake (x) (correlation coefficient r, 0.56; regression equation, y=35.284 +1.159x; and p=0.048), but no correlation between ECV-a (y) and FAPI uptake (x) (correlation coefficient r, 0.09; regression equation, y=26.386 +1.187x; and p=0.75). Neither ECV-a nor ECV-b had a significant correlation with FDG uptake (correlation coefficient r, 0.20 and 0.41; p=0.578 and p=0.238, respectively).

## CONCLUSION

ECV-b value calculated from iodine density on PCD-CT significantly had a positive correlation with FAPI uptake, but not with FDG uptake.

## CLINICAL RELEVANCE/APPLICATION

ECV value with use of PCD-CT shows a positive correlation with FAPI uptake, it can be used as a biomarker to visualize CAF and may be useful in predicting lung cancer prognosis and treatment resistance.

## M5A-SPNPM-1 FEASIBILITY STUDY OF A VIRTUAL REALITY BREAST BIOPSY SIMULATION

Stefanie B. Zalasin, MD (*Abstract Co-Author*) Nothing to Disclose
Stefanie A. Woodard, DO (*Abstract Co-Author*) Investigator, Bracco Group Institutional research support, Bracco Group
Ceren Yalniz, MD (*Abstract Co-Author*) Nothing to Disclose
Yufeng Li, PhD (*Abstract Co-Author*) Nothing to Disclose
Kathryn W. Zamora, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Kyle Kleiman (*Presenter*) Nothing to Disclose

### PURPOSE

To assess feasibility of a novel virtual reality breast biopsy simulation trainer.

### METHODS AND MATERIALS

This was a HIPAA-compliant, IRB-approved prospective feasibility study. The participants were three fellowship-trained breast radiologists with varying years of experience. Participants received an introduction to the virtual reality (VR) breast biopsy simulation and brief training session, describing how to enter the simulation and navigate controls. The participants were then instructed to perform as many breast biopsies as possible within a 15-minute period. One biopsy cycle consisted of entering the breast with the biopsy needle, taking a biopsy sample, and removing the needle. Time to successfully biopsy the mass was recorded by the VR program, and this data was recorded to assess improvement from start to finish of the simulation. A post-procedure survey was administered to all participants immediately after completion of the simulation. Qualitative open-ended subjective feedback was also obtained via Qualtrics.

### RESULTS

All three breast radiologists completed the simulation. There were no complications from the procedure, including no motion sickness or fatigue resulting in simulation termination. Results of data obtained from the simulation showed decreased time to successful biopsy (slope = -19.23) with each subsequent trial for each of the three participant breast radiologists. A decreased time to biopsy was associated with a higher cumulative number of successful biopsies ($p=0.0037$). A higher number of cumulative successful biopsies was associated with decreased number of body entries ($p=0.0332$) and biopsy fires ($p=0.0221$) before a successful tissue sample. Mean responses for Likert scale survey results were overall high. The radiologists found the simulator to be engaging (4.67/5.00 ± 0.47), realistic (2.67/3.00 ± 0.47) and would recommend the simulation to other healthcare professionals (2.67/3.00 ± 0.47). The radiologists participating in the trial also provided overall favorable subjective feedback.

### CONCLUSION

This study presents a novel approach for ultrasound-guided breast biopsy training with a VR simulation that showed to be successfully capable of recording time-to-completion of each biopsy attempt. Future studies will be directed towards assessing the utility of the simulation in improving trainee skills.

### CLINICAL RELEVANCE/APPLICATION

Ultrasound-guided breast biopsies are the most frequently performed image-guided breast procedures, but learners may lack volume. Virtual reality is an emerging technology, allowing learners to have flexibility in learning, life-like interactive experiences, and measurable feedback.

## M5A-SPNPM-2 ENVIRONMENTAL SUSTAINABILITY IN RADIOLOGY: EXCESS IMAGING UTILIZATION ATTRIBUTED TO POOR AIR QUALITY

Omar Taboun (*Abstract Co-Author*) Nothing to Disclose
Anish Kirpalani, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Hayley Panet (*Abstract Co-Author*) Nothing to Disclose
Maura J. Brown, MD (*Abstract Co-Author*) Synthesis Health Inc - research collaboration, no financial relationship at this time ( Nov 2022).
Kate Hanneman, MD, MPH (*Presenter*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc

### PURPOSE

There is growing recognition of the negative global impact of climate change on human health, including poor air quality related to pollution and wildfires. Climate disruptions are also associated with increased emergency department visits. However, there is currently no data on the association between environmental exposures and radiology volumes. The purpose of this study was to determine short-term associations of ambient air quality with emergency medical imaging utilization.

### METHODS AND MATERIALS

Daily imaging utilization counts from four emergency departments were retrospectively evaluated and linked to daily environmental data from the same geographic area over a 10-year period (2013-2022). Air quality health index (AQHI) was calculated based on daily direct measurement concentrations of ground-level ozone, nitrogen dioxide and fine particulate matter (PM2.5). A time-stratified case-crossover design was employed. Statistical analysis included conditional Poisson regression models to evaluate short-term associations of daily variations in ambient AQHI with daily emergency department imaging utilization for up to 7 days preceding imaging (lag 0-7). The moving average of mean daily AQHI was calculated to account for lagged exposure effects.

### RESULTS

Between 2013-2022, 1,666,420 imaging tests were performed with mean ambient daily AQHI of 2.8±0.7. Mean AQHI was associated with total imaging utilization at lags 0, 1, 2, 3, 4 and 5, with highest effect at lag 1 (day after exposure), gradually diminishing in magnitude and significance thereafter. A rise of 1 unit in the 3-day moving average of AQHI (representing the average exposure of air quality over the current and previous 2 days) was associated with an overall imaging utilization increase of 2.9% (IRR 1.029; 95% CI 1.025, 1.033). Poor air quality, defined using a previously established high health risk AQHI cut point (maximum AQHI =7), was associated with overall imaging utilization increase of 4.1% (IRR 1.041; 95% CI 1.033, 1.050) compared to low health risk air quality (AQHI <4) as the reference category. When stratified by imaging modality, worse AQHI was associated with increased x-ray, CT, and ultrasound imaging utilization but not MRI.

### CONCLUSION

Poor air quality is associated with increased emergency department medical imaging utilization. Individual daily effects are modest, however the cumulative impact of poor air quality on imaging utilization is substantial.

### CLINICAL RELEVANCE/APPLICATION

These results are timely given poor air quality associated with recent increases in the frequency and severity of wildfires and can be used to inform adaptation strategies to prepare for surges in imaging utilization.

## M5A-SPNPM-3 CREATING A GREENER OUTPATIENT MRI FACILITY: ENHANCING SUSTAINABILITY AND ENERGY EFFICIENCY THROUGH FAST IMAGING TECHNIQUES

Vibhas Deshpande, PhD (*Abstract Co-Author*) Researcher, Siemens AG
Susie Y. Huang, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Sean A. Woolen, MD, MS (*Abstract Co-Author*) Research Grant, Siemens AG;Investigator, Siemens AG
Amy Becker (*Abstract Co-Author*) Nothing to Disclose
Wei-Ching Lo (*Abstract Co-Author*) Employee, Siemens AG
Pan Su (*Abstract Co-Author*) Nothing to Disclose
Azadeh Tabari, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Energy consumption during active MRI scanning varies between scanners, pulse sequences and protocol. The goal of this study was to investigate the impact of MRI acquisition time reduction on energy efficiency, cost, and carbon savings through implementing fast MRI techniques for three commonly performed neurological, body, and musculoskeletal MRI exams. We hypothesized that accelerating MRI acquisition would reduce the energy consumption, electricity cost, and associated greenhouse gas emissions of MR scanning commensurately.

### METHODS AND MATERIALS

Net scan times (i.e., acquisition time = active mode - exam preparation time) were acquired for pituitary, lumbar spine (L-spine) and prostate MRI examinations on 4 identical outpatient 70-cm-bore 3T scanners (MAGNETOM Vida; Siemens Healthineers, Forchheim, Germany) at established outpatient imaging facilities during pre-implementation (3/1/2019-3/1/2020) and our new sustainable outpatient imaging facility during post-implementation periods (3/1/2022-3/1/2023) (Table 1). Power measurement logs were extracted for these protocols. Per-examination energy consumption, cost (estimated at $0.252/kWh in Massachusetts), and carbon savings were calculated retrospectively.

### RESULTS

The median net scan times for pituitary, L-spine and prostate protocols were 24.3, 25.3 and 29.8 min, respectively, during the pre-implementation period. During the post-implementation period, the net scan times were reduced by 20% for pituitary, 62% for L-spine and 48% for prostate protocols (19.5, 9.6 and 15.5 min, respectively). The per-examination energy consumption for pituitary, L-spine and prostate protocols using accelerated MRI sequences during net scan time were reduced by 3.69, 8.36 and 12.59 kWh (Fig. 1), respectively, translating to a potential cost savings of $0.95 (26%), $2.1 (62%), $3.17 (54%), and carbon savings of 0.003 (24%), 0.006 (59%) and 0.009 (53%) MTCO2eq per-MRI examination.

### CONCLUSION

The implementation of fast pituitary, L-spine and prostate MRI sequences significantly reduced the acquisition times for these three commonly performed neurological, body, and musculoskeletal MRI protocols. The results indicate that higher energy efficiency may be attained by shortening net scan times, with substantial concomitant carbon- and cost-saving potential.

### CLINICAL RELEVANCE/APPLICATION

Shortening MR examinations reduces energy expenditure during active scanning and achieves greater energy efficiency, as exemplified through three commonly performed MRI exams (pituitary, lumbar spine, prostate). The amount of carbon- and cost-savings that can be achieved through this approach is synergistic with improved patient care.

## M5A-SPNR-10 ASSOCIATIONS OF TENSOR-BASED BRAIN MORPHOMETRY WITH AUTOPSY CONFIRMED LIMBIC AGE-RELATED TDP-43 PATHOLOGY (LATE)

Konstantinos Arfanakis, PhD (*Abstract Co-Author*) Nothing to Disclose
David A. Bennett, MD (*Abstract Co-Author*) Nothing to Disclose
Abdur Raquib Ridwan, PhD (*Abstract Co-Author*) Nothing to Disclose
Mahir Tazwar, BS (*Abstract Co-Author*) Nothing to Disclose
Julie A. Schneider, MD (*Abstract Co-Author*) Nothing to Disclose
Arnold M. Evia JR, PhD (*Abstract Co-Author*) Nothing to Disclose
Rasheed Abid, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

Limbic-predominant age-related TDP-43 encephalopathy neuropathological change (LATE-NC) is common in older adults and has been associated with substantial cognitive impairment. However, the association of LATE-NC with brain morphometry has not been thoroughly investigated. In this work, we examined the association of LATE-NC with brain morphometric anomalies using tensor-based morphometry (TBM) in a large community cohort of older adults that came to autopsy (N=897).

### METHODS AND MATERIALS

Cerebral hemispheres were acquired from 897 deceased older adults participating in Rush Memory and Aging Project, Religious Orders Study, Minority Aging Research Study, and Clinical Core. Hemispheres were imaged ex-vivo on 3T MRI scanners using 2D spin-echo sequence (voxel size=0.6×0.6×1.5mm3), which was followed by detailed neuropathologic examination. The participant scans were non-linearly registered to an ex-vivo template, and the resulting deformation fields were used to calculate the logarithm of the Jacobian determinant in each voxel (LogJ maps).Voxelwise linear regression was used to test the association between deformations shown in the LogJ maps and LATE-NC stages, controlling for other age-related neuropathologies (Alzheimer's disease, Lewy bodies, arteriolosclerosis, atherosclerosis, cerebral amyloid angiopathy, gross and microscopic infarcts), age at death, sex, education, postmortem intervals, and scanners. To identify the earliest LATE-NC stage exhibiting morphometric abnormalities, LogJ values were compared between LATE-NC stages 1-5 and stage 0. Statistical significance was set at $p<0.05$.

### RESULTS

Voxelwise analysis revealed an independent association of LATE-NC with significantly lower volume in both gray and white matter regions within the temporal and frontal lobes and basal ganglia ($p<0.05$), including amygdala, hippocampus, entorhinal, parahippocampal, temporal pole, inferior temporal, middle temporal, fusiform, medial orbitofrontal, lateral orbitofrontal, insula, accumbens, and putamen cortices. Groupwise comparison of LogJ values revealed significant morphometric anomalies in small temporal lobe areas in stages 1-2, more temporal lobe as well as basal ganglia tissue in stage 3, and finally also included frontal lobe areas in stages 4-5.

### CONCLUSION

The present study showed a spatial pattern of morphometric abnormality that is consistent with the known pathological distribution of LATE-NC. The anomalies were detected as early as LATE-NC stage 1, suggesting that MRI is sensitive to the early stages of the disease.

### CLINICAL RELEVANCE/APPLICATION

This pattern may potentially be used in the development of a marker of LATE-NC, which currently can only be definitively diagnosed at autopsy.

## M5A-SPNR-11 TRACKING DISABILITY IN MULTIPLE SCLEROSIS USING DIFFUSION MRI

Els Fieremans, PhD (*Abstract Co-Author*) Scientific Advisory Board, Microstructure Imaging, Inc;Stockholder, Microstructure Imaging, Inc;Royalties, General Electric Company
Timothy M. Shepherd, MD, PhD (*Abstract Co-Author*) Co-founder, MICroStructure Imaging
Ilya Kister (*Abstract Co-Author*) Nothing to Disclose
Santiago Coelho, PhD (*Abstract Co-Author*) Nothing to Disclose
Nalini Jeet (*Abstract Co-Author*) Nothing to Disclose
Dmitry S. Novikov, PhD (*Abstract Co-Author*) Scientific Advisor, Microstructure Imaging, Inc;Stockholder, Microstructure Imaging, Inc
Benjamin Ades-Aron, PhD (*Abstract Co-Author*) Stockholder, Microstructure Imaging Inc
Valentin N. Stepanov, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study investigates microstructural changes in the normal appearing white matter (NAWM) of Multiple Sclerosis (MS) patients over time using clinically feasible diffusion tensor imaging (DTI) and diffusion kurtosis imaging (DKI). By comparing the diffusion metrics against commonly used clinical markers such as volumetrics and lesion load (LL), we aim to demonstrate their superior sensitivity in detecting subtle changes associated with disease progression in MS.

**METHODS AND MATERIALS**

This IRB-approved prospective study longitudinally monitored 36 MS patients (23 females; mean age 52 ± 11.5 years; median EDSS 4.5 ± 2.5) over an average period of 467 days (±102 days). MRI conducted using 3T Siemens Prisma and included multi-shell diffusion MRI (dMRI), with acquisition time 10 min, from which DTI and DKI metrics were extracted. WM regions of interest (ROI) were obtained using the JHU atlas. T1w MPRAGE and T2w FLAIR were used to quantify volumes of cortical gray matter (GM), basal nuclei, thalami, corpus callosum, overall WM, and lesions as well as LL using Freesurfer and Samseg. Symbol Digit Modalities Test (SDMT) was measured to evaluate cognitive decline. For all metrics, we derived changes between two timepoints, and used Spearman rank tests to assess correlations between changes in imaging markers and SDMT, adjusted for age at disease onset, with correlation coefficients (?) reported and significance set at $p < 0.05$.

**RESULTS**

Longitudinally, significant correlations were observed between changes in SDMT and dMRI metrics: Mean and Radial Diffusivities in the anterior corona radiata demonstrated negative correlations (? = -0.43, -0.40 respectively). Fractional Anisotropy in the superior longitudinal fasciculus (SLF) showed a positive correlation (? = 0.43). Additionally, Mean Kurtosis in overall WM and Radial Kurtosis in the posterior thalamic radiation and SLF correlated positively (? = 0.44, 0.58, and 0.55 respectively). In contrast, no significant correlations were found between changes in SDMT and the volumes of interest in GM or WM, or LL. The exclusion of lesions from the ROIs did not substantially alter these results, indicating that the observed correlations are primarily driven by subtle global changes in the NAWM rather than localized lesion effects.

**CONCLUSION**

Diffusion MRI (DTI and DKI) of the NAWM is sensitive to changes associated with cognitive decline in MS over time, unlike structural MRI. This study highlights the potential of dMRI as a clinically feasible method offering new insights for monitoring disease progression in MS patients.

**CLINICAL RELEVANCE/APPLICATION**

These findings highlight the potential of dMRI to enhance monitoring accuracy of MS progression in clinical settings and to inform future therapeutic strategies.

## M5A-SPNR-12 INVESTIGATING OXYGEN METABOLISM ABNORMALITIES IN PARKINSON DISEASE

Junghun Cho, PhD (*Abstract Co-Author*) Nothing to Disclose
Arpita Misra (*Presenter*) Nothing to Disclose

**PURPOSE**

Although Parkinson's disease (PD) is the second most common neurodegenerative disorder, no cure currently exists. This is partly due to the lack of sensitive biomarkers capable of detecting disease-related changes, which hinders the development of effective treatment. In this study, we introduce oxygen extraction fraction (OEF) as a novel biomarker for investigating metabolic abnormalities in PD. OEF, the ratio of oxygen tissue extracts from the blood, directly quantifies tissue viability and functionality. We investigate the differences in OEF between PD patients and healthy controls (HC), and the relationship of OEF with iron accumulation in PD.

**METHODS AND MATERIALS**

A routine multi-echo gradient echo (mGRE) data was acquired from 25 PD patients and 22 HC. OEF was calculated by using a novel integrative model of quantitative susceptibility mapping (QSM) and quantitative blood oxygen level-dependent imaging (qBOLD), termed QQ (QSM+qBOLD=QQ). Iron accumulation was measured by another parameter from QQ, non-blood tissue susceptibility (?n ). Multivariate regression analysis was used to compare OEF and ?n between PD and HC, to access relationship between OEF and ?n , and between OEF and Mini-Mental-State-Examination (MMSE).

**RESULTS**

In cortical and basal ganglia regions, OEF and ?n were significantly higher ($p<0.05$) in PD compared to HC. In PD, OEF was associated with ?n and MMSE. These results are consistent with literature expectations and suggest iron accumulation in PD brains and its compensatory increase in oxygen metabolism.

**CONCLUSION**

QQ-based OEF can be a meaningful biomarker to investigate metabolic abnormalities and their association with disease severality and progression in PD.

**CLINICAL RELEVANCE/APPLICATION**

A novel OEF mapping technique, QQ, utilizes a single routine MRI sequence without the need for impractical gas inhalation procedures to obtain OEF. Hence, QQ-based OEF may be readily applied in clinical settings to study the causes and disease progression of PD.

## M5A-SPNR-13 DIAGNOSTIC PERFORMANCE OF PETRA-MRA IN THE FOLLOW-UP OF INTRACRANIAL ANEURYSMS AFTER CLIPPING

Sang Hyun Suh, MD (*Abstract Co-Author*) Nothing to Disclose
Hee Sang Oh (*Presenter*) Nothing to Disclose

**PURPOSE**

While follow-up assessment of clipped aneurysms (CAs) using magnetic resonance angiography (MRA) can be challenging due to susceptibility artifacts, a novel MRA sequence, Pointwise Encoding Time Reduction with Radial Acquisition (PETRA) subtraction-based MRA, has been developed to reduce these artifacts. We aimed to validate the diagnostic performance of PETRA-MRA by comparing it with digital subtraction angiography (DSA) as a reference for follow-up of CAs using 3T MR scanner.

**METHODS AND MATERIALS**

Patients with clipping who underwent both PETRA-MRA and DSA between September 2019 and December 2021 were retrospectively included. Two neuroradiologists independently reviewed with the reconstructed images of PETRA-MRA to assess the visibility of the arteries around the clips and aneurysm recurrence or remnant of CA using a 3-point scale. The diagnostic accuracy of PETRA-MRA was evaluated in comparison to DSA.

### RESULTS

The study included 34 patients (28 females, mean age 59 ± 9.6 years) with 48 CAs. PETRA-MRA allowed visualization of the parent vessels around the clips in 98% of cases, compared to 39% with time-of-flight (TOF) MRA ($p < 0.0001$). DSA confirmed 14 (29.2%) residual or recurrent aneurysms. PETRA-MRA demonstrated high accuracy, specificity, positive predictive value, and negative predictive value of 99.2%, 100%, 100%, and 97.8%, respectively, while the sensitivity was 66.7%.

### CONCLUSION

This retrospective study demonstrates that PETRA-MRA provides excellent visibility of adjacent vessels near clips and has a high diagnostic accuracy in detecting aneurysm remnants or recurrences in CAs. Further prospective studies are warranted to establish its utility as a reliable alternative for follow-up after clipping.

### CLINICAL RELEVANCE/APPLICATION

Ultra short echo time MRA(PETRA-MRA) was useful in the follow-up of both coiled and clipped aneurysm by reducing metal artifacts. However, previous studies for clipped aneurysms showed the preliminary result without evaluating diagnostic performance using DSA as a reference.In this study, PETRA-MRA had an excellent diagnostic performance in clipped aneurysms. By confirming the diagnostic performance of PETRA-MRA, further studies in a prospective large cohort study are needed, which will strengthen PETRA-MRA as a reliable alternative to other imaging modalities for the follow-up after clipping.

## M5A-SPNR-14 ASSESSING THE CENTRAL VEIN SIGN IN MULTIPLE SCLEROSIS USING CONTRAST-ENHANCED SEGMENTED 3D-FLAIR* ON A 1.5 T SYSTEM: A PROSPECTIVE OBSERVATIONAL STUDY

Ayse Altintas (*Abstract Co-Author*) Nothing to Disclose
Ali Yusuf Oner, MD (*Abstract Co-Author*) Nothing to Disclose
Hande Ozen Atalay, MD (*Abstract Co-Author*) Nothing to Disclose
Ahmet Peker (*Abstract Co-Author*) Nothing to Disclose
Yunus Emre Senturk, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Central vein sign (CVS) in 3D FLAIR* imaging is becoming acknowledged as a successful technique for differentiating demyelinating plaque in multiple sclerosis (MS) from other types of white matter signal abnormalities when the early diagnosis is challenging with conventional MR imaging. The majority of current literature utilizes high magnetic field strengths in CVS assessment, such as 3T and 7T. Our objective is to assess the efficacy of CVS 3D-FLAIR* in 1.5 T systems enhanced with intravenous gadolinium-based contrast media (GBCA) and compare it with the CVS performance of GBCA-enhanced 3T FLAIR* imaging.

### METHODS AND MATERIALS

This is a prospective observational study in a single center from February 2022 to February 2023. 3D-FLAIR* was created with a 75% signal contribution from the segmented 3D EPI-T2* and a 25% signal contribution from the 3D-FLAIR imaging with an isotropic resolution of 0.8 mm. Overall, 41 GBCA-enhanced 1.5T 3D-FLAIR* and 28 GBCA-enhanced 3T 3D-FLAIR* were acquired from the participants with established MS diagnosis. First, the eligibility of each demyelinating lesion was determined based on the NAIMS-CVS criteria and assigned with number by the central rater (Y.E.S). Then the enumerated CVS-eligible lesions were classified as CVS+ or CVS- by the central rater and co-rater (A.P). Consequently, select-6* and percentage-based methods were utilized to assess the CVS efficacy in all patients.

### RESULTS

Overall, 895 lesions were eligible by the central rater based on NAIMS CVS criteria. 341 (59.7%) CVS+ lesions in GBCA-enhanced 1.5T and 226 (69.7%) CVS+ lesions in GBCA-enhanced 3T were identified. 39 of 41 participants in GBCA-enhanced 1.5T FLAIR* and 27 of 28 participants in GBCA-enhanced 3T FLAIR* met the select-6* requirements. Inter-rater and intra-rater reliability for GBCA-enhanced FLAIR* in 1.5T system are substantial (ICC1:0.79 and ICC2: 0.78 respectively). For the percentage-based system, GBCA-enhanced FLAIR* revealed a mean of 63% ± 14.8 in 1.5T systems and 72% ± 13.4 in 3T systems per participant ($p=0.015$).

### CONCLUSION

GBCA-enhanced 3D FLAIR* in 1.5T systems, albeit underperformed to 3T systems, was also efficient in the detection of CVS status considering the pre-determined threshold of the current literature for MS diagnosis.

### CLINICAL RELEVANCE/APPLICATION

With this proven diagnostic efficacy in detecting CVS, 1.5T scanners can be used to reinforce the present armada of higher-field MR scanners, in serving and reaching out to a wider number of MS patients worldwide.

## M5A-SPNR-15 VISCERAL FAT ACCUMULATION MEDIATES THE ASSOCIATIONBETWEEN HIPPOCAMPAL ATROPHY AND COGNITIVEANDEMOTIONAL IMPAIRMENTS IN MIDDLE-AGED NAFLD PATIENTS

Kuanghui Xu (*Abstract Co-Author*) Nothing to Disclose
Yihan Jin (*Abstract Co-Author*) Nothing to Disclose
Ruoyu Tang (*Abstract Co-Author*) Nothing to Disclose
Jie Li I, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaofei Chen (*Abstract Co-Author*) Nothing to Disclose
Liqiang Wu (*Abstract Co-Author*) Nothing to Disclose
Yuchi Tian (*Presenter*) Nothing to Disclose

### PURPOSE

Non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver disease and is thought to be significantly associated with brain health, particularly in terms of cognitive impairment and mood disorders. However, the neuroanatomical basis of NAFLD and how brain morphology affects cognitive and emotional function remain unclear. This study aims to analyze the changes of brain structure and its relationship with cognitive function in patients with NAFLD using voxel-based morphometry (VBM).

### METHODS AND MATERIALS

Seventy-four patients with NAFLD and sixty-two healthy controls matched for sex, age, and years of education were recruited. All participants underwent high-resolution 3D-T1WI MRI scans to obtain whole-brain structural images. The difference of gray matter volume (GMV) between the two groups was

compared by voxel-based morphometry. Partial correlation analysis and mediation effect analysis were further used to assess the relationship between GMV values in abnormal regions and cognitive function, mood symptoms, and clinical indicators in NAFLD patients.

**RESULTS**

People with NAFLD exhibit impaired cognitive function, anxiety and depression. Compared to healthy controls, NAFLD patients showed reduced GMV in the bilateral hippocampus, the left parahippocampal gyrus, the right fusiform gyrus, the left middle temporal gyrus, the right supplementary motor area (SMA), and the right cerebellar hemisphere. In patients with NAFLD, GMV values in the right hippocampus and left parahippocampal gyrus were positively correlated with DST scores, while GMV values in the right fusiform gyrus were negatively correlated with waist-to-hip ratio. Medial analysis revealed that the relationship between GMV values in the right hippocampus and cognitive function and negative emotions was entirely mediated by liver fat content.

**CONCLUSION**

Patients with NAFLD exhibit atrophy in brain regions associated with reward circuits and sensorimotor networks. Among them, atrophy of the medial temporal lobe is associated with cognitive impairment, anxiety and depression, which is exacerbated by the accumulation of visceral fat.

**CLINICAL RELEVANCE/APPLICATION**

This study emphasizes the clinical significance of changes in specific brain regions in patients with non-alcoholic fatty liver disease (NAFLD), such as atrophy in the bilateral hippocampus and the left parahippocampal gyrus, linking these alterations to cognitive impairments and mood disorders, and indicates that controlling visceral fat accumulation can improve cognitive and emotional symptoms.

## M5A-SPNR-16 DYNAMIC DIGITAL RADIOGRAPHY: A NOVEL IMAGING TECHNIQUE TO INVESTIGATE PATIENTS WITH CERVICAL PAIN

Paolo F. Felisaz, MD (*Abstract Co-Author*) Nothing to Disclose
Giancarlo Oliva (*Abstract Co-Author*) Nothing to Disclose
Maurizio Ce, MD,BA (*Abstract Co-Author*) Nothing to Disclose
Laura Macri (*Abstract Co-Author*) Nothing to Disclose
Francesca Lucrezia Rabaiotti (*Abstract Co-Author*) Nothing to Disclose
Tatiana Lisnic (*Abstract Co-Author*) Nothing to Disclose
Michaela Cellina (*Presenter*) Nothing to Disclose

**PURPOSE**

Dynamic Digital Radiology (DDR) is a new imaging technique that allows, through pulsated X-Ray emission, the acquisition of high-resolution sequential imaging to assess the movement of different anatomical structures.Our aim was to assess the added value of cervical DDR (CDDR) in patients complaining cervical pain.

**METHODS AND MATERIALS**

We prospectively included patients evaluated by our Neurosurgeons for long-term cervical pain, poorly responsive to conservative treatments, who previously underwent MRI. Patients were carefully instructed on how to perform consecutive movement of cervical spine flexion and extension and tried the movement many times.CCDR acquisition parameters were as follows: MRI consisted of a standard acquisition protocol including sagittal T1-, T2 weighted and STIR sequences, and axial T2-weighted sequences. DDR acquisition parameters were: 70 Kv, 100 mA, 15 fps, esposure time: 5msec, acquisition time: 10 sec. Image analysis was performed by two experienced neuroradiologist and one neurosurgeon in consensus. Image analysis included on MRI: spondylarthrosis signs (osteophytes, vertebral plates sclerosis), spondylolisthesis, reduction of the intervertebral space, and signs of disc degeneration. On CDDR: spondylarthrosis signs, the range of the flexion and the extension movements (subjectively classified in normal or reduced), spondylolisthesis, reduction of the intervertebral space, presence of "stiff" disc, defined as a disk maintaining the same thickness during the whole dynamic cycle. The patients' management (surgical versus conservative) was established by two experience neurosurgeons in consensus.Radiation exposure was assessed by our physician as Dose area product (DAP).

**RESULTS**

20 patients (12 male; mean age 45 years) were enrolled.CDDR showed a reduced range of the cervical movements in 19/20 patients (95%). CDDR was comparable to MRI in assessing the presence of spondylarthrosis signs (present on both examinations in 20/20 cases)Signs of disc degeneration on MRI corresponded to reduction of the reduction of the intervertebral spaces high on DDR in 20/20 patients (100%). CDDR showed spondylolisthesis in 20/20 (100%) patients, whereas MRI missed listhesis in 5/20 patients (25%). CDDR highlighted the presence of stiff disc in 18 (90%) patients. CCDR findings changed the patients' management compared with what established with the sole MRI in 4/20 patients (20%).Mean DAP was 69 dGycm2.

**CONCLUSION**

CDDR allows an optimal evaluation of spondylarthrosis and adds functional information about the range of movement excursion and about the presence of stiff discs.

**CLINICAL RELEVANCE/APPLICATION**

DDR provide additional information useful for the management of patients complaining long-term cervical pain.

## M5A-SPNR-18 DYSREGULATED FUNCTIONAL NETWORK INTERACTIONS IN THE BRAIN OF DEPRESSION: FROM THE PERSPECTIVE OF THE TRIPLE-NETWORK MODEL

Manxi Xu (*Presenter*) Nothing to Disclose

**PURPOSE**

Major Depressive Disorder (MDD) has a high incidence and disability rate, imposing a significant economic burden on families and society. However, the etiology remains unclear, and objective diagnostic markers are lacking. Studies have shown alterations in functional connectivity within three interrelated neurocognitive networks: the Default Mode Network (DMN), Salience Network (SN), and Executive Control Network (ECN), which play a crucial role in MDD onset, symptoms, and response to antidepressant treatment . We hypothesize the presence of static and dynamic abnormal connectivity patterns in these core networks of MDD patients. To test this, we employ static functional network connectivity (FNC) analysis, dynamic functional network connectivity (dFNC), the network interaction index (NII), and the dynamic functional network connectivity (dNII) to investigate interactions among DMN, SN, and ECN, proposing reliable indicators.

**METHODS AND MATERIALS**

This study included 112 MDD patients diagnosed according to DSM-5 criteria and 49 healthy controls (HC). All participants underwent independent component analysis, and NII and FNC were computed based on the identified independent components. dFNC was derived using the sliding window

method, followed by K-means clustering of windowed dFNC. Mean dynamic network interaction index (mdNII) and the variance of dynamic network interaction index (vardNII) were calculated.

**RESULTS**

The results of static functional network connectivity show that compared to HC, NII of MDD patients significantly increase (T=-2.24; P=0.03). Further research find that the abnormality of NII in MDD patients is caused by a decrease in SN-DMN connectivity (T=2.19; P=0.03); The results of dynamic functional network connectivity show that after controlling for confounding factors, mdNII of the MDD patient group significantly increase compared to the control group (T=-3.68, P<0.001). Further research find that the abnormality of mdNII in MDD patients is caused by differences in SN-DMN connectivity (reduction), and this change is not affected by the clustering form.

**CONCLUSION**

MDD patients have abnormal network functional interactions that can be captured by static and dynamic NII indicators. The abnormal network interactions are mainly caused by reduced SN-DMN connectivity. This deepens our understanding of the abnormal activity of the three networks in MDD patients, helps to reveal the pathogenesis of MDD, and provides ideas for its intervention.

**CLINICAL RELEVANCE/APPLICATION**

This study reveals altered brain network connectivity in MDD patients, suggesting that measures like the Network Interaction Index (NII) could improve diagnosis and inform personalized treatments.

## M5A-SPNR-19 RADIOMIC PROFILING OF ANEURYSMAL BLEBS IS INFLUENCED BY HEMODYNAMICS AND MECHANICAL STRESS

Andres Gudino (*Abstract Co-Author*) Nothing to Disclose
Edgar Samaniego (*Abstract Co-Author*) Nothing to Disclose
Elena Sagues (*Abstract Co-Author*) Nothing to Disclose
Navami Shenoy (*Abstract Co-Author*) Nothing to Disclose
Arshaq Saleem (*Abstract Co-Author*) Nothing to Disclose
Daniela Molina (*Abstract Co-Author*) Nothing to Disclose
Sebastian Sanchez (*Abstract Co-Author*) Nothing to Disclose
Rodrigo Jaramillo (*Abstract Co-Author*) Nothing to Disclose
Carlos Dier, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The presence of blebs increases the likelihood of aneurysms rupture. Radiomic profiling (RP) can provide information about signal intensity (SI) distribution within the aneurysm's wall. However, the specific radiomics features (RFs) of different compartments within the aneurysm, such as the bleb and the body sac, have yet to be studied. We analyzed the inter-relationship between RP of aneurysmal blebs and computational fluid dynamics (CFD) alongside finite element analysis (FEA).

**METHODS AND MATERIALS**

One hundred fourteen aneurysms were imaged from May 2019 to December 2022 with 3T-MRI. Blebs were adjudicated as focal outpouchings within the body of the aneurysms on 3-dimensional rotational angiography (3DRA). 3D Slicer was used to generate 3D models of the aneurysm's bodies and blebs. RFs were independently extracted from both the body and bleb in T1+Gadolinium (GD) MRI sequences. CFD and FEA were employed to calculate Wall Shear Stress (WSS) and Wall Tension (WT), respectively. Univariate regression models were utilized to compare the blebs and bodies of each aneurysm. Spearman's correlation analyses were conducted to assess the relationships between the blebs' RP and the metrics of WSS and WT.

**RESULTS**

Eighteen aneurysms with blebs (16%, 18/114), were identified. 56% (55/93) of the RFs showed significant differences between the blebs and the bodies of the same aneurysms. Among these RFs, 28% (5/18) were classified as first-order, while 68% (50/75) were second-order features. A total of forty-one strong or moderate correlations were identified between either WSS or WT and the RP of the blebs. Specifically, 11% (6/55) of the RFs correlated with Time-Averaged WSS, 33% (18/55) with WSS Gradient, 27% (15/55) with the Oscillatory Shear Index (OSI), and 3.6% (2/55) with WT. Blebs exhibited different SI distributions among voxels and texture patterns compared to the sacs of the aneurysm bodies. In addition, there was a notable association between the variation in texture within the blebs and low WSS alongside high OSI.

**CONCLUSION**

Blebs exhibit unique RP compared to aneurysm body sacs. The heterogeneity of the bleb's wall may be caused by distinct mechanical load and hemodynamics, as demonstrated by the co-localization with low WSS.

**CLINICAL RELEVANCE/APPLICATION**

Radiomic profiling can help identify regions of high rupture risk within the aneurysm wall.

## M5A-SPNR-4 AUTOMATED DIAGNOSIS OF IDIOPATHIC NORMAL PRESSURE HYDROCEPHALUS USING SINGLE 3D T1-WEIGHTED MRI SCAN: A HYBRID DEEP LEARNING-MACHINE LEARNING APPROACH

Seung Hyun Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Seungjun Lee, BS (*Abstract Co-Author*) Nothing to Disclose
Chong Hyun Suh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Suyoung Yun, MD (*Abstract Co-Author*) Nothing to Disclose
Wooseok Jung, MSc (*Abstract Co-Author*) Nothing to Disclose
Saehyun Kim (*Presenter*) Nothing to Disclose

**PURPOSE**

Idiopathic normal pressure hydrocephalus (iNPH), a treatable form of dementia, often remains undiagnosed due to its similarity to neurodegenerative conditions such as Alzheimer's disease (AD) and Parkinson's disease (PD). This study aimed to develop and validate automated algorithms for diagnosing iNPH using only a single 3D T1-weighted MRI scan, facilitating early detection and treatment.

**METHODS AND MATERIALS**

This multicenter study included training and external testing datasets with subjects categorized as iNPH, AD, PD, and healthy controls (HC). All participants underwent 3D T1-weighted MRI scans from various scanners. We developed a hybrid deep learning-machine learning model: 3D Swin Transformer with additional MRI postprocessing stages for measuring iNPH biomarkers (see figure: disproportionately enlarged subarachnoid space

hydrocephalus [DESH] indices including Sylvian fissure enlargement and high-convexity tightness, callosal angle, Evans' index, and normalized lateral ventricle volume) from T1-weighted MRI scans, followed by XGBoost using these features for iNPH classification. The performance of the biomarker measurement and iNPH classification was evaluated using the area under the receiver operating characteristic curve (AUC) and the intraclass correlation coefficient (ICC).

**RESULTS**

The training dataset of 452 patients (200 men, 252 women; age 73.2 ± 6.5 years) included 111 iNPH (24.6%), 101 AD (22.3%), 103 PD (22.8%), and 137 HC (30.3%). The external testing dataset of 110 patients (48 men, 62 women; age 72.4 ± 7.7 years) had 28 (25.5%) iNPH, 28 (25.5%) AD, 26 PD (23.6%), and 28 HC (25.5%). The model achieved excellent performance both in biomarker measurement (AUC: 0.956 for DESH, 0.830 for sylvian fissure enlargement, 0.956 for high-convexity tightness; ICC: 0.824 for callosal angle, 0.924 for Evans index) and iNPH classification (AUC: 0.983 for cross-validation, 0.936 for external testing), surpassing previous works lacking external validation. In addition, the performance remained high (AUC: 0.988 for cross-validation, 0.938 for external testing) even using manually labeled features for iNPH classification, indicating the robustness of the model.

**CONCLUSION**

The proposed method effectively utilizes clinically interpretable biomarkers from a single MRI scan to diagnose iNPH, demonstrating both interpretability and robust diagnostic performance.

**CLINICAL RELEVANCE/APPLICATION**

The proposed method could facilitate widespread iNPH screening from routinely acquired T1-weighted MRI scans, enabling timely diagnosis and treatment of iNPH.

## M5A-SPNR-6 INCREASED DETECTION OF CEREBRAL MICROBLEEDS WITH VENOUS ASSOCIATION IN CEREBRAL AMYLOID ANGIOPATHY AT HIGH-RESOLUTION 7T-MRI

Daniele Botta (*Abstract Co-Author*) Nothing to Disclose
Frederic Assal, MD (*Abstract Co-Author*) Nothing to Disclose
Frederic Grouiller (*Abstract Co-Author*) Nothing to Disclose
Karl-Olof Lovblad, MD (*Abstract Co-Author*) Nothing to Disclose
Felix Kurz (*Presenter*) Nothing to Disclose

**PURPOSE**

Cerebral microbleeds (MBs) are key indicators in neurovascular conditions, particularly cerebral amyloid angiopathy (CAA), within the broader category of cerebral small vessel disease. Despite their prevalence, MB pathophysiology still remains unclear, however, recent evidence based on MR images with 350µmx350µm in-plane resolution suggests an association between some MBs and adjacent small venous structures, typically missed on conventional MRI. Using highresolution ultra-high-field MRI, the objective was to assess the MB vascular environment in patients with probable CAA.

**METHODS AND MATERIALS**

We included n=5 patients with probable CAA according to the updated Boston Criteria 2.0 (3 men, 2 women) in this observational study, who were examined with a susceptibility-weighted imaging (SWI) sequence (150µmx150µm in-plane resolution, TE: 15ms, TR: 25ms, acquisition time: 6:34min) at a 7-Tesla MRI scanner (Siemens Magnetom Terra.X). Two expert readers reviewed images to find and quantify lobar MBs, and to assess their association with the venous topography.

**RESULTS**

Average patient age was 72.2 ± 8.9 years with 9.4 ± 4.6 MBs per patient (total number of MBs: 47). For each patient, 60.09% ± 12.12% of MBs had a direct spatial connection to a small venous structure. The presence of MBs with a venous association was highly correlated with the overall number of MBs per patient (r2=0.98, p=0.005), while there was a negativecorrelation of MBs with a venous association and patient age (r=-0.95, p=0.010).

**CONCLUSION**

Compared with a previous study at lower resolution that found that only a small number (14%) of MBs had a venous association, our findings suggest a significantly higher number of MBs with a relation to adjacent venous structures in patients with CAA. These insights point towards a potential venous role in the pathogenesis of CAA and MB formation, especially in younger patients. Further research with expanded cohorts and pathological confirmation is needed to substantiate these observations and clarify the mechanisms involved.

**CLINICAL RELEVANCE/APPLICATION**

The clinical relevance of this study lies in its potential to enhance our understanding of the pathophysiology of cerebral microbleeds, particularly in the context of cerebral amyloid angiopathy. By elucidating the association between MBs and adjacent small venous structures, the study provides insights into potential mechanisms underlying MB formation. Understanding the vascular environment surrounding MBs could have implications for diagnosis, prognosis, and treatment. For instance, if venous involvement is indeed found to play a significant role in MB formation, it may lead to the development of novel imaging biomarkers for early detection and monitoring of CAA-related pathology.

## M5A-SPNR-7 ULTRA-HIGH RESOLUTION PHOTON-COUNTING CT ANGIOGRAPHY FOR NEUROVASCULAR IMAGING - IMAGE QUALITY ASSESSMENT USING DEDICATED RECONSTRUCTION KERNELS AND QUANTUM ITERATIVE RECONSTRUCTION

Maria G. Matheus, MD (*Abstract Co-Author*) Nothing to Disclose
Milad Yazdani, MD (*Abstract Co-Author*) Nothing to Disclose
Sameer Tipnis, PhD (*Abstract Co-Author*) Nothing to Disclose
Maria Vittoria Spampinato, MD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Bayer AG
Justin Chetta, MD (*Abstract Co-Author*) Nothing to Disclose
Adrienn Toth, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the image quality of ultra-high resolution (UHR) photon-counting CT (PCCT) angiography using a wide range of dedicated vascular kernels and all strength levels of quantum iterative reconstruction (QIR) in a cohort of patients with intracranial saccular aneurysms.

**METHODS AND MATERIALS**

18 patients with intracranial saccular aneurysms, who had previously undergone conventional EID-CT, were prospectively enrolled. CT angiograms of the head and neck were acquired on a clinical dual-source PCCT (NAEOTOM Alpha, Siemens, Germany) in UHR mode. Two image sets were generated: the

first included images reconstructed with a variety of dedicated vascular kernels (Hv36, Hv48, Hv56, Hv64, Hv72, Hv80) and QIR-1. After a preliminary qualitative analysis by two experienced neuroradiologists, the Hv64 kernel was selected for the second set of images, assessing all strength levels of QIR (0-4). The quantitative image quality of both image sets was evaluated. Signal, noise, signal-to-noise (SNR), and contrast-to-noise (CNR) were measured by manually placing regions of interest (ROIs) on each reconstruction at 12 standard anatomical locations (grouped as "Extracranial vessels", "Large intracranial vessels", and "Small intracranial vessels). Sharpness was measured by placing line profiles perpendicular to the vessel's borders to detect attenuation values using a dedicated workstation (ImageJ, version 1.53). Vessel sharpness was defined as the maximum per-pixel change in signal intensity.

**RESULTS**

The use of sharper reconstruction kernels resulted in increased image noise and decreased SNR and CNR. However, vessel sharpness increased more than twofold from Hv36 to Hv80 at each evaluated location. The greatest difference was measured in the small intracranial arteries (from 113.91 ± 28.16 to 308.04 ± 88.25, p <.001) By reducing image noise, the higher QIR levels improved quantitative image quality. While SNR and CNR increased by a factor of 2.62 and 3.42, small intracranial vessel sharpness increased by 12.51% from QIR-0 to QIR-4.

**CONCLUSION**

A combination of sharp dedicated kernels and high QIR levels enabled the improved visualization of intracranial vessels. The optimized reconstruction parameters delivered improved vessel sharpness, at the small intracranial locations in particular, showing promising results for neurovascular imaging considering the typical location of intracranial saccular aneurysms. In the following steps, a qualitative assessment of image quality will be conducted to further analyze the impact of reconstruction kernel and QIR adjustments on overall image quality.

**CLINICAL RELEVANCE/APPLICATION**

Our results provide meaningful data for protocol optimization on photon-counting-CT for neurovascular imaging.

## M5A-SPNR-9 0.55T IMAGING OF PATIENTS WITH SPINAL HARDWARE: DIAGNOSTIC FEASIBILITY AND METAL ARTIFACT COMPARISON TO 1.5/3T MRI

Francisco F. Rivas Rodriguez, MD (*Abstract Co-Author*) Nothing to Disclose
Vikas Gulani, MD, PhD (*Abstract Co-Author*) Research support, Siemens AG;Consulting, Cook Group Incorporated
Jayapalli R. Bapuraj, MD (*Abstract Co-Author*) Nothing to Disclose
Nicole Seiberlich, PhD (*Abstract Co-Author*) Royalties, Siemens AG;Research support, Siemens AG
Shruti Mishra, MD (*Abstract Co-Author*) Nothing to Disclose
Maria Masotti (*Abstract Co-Author*) Nothing to Disclose
Lauren Kelsey, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Expected reduced susceptibility artifacts may improve spinal implant evaluation at 0.55T compared to 1.5/3T. The aim of this study is to assess inter-reader agreement of imaging findings and compare readers' assessment of image quality (IQ) and the appearance of metal artifact (MA) in patients with spinal implants between 0.55T and 1.5/3T MRI.

**METHODS AND MATERIALS**

In this IRB-approved retrospective study, patients imaged on the Siemens Healthineers Magnetom Free.Max 0.55T (n=42; 19M, 23F; avg. age 55 yrs.) with spinal hardware in situ (n=11 cervical, n=6 thoracic, n=21 lumbar, n=3 sacral, n=1 total; median hardware levels=2) between 12/2021-3/2024 were included. Of these, 19 patients had an exam at high-field (HF) (n=18, 1.5T; n=1, 3T) with the same hardware in situ. All exams were anonymized and scored independently by three board-certified neuroradiologists (R1-3). Readers selected diagnoses/imaging findings from a pick-list for all 61 exams. For the 19 paired exams, paired sequences were rated using a 4-point Likert scale for IQ and MA (1=non-diagnostic/severe artifacts, 4=excellent/minimal artifacts). Wilcoxon signed-rank tests were applied to determine sequence-wise differences between 0.55T and HF ratings for IQ and MA. Raw agreement and Cohen's kappa were applied to assess diagnostic agreement independently for each field-strength cohort.

**RESULTS**

In both 0.55T and HF, raw agreement for the following findings ranged between 81-95%: cord signal abnormality, suspicion for osteomyelitis/discitis, suspicion for osseous metastatic disease, and compression fracture. Agreement on post-operative fluid collection and spinal canal stenosis was 64.3% and 66.7% at 0.55T, and 78.9% and 52.6% at HF, respectively. Agreement on neural foraminal stenosis was lowest in both cohorts, 47.6% at 0.55T and 36.8% at HF. No sequence at 0.55T was rated statistically significantly inferior to HF in either IQ or MA. Statistically significant results where a sequence was rated higher at 0.55T compared to HF were as follows for IQ: sagittal T1w TSE (R1: p=0.03) and as follows for MA: axial T1w TSE (R1: p=0.01; R2: p=0.02), sagittal T1w TSE (R1: p=0.01), axial T2w TSE (R1: p=0.01), sagittal T1w TSE Dixon in-phase post-contrast (R2: p=0.04), sagittal T2w STIR (R2: p=0.01).

**CONCLUSION**

Imaging patients with spinal hardware at 0.55T results in comparable inter-reader agreement for clinically relevant findings/diagnoses compared to 1.5/3T. The evaluated routine sequences were rated as having equivalent or improved IQ and MA compared to HF by three neuroradiologists.

**CLINICAL RELEVANCE/APPLICATION**

Post-operative spinal hardware imaging and diagnostic evaluation may be comparably or superiorly performed at 0.55T when compared to conventional 1.5/3T field strengths.

## M5A-SPOB-1 DIAGNOSTIC ACCURACY OF CONTRAST ENHANCED ULTRASOUND QUANTITATIVE PARAMETERS VIS-A-VIS DYNAMIC MAGNETIC RESONANCE IMAGING PARAMETERS FOR CHARACTERIZATION OF SONOGRAPHICALLY COMPLEX ADNEXAL MASSES: A PILOT STUDY

Hemal Grover, MD (*Abstract Co-Author*) Nothing to Disclose
Sayantan Patra, MD (*Abstract Co-Author*) Nothing to Disclose
Geetika Khanna, MD (*Abstract Co-Author*) Nothing to Disclose
Shabnam B. Grover, MD, DMRD (*Presenter*) Nothing to Disclose

### PURPOSE

Contrast enhanced ultrasound (CEUS) using second generation microbubble contrast, eliminated in expired air, has not yet been extensively explored for evaluation of adnexal masses. Therefore, aim of this study was to compare diagnostic accuracy of CEUS Quantitative Parameters vis-ą-vis Dynamic MRI (DyMRI) parameters for characterization of complex adnexal masses.

### METHODS AND MATERIALS

This was a retrospective analysis of an IRB approved study comprising 30 patients with 32 complex adnexal masses who underwent both CEUS DyMRI, prior to surgical resection. Histopathology results were considered as gold standard. CEUS was performed by standard technique on Siemens equipment using Sonovue® second generation ultrasound contrast. Video clips were acquired for at least 90 seconds post contrast. Equipment in-built Contrast Dynamics software spontaneously generated quantitative parameters, namely: Time to peak,Tp; Peak enhancement,Pe; Mean transit time,MTT; Area Under the Curve,AUC also provided time intensity curve (TIC). DyMRI was performed on Phillips 3T MRI equipment as per standard protocol for adnexal masses. TIC for DyMRI, were generated from in-built software type II type III curves were considered malignant. Additionally, ROC curve analysis was done for both modalities to obtain discriminant cut off values. Subsequently, diagnostic accuracy of each technique, for benign versus malignant characterization, was calculated based on the best discerning parameters. Sensitivity, specificity, PPV, NPV diagnostic accuracy were calculated based on histopathology results.

### RESULTS

Histopathology revealed 20 adnexal masses as malignant 12 benign. For CEUS, best determinant parameters were found to be AUC followed by PE MTT. For DyMRI, the same were wash-in rates, wash-out rates AUC. Sensitivity, specificity, positive negative predictive values for CEUS were 90%, 75%, 83.3% 81.8%; for DyMRI it was 90%, 91.67%, 94.74% 84.62%. Diagnostic accuracy of CEUS DyMRI were 84.38% 90.63% respectively. (Composite figure combining imaging statistics, submitted)

### CONCLUSION

CEUS shows comparable diagnostic accuracy to DyMRI, a vital component of adnexal MRI evaluation. The major advantages of CEUS are two fold. First being lower cost, which is almost a fifth of DyMRI. Secondly, since Sonovue is excreted through lungs, it can be safely used in patients with renal compromise, who cannot undergo Gadolinium MRI.

### CLINICAL RELEVANCE/APPLICATION

Significantly lower cost safety in patients with renal compromise favor further exploration wider clinical application of CEUS, especially in low resource settings, lacking MRI facilities.

## M5A-SPOB-3 VALUE OF VIRTUAL MAGNETIC RESONANCE ELASTOGRAPHY IN THICK PLACENTA

Jiejun Cheng (*Abstract Co-Author*) Nothing to Disclose
Jialu Xu (*Presenter*) Nothing to Disclose

### PURPOSE

We aimed to explore the value of diffusion weighted imaging (DWI)- based virtual magnetic resonance elastography (vMRE) in predicting preterm birth of pregnancies with thick placenta.

### METHODS AND MATERIALS

Twenty-five preterm birth of pregnancies with thick placenta(TP) and normal birth of pregnancies with thick placenta were included in this prospective study. Diffusion-weighted imaging (b-value of 50 ,200and 800 s/mm2 ) were performed on all pregnant women using a 1.5 T magnetic resonance

imaging (MRI)scanner. DWI-based vMRE parameter [the stiffness value (μdiff)], and apparent diffusion coefficient (ADC) were calculated and compared between groups. The predictive effciency was compared by the logistic regression analysis and receiver operating characteristic curve analysis.

**RESULTS**

The average thickness of placenta was 49.320±8.568mm in pregnancies without preterm birth versus 58.741±9.010mm in pregnancies with preterm birth. ADC of placenta was lower in pregnancies with preterm birth than without preterm birth(1.570±0.269×10-3 mm2 /s versus 1.768±0.174×10-3 mm2 /s, p=0.034); But the μdiff value increased in pregnancies with preterm birth than without preterm birth(5.571±0.563 kpa versus4.825±0.528kpa, p=0.007). The placental stiffness was predictive risk factor for preterm birth in pregnancies with TP.The area under AUC was 0.851.

**CONCLUSION**

vMRE quantifies placenta elastography in TP pregnancies. Placental vMRE might be a vital non-invasive supplement for predicting preterm birth in pregnancies with thick placenta.

**CLINICAL RELEVANCE/APPLICATION**

Placental vMRE might be a useful tool to assess placental function and a vital non-invasive supplement for predicting preterm birth in pregnancies with thick placenta.

## M5A-SPOB-4 LESION-BASED EVALUATION OF AN ECHOGENIC COMPONENT-BASED AI/CADX MODEL FOR THE CLASSIFICATION OF MALIGNANT AND BENIGN ADNEXAL LESIONS WITH ULTRASOUND IMAGING

Ernst Lengyel (*Abstract Co-Author*) Nothing to Disclose
Maryellen L. Giger, PhD (*Abstract Co-Author*) Stockholder, Hologic, Inc;Royalties, Hologic, Inc;Shareholder, Quantitative Insights, Inc;Co-founder, Quantitative Insights, Inc;Shareholder, QView Medical, Inc;Royalties, General Electric Company;Royalties, Median Technologies;Royalties, Riverain Technologies, LLC
Hui Li, PhD (*Abstract Co-Author*) Nothing to Disclose
Jacques S. Abramowicz, MD (*Abstract Co-Author*) Author with royalties, Wolters Kluwer nv;Medical Advisory Board, Samsung Electronics Co, Ltd
Roni Yoeli-Bik, MD (*Abstract Co-Author*) Nothing to Disclose
Ryan Longman (*Abstract Co-Author*) Nothing to Disclose
Heather Whitney, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Due to their heterogeneous nature, up to one-third of adnexal lesions assessed by qualitative ultrasound-based risk models are classified as indeterminate. Artificial intelligence/ computer-aided diagnosis (AI/CADx) tools that provide an automatic, quantitative assessment might improve the ability to reliably classify benign and malignant lesions. We previously developed an AI/CADx pipeline for automatic segmentation and echogenic component-based radiomic feature extraction of adnexal lesions on ultrasound merged with manual solid elements detection with high performance (AUC = 0.91 [0.83, 0.98]). The goal of this study was to evaluate the lesion-by-lesion likelihood of malignancy using AI/CADx at a target operating point along withthe Assessment of Different NEoplasias in the adneXa (ADNEX) model for reference.

**METHODS AND MATERIALS**

A retrospective dataset of sonographic images of adnexal lesions (1 per case, no markups; cancer prevalence 27.9%) had been collected and split into training/validation (95 lesions; 70%) and independent test sets (41 lesions; 30%). In the test set, we evaluated the sensitivity, specificity, PPV, and NPV at target 95% sensitivity (established from the training set) via a posteriori bootstrapping of the likelihood of malignancy 200 times. We also compared the AI/CADx lesion-by-lesion likelihood of malignancy with the ADNEX performance at 10% cut-off.

**RESULTS**

For the AI/CADx model at target 95% sensitivity, the sensitivity, specificity, PPV, and NPV were 0.99 [0.87, 1.00], 0.71 [0.54, 0.83], 0.58 [0.48, 0.71], and 0.41 [0.35, 0.45], respectively. All malignant and 22/29 benign lesions were correctly classified by both the AI/CADx and ADNEX models. Both models incorrectly classified three benign lesions as malignant (a teratoma, a cystadenofibroma, and a fibroma). The AI/CADx model incorrectly classified three additional benign lesions (two cystadenofibromas and teratoma); the ADNEX model incorrectly classified one additional benign lesion (an infarcted benign cyst with torsion).

**CONCLUSION**

Lesion-based analysis of a novel AI/CADx pipeline designed to classify adnexal lesions on ultrasound as malignant or benign showed comparable classification to the ADNEX model with the additional benefit of an automated pipeline. All malignant cases were correctly classified by both models. Three unique false positive results by AI/CADx indicate the potential for additional development particularly for cystadenofibromas and teratomas.

**CLINICAL RELEVANCE/APPLICATION**

An AI/CADx-based pipeline for automatic segmentation and classification of malignant and benign adnexal lesions on ultrasound has the potential to reduce diagnostic variability and improve the decision-making process.

## M5A-SPPD-1 MATERNAL TOBACCO SMOKING ASSOCIATED WITH PLACENTA VOLUMES DIFFERENCES AND ALTERED TEXTURE FEATURES

Rupa Radhakrishnan, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Ramana V. Vishnubhotla, PhD (*Abstract Co-Author*) Nothing to Disclose
Ashok Panigrahy, MD (*Abstract Co-Author*) Nothing to Disclose
Senthilkumar Sadhasivam (*Abstract Co-Author*) Nothing to Disclose
Jonathan Class, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The placenta plays an important role in fetal development and neuroprotection. In a previous study, we showed that prenatal opioid exposure and smoking was associated with increased placental volumes. This study aims to assess morphological abnormalities in the placenta using placental texture analysis in pregnant women with substance exposure and smoking, compared to control pregnant women.

### METHODS AND MATERIALS

This was a prospective IRB approved study that recruited pregnant women with prenatal opioid and other substance exposure and nonsubstance using controls. Two-dimensional (2D) MR images of the placenta were acquired using a Half-Fourier Single-shot Turbo spin-Echo (HASTE) sequence. Placenta region of interest masks were manually segmented. Labeled images were run through a radiomics pipeline with 2D resampled data. Second order statistical features based on gray level co-occurrence matrix, gray level run length matrix, and gray level size zone matrix were assessed. Comparisons were made for those with prenatal opioid and tobacco exposure and placenta size using a robust linear regression while accounting for demographic variables (infant sex, race, maternal age, gestational age, maternal body mass index) and placenta volume.

### RESULTS

There were 43 pregnant mothers, including 23 with opioid use, 17 with tobacco use and 20 controls without opioid or tobacco use. Average gestational age was (M=34.3, SD=3.2) in the opioid group (M=34.1, SD=3.3) in the tobacco group, and (M=33.7, SD=3.2) in controls. Tobacco smoking was significantly associated with larger placenta volumes (p=0.008), as well as differences in contrast (p=0.02), difference average (measure of overall homogeneity; p=0.01), inverse difference (measure of local homogeneity; p=0.04), and zone percentage (measure of coarseness; p=0.03). Opioid exposure alone was not associated with placental textural feature differences.

### CONCLUSION

We identified maternal smoking to be associated specific differences in placenta texture features on placental MRI compared to non-smoking controls.

### CLINICAL RELEVANCE/APPLICATION

The results of this study suggest the impact of maternal smoking on placental volume and its texture. Alterations in placental texture have been reported in fetuses with growth restriction. Future steps would be to understand how placenta texture features may predict fetal and infant growth and development in pregnancies with prenatal substance exposure.

## M5A-SPPD-2 EXTERNAL VALIDATION OF THE ARTIFICIAL INTELLIGENCE-BASED ALGORITHM FOR SCREENING OF ILEOCOLIC INTUSSUSCEPTION USING PEDIATRIC ABDOMINAL RADIOGRAPHS: A MULTICENTER RETROSPECTIVE STUDY

### PURPOSE

To upgrade and validate the artificial intelligence (AI) algorithm for screening ileocolic intussusception on pediatric abdominal radiographs using multicenter data.

## METHODS AND MATERIALS

Pediatric patients (= 5 years old) who visited the emergency department and underwent both abdominal radiographs and ultrasonography on the same date for the evaluation of ileocolic intussusception from March 2012 to February 2022 at Hospital A, from March 2020 to February 2022 at Hospital B, and from March 2016 to February 2022 at Hospital C were included retrospectively. Patients were categorized into control and intussusception groups based on the ultrasound (US) results. The AI algorithm was retrained using additional data from Hospital A, utilizing the You-Only-Look-Once (YOLO)-v4-p5 model. For external validation, data from Hospitals B and C were utilized. Two radiologists assessed the presence of intussusception using abdominal radiographs, and the diagnostic performance was compared with the upgraded AI model using logistic regression with a generalized estimating equation.

## RESULTS

Abdominal radiographs from a total of 431 patients, including 143 patients with intussusception at Hospital A, were used to develop the upgraded algorithm. For external validation, 68 patients (M:F = 42:26, mean age 1.6 ± 1.5 years) with 19 cases of intussusception from Hospital B, and 90 patients (M:F = 47:43, mean age 1.5 ± 1.3 years) with 30 cases of intussusception from Hospital C were included. When comparing the diagnostic performances of radiologists with that of the AI algorithm, the sensitivity (75.5% vs. 44.9%, p<0.001), accuracy (82.3% vs. 74.7%, p=0.029), and negative predictive value (NPV) (88.6% vs. 78.1%, p<0.001) were significantly higher in AI compared to the radiologists overall. However, there were no statistically significant differences in specificity (85.3% vs. 88.1%, p=0.479) and positive predictive value (PPV) (69.8% vs. 62.9%, p=0.311).

## CONCLUSION

This multicenter external validation study demonstrates the potential use of AI as a screening tool for ileocolic intussusception on pediatric abdominal radiographs. Presenting an applicable way to use AI in pediatric abdominal emergency cases is clinically significant, and demonstrating external validation results is necessary to ensure safety and assess its potential for real-world implementation.

## CLINICAL RELEVANCE/APPLICATION

Intussusception is one of the important emergent abdominal diseases of young infants, needing immediate treatment. We wanted to know whether AI could help to detect children who need further evaluation and to focus external validation of the AI algorithm on abdominal radiographs using multicenter data.

# M5A-SPPD-3 A NEW FRONTIER: PEDIATRIC APENDIC RADS AND ITS IMPACT ON PEDIATRIC APPENDICITIS DIAGNOSIS

Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*) Nothing to Disclose
Cesar Passos Braga, MD (*Abstract Co-Author*) Nothing to Disclose

Victor A. Jabour, MD (*Abstract Co-Author*) Nothing to Disclose
Hugo Franco, MD (*Presenter*) Nothing to Disclose

## PURPOSE

- Ultrasonography plays a crucial role in evaluating suspected cases, providing varied assessments of appendicitis likelihood, especially in children, since ultrasound is a diagnostic method free from ionizing radiation, low cost, quick to access, and with real-time evaluation.- This study introduces PEDIATRIC APENDIC-RADS to standardize ultrasound reporting for acute appendicitis among the pediatric age group, aiming to improve objective descriptions of direct and indirect signs, stratifying the risk for acute inflammatory process of the cecal appendix with a final numerical classification, assisting clinicians and pediatricians in the management and follow-up of suspected patients, especially in doubtful cases.

## METHODS AND MATERIALS

- This study examines retrospectively consecutive patients of age from 0 to 16 years old undergoing abdominal ultrasound for acute appendicitis, with main outcome being histopathological confirmation post-surgery.- Imaging results were categorized into five PEDIATRIC APENDIC-RADS groups at the moment of examination.- Statistical analysis includes descriptive stats, chi-square, Fisher's exact, likelihood ratio tests, ROC curve, and calibration belt construction.

## RESULTS

- A total of 356 patients were assessed for suspected acute appendicitis using ultrasonography.- Of the diagnosed patients, 67% were male, primarily exhibiting symptoms such as nausea and/or vomiting (81%), right iliac fossa pain (57%), and sudden decompression in the right iliac fossa (43%).- Stratification into PEDIATRIC APENDIC-RADS categories revealed a significant variation in the incidence of acute appendicitis, with incidence rates of 19% for category 0 (unvisualized appendix) and 4.8%, 9.5%, 4.8%, and 62% for categories 1 through 4, respectively (p<0.001).

## CONCLUSION

- The PEDIATRIC APENDIC-RADS showed excellent discriminative ability, as evidenced by an AURTOC of 0.950 (95% CI, 0.899-1).- Model calibration was deemed adequate.- PEDIATRIC APENDIC-RADS categorization shows excellent performance in standardizing ultrasound-derived acute appendicitis probability, potentially enhancing physician communication and patient management standardization.

## CLINICAL RELEVANCE/APPLICATION

- In daily practice, clinicians and pediatricians can use PEDIATRIC APENDIC-RADS to quickly assess ultrasound findings, categorize patients into risk groups, and make informed decisions about further management, all while minimizing radiation exposure and improving patient care.

Saikiran Rapaka, PhD (*Abstract Co-Author*) Employee, Siemens AG
Pooyan Sahbaee, PhD (*Presenter*) Employee, Siemens AG

### PURPOSE

To develop a deep learning-based method for decomposing materials such as calcium, iodine, and gadolinium in spectral CT which is robust across various sizes and doses

### METHODS AND MATERIALS

A clinical photon-counting CT system (NAEOTOM Alpha, Siemens Healthineers) was simulated using the DukeSim platform (Duke University). Images were generated from two different datasets: cylindrical phantoms (12 phantoms; 20-42 cm diameter) and anthropomorphic abdominal phantoms (58 phantoms; XCAT, Duke University). Both datasets included clinically-relevant contrast agents (iodine (0-7 mg/mL), gadolinium (0-5 mg/mL)) and biological materials (soft tissue, calcium). Acquisition was simulated at 120 kV using 20-65 keV energy thresholds and at multiple size dependent dose levels for each phantom to create variable image quality across the dataset. The model was trained in two phases using a U-Net architecture: an initial feature detection of material per voxel followed by an estimate of iodine or gadolinium concentration. Models were trained with hybrid data containing cylindrical phantoms and a variable number (0-8) of XCAT phantoms. Model performance was evaluated by classification accuracy for the feature network and root-mean-squared error (RMSE) for the material concentration network.

### RESULTS

The model demonstrated high classification accuracy (92% iodine, 86% gadolinium, 95% calcium) and material concentration RMSE (0.57 mg/mL iodine, 0.39 mg/mL gadolinium) compared to ground truth values. Model performance increased when including a greater number of anthropomorphic models in the training dataset (53% with 0 XCATs to 91% with 8 XCATs). Material classification and concentration accuracy remained consistent across phantom size and dose conditions.

### CONCLUSION

A deep learning based approach to material decomposition trained using a hybrid dataset was able to accurately quantify iodine and gadolinium in the simulated images. The performance of the algorithm was maintained in conditions of low image quality. Future work will apply this algorithm to clinical data.

### CLINICAL RELEVANCE/APPLICATION

This robust material decomposition technique could potentially enhance the clinical viability of characterizing materials in spectral CT, independent of patient size and radiation dose.

## M5A-SPPH-10 A COMPARISON OF IMAGE NOISE AND TEXTURE IN CONTRAST-ENHANCED ABDOMINAL CT BETWEEN DEEP LEARNING IMAGE RECONSTRUCTION (DLIR) AND ADAPTIVE STATISTICAL ITERATIVE RECONSTRUCTION-V (ASIR-V)

Jianxin Guo (*Abstract Co-Author*) Nothing to Disclose
Jianying Li, PhD (*Abstract Co-Author*) Employee, General Electric Company
Le Cao (*Presenter*) Nothing to Disclose

### PURPOSE

To compare image noise and texture in contrast-enhanced abdominal CT between deep learning image reconstruction (DLIR) and adaptive statistical iterative reconstruction-V (ASIR-V).

**METHODS AND MATERIALS**

Contrast-enhanced abdominal CT images of 40 patients with hepatic lesions were retrospectively analyzed. Images in the portal phase were reconstructed at 1.25mm slice thickness using the 10, 30%, 50%, 70% and 90% ASIR-V and DLIR at low (DLIR-L), medium (DLIR-M) and high (DLIR-H) settings. CT number and standard deviation (SD) of the hepatic parenchyma, spleen, and paravertebral muscle were measured. The CT number skewness on liver parenchyma, spleen and paravertebral muscle were calculated to reflect image texture. Noise texture was also evaluated using a five-point discrete visual scale: 5, no pixilation or blotchy appearance; 4, minor pixilation or blotchy appearance not affecting diagnostic confidence; 3, moderate pixilation or blotchy appearance mildly limiting diagnostic confidence; 2, elevated pixilation or blotchy appearance reducing diagnostic confidence; and 1, major pixilation or blotchy appearance with poor diagnostic confidence. The measurements among the two algorithms were analyzed using SPSS22.0, with $P<0.05$ indicating statistically significant difference.

**RESULTS**

For both reconstruction algorithms, image noise in hepatic parenchyma, spleen, and paravertebral muscle decreased with the increase of reconstruction strength. The CT number skewness of ASIR-V increased with reconstruction percentage, but the CT number skewness of DLIR remained constant or decreased with the increase of reconstruction strength, and was lower than ASIR-V images. The 70% and 90% ASIR-V images appeared “too smooth” and “speckled”. DLIR had higher subjective scores and DLIR-H was rated the highest.

**CONCLUSION**

DLIR can effectively reduce image noise without changing image noise texture and does not appear too smooth with higher reconstruction strength.

**CLINICAL RELEVANCE/APPLICATION**

To compare image noise and texture in contrast-enhanced abdominal CT between deep learning image reconstruction (DLIR) and adaptive statistical iterative reconstruction-V (ASIR-V).

## M5A-SPPH-12 APPLICATION OF MODIFIED POSITIONING TO REDUCE BEAM HARDENING ARTIFACTS IN NECK CT IMAGING FOR THYROID EVALUATION

Huijuan Huang (*Abstract Co-Author*) Nothing to Disclose
Wencong Yang (*Abstract Co-Author*) Nothing to Disclose
Dongyi Chen (*Abstract Co-Author*) Nothing to Disclose
Furong Luo (*Abstract Co-Author*) Nothing to Disclose
Huijun Xiao (*Abstract Co-Author*) Nothing to Disclose
Weihua Lin (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the feasibility of a modified positioning (MP) in reducing beam hardening artifacts for thyroid evaluation in neck CT imaging.

**METHODS AND MATERIALS**

This prospective study enrolled 153 patients who were suspected of thyroid diseases and needed contrast-enhanced neck CT imaging, randomized into the MP group (n=70) and the conventional position group (CP, n=83). An auxiliary postural support device was used in the modified position group to ensure the patient's head was tilted back, shoulders sunk, and neck protruded during scanning, and no auxiliary postural device was used in the conventional position group, with all other scanning parameters being the same. Objective image quality was assessed by comparing the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) in both the heaviest and minimal artifact areas of the thyroid with two sides, along with the artifact-involved area percentage and artifact index between the two groups. Additionally, subjective image quality evaluations regarding the thyroid and the whole neck were performed independently by a junior and a senior radiologist using a 5-scale method.

**RESULTS**

The MP images had lower artifact-involved area percentages (left 0% vs. 43.8%, right 0% vs. 40.7%, both $P<0.001$), and higher SNR and CNR (left thyroid: SNR 16.83 vs. 7.1, CNR 11.02 vs. 7.33; right thyroid: SNR 16.7 vs. 6.9, CNR 12 vs. 6.7, all $P<0.001$) than the CP group. The artifact index was also significantly lower in the MP group for both sides (left 6.7 vs. 12.7, right 7.03 vs. 11.7, $P=0.015$). MP images had higher scores than the CP group on both thyroid (score>3 points: 62/70[88.6%] vs. 33/83[39.8%] for reader 1, 62/70[88.6%] vs. 32/83[38.6%] for reader 2, both $P < 0.05$) and neck (score>3 points: 54/70[77.2%] vs. 38/83[45.8%] for reader 1, 58/70[82.8%] vs. 46/83[55.4%] for reader 2, both $P< 0.05$) evaluation.

**CONCLUSION**

The modified positioning reduces photon starvation and beam hardening artifacts in lower neck CT imaging, and improves the display of thyroid.

**CLINICAL RELEVANCE/APPLICATION**

The imaging quality of thyroid in neck CT scanning is often interfered with beam-hardening artifacts resulting from adjacent anatomies. This study found a modified position could reduce artifacts and improve image quality in neck CT imaging, which has important clinical applications in the diagnosis of thyroid diseases.

## M5A-SPPH-3 SPECTRAL POST-PROCESSING (SPP) IN CLINICAL PHOTON-COUNTING CT (PCCT): IMAGE QUALITY COMPARISON OF POST-PROCESSED SPECTRAL IMAGES WITH DIRECT RECONSTRUCTIONS FROM SCANNER CONSOLE

Richard W. Ahn, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Liqiang Ren, PhD (*Abstract Co-Author*) Nothing to Disclose
Lakshmi Ananthakrishnan, MD (*Abstract Co-Author*) Nothing to Disclose
Xinhui Duan, PhD (*Abstract Co-Author*) Nothing to Disclose
Kristina Hallam (*Abstract Co-Author*) Employee, Siemens AG
Areej Aljabal, PhD (*Abstract Co-Author*) Nothing to Disclose
Afrouz Ataei, PhD (*Abstract Co-Author*) Nothing to Disclose
Xunbo Xu, ARRT (*Presenter*) Nothing to Disclose

**PURPOSE**

The first-generation commercial photon-counting CT <NAEOTOM Alpha, Siemens> uses a spectral post-processing <SPP> file format to store spectral data and retrospectively generate spectral images. The purpose of this phantom and patient study is to compare attenuation <HU> and noise on spectral reconstructions created from the SPP file to reconstructions generated at scanner console.

**METHODS AND MATERIALS**

The ACR CT accreditation phantom was scanned using 120 kV, 125 mAs, pitch 0.8, collimation 144x0.4mm and CTDIvol 12 mGy. Two sets of spectral images were generated from ACR phantom study on scanner console and at a thin client workstation using the SPP file <image thickness 1, 3 and 5 mm, kernel Qr44, virtual monoenergetic images of 50, 60, 70 ,100, 140 keV, IMD and virtual unenhanced <VNC> images>. Five ROI of the same size were placed on polyethylene, acrylic, bone, air and water rods. For patient study, three patients, who underwent abdomen and pelvis with IV contrast exams, were picked, representing three sizes: medium <M: BMI 21.8kg/m2>, large <L: BMI 29.3kg/m2>, and extra-large <XL: BMI: 34.7kg/m2>. All the three exams were performed on the same scanner as the phantom study with protocol settings: 120 kVp, IQ level 147, collimation 144x0.4mm and pitch 0.8. Radiation dose levels <CTDIvol> were M: 5.5mGy, L: 10.7mGy, XL: 12.1mGy. The images were generated from the scanner console and syngo.via including iodine density map <IMD>, virtual monoenergetic image <60keV> with a reconstruction kernel Qr44 and 5 mm thickness. Six circular ROI were placed on different anatomical areas, including aorta, liver, spleen, kidney, muscle, and subcutaneous/intraperitoneal fat. Analysis was performed to evaluate the difference in HU and SD at each ROI location.

**RESULTS**

For the phantom study, CT number differences in all the images were less than 1.0 HU, with exceptions including [-1.8, -0.8] HU <min, max> for bone at 50 keV and [-10.6, 9.7] HU for air and bone in IMD. A noise comparison revealed SPP-generated images with a higher noise level at 5 mm slice thickness. The noise differences translated to a CNR difference of [-0.09, 0.14]. For patient studies, there is no significant difference <p<0.05> on HU and noise level between images generated from scanner console and syngo.via.

**CONCLUSION**

For reconstructions created from an SPP file versus the scanner console, a slight difference in noise was noted in a phantom, but no significant difference in HU and noise level in patients.

**CLINICAL RELEVANCE/APPLICATION**

SPP files may be used to archive spectral information if certain spectral reconstructions are not imminently required for clinical reading. Spectral results can be generated from an SPP file with a similar image quality as the scanner.

## M5A-SPPH-4 IMAGE QUALITY AND LESION DETECTABILITY OF DOUBLE LOW-DOSE CT USING DEEP LEARNING-BASED IMAGE RECONSTRUCTION ALGORITHM

Hyojeong Lee (*Abstract Co-Author*) Nothing to Disclose
Jeong Kyong Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Yewon Lim, MD (*Abstract Co-Author*) Nothing to Disclose
Jin Sil Kim, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study assessed whether image quality and detectability of focal liver lesions in double low-dose hepatic multiphase CT(DLDCT), aimed at reducing both radiation and iodine levels by approximately 30% using a vendor-agnostic deep learning model(DLM), are comparable to those obtained from standard-dose CT(SDCT) using hybrid iterative reconstruction.

**METHODS AND MATERIALS**

We evaluated CT images from 73 patients who underwent hepatic multiphase CT with a dual-source scanner for low-radiation-dose CT and low-concentration iodine contrast between June and October 2023 and had a prior SDCT within the past year. Two radiologists graded overall image quality, perceived artificial enhancement, and liver contour sharpness on arterial and portal phase images using a 5-point scale for qualitative analysis. For quantitative image quality analysis, measurements included image noise, signal-to-noise ratio, and contrast-to-noise ratio within the liver. Lesion conspicuity and detection were analyzed using generalized estimating equation analysis and the jackknife free-response receiver operating characteristic figures-of-merit(FOM), respectively.

**RESULTS**

DLDCT significantly reduced the effective dose(10.3±6.0mSv vs. 16.4±7.1mSv) and iodine concentration(270mgI/mL vs. 350mgI/mL) compared to SDCT (P<0.001). The mean overall quality scores for arterial and portal phase images were significantly higher for DLDCT using DLM than for SDCT(arterial phase: 4.93±0.24 vs. 4.77±0.45, P<0.001; portal phase: 4.92±0.26 vs. 4.83±0.38, P<0.001). DLDCT demonstrated significantly better quantitative outcomes for liver lesion contrast-to-noise ratio(P<0.05). Lesion detectability was significantly higher in DLDCT images using DLM compared to SDCT images (0.978 vs. 0.917, respectively; P=0.0018).

**CONCLUSION**

DLDCT using DLM can provide better conspicuity and image quality than SDCT using lower radiation and contrast media concentration.

**CLINICAL RELEVANCE/APPLICATION**

Reducing the radiation dose and iodine concentration in liver dynamic CT imaging can lessen the patient burden associated with CT follow-up and be considered possible for CT surveillance of chronic liver disease.

## M5A-SPPH-5 THE ENIGMA OF AIR BUBBLE ARTIFACTS IN CT IMAGING:CAUSES AND IDENTIFICATION

Yini Chen (*Abstract Co-Author*) Nothing to Disclose
Bo Sun (*Abstract Co-Author*) Nothing to Disclose
Renwang Pu JR, MBBCh, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Yiwei Qi (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to elucidate the imaging features and formation mechanism of the infrequent CT air bubble artifacts.

**METHODS AND MATERIALS**

A retrospective analysis was conducted on 113 head CT cases. A meticulous comparative assessment was eventually completed on 7 cases.All imaging procedures were performed using a GE Discovery HD750 CT scanner.The parameters : a tube voltage of 120kVp, tube current of 200mA, slice thickness of 5.0mm, slice interval of 2.0mm, rotation time of 0.8S, and a gantry tilt angle of 0°.During the Imaging evaluation, the window level was set at 40 HU, while the window width varied from 20,40,60,80,100,150, to 300HU, respectively, encompassing the semioval center level and lateral ventricular level, with scores assigned based on a four-point Likert scale. The attenuation range, distribution and morphology of Air Bubble Artifacts were recorded.To

further investigate the distribution of artifact throughout the entire brain, MATLAB 2022a was employed. To interpret the resulting map, a grayscale inversion was applied,yielding a volumetric attenuation distribution map. Three phantoms filled with purified water, tube cooling oil and air were selected to investigate the causes of the artifact.

**RESULTS**

1.The optimal window width for effectively displaying these artifacts was determined to be 60 HU.2.The CT values for air bubble artifact ranged from 8.00 to 19.89 HU, with a mean value of approximately 11.81±4.09HU and a range of attenuation variability from 28.00% to 68.28%.3. The distribution of air bubble artifact across 16 specific regions within two levels in the 7 cases was randomly shown.4.The images of air bubble artifact were irregular, and the patchy configuration(80.77%,42/52)of hypoattenuations were the most common morphology.5.The volume attenuation distribution maps revealed CT value attenuation in both the gray and white matter regions of the entire brain.6.The average difference value between air and cooling oil was 839.43 HU.

**CONCLUSION**

The Air bubble artifact is a visible density reduction area(patchy configuration or band-like of hypoattenuation)under the condition of narrow window width of CT images when an excessive number of air bubbles in the CT tube cooling oil randomly appear along the X-ray path together with cooling oil circulation. The appearance, location and number of air bubble artifacts are random, with the hypoattenuation having a heterogeneous distribution and measuring less than 20HU.

**CLINICAL RELEVANCE/APPLICATION**

If a patchy or band-like hypoattenuation is observed in a head CT scan, which is inconsistent with clinical manifestations, the possibility of air bubble artifact should be considered. Regular CT quality control is essential to ensure accurate imaging diagnosis.

## M5A-SPPH-6 CLINICAL VALUE OF THE WHOLE HEART MOTION CORRECTION ALGORITHM IN CTA EXAMINATION OF THE CORONARY COMBINED THORACO-ABDOMINAL AORTA IN PATIENTS WITH TYPE A AORTIC DISSECTION PRESENTING PERICARDIAL EFFUSION

Suping Chen (*Abstract Co-Author*) Nothing to Disclose
Naiming Wu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the impact of the whole-heart motion correction algorithm (SSF2) on image quality and AI measurements in patients with type A aortic dissection presenting pericardial effusion (PE).

**METHODS AND MATERIALS**

Coronary combined thoraco-abdominal aortic CTA data from 25 patients with type A aortic dissection presenting PE were retrospectively included, and images were processed using the standard algorithm (STD), the coronary motion correction algorithm (SSF1), and SSF2. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of the true lumen of the aorta (TL), left circumflex branch (LCX), left anterior descending branch (LAD), and right coronary artery (RCA) were collected. Subjective image evaluation of aortic and coronary arteries was performed using a 5-point scale. Fractional flow reserve derived by CT (FFR-CT), stenosis, and transluminal attenuation gradient (TAG) were automatically generated by commercial coronary analysis software.

**RESULTS**

The mean heart rate was 81.86±15.22 bpm, and the mean thickness of PE was 18.01±5.65 mm. The SNR of the TL and LAD was the highest on the SSF2 images, followed by SSF1, and the lowest on the STD images (all $p<0.05$). The CNR values of TL, LCX, LAD, and RCA were ranked: SSF2 > SSF1 > STD (all $P<0.05$). The subjective score on aorta was not statistically different among the three groups of images, and that on coronary arteries was highest for SSF2 images [5(4,5)], second for SSF1 images [4(3,4)], and the lowest for STD [3(2,4)], with $P<0.05$. The analyzability of FFR-CT for the STD, SSF1, and SSF2 images was 21/25 (84%), 22/25 (88%), and 23/25 (92%). For all three coronary arteries, there were no statistically significant differences in FFR-CT values, stenosis, or TAG (all $P > 0.05$).

**CONCLUSION**

For CTA in type A aortic dissection with pericardial effusion, SSF2 improves true-false lumen contrast, reduces coronary motion artifacts, and improves coronary artery visualization without interfering with automatic measurements by the AI software.

**CLINICAL RELEVANCE/APPLICATION**

Pericardial effusion is a risk factor for coronary stenosis in type A aortic dissection; however, the presence of pericardial effusion affects the visualization of the coronary arteries on CTA images. SSF2 improves the true-false lumen contrast of the aorta and improves the display of coronary arteries, showing high clinical application value.

## M5A-SPPH-7 SHARPNESS EVALUATION OF CHEST MULTI PLANAR RECONSTRUCTION IMAGES WITH NORMAL AND SUPER HIGH-RESOLUTION MODE OF CZT-BASED PHOTON-COUNTING DETECTOR CT

Keisuke Fujii, PhD (*Abstract Co-Author*) Nothing to Disclose
Tatsushi Kobayashi, MD (*Abstract Co-Author*) Support, Canon Medical Systems Corporation
Hiroki Taguchi (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Yoshihisa Muramatsu, PhD, RT (*Abstract Co-Author*) Nothing to Disclose
Tomoaki Sasaki, MD (*Abstract Co-Author*) Nothing to Disclose
Keiichi Nomura, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

CZT-based Photon-counting detector (PCD) CT scanner has normal-resolution (NR) and super-high-resolution (SHR) modes. It is clinically important to evaluate how much not only axial SHR images, but also coronal and sagittal SHR images have higher sharpness than those with the NR mode. Thus, the aim of this study is to compare sharpness of multi planar SHR images with the CZT-based PCD-CT scanner with that of the NR images.

**METHODS AND MATERIALS**

A standard adult male thoracic phantom (LSCT-001, Kyoto Kagaku, Japan) with spherical nodules enclosed in lung fields at lung apex, tracheal bifurcation, and lung base was scanned with a CZT-based PCD-CT (TSX-501R, Canon Medical Systems, Japan). The scanning conditions were tube voltage of 120 kVp, tube current of 250 mA, rotation time of 0.5 s, and pitch factor of 0.8. The axial, coronal, sagittal NR and SHR images were reconstructed with adaptive iterative dose reduction three-dimensional (AIDR3D) algorithm of the standard strength at 200 mm field of view. The reconstruction conditions for NR images were slice thickness of 0.6 mm, reconstruction kernel of soft tissue (FC13) and lung (FC51), and matrix size of 512. The reconstruction conditions for SHR images were slice thickness of 0.2 mm, reconstruction kernel of soft tissue (FC13) and lung (FC54), and matrix size of

1024. We evaluated sharpness of each image using the analysis method devised by Imai et al. First, 180- or 360-line segments centered on a 10 mm diameter nodule (?270 HU) of each image were set in the radial direction at a central angle interval of 1°, and the edge profiles were obtained by calculating the average CT values of the pixels located at the same distance from the center of the nodule. Next, we modeled the edge profiles using stochastic differential equations, and derived a formula for the edge profile as a solution to the equation. The differential profile was obtained by subtracting the two adjacent mean CT values in the edge profile. The ratio between contrast obtained from the estimated edge profiles and maximum values of the differential profiles was defined as the sharpness index.

**RESULTS**

The sharpness of axial, coronal and sagittal SHR images for soft tissue kernel was approximately 1.4, 1.6 and 1.4 times higher than the NR images, respectively. The sharpness of axial, coronal and sagittal SHR images for lung kernel was approximately 1.5, 1.7 and 1.4 times higher than the NR images, respectively.

**CONCLUSION**

The multi planar SHR images with a CZT-based PCD-CT scanner were found to have approximately 1.5 times higher sharpness than the NR images.

**CLINICAL RELEVANCE/APPLICATION**

This study highlights the advantages of using the SHR mode with a CZT-based PCD-CT scanner for evaluating the microstructure of lung nodules in thoracic imaging.

## M5A-SPPH-9 IMPROVING CLARITY AND DIAGNOSTIC CONFIDENCE OF CORONARY STENT IN CORONARY CT ANGIOGRAPHY FOR PATIENT WITH HIGH HEART RATES USING A SECOND-GENERATION WHOLE- HEART MOTION CORRECTION ALGORITHM (SSF2)

Jianying Li, PhD (*Abstract Co-Author*) Employee, General Electric Company
Jianxin Guo (*Abstract Co-Author*) Nothing to Disclose
Tingting Qu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the effect of a whole- heart motion correction algorithm (SSF2) on image quality and diagnostic confidence of coronary stent in coronary CT angiography (CCTA) for patients with high heart rates.

**METHODS AND MATERIALS**

Seventeen patients (with 22 stents) with high heart rates (88.79±11.40 bpm, 76-112 bpm) underwent CCTA. Images were reconstructed using standard algorithm without motion correction (STD), with the first-generation snapshot freeze (SSF1) and SSF2 motion correction. Subjective scoring (5-point method) and objective evaluation of stents were performed. Subjective evaluation included the severity of stent motion artifacts, clarity of stent display, and diagnostic confidence within the stent. Objective evaluation included CT and SD values of the fat outside the stent with the most severe stent artifacts, in-stent lumen diameter, external stent diameter and severity of blooming artifact (blooming artifact = (external stent diameter - in-stent lumen diameter)/external stent diameter * 100).

**RESULTS**

SSF2 had significantly smaller motion artifacts (0.36±0.58) and higher stent clarity scores (4.05±0.58) compared to STD (1.86±1.04, 2.77±0.92) and SSF1 (1.23±0.69, 3.23±0.61). The diagnostic confidence score of SSF2 was significantly higher than that of STD, but compatible to SSF1 ($P>0.05$). There was a statistically significant difference in fat CT and SD values among the three groups (all $P<0.05$), with SSF2 having the lowest values STD the highest. The stent reconstructed with STD had the smallest in-stent lumen diameter and the largest blooming artifact (all $P<0.05$), but no difference between SSF1 and SSF2 in these two values.

**CONCLUSION**

The application of SSF2 in CCTA significantly reduces the motion artifacts of coronary stents for patients with high heart rates compared to STD and SSF1, resulting in better display of the coronary arteries inside the stents and improved diagnostic confidence.

**CLINICAL RELEVANCE/APPLICATION**

SSF2 technology can make coronary stent display clearer and improve diagnostic confidence, making it a highly recommended coronary reconstruction technique.

# Abstract Archives of the RSNA, 2024

## M5A-SPVA-1 ASSOCIATION STUDY ON ABDOMINAL AORTIC HEMODYNAMIC PARAMETERS BASED ON 4D-FLOW MRI WITH RENAL FUNCTION IN CHRONIC KIDNEY DISEASE

Qinling Zong (*Abstract Co-Author*) Nothing to Disclose
Jiule Ding (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the correlation between renal function and abdominal aortic hemodynamic parameters based on 4D-Flow MRI in patients with chronic kidney disease (CKD).

### METHODS AND MATERIALS

A prospective study was conducted on 73 patients diagnosed with CKD between March 2021 and May 2023, as well as 13 volunteers without kidney injury. According to the estimated glomerular filtration rate (eGFR), the subjects were divided into CKD1-3 group (n = 34), CKD4-5 group (n = 39), and control group (n = 13). All subjects underwent 4D-Flow MRI examination of the abdominal aorta, measuring pulse wave velocity (PWV), and peak velocity and maximum wall shear stress (WSS) at the proximal plane (Plane_1) and the higher renal artery opening plane (Plane_2) of abdominal aorta. The differences in 4D-Flow MRI hemodynamic parameters among the three groups were compared. The correlation between 4D-Flow MRI hemodynamic parameters and eGFR and the independent influencing factors that affect eGFR was analyzed.

### RESULTS

There were significant differences in abdominal aortic PWV and maximal WSS of Plane_1 and Plane_2 among the three groups (all $P<0.05$). Abdominal aortic PWV was mildly negatively correlated with eGFR (?=-0.298, P=0.005). There was a mild positive correlation between maximal WSS of Plane_1 and Plane_2 with eGFR (?=0.394, $P<0.001$; ?=0.293, P=0.006). Abdominal aortic PWV and maximal WSS of Plane_1 were independent influencing factors of eGFR (all $P<0.05$).

### CONCLUSION

There is an independent correlation between renal function and abdominal aortic hemodynamic parameters based on 4D-Flow MRI in patients with CKD, and reduced abdominal aortic compliance is an important influencing factor in the progression of CKD.

### CLINICAL RELEVANCE/APPLICATION

1. It is feasible to apply 4D-Flow MRI for quantitative evaluation of abdominal aortic compliance in patients with CKD. 2. There is an independent correlation between renal function and abdominal aortic hemodynamic parameters based on 4D-Flow MRI in patients with CKD, and reduced abdominal aortic compliance is an important influencing factor in the progression of CKD.

## M5A-SPVA-3 NON-CONTRAST ENHANCED MR-ANGIOGRAPHY OF THE ABDOMINAL ARTERIES: INTRAINDIVIDUAL COMPARISON OF RELAXATION-ENHANCED ANGIOGRAPHY WITHOUT CONTRAST AND TRIGGERING (REACT) AND 4D CONTRAST-ENHANCED MR-ANGIOGRAPHY

Carsten H. Gietzen, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to evaluate a novel 3D isotropic flow-independent non-contrast-enhanced magnetic resonance angiography (non-CE-MRA) sequence (Relaxation-Enhanced Angiography without Contrast and Triggering (REACT)) for imaging of the abdominal arteries by comparing image quality and the assessment of vessel stenosis to 4D contrast-enhanced MRA (4D CE-MRA).

## METHODS AND MATERIALS

Thirty patients (mean age 35.7 ± 16.8 years; 20 females) referred for abdominal vessel imaging using a standardized protocol at 3 T were included in this retrospective, single center study. The protocol comprised both 4D CE-MRA and REACT (navigator-triggering, Compressed SENSE factor 10 for acceleration of data acquisition, nominal scan time 02:54 min, and reconstructed voxel size 0.78 x 0.78 x 0.85 mm3) sequences. Two radiologists independently evaluated abdominal arteries for the presence of stenosis, vascular variants, and other vascular findings (e.g., dissection). The subjective image quality of arteries was assessed using a 4-point Likert scale (1 = non-diagnostic, 4 = excellent). Vessels were classified based on size: (1) abdominal aorta (supra- and infrarenal segments), (2) large arteries (celiac trunk, superior mesenteric artery, renal arteries), (3) medium arteries (splenic artery, common and proper hepatic artery), and (4) small arteries (gastric arteries, hepatic arteries, inferior mesenteric artery).

## RESULTS

REACT had a total acquisition time of 5:36 ± 00:40 minutes while 4D CE-MRA showed an acquisition time (including the native scan and bolus tracking sequence) of 3:45 ± 00:59 minutes ($p < .001$). Considering 4D CE-MRA as the reference standard, REACT achieved a sensitivity of 87.5% and specificity of 100% for relevant (= 50%) stenosis, while detecting 89.3% of variants and 100% of other findings. While 4D CE-MRA yielded higher values for large arteries (4D CE-MRA: 3.61 ± 0.61, REACT: 3.35 ± 0.72; $p < .001$), vessel quality was comparable between both sequences for the aorta (4D CE-MRA: 3.94 ± 0.24, REACT: 3.88 ± 0.44; $p = .044$), medium (4D CE-MRA: 2.93 ± 0.96, REACT: 2.77 ± 0.90; $p = .028$), and small arteries (4D CE-MRA: 2.15 ± 0.85, REACT: 2.04 ± 0.86; $p = .032$).

## CONCLUSION

In a short scan time of about 5 min, REACT provides good diagnostic performance for the detection of relevant stenoses, variants, and other findings of the abdominal arteries while yielding to 4D CE-MRA comparable image quality.

## CLINICAL RELEVANCE/APPLICATION

The findings of this study highlight the potential of REACT for vessel imaging without gadolinium contrast and may expand its use for imaging of the abdominal vasculature.

## M5B-SPBR-1 IMPROVING THE PERFORMANCE OF AI-BASED SYSTEMS FOR BREAST CANCER DETECTION USING SELF-SUPERVISED-LEARNING TECHNIQUES

Svati S. Long, MD (*Abstract Co-Author*) Nothing to Disclose
Pierre Fillard, PhD (*Abstract Co-Author*) Employee, Therapixel SA;Stockholder, Therapixel SA
Stanislas Chambon (*Abstract Co-Author*) Nothing to Disclose
Yaroslav Nikulin (*Abstract Co-Author*) Nothing to Disclose
Serena Pacile, PhD (*Presenter*) Employee, Therapixel SA

### PURPOSE

The aim of this work is to highlight the benefits of using a self-supervised-learning (SSL) technique over a standard supervised learning (SL) technique to pre-train the backbone of a Deep Neural Network (DNN) that detects cancer in 2D and 3D mammography images.

### METHODS AND MATERIALS

The algorithm used in this work is based on MammoScreen3 software (by Therapixel) . It uses an ensemble of DNNs to detect malignant lesions on both DBT and FFDM images and to predict for each detection a malignancy score. Each DNN exhibits the same structure. It builds upon a backbone that plays the role of the feature extractor and 2 heads that play the roles of predictors. One head predicts the lesions localizations and one head predicts their malignancy scores. The backbone is, preliminary pre-trained to perform an auxiliary task, a crucial and necessary way to ensure good final performances of the algorithm. Then, the entire DNN (backbone and predictors) is fine-tuned with SL.This work compares two versions of the algorithm, hereafter referred to as MS_SL and MS_SSL, for which the backbones are either pre-trained with SL or with SSL. To obtain MS_SL, the backbones are pre-trained with SL to predict for a given patch its label: healthy tissue or different types of lesions.. To obtain MS_SSL, the backbone is pre-trained with the SSL technique MoCo on roughly 4 millions unlabeled 2D and 3D images.MS_SSL is compared against MS_SL and GMIC, used as a state-of-the-art reference, on a test set composed of 27,336 FFDM Hologic images (1,413 malignant images, 25,923 benign images). The performances are given in terms of AUC-ROC / Image. The statistical gains in AUC are estimated with Delong’s method. The Precision-Recall curves (with their corresponding AP: AveragePrecision / image) are also plotted and compared.

### RESULTS

MS_SSL exhibits an AUC of 0.9255 (0.9173 0.9337), while MS_SL has an AUC of 0.9215 (0.9133 0.9298) and GMIC an AUC of 0.8710 (0.8606 0.8814). MS_SSL outperforms both MS_SL with a gain in AUC of 0.0040 (0.0005 0.0074) $p = 0.0119$ and GMIC with a gain in AUC of 0.0545 (0.0453 0.0637) $p < 0.0001$. The superiority of MS_SSL can also be observed in terms of AP with a gain of +18% and 2% compared to GMIC and MS_SL respectively.

### CONCLUSION

Pre-training the backbone of a DNN with SSL leads to slightly better test performances than with SL with the extra benefit of requiring no labeled data. It opens new perspectives for the development of DNNs algorithms for breast cancer screening.

### CLINICAL RELEVANCE/APPLICATION

Data scarcity and labeling cost of mammography images prevents the training of large DNN with SL. SSL offers promising perspectives to cope with these constraints and to enhance DNN’s performances.

## M5B-SPBR-10 AN AI-DRIVEN SAFEGUARD REVIEW PROCESS HELPS DETECT AGGRESSIVE BREAST CANCERS

Jacqueline S. Holt, MD (*Abstract Co-Author*) Nothing to Disclose
Bryan Haslam, PhD (*Abstract Co-Author*) Employee, RadNet, Inc
Mireille P. Aujero, MD (*Abstract Co-Author*) Nothing to Disclose
Jiye G. Kim, PhD (*Presenter*) Employee, RadNet, Inc

### PURPOSE

With considerable variability in radiologist performance interpreting screening mammograms, one approach to reduce missed cancers is a safeguard review process where AI identifies exams at risk of potential missed cancers, triggering review by a second, experienced breast imager. Here, we sought to test whether cancers detected through this process include aggressive cancers that would particularly benefit from immediate intervention for better prognosis.

**METHODS AND MATERIALS**

An AI-driven safeguard review process was implemented prospectively in a community practice from July 2021 - June 2022. A custom-built AI algorithm was used to flag the most suspicious screening DBT exams that had not been recalled by the initial interpreting radiologist. An expert breast imaging specialist performed a second, safeguard review of each of the flagged exams, and consulted with the initial interpreting radiologist for discordant interpretations. Cancers detected during this period were followed up for pathology, nodal status, cancer size, hormonal status, and cancer stage. Cancers were deemed aggressive if an invasive cancer had lymph node involvement, had triple-negative status, or was stage IIA or greater. Patient demographics (e.g., age and race/ethnicity) were also collected.

**RESULTS**

Out of a total of 40,532 screening exams during this period, 2,296 were flagged by the AI for a safeguard review. The safeguard reviewer identified 130 of these exams with potential misses, resulting in the detection of 41 cancers. These additional 41 cancers were found on top of the 219 cancers detected without the safeguard process. 43.9% of the additional cancers caught were from patients with dense breasts, 75.6% were invasive, 9.8% were triple-negative, and 12.2% were stage IIA or greater. Together, 22.0% of these cancers were deemed aggressive, compared to 19.2% of the cancers caught without the safeguard process. The cancers detected through the AI-driven safeguard process were from patients with similar demographics (age, race, and ethnicity) to those whose cancers detected without the safeguard process.

**CONCLUSION**

The AI-driven safeguard review process resulted in the detection of more breast cancers that would have otherwise been missed. These cancers consisted of mostly invasive cancers with a substantial proportion being aggressive cancers. This result suggests that a combination of modern deep learning AI plus targeted safeguard review is practical and provides significant improvement in detecting important cancers in a community practice.

**CLINICAL RELEVANCE/APPLICATION**

An AI-driven safeguard process can reduce missed cancers, a substantial proportion of which are aggressive cancers that require early detection and treatment for improved prognosis.

## M5B-SPBR-4 AUTOMATED MACHINE-LEARNING-BASED UNENHANCED RADIOMICS FOR IDENTIFICATION OF HER2-LOW BREAST CANCERS USING DIFFUSION-WEIGHTED IMAGING

Chunmei Li, MD (*Abstract Co-Author*) Nothing to Disclose
Min Chen, PhD (*Abstract Co-Author*) Nothing to Disclose
Xue Li (*Presenter*) Nothing to Disclose

**PURPOSE**

Developing new antibody-drug conjugates requires precise identification of human epidermal growth factor receptor 2 (HER2)-low breast cancers. This study aims to investigate the potential application of an automated machine learning model in developing unenhanced apparent diffusion coefficient (ADC)-based radiomics for distinguishing between HER2-zero and HER2-low/ positive breast cancers, as well as HER2-zero and HER2-low breast cancers.

**METHODS AND MATERIALS**

This study enrolled 169 patients with invasive breast cancer (27 HER2-zero, 96 HER2-low, and 46 HER2-positive). A total of 1200 radiomics features and 11 clinicopathologic features were extracted from each lesion. PyCaret was used to construct an automated machine learning pipeline for two binary classifications: HER2-zero versus HER2-low and HER2-zero versus HER2-low/ positive breast cancers. The performance of 13 machine learning models, based on the training cohort, was compared using AUC to obtain the optimal model. The optimal model was subsequently validated using an internal validation cohort. Students' t-tests, Mann-Whitney U tests or Chi-Square tests were used. The performance of the best model was evaluated through accuracy, AUC, sensitivity, positive predictive value, and F1 score.

**RESULTS**

For HER2-zero versus HER2-low breast cancers, the Gradient Boosting Classifier exhibited superior classification performance for the radiomics model, achieving an AUC of 0.75 in the validation cohort. The Random Forest Classifier (RF) demonstrated the best performance for the clinical-radiomics model with an AUC of 0.79 in the validation cohort. For HER2-zero versus HER2-low/ positive breast cancers, the RF was the optimal choice for both the radiomics and the radiomics-clinicopathologic models, each achieving an AUC of 0.82 in the validation cohort.

**CONCLUSION**

In conclusion, non-invasive prediction of HER2 expression status is challenging for radiologists. However, automated machine learning methods based on unenhanced radiomics have demonstrated promising outcomes. This approach facilitates the automated execution of machine learning workflows, saving time for radiologists and thereby enabling more efficient treatment guidance for patients with HER2-low breast cancer.

**CLINICAL RELEVANCE/APPLICATION**

The application of automated machine learning with ADC-based radiomics for the identification of HER2-low breast cancers is both feasible and advantageous.

## M5B-SPBR-6 PATIENT PERCEPTION OF ARTIFICIAL INTELLIGENCE USE IN INTERPRETATION OF SCREENING MAMMOGRAMS: A SURVEY STUDY

Emily E. Knippa, MD (*Abstract Co-Author*) Nothing to Disclose
Basak E. Dogan, MD (*Abstract Co-Author*) Research Grant, Seno Medical Instruments, Inc;Research Grant, MedCognetics, Inc
Yin Xi, PhD (*Abstract Co-Author*) Nothing to Disclose
Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess patient perceptions of the use of artificial intelligence (AI) in the interpretation of screening mammograms.

**METHODS AND MATERIALS**

In a prospective, IRB approved trial, all patients undergoing screening in our institution between 02.01.2023-08.01.2023 were offered a 29-question survey to assess their perception of AI use in their screening mammography interpretation. Age, race, education and income level, history of personal/family of breast cancer and prior breast biopsy were collected. Univariate and multivariate logistic regression was used to identify the independent factors associated with patients' acceptance of AI use.

**RESULTS**

Of 518 patients, most patients were between the ages of 50-79 (65.5%), at least college graduates (67.0%), and Non-Hispanic White [50.6% (NHW),18.1% Non-Hispanic Black (NHB), 13.3% Hispanic, 8.9% Asian, 9.1% multiracial or missing]. Patient-reported knowledge of AI was none or minimal in 76.4%. Most (74.1%) preferred to be consented to before AI is used. Stand-alone use was accepted by 4.4%. After an AI-interpreted abnormal screening, 91.3% requested radiologist review before scheduling a follow-up exam, compared to 64.7% of radiologist recall reviews by AI ($p<0.001$). In cases of discrepancy between AI and radiologist, higher rate of patients would undergo diagnostic for radiologist recalls compared to AI recalls (59.3% vs 52.5%, $p=0.03$). The majority held the vendor, hospital, and the radiologist accountable for AI diagnostic errors (57.7% for false negatives, 53.7% for false positives). At least moderate concern about loss of personal interaction, transparency, proof of technology, loss of privacy and bias was expressed by, 76.6%, 74.2%, 73.0%, 65.1% and 63.2% respectively. Higher education was associated with higher acceptance [OR (95%CI; 2.05(1.31-3.20, $p=0.002$). Concerns about data privacy and bias were higher among Hispanic [OR(95%CI); 2.41(0.99-5.89, $p=0.05$), 3.32(1.15-9.61, $p=0.005$), respectively] and NHB [OR(95%CI); 2.87(1.25-6.58, $p=0.03$), 4.31(1.50-12.39, $p=0.005$) NHW patients.

**CONCLUSION**

Patients support AI use as a second reader of screening mammograms, despite concerns about loss of personal interaction, privacy, transparency, and bias. Education level is significantly associated with AI acceptance. Accountability for AI-related diagnostic errors remains unclear.

**CLINICAL RELEVANCE/APPLICATION**

The safe and effective implementation of AI should include patient input to facilitate informed decision-making.

## M5B-SPBR-7 VARIATIONAL MODE DECOMPOSITION-AIDED DEEP LEARNING FRAMEWORK FOR IMPROVING CLASSIFICATION OF BREAST LESIONS IN ULTRASOUND IMAGES

Mostafa Fatemi, PhD, PhD (*Abstract Co-Author*) Nothing to Disclose
Azra Alizad, MD (*Abstract Co-Author*) Nothing to Disclose
Manali Saini, MEng, PhD (*Abstract Co-Author*) Nothing to Disclose
Sara Hassanzadeh, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine the performance of a novel variational mode decomposition-assisted deep learning framework in differentiating malignant from benign breast masses.

**METHODS AND MATERIALS**

In our proposed framework, breast ultrasound images were first decomposed by using two-dimensional variational mode decomposition (2D-VMD) for extracting low level features of lesions. The decomposed images were given as inputs along with the original images to the proposed low-complex deep learning classification model comprising depth-wise separable convolutional layers with mixed pooling, squeeze and excite block. The proposed deep learning framework was applied on two public data, UDIAT and BUSI as well as in our in-clinic data set. The in-clinic study included 655 female patient volunteers. The study was HIPAA compliant and approved by our Institutional Review Board. Signed informed consent was obtained from each enrolled patient.

**RESULTS**

The results of our study demonstrated robust performance of the proposed framework across three datasets— two public datasets and an in-clinic breast dataset —with accuracies of 98%, 93%, and 89% and specificity of 100, 93, 94 %, respectively. Further analysis of the proposed network without using 2D-VMD indicated a decrease of 5% in the classification accuracy. Further, the low complex architecture of the model reduced time to diagnose malignancy to about 2ms per image, five times faster than the conventional methods.

**CONCLUSION**

Our results indicates that the addition of 2D-VMD can significantly improve the overall classification accuracy by capturing the lesion-specific boundary features in the decomposed modes, which further boosts the performance of deep learning model. The proposed framework exhibits high classification performance and computational efficiency, which are crucial for timely diagnosis of malignancy and reducing the need for unnecessary benign biopsies. Thereby, the proposed framework is feasible for use in real-time diagnostic applications.

**CLINICAL RELEVANCE/APPLICATION**

The proposed deep learning method improves breast lesion classification with low computational complexity, aiding faster decision-making in clinical settings that could lead to better patient outcome.

## M5B-SPBR-8 IMPACT OF NEW TECHNOLOGIES ON A BREAST CANCER SCREENING PROGRAM

Marina Alvarez Benito, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Jose Luis Raya Povedano, MD (*Abstract Co-Author*) Nothing to Disclose
Esperanza Elias Cabot (*Abstract Co-Author*) Nothing to Disclose
Sara Romero Martin (*Abstract Co-Author*) Nothing to Disclose
Eduardo Gutierrez Dorta, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To analyze the impact of digital breast tomosynthesis (DBT) and artificial intelligence (AI) on the detection rate, recall rate, and workload of a population-based breast cancer screening program. The reference technique was the standard double reading strategy with digital mammography (DM).

**METHODS AND MATERIALS**

A total of 23,996 consecutive screening studies classified into four groups were retrospectively analyzed: DM group (5,045 DM studies conducted between March 2020 and March 2021), DBT group (6,953 DBT studies conducted between March 2020 and March 2021), DM+AI group (5,049 DM studies conducted between March 2021 and March 2022), and DBT+AI group (6,949 DBT studies conducted between March 2021 and March 2022). The studies performed between March 2021 and March 2022 were processed by an AI system that assigned each study a score (0 - 100) and risk category (low, intermediate, high) based on the probability of malignancy. Ten specialized radiologists independently performed double reading without consensus, determining whether patients should be referred to a reference unit or scheduled for follow-up at two years. In cases assessed by AI, the radiologists had access to the information provided by the system during the reading process.Recall and detection rates were obtained for the different reading strategies: double reading DM (standard strategy), double reading DBT, single reading and double reading DM+AI, and single reading and double reading DBT+AI. The strategies were compared using the chi-square test.

## RESULTS

Compared to double reading DM, single reading DM+AI increased the detection rate by 1.6‰ (7.3‰ vs 5.7‰, p=0.325), with a 2.1% decrease in the recall rate (4.1% vs 6.2%, p<0.001) and a 50% decrease in reading volume. Double reading DM+AI increased the detection rate by 2.4‰ (8.1‰ vs 5.7‰; p=0.151), with a 0.5% increase in the recall rate (6.7% vs 6.2%) and the same reading volume. Compared to double reading DM, single reading DBT+AI increased the detection rate by 2.8‰ (8.5‰ vs 5.7‰; p=0.082), with a 2.7% decrease in the recall rate (3.5% vs 6.2%, p<0.001) and a 50% decrease in reading volume. Double reading DBT+AI increased detection rate by 3.9‰ (9.6 vs 5.7‰; p=0.018), with a 0.4% decrease in the recall rate (5.8 vs 6.2; p=0.301) and the same reading volume.

## CONCLUSION

The single DBT-AI-supported reading strategy achieved better detection rates compared to single or double DM reading with and without AI support and compared to single or double DBT reading. The double DBT-AI-supported reading strategy had the highest detection rate but increased the recall rate and doubled the workload.

## CLINICAL RELEVANCE/APPLICATION

AI-supported single or double DBT readings significantly improved detection and recall rates compared to double DM readings.

## PURPOSE

Predicting the risk of breast cancer recurrence after treatment remains challenging. Current follow-up is mostly one-size-fits-all surveillance using Mammography or DBT. This appears insufficient as many recurrences are still diagnosed as interval cancers. This study aims to develop a deep-learning model based on the clinical characteristics of the cancer and the provided therapy, enriched with multi-time-point pretreatment mammograms to predict the recurrence of breast cancer after initial therapy.

## METHODS AND MATERIALS

We retrospectively collected data on 3188 breast cancer patients from our institution presenting between January 1, 2004, and December 31, 2020. 401 of these patients (12.6%) presented with local breast cancer recurrence during surveillance. Relevant preoperative information was extracted from medical reports, encompassing demographic, clinical, radiologic, pathology, and treatment data. Additionally, 18079 multi-time-point digital screening mammograms obtained before the therapy of the first cancer were collected and we integrated them synergistically into our model. The dataset was split into training (2550 patients), validation (319 patients), and test (319 patients) cohorts. We compared our approach with commonly used machine learning methods relying on clinical data only and image-based deep learning models. Prediction performance was assessed based on the area under the receiver operating characteristic curve (AUC).

## RESULTS

Our hybrid model achieved an AUC of 0.738 (95% CI: 0.702, 0.753), which was significantly better than the AUCs of 0.690 (95% CI: 0.686, 0.710) for a common machine learning model using only clinical factors and 0.618 (95% CI: 0.607, 0.633) for an imaging only based DL model, improving accuracy by 0.048 (95% CI: 0.016, 0.064, p<0.01) and 0.120 (95% CI: 0.024, 0.134, p<0.01) respectively.

## CONCLUSION

Combining pretreatment mammograms from multiple time points with detailed medical reports significantly enhances the accuracy of predicting breast cancer recurrence following conventional therapy.

## CLINICAL RELEVANCE/APPLICATION

This study highlights the benefits of integrating comprehensive clinical data and sequential mammograms into predictive models to increase the precision of predicting breast cancer recurrence. This could be used for selecting specific follow-up schedules for breast cancer patients.

Enver G. Tahir, MD (*Abstract Co-Author*) Nothing to Disclose
Caroline Hancken-Pauschinger (*Abstract Co-Author*) Nothing to Disclose
Jennifer Erley, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze the long-term influence of a surgically corrected dextro-transposition of the great vessels (D-TGA) on left and right ventricular (LV, RV), as well as valvular function compared to healthy controls, as well as to assess the impact of pulmonary artery valve re-surgery.

### METHODS AND MATERIALS

In this retrospective single-center study, 42 adults with D-TGA who underwent arterial switch operation (ASO) during childhood received a follow-up cardiac magnetic resonance imaging (CMR) exam (3T, Ingenia, Philips) between 2021 and 2023 (49% female, age 33 ±10), more than 20 years after the initial surgery. LV and RV volumes (indexed to body surface area), ejection fraction (EF), and global longitudinal strain (GLS) of the LV (Feature Tracking, Cvi42, Circle Vascular Imaging) were analyzed. Results were compared with a healthy control group (n=15, 47% female, age 55.7 ± 12.4) Patients with re-surgery (of the pulmonary artery or aorta) were compared with patients without re-surgery. Generalized linear models (including age, sex, body surface area) and Mann-Whitney U test were applied.

### RESULTS

D-TGA patients who underwent ASO showed a significantly impaired LV GLS (-14.0% ± 6.2 vs. -17.3% ± 2.4, $p<0.049$). At the same time, LV EF (62% ± 5) was not significantly different to controls ($p=0.630$). Radial and circumferential strain, as well as RV volumes and EF were also not different between D-TGA patients and controls. 12/42 D-TGA patients underwent re-surgery of the pulmonary arteries or pulmonary valve, the most frequent was pulmonary-conduit after over 20 years after the first surgery. Patients with re-surgery of the pulmonary artery or valve showed a significantly higher maximum flow velocity (TP Vmax) ($p=0.042$) and a significantly lower stroke volume (TP SV) above the pulmonary valve ($p=0.034$) in the follow-up CMR exam.

### CONCLUSION

D-TGA patients who underwent ASO show a reduced LV GLS compared to healthy controls despite normal EF after a follow-up of over 20 years, as subtle sign of decreased LV contractility. D-TGA patients with re-surgery of the pulmonary artery showed a flow acceleration and a reduced stroke volume above the pulmonary valve, indicating truncus pulmonalis valve stenosis.

### CLINICAL RELEVANCE/APPLICATION

Reduced GLS could serve as a potential indicator of subtle left ventricular dysfunction in adult D-TGA patients. D-TGA patients with re-surgery of the pulmonary artery exhibit signs of pulmonary valve stenosis and potentially adverse RV remodeling, which should be closely integrated into clinical follow-ups.

## M5B-SPCA-10 DIFFERENCES IN PULMONARY TRANSIT TIME AND PULMONARY VASCULAR VOLUME BETWEEN SYSTEMIC AMYLOIDOSIS PATIENTS WITH AND WITHOUT CARDIAC INVOLVEMENT

Sharmila Dorbala, MPH (*Abstract Co-Author*) Research Grant, Pfizer Inc;Research Grant, General Electric Company;Research Grant, Attralus;Research Grant, Koninklijke Philips NV;Consultant Pfizer Inc ;Consultant, General Electric Company;Consultant, Johnson & Johnson;Speaker, Ionetix

Raul San Jose Estepar, PhD (*Abstract Co-Author*) Nothing to Disclose
Michael Jerosch-Herold, PhD (*Abstract Co-Author*) Nothing to Disclose
Olivier Clerc (*Abstract Co-Author*) Nothing to Disclose
Sumit Gupta, MBBS, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Systemic light chain (AL) amyloidosis causes deposition of amyloid fibrils in various organs including the heart and lungs. Pulmonary transit time (PTT) and pulmonary vascular volume (PVV) are physiological parameters reflecting cardiopulmonary hemodynamics which are shown to predict adverse cardiovascular outcomes independently. This study explores PTT and PVV differences between AL amyloidosis with and without cardiac involvement.

### METHODS AND MATERIALS

A retrospective single center cross-sectional cohort study analyzed subjects with biopsy-proven AL amyloidosis grouped into 3: 1) recently diagnosed AL amyloidosis with cardiac involvement (AL-CMP; n=58), 2) AL amyloidosis treated with cardiac involvement (AL-CMP-rem; n=24), and 3) recently diagnosed AL amyloidosis without cardiac involvement (AL-non-CMP; n=17). Evaluation included serum biomarkers and cardiac magnetic resonance. PTT was calculated from rest perfusion images utilizing regions of interest placed within the basal right and left ventricular blood pool. PTT was normalized for heart rate (PTTn). PVVi was estimated as PTT(s) × cardiac output (ml/s) indexed to body surface area. One-way ANOVA was used to compare groups. The Pearson correlation coefficient was used to assess relationships.

### RESULTS

Patients in the 3 groups (AL-CMP; AL-CMP-rem; AL-non-CMP) were comparable based on age [62.8(7.8); 63.5(7.0); 58.1(8.8)] and gender (male, 53.4%; 50%; 70.6%). PTTn was longer ($p<0.001$) in AL-CMP group [14.3 (5.0)] compared to both AL-CMP-rem [11.4(5.8)] and AL-non-CMP [8.9(3.5)] groups. PVVi was higher ($p<0.001$) in AL-CMP group [29.0(24.1 - 36.7) mL/ m2] compared to both AL-CMP-remission [24.6 (19.2 - 31.5) mL/ m2] and AL-non-CMP [19.7 (15.2 - 26.3)] groups. PTTn and PVVi correlated with left ventricular mass index (0.44; 0.50) and left atrial area index (0.35; 0.46); and negatively correlated with LVEF (-0.51; -0.36) and RVEF (-0.43; -0.31). PTTn and PVVi correlated with Global ECV fraction(0.47; 0.39), which represents expansion of extracellular space and iECV (0.50;0.51), a measure of total amyloid burden. Native T1, T2, ECV and iECV ($p<0.05$)were higher in subjects with cardiac involvement compared to those without cardiac involvement and were similar between the AL-CMP and AL-CMP-rem groups.

### CONCLUSION

PTT and PVV are higher in AL-CMP compared to AL-CMP-rem group despite similar ventricular ejection fractions, suggesting that differences may be due to factors related to pulmonary circulation.

### CLINICAL RELEVANCE/APPLICATION

PTT and PVV may be useful biomarkers in systemic amyloidosis patients and provide additional information about cardiopulmonary hemodynamics when combined with currently used biomarkers that evaluate cardiac structure and function.

## M5B-SPCA-2 HIGH RESOLUTION MODIFIED DIXON DUAL PHASE STEADY STATE ANGIOGRAPHY WITH SYSTOLIC AND DIASTOLIC PHASE IN PEDIATRIC PATIENTS WITH COMPLEX CONGENITAL HEART DISEASE

Christoph Katemann (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Julian A. Luetkens, MD (*Abstract Co-Author*) Speakers Bureau, Koninklijke Philips NV;Research Consultant, Bayer AG
Alexander Isaak, MD (*Abstract Co-Author*) Nothing to Disclose
Shuo Zhang, PhD (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Christopher Hart (*Abstract Co-Author*) Nothing to Disclose
Lucia Danny Beissel, MD (*Presenter*) Nothing to Disclose

### PURPOSE

3D magnetic resonance angiography (MRA) is crucial for diagnostic evaluation and interventional planning in pediatric patients with complex congenital heart disease (CDH). The aim of this study is to evaluate the impact of a 3D modified Dixon (mDixon) dual phase steady state MRA on the diagnostic assessment in patients with complex CDH.

### METHODS AND MATERIALS

In this prospective study from July 2023 to April 2024, patients with various types of complex CDH (e.g. Tetralogy of Fallot, hypoplastic left heart syndrome and atrioventricular septal defect) underwent clinically indicated cardiovascular magnetic resonance (CMR) at 3 Tesla. A free breathing 3D mDixon steady state MRA with respiratory navigator gating was used for diastolic and systolic imaging in one single acquisition. Optimal trigger delay for systolic imaging was obtained from 4-chamber cine views. Trigger delay for diastolic imaging was set to end diastole. Vessel diameter (main pulmonary artery, left pulmonary artery, right pulmonary artery, aortic isthmus, aorta ascendens, aorta descendens) and image quality in different venous und arterial vessels (5=excellent to 1=non-diagnostic) were assessed in each phase. For statistical analysis paired t-test and Wilcoxon test were used, as appropriate.

### RESULTS

36 pediatric patients were included (7.9±7.4 years). Vessel diameter were significantly greater in systole than in diastole (e.g. main pulmonary artery 25.1±6.8mm vs. 20.4±6.2mm; P=0.00009). Especially due to flow artifacts in systole, image quality was better in diastole than in systole for main pulmonary artery and aorta (e.g. main pulmonary artery 4.5 [interquartile range 3-5,] vs. 3 [interquartile range, 2-4.25]; P=0.01). There was no difference in image quality between systole and diastole in the pulmonary veins or arteries, coronaries, superior and inferior vena cava and in supraaortic vessels. Primarily due to arrhythmia and high pulse rate, there was a non-diagnostic image quality in two patients in the diastolic phase whereas good image quality could be achieved in systolic phase which is less susceptible to heart rate changes.

### CONCLUSION

In pediatric patients with complex congenital heart disease, 3D mDixon dual phase steady state MRA offers additional diagnostic value and at the same time does not extend acquisition times. The additional systolic image could allow a more precise pre-procedural sizing of implants by avoiding an underestimation of diameters and can have diagnostic implications as they are more robust even in arrhythmic patients.

### CLINICAL RELEVANCE/APPLICATION

The additional systolic phase means an improvement of steady state MRA, especially in cases of arrythmia or high heart rate, and allows more precise pre-procedural sizing of implants.

## M5B-SPCA-3 PREDICTING CORONARY CALCIUM SCORE FROM CHEST X-RAYS USING AI

Bruno A. Rocha, MD (*Abstract Co-Author*) Nothing to Disclose
Igor R. Oliveira, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and evaluate the accuracy of an artificial intelligence tool based on Convolutional Neural Networks (CNNs) for predicting the coronary calcium score (Agatston score) from chest X-rays. The goal is to provide an accessible alternative for cardiovascular risk stratification.

**METHODS AND MATERIALS**

This retrospective study analyzed radiological reports of patients who underwent coronary calcium score CT scans, alongside chest radiographs conducted within one year of the CT study. The dataset included 10,000 patients, all anonymized to protect confidentiality. The training data was divided into a training set (70%), a validation set (10%), and a test set (20%). Exclusion criteria included patients with coronary stents or revascularization. Chest X-ray images were preprocessed using the "torch-xray-vision" library, focusing on the heart and aortic region. Patients were categorized into two groups based on their CACS: zero and non-zero. A convolutional neural network (CNN) was trained using Python 3.11 and the TensorFlow library with VGG-19 architecture, to classify individuals into these categories using chest X-rays as input. Performance was evaluated using the area under the receiver operating characteristic curve (AUC), confusion matrix, sensitivity, and specificity.

**RESULTS**

The VGG-19 model with segmented images focusing on the "0 and greater than 0" CACS categories achieved an AUC of 0.75, with a sensitivity of 71,6% and a specificity of 62,3%, positive predictive value of 65,5% and negative predictive value of 68,7%. This indicates a significant ability to differentiate between patients with varying levels of coronary artery calcification and accurately identify those with and without elevated CACS. Factors contributing to this performance include image segmentation, focusing on calcification detection.

**CONCLUSION**

The study successfully developed a machine learning tool capable of predicting the coronary calcium score with accuracy. This tool provides a viable means for early detection of cardiovascular risks, offering significant utility in clinical decision-making.

**CLINICAL RELEVANCE/APPLICATION**

The tool aims to optimize resources by screening large populations, identifying individuals who could benefit from further cardiovascular risk stratification with standard cardiac CT scans. This enhances public health outcomes by providing a scalable solution, particularly for settings with limited diagnostic resources.

## M5B-SPCA-4 DIAGNOSTIC ACCURACY OF ARTIFICIAL-INTELLIGENCE BASED CAD-RADS EVALUATION IN ASYMPTOMATIC MALE ATHLETES

Jean-Francois Paul, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Jens Kubler, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate deep-learning based assessment of coronary stenosis in an asymptomatic low-risk cohort of athletes.

**METHODS AND MATERIALS**

The artificial intelligence (AI)-based model was applied to an in-house prospectively recruited cohort of asymptomatic male marathon runners who underwent coronary computed tomography angiography (CCTA). CCTA stenosis quantification was performed with AI-models (CorEx, Spimed-AI) and compared with visual quantitative assessment using the Coronary Artery Disease-Reporting and Data System 2.0 (CAD-RADS).

**RESULTS**

94 male patients with a mean age of 53 ± 7 years were evaluated. Coronary artery disease (CAD, i.e. =1% stenosis, CAD-RADS 1 or higher) was present in 34/94 (36%) patients, significant CAD (i.e. >50% stenosis, CAD-RADS 3 or higher) was present in 3/94 patients (3%) after visual analysis. AI-based evaluation detected CAD in 53/94 patients (56%) with 91.2% sensitivity, 63.3% specificity, 58.5% positive predictive value, 92.7% negative predictive value and 73.4% diagnostic accuracy. AI-based evaluation detected significant CAD in 12/94 (13%) patients with 100% sensitivity, 90.1% specificity, 25.0% positive predictive value, 100% negative predictive value and 90.4% diagnostic accuracy.

**CONCLUSION**

AI-based CAD assessment of significant stenosis (CAD-RADS 3 or higher) indicates high diagnostic accuracy in a low-risk population.

**CLINICAL RELEVANCE/APPLICATION**

AI-based quantification of coronary artery stenosis to accelerate workflow.

## M5B-SPCA-5 LEFT VENTRICULAR ABNORMALITY DETECTION USING AI-MEASURED CARDIO-THORACIC RATIO ON CHEST RADIOGRAPHS

Dongmyung Shin, PhD (*Abstract Co-Author*) Researcher, RadiSen Co, Ltd
Joshua Ra (*Abstract Co-Author*) Nothing to Disclose
Heejun Shin, BS (*Abstract Co-Author*) Nothing to Disclose
Minkyung Lee (*Presenter*) Nothing to Disclose

**PURPOSE**

To present an AI model measuring cardiothoracic ratio (CTR) on chest x-ray radiographs (CXRs) and examine the correlation between CTR and echocardiographic diagnoses of severe left ventricular hypertrophy (SLVH) and dilated left ventricle (DLV).

**METHODS AND MATERIALS**

[Data] 71,589 CXRs of 24,689 patients were used in our study (CheXchoNet). The data was approved by the IRB and is publicly available. Patients underwent echocardiograms within one year of their X-ray scans, which diagnosed them with either SLVH or DLV. We constructed a composite binary label based on the presence of either condition (9,861/61,728 composite positive/negative). We used commercially available AI software to measure CTRs on individual CXRs. [Analysis] We first examined the histograms of CTR values according to the composite labels to check whether there was a significant difference between the two groups using a t-test. Then, we calculated sensitivity, specificity, area under the curve (AUC), and the Youden index with ground truth to the composite labels by changing the threshold of CTR for binary classification. Finally, we developed a classification AI model (multilayer perceptron with two fully connected layers) that takes a CTR value, age, and sex of a patient as inputs and predicts a binary composite label. We used 80% of CXRs for training and the remaining data for evaluation. We repeated the AUC and Youden index calculations.

**RESULTS**

The average CTR value was significantly higher in composite SLVH/DLV positive patients compared to negative patients (mean ± std: 0.56 ± 0.07 for positive; 0.51 ± 0.07 for negatives; p-value < 0.001). The binary classification of the composite label showed an AUC of 0.69, and the Youden index of 0.30 was maximized when CTR > 0.53, reporting a sensitivity of 0.70 and specificity of 0.60. When sex, age, and CTR were used as inputs in the classification AI model, an AUC was 0.71, and the Youden index was 0.32, with a sensitivity of 0.74 and specificity of 0.58. When CTR values were not included as inputs, the AUC dropped significantly to 0.54, implying the importance of CTR measurements for accurate prediction of composite SLVH/DLV labels.

**CONCLUSION**

We propose an AI model that provides automated measurements of CTR on chest radiographs and shows its potential to predict the echocardiographic diagnoses of left ventricular structural abnormalities.

**CLINICAL RELEVANCE/APPLICATION**

Automated and precise measurement of CTR using AI models can assist radiologists in the identification of cardiomegaly on chest radiographs. This may facilitate clinical decision-making to pursue confirmatory imaging with echocardiography for earlier recognition of left ventricular hypertrophy and dilation.

## M5B-SPCA-6 ASSESSMENT OF EARLY RIGHT VENTRICULAR DYSFUNCTION IN PULMONARY HYPERTENSION PATIENTS USING CARDIOVASCULAR MAGNETIC RESONANCE FEATURE TRACKING TECHNIQUE

Jianxiu Lian (*Abstract Co-Author*) Nothing to Disclose
Jian-Xing Qiu, MD (*Abstract Co-Author*) Nothing to Disclose
Jia Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the feasibility of CMR-FT technology for quantitatively assessing the myocardial strain of the RV in PH patients.

**METHODS AND MATERIALS**

22 PH patients (PH group, 9 males, mean age: 22?92years) and 20 healthy controls (Control group, 9 males, mean age: 19?73years) who all underwent CMR were retrospectively enrolled. All participants underwent 3.0T CMR examination (Ingenia CX, Philips Healthcare, the Netherlands) with a 32-channel abdominal coil. The sequence of b-SSFP cines were performed for CMR-FT assessment. Scan parameters were as follows: TR=45.6 ms , TE=1.4 ms , field of view (FOV)=340×340 mm , slice thickness=8 mm, voxel size=1.6×1.6×8 mm3.CMR-FT technique was used to measure 3D basal, mid-cavity, apical and global myocardium longitudinal strain (LS), circumferential strain (CS) and radial strain (RS) of RV with CVI 42.0 software. The software automatically detected the endocardial contours of RV during both the diastolic and systolic phases. Subsequently, the epicardial contours of RV were manually drawn and adjustments were made to ensure accurate delineation layer by layer. The SPSS26.0 software was used to obtain statistical results about the differences between the two groups' myocardial strain parameters of RV using Student's t-test or Mann-Whitney U test. Receiver operating characteristic (ROC) analysis was performed to assess the clinical utility of all strain parameters and calculate the cut-off value. Statistical significance was set at $P < 0.05$.

**RESULTS**

RSGlobal,CSGlobal,LSGlobal,RSBasal,RSMid,CSMid,CSApical,LSMid and LSApical were significantly changed in the PH group compared with the controls (all P< 0 .05). ROC curve analysis was performed for strain parameters between the PH group and control group when obvious deference existed. RSGlobal,CSGlobal,LSGlobal,RSBasal,RSMid,CSMid,CSApical,LSMidand LSApical were predictors for PH patients,while LSApical showed the best performance (Cut-off value=-15.15%, AUC=0.92, Sensitivity=0.773, Specificity=0.95).

**CONCLUSION**

RV myocardial strain parameters especially LSApical were feasible to reflect the progression of PH patients and have the potential to be the predictors for early detection of RV dysfunction in PH patients .

**CLINICAL RELEVANCE/APPLICATION**

RV myocardial strain parameters attained from CMR-FT technology were feasible to reflect the progression of PH patients and had the potential to early detect RV dysfunction in PH patients, and could help clinician make an accurate diagnose and timely treatment to improve patients' long-term outcome.

## M5B-SPCA-7 LIPOMATOUS HYPERTROPHY OF THE INTERATRIAL SEPTUM (LHIS) IN DIFFERENT SUBPOPULATIONS: A POTENTIAL NOVEL EPICARDIAL ADIPOSE TISSUE BIOMARKER?

Gudrun Feuchtner, MD (*Abstract Co-Author*) Nothing to Disclose
Gerlig Widmann, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Pietro Giacomo Lacaita, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Epicardial adipose tissue (EAT) is a novel biomarker for cardiovascular risk stratification. Lipomatous hypertrophy of the interatrial septum (LHIS) is a distinct compartment of the EAT. While its association with obesity is known, no texture analysis has been performed yet among different subpopulations.Therefore, the purpose of our study was to quantify LHIS texture by computed tomography (CT) in different subpopulations, and to evaluate its association with cardiovascular risk factors (CVRF).

### METHODS AND MATERIALS

5466 patients (age, 59.7+/-11.4;41.4% females) undergoing coronary CT angiography (CTA) for clinical indications were recruited retrospectively and screened for LHIS.LHIS-density (HU), coronary stenosis severity (CAD-RADS), coronary artery calcium (CAC) score, and high-risk plaque (HRP) were quantified by CTA.The major cardiovascular risk factors and comorbidities were collected.

### RESULTS

324 patients had LHIS. LHIS-density was lower in obese (BMI>30kg/m2)(20.4 vs 13.6HU;p=0.02) BMI was inversely correlated with LHIS density (HU) (BetaR -0.031;95%CI:-0.054- -0.008;p=0.007). Multivariate regression model showed an association of both BMI and LHIS-density (HU) with COPD, while BMI was less strongly (OR:0.94:95%CI: 0.896-0.985;p=0.01) than LHIS-density (HU)(OR:1.01; 95%CI:1.005-1.025,p=0.003) associated. After adjusting for age and CAC score, BMI was no longer significant significance (OR:0.95;95%CI:0.907-1.004);p=0.072) only LHIS -density (HU) (OR:1.02;95% CI:1.005-1.026, p=0.005) remained associated. BMI was not associated with LHIS (OR:1.0,p=0.681), only age and COP (OR 1.02 and OR 9.13, both p<0.001). 151(72.6%) of 208 patients with COPD had LHIS, which is markedly higher than in the literature. LHIS density in COPD patients was higher (-10.93HU vs -21.1HU;p<0.001). CAC and coronary stenosis severity (CAD-RADS and >50% stenosis) were not different (p=0.106;p=0.156 and p=0.350). High-risk plaques were observed more frequently in COPD patients with severe GOLD stages >= 2 (32.3% vs 20.1%;p=0.044).

### CONCLUSION

LHIS texture is distinct in different subpopulations: In obese, LHIS density is lower. In COPD patients LHIS tissue density is higher, suggestive for higher brown fat component. Coronary stenosis severity and calcium were not different, HRP were more frequent in severe COPD.

### CLINICAL RELEVANCE/APPLICATION

LHIS is a distinct compartment of the EAT, with a different texture among different subpopulations.

## M5B-SPCA-8 PRELIMINARY STUDY ON THE ASSESSMENT OF RIGHT VENTRICULAR SYSTOLIC FUNCTION AND ITS CORRELATION WITH CLINICAL INDICES IN PATIENTS WITH STABLE COPD USING CARDIAC MAGNETIC RESONANCE

Jianlin Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Hao Woo (*Abstract Co-Author*) Nothing to Disclose
Dong Yang, BMedSc, MMEd (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the value of cardiac magnetic resonance (CMR) in evaluating right ventricular systolic function in patients with stable chronic obstructive pulmonary disease (COPD) and its correlation with relevant clinical indexes.

### METHODS AND MATERIALS

From April 2015 to February 2021, 35 patients with stable COPD diagnosed in the respiratory department of Zhongshan Hospital affiliated with Dalian University were enrolled. These patients were divided into a cardiac decompensation group (15 cases) and a compensation group (20 cases) based on a 6-minute walking test. Within one week, all participants underwent pulmonary function tests (FEV1/FVC), measurement of CMR right ventricular ejection fraction (RVEF), cardiac index (RVCI), right ventricular median transverse diameter change fraction (RVFMDC), brain natriuretic peptide levels, COPD assessment test (CAT), and other clinical indexes.

### RESULTS

No significant differences were observed in age, sex, or blood pressure between the cardiac function compensation and decompensation groups ($P > 0.05$). Significant differences were found in RVEF (51.50±2.34% vs 49.11±3.36%), RVCI (1.91±0.21 ml/min/m2 vs 1.28±0.19 ml/min/m2), and RVFMDC (32.28±7.43% vs 25.56±2.22%) between the two groups ($P < 0.05$). There were no significant differences in other indexes of right ventricular systolic function ($P > 0.05$). A negative correlation was noted between RVCI and CAT score ($r = -0.656$, $P < 0.001$), RVEF and CAT score ($r = -0.538$, $P < 0.001$), RVEF and NT-proBNP ($r = -0.394$, $P = 0.019$), and between RVFMDC and both CAT score ($r = -0.655$, $P < 0.001$) and NT-proBNP ($r = -0.317$, $P = 0.05$).

### CONCLUSION

CMR can reliably evaluate the changes and degree of right ventricular systolic function in patients with stable COPD, which is helpful for early clinical evaluation and diagnosis.

### CLINICAL RELEVANCE/APPLICATION

The results of this study indicate that using 1.5T MRI equipment for CMR technology is a feasible and effective method to quantitatively evaluate the right ventricular systolic function of patients with stable chronic obstructive pulmonary disease (COPD). Additionally, it confirms that the COPD assessment test (CAT) score and brain natriuretic peptide levels are important factors affecting right ventricular systolic function.These findings can provide an important reference basis for the formulation of clinical treatment plans and efficacy evaluation in such patients.

## M5B-SPCA-9 SYSTEMIC RIGHT VENTRICLE TORSION IN CONGENITALLY CORRECTED AND COMPLETE TRANSPOSITION OF THE GREAT ARTERIES USING MOTION TRACKING ANALYSIS OF CARDIAC CINE MAGNETIC RESONANCE

Kei Inai (*Abstract Co-Author*) Nothing to Disclose
Shuji Sakai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Seiko Shimizu (*Abstract Co-Author*) Nothing to Disclose
Yurie Shirai (*Abstract Co-Author*) Nothing to Disclose
Michinobu Nagao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akihiro Inoue, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In congenitally corrected transposition of great arteries (cTGA) and complete transposition of great arteries(TGA), the anatomic right ventricle (RV) can be carrying the systemic circulation. The dysfunction of anatomic RV corresponding to the systemic circulation and tricuspid valve regurgitation influences the prognosis of patients. No good kinetic parameter has been found to identify patients who survive to old age in a non-repair, so called natural course in cTGA. We hypothesize that the appearance of right ventricular torsion associated with right ventricular remodeling of the systemic circulation underlies the maintenance of pump function.

## METHODS AND MATERIALS

We analyzed 50 patients with cTGA and TGA who underwent cardiac cine magnetic resonance image retrospectively. We calculated the time-torsion curve all around in each segments using short-axis cine images of the basal to apex of the systemic right or left ventricle(LV) and the motion tracking method. The torsion (degrees/cm) in each segments during ventricular contraction was extracted and compared to the left ventricular torsion of the systemic RV or LV with cTGA and TGA and 20 healthy controls.

## RESULTS

The torsion was significantly decreased in the following order: control, systemic LV, and RV(1.93±0.46 degree/cm vs. 1.17±0.47 degree/cm vs. 0.93±0.62 degree/cm, $p<0.05$). In the systemic RV of cTGA, the torsion in the natural course (n=13) was significantly higher than that after repair (1.39±0.64 degree/cm vs 0.57±0.29 degree/cm, $p<0.05$). The torsion of cTGA in the natural course was comparable to that of systemic LV group, suggesting maintenance of pump function in the RV. On the other hand, the decreased torsion of cTGA that requires repair suggested that it was difficult to maintain pump function.

## CONCLUSION

The presence of torsion preserved in the Systemic RV suggests remodeling of the Systemic RV and may contribute to the maintenance of pump function in the natural course of cTGA.

## CLINICAL RELEVANCE/APPLICATION

In the natural course of cTGA, the torsion appeared to be equally present in the RV as in the LV, suggesting that RV torsion may be a useful indicator for prognosis of cTGA and for determining repair procedures.

## M5B-SPCH-1 PROGNOSTIC VARIABILITY IN PATHOLOGIC T3 NON-SMALL CELL LUNG CANCER WITH SEPARATE NODULES: THE IMPACT OF SEPARATE NODULE CHARACTERISTICS ON SURVIVAL OUTCOMES

Joon Beom Seo, MD, PhD (*Abstract Co-Author*) Stockholder, Promedius Inc;Stockholder, Coreline Soft, Co Ltd;Stockholder, Anymedi Inc
Sang Min Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Jooae Choe, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Eun Jin Chae, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Sohee Park, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Patients with T3 non-small cell lung cancer (NSCLC) with separate nodules (SNs) have been reported to have better prognosis than those with other T3 descriptor-tumors. However, significant heterogeneity might exist in patients with pathologic T3-SNs but there have been limited attempts to identify prognostic subgroup in pT3-SN tumors based on imaging and pathological features of SNs.

### METHODS AND MATERIALS

This retrospective study included patients with pT2b-pT3 NSCLC who underwent lobectomy/pneumonectomy between 2010 and 2021. Imaging and pathological features of primary tumors and their SN(s) were recorded. Recurrence-free survival (RFS) and overall survival (OS) were evaluated using Cox proportional hazards model.

### RESULTS

The patients (1107 patients) included in the study had pT2b (498 patients), pT3 without SN (468 patients), and pT3 with SN (141 patients) tumors. Subsolid SN was an independent favorable prognostic factor for both RFS (hazard ratio [HR]: 0.26; P = .001) and OS (HR, 0.11; P < .001). Moreover, SN numbers was a significant prognostic factor for RFS (HR, 0.11; P < .001). In patients with pT3-solid SN tumors, a distance of > 3 cm from the primary tumor (HR, 1.92; P = .04) was the only prognostic factor for shorter OS. Moreover, pT3-subsolid SN and pT2b tumors were associated with comparable RFS and OS; whereas pT3-solid SN and other T3 descriptor-tumors were associated with comparable RFS and OS (log-rank, P > .999 for all).

### CONCLUSION

Patients with surgically resected pT3-SN NSCLC showed different prognosis according to the presence of GGO components of SNs. Prognosis of pT3 tumors with subsolid SNs was comparable to that of pT2b but the prognosis of pT3 tumors with solid SNs were comparable to other T3 descriptors.

### CLINICAL RELEVANCE/APPLICATION

Although previous studies have shown that SN could potentially offer a significantly better prognosis among patients with pT3, there is significant heterogeneity among patients with pT3-SN and subcategorizing these patients based on CT characteristics of the SN revealed subgroups with different outcomes. Furthermore, CT characteristics of SN emerged as a significant prognostic factor in patients with pT3-SN.

## M5B-SPCH-2 PREDICTING SPREAD THROUGH AIR SPACES STATUS OF LUNG ADENOCARCINOMA WITH “ONE-STOP” CHEST SPECTRAL AND PERFUSION IMAGING CT

Junli Tao (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the spectral and perfusion computed tomography (CT) findings of lung adenocarcinoma with spread through air spaces (STAS) positive or negative, compare the accuracy of spectral and perfusion in predicting STAS status, and explore whether the combined modle can improve the prediction efficiency of STAS status.

### METHODS AND MATERIALS

Patients who underwent “one-stop” chest spectral and perfusion CT were prospectively enrolled from June 2022 to February 2024. A total of 187 patients with STAS + (n = 62) and STAS - (n = 125) were included. Differences in CT imaging characteristics between STAS + and STAS - were compared. Spectral parameters (CT40keV, C T70keV, CT100keV, iodine concentration [IC], water concentration [WC], and effective atomic number [Zeff]) of the lesions in the arterial and venous phases were measured. The perfusion parameters, including blood volume (BV), blood flow (BF), mean transit time (MTT), and time to peak (TTP), were measured simultaneously. The differences in the spectral and perfusion parameters between the groups were examined. Receiver operating characteristic (ROC) curves were calculate and compare the area under the curve (AUC) in both groups.

**RESULTS**

Patients with STAS + or STAS - had different maximum diameter, nodule type, shape, and lymph node metastasis (P = 0.001, 0.001, 0.001, and 0.013, respectively). In the arterial and venous phases, the values of spectral parameters (CT40keV, CT70keV, IC, and Zeff) were greater in the STAS + group than the STAS - (P < 0.05). Similarly, the values of the perfusion parameters (BV, BF, MTT) were greater in the STAS + group than STAS - group (P < 0.01), while the TTP was longer than that in the STAS + group (P < 0.01). The AUC of the arterial and venous phases was 0.83 (95% [CI]: 0.72-0.86) and 0.84 (95% [CI]: 0.73-0.88), respectively. There was no significant difference between them(P > 0.05). When combined the spectral parameters, the AUC was lower than perfusion parameters. For the spectral parameters, the AUC was 0.86 (95% [CI]: 0.76-0.90). For the perfusion parameters, the AUC was 0.90 (95% CI: 0.83-0.95). Finally, Combining spectral and perfusion parameters, the AUC of the combined model was 0.96 (95% CI: 0.88-0.99), which was higher than all other models.

**CONCLUSION**

Spectral and perfusion CT both have the capability to differentiate lung adenocarcinoma STAS status. Compared to spectral, perfusion CT imaging has higher diagnostic efficiency in distinguishing STAS status. Combining spectral and perfusion, the combined model was superior than the other models.

**CLINICAL RELEVANCE/APPLICATION**

"One-stop" chest spectral and perfusion CT imaging can predict the lung adenocarcinoma STAS status noninvasively and preoperatively, which is helpful to optimize clinical treatment plan.

## M5B-SPCH-3 PREDICT TUMOR SPREAD THROUGH AIR SPACES IN PERIPHERAL STAGE I LUNG ADENOCARCINOMA USING A VISION TRANSFORMER MODEL

Xiaofeng Li (*Presenter*) Nothing to Disclose

**PURPOSE**

Preoperative assessment of tumor spread through air spaces (STAS) is crucial for surgical planning in early-stage lung cancer. The Vision Transformer (ViT)-based deep learning (DL) models outperformed other traditional neural networks but the value of predicting STAS in peripheral stage I lung adenocarcinoma is unclear. This study aims to develop a 3D ViT model based on enhanced CT images of the tumor and 3mm peritumoral to predict STAS in peripheral stage I lung adenocarcinoma.

**METHODS AND MATERIALS**

We retrospective analysis the preoperative CT data from patients diagnosed with lung tumors from January 2022 to December 2023, with additional data collected from another hospital serving as an external validation set. Inclusion criteria were: 1) Clinical stages T1-T2aN0M0 as defined by the 8th AJCC staging system; 2) The peripheral lesion located in the outer two-thirds of the lung field on chest CT axial images, with the tumor's center within this region; 3) Postoperative pathological diagnosis confirmed as adenocarcinoma. Exclusion criteria included: 1) Preoperative CT diagnosis or postoperative pathological diagnosis of double primary or multiple primary (>2) lung cancers; 2) Preoperative anticancer treatments such as radiotherapy, chemotherapy, immunotherapy, or targeted therapy. A senior radiologist independently delineated the region of interest (ROI) around the lung cancer tumors using the 'Grow From Seeds' feature in 3D-slicer software, performing an external expansion of 3mm on the delineated tumor areas. The CT images were then cropped to a size of 64x64x64 pixels around the tumor. The 3D Vit algorithm was employed to train the model, which was also validated on an independent external dataset. Model evaluation metrics included AUC, Accuracy, F1-Score, Precision, and Recall.

**RESULTS**

The training set included 208 patients (median age, 62 years; male: female 55%: 45%), with 45 (21.63%) cases positive for STAS. Comparisons between centers showed no significant statistical difference in clinical and pathological variables (P > 0.05). The DL model using the 3D Vit algorithm demonstrated performance metrics of AUC, Accuracy, Precision, and Recall in the training set and external validation set as follows: 0.9757, 0.9901, 1, 0.9514; and 0.7766, 0.8415, 0.6932, 0.7, respectively. The confusion matrix also confirmed the model's robust diagnostic efficacy.

**CONCLUSION**

The 3D Vit model based on the tumor and 3mm peritumoral exhibits significant predictive capability for STAS in peripheral stage I lung adenocarcinoma.

**CLINICAL RELEVANCE/APPLICATION**

Preoperative predict STAS in peripheral stage I lung adenocarcinoma is crucial for the thoracic surgeon to choose the surgical approach. DL models based on the 3D VIT can improve the performance.

## M5B-SPCH-4 ADVANCING EGFR MUTATION SUBTYPES PREDICTION IN NSCLC BY COMBINING 3D PRETRAINED CONVNEXT, RADIOMICS, AND CLINICAL FEATURES

Fang Zhou, MD (*Abstract Co-Author*) Nothing to Disclose
Chantao Huang (*Abstract Co-Author*) Nothing to Disclose
Zhixuan Song (*Abstract Co-Author*) Nothing to Disclose
Peng Hao (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this study was to develop a novel approach for predicting the expression status of Epidermal Growth Factor Receptor (EGFR) and its subtypes in patients with Non-Small Cell Lung Cancer (NSCLC) by utilizing a Three-Dimensional Convolutional Neural Network model called ConvNeXt, along with radiomics features and clinical features.

**METHODS AND MATERIALS**

This retrospective study included a total of 732 NSCLC patients with available CT imaging and EGFR expression data. The regions of interest (ROI) were manually segmented and clinical pathological characteristics were collected. Radiological and deep learning features were extracted. These cases were randomly divided into training, validation and testing sets. Feature selection was performed and XGBoost was used to create individual and combined models to predict the presence of EGFR and subtype mutations. The effectiveness of the models was evaluated using ROC curves and PRC curves.

**RESULTS**

Seven models were established based on deep learning features, radiomic features, clinical data and their combinations. In terms of predicting EGFR mutations, compared with other prediction models, the ModelCNN-radiomic-clinical model showed the best performance with an AUC of 0.801. When distinguishing between EGFR subtypes ex19del and L858R, the ModelCNN-radiomic model had the highest AUC value of 0.775.

### CONCLUSION

Both deep learning models and models based on radiomic features can provide highly accurate non-invasive predictions of EGFR status and its subtypes. The fusion model has the potential to enhance the non-invasive methods for predicting EGFR mutations and subtypes, providing a more reliable prediction method.

### CLINICAL RELEVANCE/APPLICATION

This study's fusion model combining 3D-CNN ConvNeXt, radiomics, and clinical features offers a more accurate and non-invasive method for predicting EGFR mutations and subtypes in NSCLC patients, thereby potentially improving personalized treatment strategies.

## M5B-SPCH-5 CT-BASED VISION TRANSFORMER PREDICTS OUTCOMES IN PATIENTS WITH NON-SMALL CELL LUNG CANCER RECEIVING IMMUNOTHERAPY

Ting Xu (*Abstract Co-Author*) Nothing to Disclose
Shuxing Wang (*Abstract Co-Author*) Nothing to Disclose
Xiaowen Liu (*Abstract Co-Author*) Nothing to Disclose
Jingshan Gong, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop and validate multimodal deep learning model on the basis of CT-based Vision Transformer (ViT) to predict outcomes in patients with non-small cell lung cancer (NSCLC) receiving immunotherapy.

### METHODS AND MATERIALS

This retrospective study enrolled 329 patients with advanced NSCLC receiving immunotherapy at two centers from October 2019 to October 2023. Patients from center 1 (n=210) were used as the training set, and the external test set included the 119 patients from center 2. ViT was implemented to extract deep learning features of NSCLCs from preoperative chest CT images and generate immunotherapy response deep learning score (irDLS). Patients were stratified into high-irDLS and low-irDLS groups based on optimal cut-off value of irDLS in training set. Cox proportional hazards regression model was used to assess the correlation between variables and progression-free survival (PFS) and overall survival (OS), calculating hazard ratio (HR) and 95% confidence intervals (CIs). Kaplan-Meier method was employed to plot PFS and OS curves, with Log-rank test used for intergroup comparisons.

### RESULTS

The HR of irDLS was 0.699 (95% CI: 0.496, 0.984; P=0.003) for PFS, and 0.608 (95% CI: 0.371, 0.994; p=0.045), respectively. It could predict 1-, 3- and 5-year DFS with an area under the receiver operating characteristic curve (AUC) of 0.748, 0.725 and 0.726, and 1-, 3- and 5-year OS with AUC of 0.770, 0.773 and 0.764 in the external test set, respectively. When irDLS combining with PLR, clinical stage and bone metastasis, the multimodal model predicted 1, 3, and 5-year PFS with AUC of 0.775, 0.812, and 0.841 in the external test set, respectively.

### CONCLUSION

The radiomics signature derived from preoperative CT using ViT could non-invasively predict outcomes in patients with NSCLC receiving immunotherapy. The multimodal model integrating radiomics signature and clinical data was able to predict survival of patients with NSCLC receiving immunotherapy with high performance, which could provide decision-making support for selecting suitable patients receiving immunotherapy.

### CLINICAL RELEVANCE/APPLICATION

In this bi-center study, the multimodal model integrating immunotherapy response deep learning score, derived from preoperation CT images through Vision Transformer, and clinical data could obtain high predictive performance for outcomes in patients with NSCLCs receiving immunotherapy. The radiomics signature showed the potential to be a surrogate imaging biomarker for selection of patients who would be benefit for immunotherapy noninvasively.

## M5B-SPCH-6 ASSESSING THE EFFICIENCY OF ELIGIBILITY CRITERIA FOR LOW-DOSE COMPUTED TOMOGRAPHY LUNG SCREENING IN CHINA ACCORDING TO CURRENT GUIDELINES

Ning Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Yanyan Tang (*Presenter*) Nothing to Disclose

### PURPOSE

The efficiency of the LCS for each guideline criterion was expressed as the efficiency ratio (ER). The inclusion rates, eligibility rates, LC detection rates, and ER based on the different eligibility criteria of the four guidelines were comparatively analyzed. The four guidelines were as follows: China guideline for the screening and early detection of lung cancer (CGSL), National Comprehensive Cancer Network (NCCN), the United States Preventive Services Task Force (USPSTF) , and International Early Lung Cancer Action Program (I-ELCAP).

### METHODS AND MATERIALS

Between 2005 and 2022, 31,394 asymptomatic individuals were screened using low-dose computed tomography (LDCT) at our institution. Demographic data and relevant LC risk factors were collected. The efficiency of the LCS for each guideline criterion was expressed as the efficiency ratio (ER). The inclusion rates, eligibility rates, LC detection rates, and ER based on the different eligibility criteria of the four guidelines were comparatively analyzed. The four guidelines were as follows: China guideline for the screening and early detection of lung cancer (CGSL), National Comprehensive Cancer Network (NCCN), the United States Preventive Services Task Force (USPSTF) , and International Early Lung Cancer Action Program (I-ELCAP).

### RESULTS

Of 31,394 participants, 298 (155 women, 143 men) were diagnosed with LC. For CGSL, NCCN, USPSTF, and I-ELCAP guidelines, the eligibility rates for guidelines were 13.92%, 6.97%, 6.81%, 53.46%, ERe for eligibility criteria were 1.46%, 1.64%, 1.51%, and 1.13%, respectively, and for the inclusion rates, they were 19.0%, 9.5%, 9.3%, and 73.0%, respectively. LCs which meet the screening criteria of CGSL, NCCN, USPSTF, and I-ELCAP guidelines were 29.2%, 16.4%, 14.8%, and 86.6%, respectively. The age and smoking criteria for CGSL were stricter, hence resulting in lower rates of LC meeting the screening criteria.The CGSL, NCCN, and USPSTF guidelines showed the highest underdiagnosis in the 45-50 age group (17.4%), while the I-ELCAP guideline displayed the highest missed diagnosis rate (3.0%) in the 35-39 age group. Males and females significantly differed in eligibility based on the criteria of the four guidelines (P<0.001).

### CONCLUSION

The I-ELCAP guideline has the highest eligibility rate for both males and females. but its actual efficiency ratio for those deemed eligible by the guideline was the lowest. Whereas the NCCN guideline has the highest ERe value for those deemed eligible by the guideline.

### CLINICAL RELEVANCE/APPLICATION

These findings provide valuable insights for improving LCS guidelines in the Chinese population.

## M5B-SPCH-7 EVALUATION FOR OSTEOPOROSIS ON LOW-DOSE CHEST CT (LDCT) OBTAINED FOR LUNG CANCER SCREENING: A RETROSPECTIVE STUDY OF 784 PATIENTS

Cihan Duran, MD (*Abstract Co-Author*) Nothing to Disclose
Migena Gjoni (*Abstract Co-Author*) Nothing to Disclose
Muhammad O. Awiwi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate for osteoporosis in asymptomatic patients presenting for lung cancer screening.

### METHODS AND MATERIALS

A retrospective review of 784 patients with low-dose CT (LDCT) was performed. Patients with a dual-energy X-ray absorptiometry (DEXA) scan performed within 4 months of the LDCT were selected. Vertebral trabecular bone attenuation was measured between T7-L1. T-scores were recorded from DEXA scans (a T-score of =-2.5 was considered diagnostic of osteoporosis; and a T-score between -1.0 and -2.4 was considered osteopenia). FRAX scores were calculated. Thoracic vertebral compression fractures were recorded.

### RESULTS

93% of patients were female. Osteoporosis was present in 31% of the patients and 52% had osteopenia. Receiver operator curve (ROC) analysis was performed and an AUC value of 0.748 (95% CI: 0.701-0.795) was obtained for diagnosing osteoporosis using CT-trabecular bone attenuation. A median trabecular bone attenuation cutoff value of <130 HU yielded a sensitivity of 92% and a specificity of 22%; whereas a cutoff value of <70 HU yielded a sensitivity of 23% and a specificity of 95% for diagnosing osteoporosis. A cutoff value of <130 HU identified 89% of patients for whom osteoporosis treatment was indicated based on their FRAX scores. A sub-analysis was performed on individuals between 50-64 years of age (who are younger than the recommended age for routine DEXA screening) and 23% (44/192) of whom had osteoporosis, and 8% (16/192) had vertebral compression fractures.

### CONCLUSION

Low vertebral trabecular bone attenuation calculated from lung cancer screening LDCT is suggestive of osteoporosis. Sensitivities and specificities were calculated at various cutoff values.

### CLINICAL RELEVANCE/APPLICATION

Low vertebral trabecular bone attenuation values calculated on lung cancer screening LDCT may be used to recommend further evaluation with DEXA scan. LDCT evaluation for osteoporosis is particularly important for individuals younger than the current recommended DEXA screening age of 65 years.

## M5B-SPCH-9 LONG TERM OUTCOMES OF A MULTIDISCIPLINARY LUNG CANCER LOW DOSE CT SCREENING PROGRAM FROM A LARGE CANADIAN COMMUNITY HOSPITAL CENTER

Anna Bendzsak (*Abstract Co-Author*) Nothing to Disclose
Kassandra Bisson (*Abstract Co-Author*) Nothing to Disclose
Garima Sharma (*Abstract Co-Author*) Nothing to Disclose
Daniel Levay (*Abstract Co-Author*) Nothing to Disclose
Brandon Sheffield (*Abstract Co-Author*) Nothing to Disclose
Parneet Cheema (*Abstract Co-Author*) Nothing to Disclose
Kashif Irshad (*Abstract Co-Author*) Nothing to Disclose
Marc G. Ossip, MD, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

To report results of 8 years of lung cancer screening in a large Canadian community hospital. William Osler Health System (WOHS) High Risk Lung Cancer Screening Program was established in 2012 and is the longest running multidisciplinary lung cancer screening program in Canada outside of a research or pilot study.

### METHODS AND MATERIALS

Retrospective review of patients who had lung cancer screening in the WOHS High Risk Lung Cancer Screening Program between February 2012 to December 2019 with follow-up until April 2023. Eligibility for screening was age 55-77, minimum 30-pack-year smoker, no prior lung cancer, no CT scan within 12 months of initial Low Dose Computed Tomography (LDCT) and former smokers must have quit within 15 years.

### RESULTS

During the 8 years, 5460 patients were enrolled, with an average of 683 new patients per year (27% annual growth rate). Median age at entry was 63 and 61% were males. The retention rate was 74%. A total of 14,048 LDCT were completed, of which 88.6% were reported with recommendations for routine follow up, 11.4% for shorter term follow up, and 2% leading to biopsy. Biopsy was performed on 5.3% of patients (n=287), either CT guided +/- endobronchial ultrasound / mediastinoscopy (EBUS/med) in 3.8%, and EBUS/med alone in 1.4%. The pneumothorax rate per CT biopsy was 41%, and the chest tube rate 14%. Of the 225 CT guided biopsies, 52.4% were malignant, 11.6% atypical/suspicious for cancer, 21.8% benign, and 4.2% non-diagnostic. Of the 118 malignant cases, 50% were non-small cell lung cancer (NSCLC) adenocarcinoma, 28% NSCLC squamous cell, 11% NSCLC not otherwise specified, 3% large cell neuroendocrine, 4% small cell lung cancer, 2% carcinoid and 1% metastatic non lung cancer. In patients with atypical / suspicious CT biopsy pathology results, 69.2% had a subsequent malignancy diagnosis, and of those with non-diagnostic or benign CT biopsy pathology results, 38.7% and 23.4% had a subsequent malignancy diagnosis, respectively. Surgical resections were performed on 198 patients (3.6%). Overall surgical malignancy rate was 88.8%, if presurgical biopsy was performed 93.4% and if not performed 76.0%. The cancer detection rate was 4.2% (lung cancer 4.0%, n=221), with a prevalence of 40%. The average lung cancer size was 2.3 cm and 26% were lymph node positive. The clinical or surgical stage of lung cancers detected was primarily early stage: stage I (62.0%), II (11.3%), III (16.7%) and IV (10%).

### CONCLUSION

Eight years of lung cancer screening in a community hospital detected a high rate of cancers, primarily early stage, with a low rate of lung biopsies required.

## CLINICAL RELEVANCE/APPLICATION

Lung cancer screening in a community hospital is feasible and can result in similar lung cancer detection rates and stage shift as reported in the literature.

## M5B-SPER-1 NEW PHOTO-REALISTIC ILLUMINATION TECHNIQUE APPLIED TO NAKED-EYE AUTO-STEREOSCOPIC DISPLAYS FOR 3D POSTMORTEM CT IMAGES OF SKULL FRACTURES

Wataru Fukumoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Keigo Chosa (*Abstract Co-Author*) Nothing to Disclose
Shintaro Morishita (*Abstract Co-Author*) Nothing to Disclose

Haruka Higashibori (*Presenter*) Nothing to Disclose

### PURPOSE

Post-mortem CT (PMCT) is a supplementary diagnostic modality in forensics; it facilitates detecting bone fractures. In forensics, not only bone fractures but also the power and direction of the applied external force must be assessed to determine the cause of death. Although the three dimensional (3D) CT image is one of the most interpretable presentation format, current standard displays are 2D modalities and the true depth and direction information which is the essence of 3D is still lacking. We developed a photo-realistic illumination (PRI) technique that simulates the interaction of photons with the scanned object. It yields photo-realistic images on naked-eye auto-stereoscopic (NEAS) displays. We compared it with the conventional volume rendering (VR) technique applied to 3D-PMCT images of skull fractures.

### METHODS AND MATERIALS

We enrolled 16 cadavers with skull fractures (11 males, 5 females; 9 traffic accident, 4 falls, 3 drifting in the sea) who had undergone autopsy and PMCT studies between 2019 and 2023 at our center for cause-of-death investigations. The scans were performed on a 16-row multi-detector CT scanner (Aquilion Lightning; Canon Medical Systems). The 3D-PMCT images with the PRI technique applied to NEAS display and the conventional VR technique were reconstructed from axial CT images of 0.5-mm slice thickness with soft kernel. A forensic radiologist, a forensic pathologist, and a medical student assigned a confidence score ranging from 1 (poor) to 5 (excellent) in their assessment of the image quality with respect to the detection of skull fractures and the estimation of the external force. Image-quality differences between the scans obtained with the two techniques were analyzed with the two-sided Wilcoxon signed-rank test.

### RESULTS

The mean image-quality scores regarding both the detection of skull fractures and the estimation of the external force were 3.6 (SD 1.0) for the PRI technique on the NEAS display; they were 2.7 (SD 0.9) and 2.6 (SD 0.7), respectively, for the VR technique (both $p<0.01$).

### CONCLUSION

For the assessment of skull fractures in cadavers, our new PRI technique applied on NEAS displays of 3D-PMCT images was superior to the conventional VR technique.

### CLINICAL RELEVANCE/APPLICATION

As our new PRI technique applied to NEAS displays facilitates the assessment of skull fractures and the estimation of the external force, it may be useful for pre-autopsy forensic pathology examinations.

## M5B-SPGI-11 DECODING GASTRIC TUMOR HETEROGENEITY: A RADIOMICS APPROACH TO DISTINGUISH GASTRIC CANCER VARIANTS

LI YANG (*Abstract Co-Author*) Nothing to Disclose
Jia-Liang Ren, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaoxiao He (*Presenter*) Nothing to Disclose

### PURPOSE

To establish diagnostic models for differentiating gastric neuroendocrine carcinoma (g-NEC) and gastric mixed adeno-neuroendocrine carcinoma (g-MANEC) from gastric adenocarcinoma (g-ADC) based on traditional contrast enhanced CT imaging features and radiomics features.

### METHODS AND MATERIALS

A retrospective collection of 90 patients with g-(MA)NEC (g-MANEC and g-NEC), confirmed by surgical pathology and without pre-surgical anti-tumor treatment, was conducted. These patients were matched 1:1 by pathological T-stage with 90 patients diagnosed with g-ADC post-operatively. Traditional contrast enhanced CT imaging features were analyzed using univariable and multivariable logistic regression. Tumor segmentation was performed using Slicer software, and radiomics features were extracted using the PyRadiomics platform. Feature selection was conducted through univariable analysis, correlation analysis, LASSO, and multivariable stepwise logistic regression to establish a radiomics model and calculate the Radiomics score (Rad-score). The independent predictors from the clinical model and Rad-score were integrated to create a combined model. The diagnostic performance of the models was assessed and compared using ROC curves and DeLong's test. The models' diagnostic efficacy was further validated in subgroup of g-NEC vs. g-ADC and g-MANEC vs. g-ADC cases.

### RESULTS

The tumor necrosis and lymph node metastasis were identified as independent predictors for differentiating g-(MA)NEC from g-ADC ($P < 0.05$). The clinical model demonstrating AUCs of 0.700 in the training cohort and 0.667 in the validation cohort. From 1502 extracted radiomic features, five were retained to establish the radiomics model, which showed AUCs of 0.809 in the training cohort and 0.802 in the validation cohort. The combined model yielded AUCs of 0.853 and 0.812 in the training and validation cohort and significantly outperformed the clinical model in both cohorts ($P < 0.05$). Subgroup analysis revealed that the combined model exhibited acceptable performance in differentiating g-NEC from g-ADC and g-MANEC from g-ADC, with AUCs of 0.887 and 0.823 in the training cohort and 0.852 and 0.762 in the validation cohort.

### CONCLUSION

Combined model based on traditional CT imaging and radiomic features provide a non-invasive and effective preoperative diagnostic method for differentiating g-(MA)NEC from g-ADC.

### CLINICAL RELEVANCE/APPLICATION

The biological behaviors of g-(MA)NEC and g-ADC are different, with the former characterized by higher aggressiveness and poorer prognosis. This distinction is also reflected in their treatment approaches, where first-line pharmacological therapies and surgical techniques vary between the two.

## M5B-SPGI-12 ABDOMINAL CONTRAST-ENHANCED CT RADIOMICS INPREDICTING SECONDARY IMATINIB RESISTANCE IN HIGH-RISK GASTROINTESTINAL STROMAL TUMORS

LI YANG (*Abstract Co-Author*) Nothing to Disclose
Jia-Liang Ren, MD (*Abstract Co-Author*) Nothing to Disclose
Qing Hao (*Presenter*) Nothing to Disclose

### PURPOSE

This study evaluated the potential of radiomics from contrast-enhanced abdominal CT to predict secondary resistance to adjuvant imatinib therapy in high-risk gastrointestinal stromal tumors (GISTs).

### METHODS AND MATERIALS

Clinical data from high-risk GIST patients who underwent imatinib adjuvant therapy and monitored post-operatively were analyzed. Ninety-two patients, including 19 resistant cases at Center 1, were divided into training (n=64) and internal validation (n=28) sets at a 7:3 ratio. An additional 12 patients including 2 resistant cases from Center 2, were included as external validation set. Clinical attributes and conventional CT imaging findings were documented. A clinical model was developed using univariate and multivariate logistic regression. Radiomics features were extracted from 3D segmented

tumors on thin-layer venous phase image by using PyRadiomics platform. After correlation analysis and recursive feature elimination, radiomics models employing logistic regression, support vector machines, random forests, and decision trees, were constructed. The most effective model based on predictive performance was select, generating a rad-score. A combination model integrating independent predictors from both the clinical model and the rad-score was developed. The predictive performance of the three models was evaluated using ROC curves and the DeLong test.

**RESULTS**

Significant predictors of imatinib resistance included blurred margins and blood supply/dilated draining vessels ($P < 0.05$). The clinical model demonstrated AUCs of 0.874 (95% CI, 0.762-0.985) and 0.803 (95% CI, 0.608-0.998) in training and internal validation sets, respectively. Following feature selection, the best-performing radiomics model utilized a decision tree with three features, achieving AUCs of 0.882 in the training set and 0.864 in the internal validation set. The combination model had AUCs of 0.963 (95% CI, 0.925-1.000) and 0.939 (95% CI, 0.861-1.000) in the training and internal validation sets, respectively. The combination model demonstrated superior accuracy and specificity with values of 0.917,0.900.

**CONCLUSION**

The combination model, incorporating conventional imaging characteristics and radiomics features from contrast-enhanced abdominal CT, robustly predicts imatinib resistance post-surgery in GIST patients.

**CLINICAL RELEVANCE/APPLICATION**

Approximately 50% of GIST patients develop secondary resistance to imatinib within 2 years, leading to treatment failure and poor prognosis. The proposed model offers an innovative strategy for early and precise detection of potential resistance in high-risk GIST patients, enhancing follow-up management strategies.

## M5B-SPGI-2 QUANTITATIVE MULTIPARAMETRIC VOLUMETRIC PREDICTION OF REBLEEDING AFTER ESOPHAGEAL VARICEAL LIGATION IN CIRRHOSIS BY SPECTRAL COMPUTED TOMOGRAPHY

Guo Yu (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the clinical value of energy-spectral CT multiparametric volumetric quantification in predicting the risk of rebleeding within 1 year after endoscopic lancing of esophageal varices (EVL) in patients with ruptured esophageal variceal hemorrhage (EVB) in cirrhosis.

**METHODS AND MATERIALS**

Thirty-five patients who were first ligated for ruptured esophageal variceal hemorrhage due to cirrhosis were collected and underwent portal vein energetic CT, and the patients were followed up for 1 year, and were divided into a no-rebleeding group and a rebleeding group on the basis of whether or not they had rebleeding within 1 year of the endoscopic ligation treatment. The hepatic VACR post-processing software was used to automatically extract the liver in the portal vein stage to realize the extraction of the whole liver, and then the liver was automatically divided into the left and right lobes by using the automatic segmentation of the liver based on the portal vein, and the volume measurements and VR reconstruction were carried out for the whole liver and the different lobes of the liver. The liver volume, portal and arterial effective atomic number, iodine (water) concentration, water (iodine) concentration, standardized iodine concentration, and single-energy CT value of 40-140 keV were measured for the whole liver and different liver lobes. Standardized iodine concentrations were calculated for each energy spectrum parameter. The correlation between energy-spectrum CT multiparameter volumetric quantification and rebleeding in cirrhotic EVB patients undergoing EVL within 1 year was analyzed.

**RESULTS**

There were statistically significant differences between IC, WC, whole liver Zeff, whole liver Zeff in portal phase, whole liver Zeff in arterial phase, and aortic IC, and the AUC values of the area under the curve of the working characteristics (ROC) of the subjects were 0.835, 0.804, 0.735, 0.788, and 0.761. Construction of a rebleed occurring within 1 year after endoscopic treatment of gastroesophageal varices in cirrhotic liver Nomogram column-line graph prediction model with an AUC of 0.866 [95% CI (0.740,0.992)].

**CONCLUSION**

The risk of postoperative rebleeding in patients with cirrhotic EVB can be effectively predicted based on the energy spectrum parameters before endoscopic treatment, which is important for guiding clinical treatment.

**CLINICAL RELEVANCE/APPLICATION**

Spectral CT has good predictive properties and can be used as a risk assessment tool for clinical rebleeding of ruptured esophagogastric fundal varices.

### PURPOSE

Recently a novel scoring system nac-VIRADS (Neoadjuvant Chemotherapy VI-RADS) was proposed to assess radiological response based on MRI after chemotherapy in patients with MIBC (muscle-invasive bladder cancer).The aim of this study is to determine the diagnostic accuracy of nac-VIRADS in predicting response to systematic therapy in patients with MIBC, validating this innovative score and evaluating inter-reader agreement.

### METHODS AND MATERIALS

This prospective study included patients with non-metastatic MIBC who underwent trans-urethral resection of bladder tumor (TURBT) and/or repeated TUR, followed by neoadjuvant chemotherapy (NAC), radical cystectomy (RC), and extended pelvic lymph node dissection. Patients underwent pre- and post-treatment multiparametric MRI. Radiological response was evaluated by two experienced urogenital radiologists using nac-VIRADS scoring system. The reference standard was based on histopathologic reports and tumor regression grades from RC. Nac-VIRADS performance was assessed by means of ROC analysis, according to both readers' assessments, deriving sensitivity, specificity, PPV, NPV, and accuracy. Interreader agreement was determined with Cohen's k statistics. Univariable and multivariable analyses were implemented.

### RESULTS

55 patients were included. n=13 were classified as nac-VIRADS 1-2, n=14 as nac-VIRADS 3, n=22 as nac-VIRADS 4, and n=6 as nac-VIRADS 5. Overall, there was agreement between nac-VIRADS scoring and radical cystectomy pathology report and tumor regression grade, except for two cases scored as nac-VIRADS 3 with ypT3aN1 and TRG-3 pathology findings. Diagnostic performance showed a range of 90%-94% sensitivity, 86%-90% specificity, 87%-92% positive predictive value (PPV), and 89%-92% negative predictive value (NPV). AUC was 0.84 (95% CI: 0.80-0.88) for the more experienced reader. Inter-reader agreement was almost perfect (K = 0.88). Hematuria correlated with disease progression.

### CONCLUSION

Nac-VIRADS scoring system offers a reliable and reproducible approach, employing a clear algorithm, to assess the response to systemic therapy in patients with MIBC. Its implementation has the potential to significantly influence therapeutic decision-making and enhance overall patient survival.

### CLINICAL RELEVANCE/APPLICATION

The radiological restaging of patients with MIBC undergoing neoadjuvant therapy offers the opportunity to radically change patient management, improving and refining therapeutic decisions, increasing the percentage of patients who can benefit from non-radical treatments, avoiding radical cystectomy, and enhancing patient quality of life.

## M5B-SPGU-2 DEVELOPMENT AND VALIDATION OF AN INTEGRATIVE DEEP LEARNING MODEL FOR PREDICTING HRR GENE MUTATION AND RESPONSE TO TARGETED THERAPY IN METASTATIC CASTRATION-RESISTANT PROSTATE CANCER: A MULTICENTER STUDY

Xiang Liu (*Presenter*) Nothing to Disclose

### PURPOSE

To develop and validate an integrative deep learning model for predicting homologous recombination repair (HRR) gene mutations and the response to targeted poly (ADP-ribose) polymerase inhibitor (PARPi) treatment in patients with metastatic castration-resistant prostate cancer (mCRPC).

### METHODS AND MATERIALS

In this multicenter study, 210 patients with mCRPC were included between September 2018 and November 2023. Among them, 118 patients from Center 1 were assigned into the training cohort and 92 patients into the validation cohort. All patients underwent HRR gene sequencing, multiparametric prostate MRI and biopsy histology. An integrative model was constructed using a deep learning model (ResNet-50) based on multiparametric MRI features and

histologic features to predict HRR gene mutation. The predictive performance was assessed using the ROC curve analysis. Additionally, 78 mCRPC patients from Center 2 who have received PARPi targeted therapy were included to assess the performance of the established integrative model in predicting the response to the targeted therapy. Radiographic progression-free survival (rPFS) was used as the endpoint and Kaplan-Meier analysis was used for further assessment of predictive efficacy for PARPi treatment.

**RESULTS**

An integrative model consisted of multiparametric MRI and histologic features was established for predicting HRR gene mutation. This integrative model achieved an AUC of 0.84 and 0.79, sensitivity of 0.86 and 0.82, and specificity of 0.80 and 0.75 in the training and validation cohorts, respectively. Kaplan-Meier analysis showed that the integrative model was associated with the rPFS in response to PARPi treatment (log-rank $P < 0.05$).

**CONCLUSION**

The integrative model based on prostate MRI and histologic features can be helpful for predicting HRR gene mutation and PARPi therapy response in patients with mCRPC.

**CLINICAL RELEVANCE/APPLICATION**

A multimodal integration model consisted of multiparametric MRI and biopsy histology can assist in predicting HRR gene status and the therapy response when HRR sequencing is not available due to the lack of facility or limited tissue sample.

## M5B-SPGU-3 DIAGNOSTIC PERFORMANCE OF THE CLEAR CELL LIKELIHOOD SCORE INTEGRATED WITH CYSTIC DEGENERATION AND NECROSIS FOR IDENTIFYING CLEAR CELL RENAL CELL CARCINOMA IN CT1 SOLID RENAL MASSES ON IMAGING

Yuwei Hao (*Abstract Co-Author*) Nothing to Disclose
Mengqiu Cui (*Abstract Co-Author*) Nothing to Disclose

Huiping Guo (*Abstract Co-Author*) Nothing to Disclose
Bai Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Xueyi Ning (*Abstract Co-Author*) Nothing to Disclose
Honghao Xu (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic value of clear cell likelihood score(ccLS) integrated with cystic degeneration and necrosis in clear cell carcinoma (ccRCC) in cT1 solid renal masses(SRMs).

**METHODS AND MATERIALS**

This retrospective study consecutively included 299 patients (203 males, 96 females; mean age, 54±13years) who underwent MRI from our hospital between January 2022 and November 2023, showing a total of 305 renal masses with pathologically confirmed cT1 SRMs. Five abdominal radiologists were trained in the ccLS algorithm and the assessment of cystic degeneration and necrosis, two radiologists scored independently all cT1 SRMs using ccLS v2.0 and ccLS integrated with cystic degeneration and necrosis (cn-ccLS, if the lesion has cystic degeneration or necrosis, the score is increased by one on the basis of ccLS, and the original ccLS 5 score remains unchanged) respectively, with disagreements resolved through consultation. Random-effects logistic regression modeling was used to evaluate the diagnostic performance of ccLS v2.0 and cn-ccLS for ccRCC, and the area under curve (AUC) of ccLS and cn-ccls were compared using the DeLong's test. Three other radiologists scored independently 100 cT1 SRMs from January 2022 to December 2022. The interobserver agreement of the ccLS score was evaluated using the Weighted Kappa test, and differences in the weighted Kappa coefficients was compared using the Gwet consistency coefficient.

**RESULTS**

The sample included 229 ccRCCs, 76 other renal masses. The mean size of all lesions was 3.4±1.2cm. In cT1 SRMs, the pooled sensitivity, specificity, accuracy of ccLS v2.0 for diagnosing ccRCC were 74%, 88%, 53%, as compared with 94%, 82%, 91% with cn-ccLS, respectively. The AUC of cn-ccLS was significantly higher than that of ccLS v2.0 for diagnosis of ccRCC (0.88 vs 0.81; $P<0.001$). In cT1a SRMs, the pooled sensitivity, specificity, accuracy of ccLS v2.0 for diagnosing ccRCC were 73%, 86%, 53%, as compared with 90%, 78%, 87% with cn-ccLS, respectively. The AUC did not differ significantly between cn-ccLS and ccLS v2.0 (0.84 vs 0.80; $P>0.05$). In cT1b SRMs, the pooled sensitivity, specificity, accuracy of ccLS v2.0 for diagnosing ccRCC were 75%, 94%, 80%, as compared with 98%, 94%, 98% with cn-ccLS, respectively. The AUC of cn-ccLS was significantly higher than that of ccLS v2.0 for diagnosis of ccRCC (0.96 vs 0.85; $P<0.001$). Interobserver agreement of cn-ccLS was significantly higher than that of ccLS v2.0 (0.74 vs 0.66; $P<0.001$).

**CONCLUSION**

Incorporating cystic degeneration and necrosis significantly enhances the diagnostic performance of the ccLS v2.0 system for ccRCC in cT1 SRMs, particularly in cT1b SRMs.

**CLINICAL RELEVANCE/APPLICATION**

Assist radiologusts in daily diagnosis work.

## M5B-SPGU-5 DEEP LEARNING FOR DISTINGUISHING PROSTATE CANCER AND BENIGN DISEASE OF PATIENTS WITH GRAY-ZONE PROSTATE-SPECIFIC ANTIGEN LEVELS AND PI-RADS 3 LESIONS

Li Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

When the PSA level of PI-RADS 3 patients is also in the" gray area" of 4-10 ng/ml, it will be more difficult to differentiate the nature of the disease before operation. In this study, we analyzed the imaging features of patients with PI-RADS and PSA in the"double gray area" and their efficacy in differentiating benign from malignant disease using deep learning(DL) approaches with conventional neural networks.

**METHODS AND MATERIALS**

In all, 274 patients (184 non-PCa and 90 PCa) with the PSA level in the" gray area" (4-10 ng/ml) of PI-RADS 3 scores patients that underwent mpMRI were included in this retrospective study. Among the 274 patients, 280 lesions (>50 mm3) were extracted (184 non-PCa and 96 PCa). MpMRI exams were prospectively reported using PI-RADS V2.1 by two experienced radiologists. The proposed DL framework is illustrated in Figure 1. We developed a

framework using DenseNet 121 as the backbone. The 280 lesions were randomly divided with a 8:2 ratio into training and test sets. Data on the clinical risk factors related to PCa with PI-RADS and PSA in the"double gray area" were collected for all patients (table 1). Lesion volumes of interest (VOI) from T2-weighted imaging (T2WI) and apparent diffusion coefficient (ADC) imaging were annotated by two radiologists. We used AUCs with 95% CIs to assess the performance on the test set and clinical model for the diagnosis of PCa with PI-RADS and PSA in the"double gray area". The difference in AUCs between the models were tested for statistical significance using DeLong's test.

**RESULTS**

The univariate logistic regression analysis suggested that among clinical factors, patient age, prostate volume, tPSA, PSAD were significant factors for predicting PCa in patients with the"double gray area"(table 1). The multiple logistic analysis showed that the PSAD and prostate volume were important factors that could be used as independent predictors. The outcomes of the univariate and multiple logistic regression analyses are presented in table 2. The AUC, sensitivity, and specificity of the clinical model were 0.688(0.604-0.773), 0.642 (0.524-0.716), and 0.746 (0.655-0.841), respectively. The DL model based on case level yielded an AUC, sensitivity, and specificity of 0.872(0.818-0.926), 0.85 (0.74-0.95) and 0.87 (0.76-0.94) for identification of PCa with PI-RADS and PSA in the"double gray area" in the test data set, significantly improving performance over the clinical model (figure 2).

**CONCLUSION**

DL, is an effective and non-invasive method for predicting PCa with PI-RADS and PSA in the"double gray area". Thus can provide clinicians a more accurate quantitative tool than the PI-RADS for clinical decision making.

**CLINICAL RELEVANCE/APPLICATION**

deep learning predicting PCa with PI-RADS and PSA in the"double gray area"

## M5B-SPGU-7 DEEP LEARNING AND RADIOMICS-BASED DETECTION OF FOCAL ABNORMALITIES IN ADRENAL GLANDS

Xiaodong Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Yaofeng Zhang (*Abstract Co-Author*) Nothing to Disclose
Yuanchong Chen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To set up a 3D V-Net-based segmentation model of adrenal lesions, a 3D ResNet-based classification model, radiomics-based models as well as the volumetric reference interval (VRI) for detecting abnormalities in adrenal glands.

**METHODS AND MATERIALS**

Different detecting methods included are 3D ResNet-based classification model, 3D V-Net-based lesion segmentation model, radiomics-based classification model (standard radiomics and deep learning-based radiomics), and the reference interval of adrenal volume. A total of 1086 CT image series with focal adrenal lesions were retrospectively collected, annotated, and used for the training of the adrenal lesion segmentation model. Another group of 3861 image series with bilateral normal adrenal glands along with the aforementioned dataset were used for the training of the 3D ResNet-based classification model and radiomics-based models. The VRIs are set as [1288.18, 4166.55] mm3 and [1457.80, 4941.88] mm3 for right and left adrenal gland. With the use of different thresholds of the largest diameter of the adrenal lesion, the other cohort consisting of 699 patients with pathologically confirmed adrenal lesions (external validation dataset 1) was included for validation of the detection performance of various methods in pre-surgical cases. Another consecutive cohort of patients with a history of malignancy (N = 479) was used for validation in the screening population (external validation dataset 2). The diagnosis of adrenal abnormalities from radiology reports of the external validation cases were compared with these detection methods.

**RESULTS**

At the threshold of 10 mm, the 3D ResNet-based model, the 3D V-Net-based lesion segmentation model, the standard radiomics-based model, the deep learning-based-radiomics-based model, and the VRI showed varied sensitivities (91.3%, 99.0%, 86.0%, 74.3%, and 78.1%) and accuracies (92.3%, 98.4%, 87.5%, 80.1%, and 84.7%) in external validation dataset 1. Different sensitivities (58.3%, 69.4%, 65.7%, 41.7%, and 40.7%) and accuracies (86.8%, 92.8%, 82.9%, 82.6%, and 88.8%) were showed in external validation dataset 2. The lesion segmentation model had the best performance among all other methods ($P < 0.05$), without significant difference compared to radiology reports ($P = 0.090$ and $P = 0.505$ for external validation datasets 1 and 2) while others do ($P < 0.05$).

**CONCLUSION**

The 3D V-Net-based segmentation model of adrenal lesions has the best performance in detecting abnormal adrenal glands in both pre-surgical and screening cases.

**CLINICAL RELEVANCE/APPLICATION**

A 3D V-Net-based segmentation model of adrenal lesions can be used for the detection of abnormalities of adrenal glands, with higher performance compared to other models, in various clinical scenarios.

## M5B-SPGU-9 DEVELOPMENT OF LEXICON TERMS FOR STRATIFICATION OF PI-RADSV2 3+1 LESIONS: MULTI-READER EXPERIENCE AND COMPLEMENTARY UTILITY OF AI

## PURPOSE

Focally DCE enhancing peripheral zone PI-RADS 3 lesions are upgraded to PI-RADS 4 (PI-RADS 3+1) based on PI-RADS v2.1 and remain challenging even for experienced readers. Thus, better mpMRI based stratification is needed for the decision biopsy or follow-up. We aimed to risk-stratify PI-RADS 3+1 lesions by definition of a new expert-based lexicon of terms, to investigate the usability of the lexicon by application by 2 additional experienced prostate readers, and to evaluate the contribution of deep learning models.

## METHODS AND MATERIALS

86 MR lesions clinically assessed as PI-RADS 3+1 in 75 patients and 83 examinations were retrospectively evaluated in consensus by two expert uroradiologists by application of a newly created feature catalogue. The same lesions were then re-evaluated by two additional experienced prostate radiologists with inter-reader agreement assessed using ICCs. The catalogue included sequence-specific (T2w, DWI and DCE) and inter-sequence correlative items, in total 14 categories, and 59 individual lexicon phrases/terms within the categories. Value of lexicon items for sPC prediction was assessed utilizing the expert read and extended TRUS/MRI biopsy histopathological correlation, utilizing L1-penalized logistic regression models. Bi- and multiparametric deep learning models for automated lesion segmentation were evaluated in conjunction with feature items in combined models.

## RESULTS

Expert consensus read established an upper threshold for sensitivity and specificity in lesional assessment. Independent application of the lexicon terms by the readers confirmed utility of the terms for single-readers. In univariate analysis the feature "T2w configuration: irregular/microlobulated/spiculated" showed statistical significance (OR 9.2; adj. p-value: 0.016) and strongest sPC correlation. Solely feature-based models did not benefit from integrating DCE features. In contrast, multiparametric AI models (AI-driven or AI-enhanced) did benefit from DCE consideration.

## CONCLUSION

A new feature lexicon demonstrated utility for risk-stratification of clinical PI-RADS 3+1 lesions. DCE imaging seems more beneficial for AI compared to readers.

## CLINICAL RELEVANCE/APPLICATION

Lexicon of terms with and without AI demonstrated potential to risk-stratify PI-RADS 3+1 lesions.

Printed on: 05/28/25

## M5B-SPHN-3 THE CASCADE ARTIFICIAL INTELLIGENT FRAMEWORK OF SEGMENTATION-DISCRIMINATION APPROACH FOR AUTOMATIC ALL-IN-ONE DIAGNOSIS OF OSSICULAR CHAIN DEFORMITY AT CT

Xinyi Meng (*Abstract Co-Author*) Nothing to Disclose
Liangliang Shang (*Abstract Co-Author*) Nothing to Disclose
GAO YANJUN (*Abstract Co-Author*) Nothing to Disclose
Liuxu Jin (*Abstract Co-Author*) Nothing to Disclose
Yishan Li (*Abstract Co-Author*) Nothing to Disclose
Xiaoyue Zhang (*Abstract Co-Author*) Nothing to Disclose
Rui Wang (*Presenter*) Nothing to Disclose

### PURPOSE

Diagnosing ossicular chain deformity (OCD) in radiology not only consumes time and effort but also carries a risk of misdiagnosis. Advanced artificial intelligence (AI)-assisted diagnostic technology has the potential to enhance the performance of radiologists in diagnosing OCD. This study aimed to develop and validate a cascading AI framework that employs a segmentation-discrimination strategy for the automatic detection of various OCD in CT scans.

### METHODS AND MATERIALS

In this retrospective analysis, our method utilized the nnU-Net framework for the automatic segmentation of auditory ossicles, alongside machine learning (ML) models to detect abnormalities in patients' auditory ossicles. We assessed and compared the efficacy of our selected ML approach in identifying OCD patients against deep learning networks (such as Res-Net and Dense-Net) and the volume-threshold algorithm, using area under the curve, sensitivity, specificity, and accuracy to evaluate the models' discriminative performance at the ossicular level. Additionally, to gauge the overall effectiveness at the patient level, we calculated and compared sensitivity, specificity, and accuracy across various models.

### RESULTS

A total of 1858 temporal bone CT images were divided into the training set (n = 1302) and the test set (n = 556); The final diagnosis (OCD-positive or OCD-negative) was determined by an experienced senior radiologist. In terms of ML, the logistic regression (LR) model outperformed others in the discrimination of abnormal malleus (accuracy was 0.903), while the random forest (RF) model excelled in distinguishing between abnormal incus (accuracy was 0.853) and stapes (accuracy was 0.863). Consequently, our segmentation-discrimination approach involved the LR model being selected for distinguishing abnormal malleus and the RF model for discerning abnormal incus and stapes as the optimal models for auditory ossicles discrimination. At the patient level, our method achieved a diagnostic accuracy of 0.874, while Res-Net, Dense-Net, and volume-threshold achieved accuracies of 0.849,0.827, and 0.766, respectively.

### CONCLUSION

The method of the cascaded AI framework based on segmentation-discrimination strategy demonstrates high performance in identifying patients with various types of OCD in CT scans.

### CLINICAL RELEVANCE/APPLICATION

Firstly, our research offers radiologists guidance for diagnosing OCD, aiding early treatment and improving patient well-being. Furthermore, our method reduces diagnostic errors, enhances proficiency, and fills gaps in AI diagnosis of small organs like the temporal bone. Finally, we're also developing an AI-assisted platform for automated diagnosis of temporal bone diseases.

## M5B-SPHN-4 DEEP LEARNING RECONSTRUCTION OF DIFFUSION-WEIGHTED MRI ENABLES SHORTER EXAMINATION TIMES WHILE MAINTAINING IMAGE QUALITY IN HEAD AND NECK IMAGING

Jan M. Brendel (*Abstract Co-Author*) Nothing to Disclose
Haidara Al Mansour, MD, MEng (*Presenter*) Nothing to Disclose

**PURPOSE**

Diffusion weighted imaging of the head and neck region is instrumental for a wide range of clinical applications; however, it could be challenging due to high degree of artifacts and reduced image quality. Deep learning reconstruction may enhance image quality of head and neck DWI. The purpose of this study is to investigate the performance of an accelerated and deep learning reconstructed diffusion- weighted imaging (DWIDL) of the head and neck in terms of image quality and diagnostic confidence.

**METHODS AND MATERIALS**

This is a retrospective study of patients who underwent clinically indicated head and neck diffusion-weighted imaging of the head and neck at 1.5T and 3T from August 2023 to January 2024 at a tertiary care center. Imaging was performed at a low b-value (0 or 50 sec/mm2) and a high b-value (800 sec/mm2) and apparent diffusion coefficient (ADC) maps were computed. After acquiring the standard single shot EPI DWI sequences, the identical raw MR dataset underwent retrospective undersampling. This process entailed reconstructing a reduced number of signal averages using a novel DL based reconstruction algorithm (DWIDL) resulting in accelerated datasets.

**RESULTS**

A total of 30 patients (mean age, 55 ± 19 years; range, 24- 84; 18 men) with various pathologies were included. Scan time was reduced by 68% at 1.5 Tesla and up to 55% at 3 Tesla. All readers observed no discernible difference between DWI and DWIDL concerning image quality parameters or diagnostic confidence in both low and high b-value images, as well as the ADC (all $P > 0.05$).

**CONCLUSION**

Deep learning reconstruction of diffusion-weighted MRI of the head and neck imaging is feasible, enabling a significant reduction in examination time without compromising image quality or diagnostic confidence. This technique paves the way for an accelerated and diagnostic DWI of the head and neck.

**CLINICAL RELEVANCE/APPLICATION**

This technique paves the way for an accelerated and diagnostic DWI of the head and neck.

## M5B-SPHN-5 GROUND TRUTH ADEQUACY IN RADIOMICS AND ARTIFICIAL INTELLIGENCE STUDIES OF LYMPH NODE CLASSIFICATION IN HEAD AND NECK CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

Saba Ghazimoghadam (*Abstract Co-Author*) Nothing to Disclose
Antika Roy, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Radiomics and artificial intelligence (AI) studies report promising results for lymph node classification in head and neck cancer. However, the reliability and generalizability of these studies is contingent on the quality of the ground truth (GT) data utilized to train these algorithms and robustness of the methodology used to ensure proper radiological-pathologic correlation. In this study, we performed a comprehensive evaluation of existing studies focusing on GT, evaluating the methodology, adequacy, and potential gaps.

**METHODS AND MATERIALS**

We conducted a systematic search on Embase and PubMed using PRISMA standard from 2013 to 2023. The search included papers using different machine learning/AI and radiomic-based algorithms to classify LN metastases in head and neck cancer on CT or MRI imaging. The study excluded studies that performed only lymph node segmentation, studies using ultrasound, or studies that analyzed the PET (metabolic) part only without radiomic or AI(ML/DL) model analysis on CT or MRI. We extracted ground truth related information into different columns focusing on information on nodal levels evaluated, number of experts involved, primary tumor site, node size, classification type, GT used (biopsy, surgical specimens, or other), methodology for image path correlation, and model analysis.

**RESULTS**

Between 2013 and 2023, a total of 1337 records were identified from PubMed and Embase. After application of our inclusion/exclusion criteria, 60 studies were included for analysis. We categorized 6 types of ground truth from these studies. 79% of the selected studies classified the lymph nodes as malignant vs benign. Most studies used some histopathological results as a standard for GT masks for LN classification. However, our meta-analysis identified only 13 papers out of 60 that provided any details on radiological-pathological correlation of individual lymph nodes. The expertise of the evaluators varied, and 14 papers did not mention the experience level of the experts. None of the studies specifically discussed how radiologically normal but pathologically abnormal nodes with early metastasis were correlated.

**CONCLUSION**

Many studies either lack or provide insufficient information on ground truth determination and radiologic-pathologic correlation. Given that that GT information is central to the validity of the algorithms, we recommend that more emphasis be placed on the adequacy of GT and methodology for radiologic-pathologic correlation in future studies and guidelines for algorithm development.

**CLINICAL RELEVANCE/APPLICATION**

This study reveals a significant gap that can prevent generalizability and successful future translation of AI algorithms used for evaluation of cervical lymph nodes in clinical practice.

### PURPOSE

Assessment of imaging-based pancreatic phenotypes such as volume and fatty infiltration may help to improve personalized prevention and prognostication in patients with metabolic disease. With advances in artificial intelligence, fully automated approaches to quantify pancreatic phenotypes from cross-sectional imaging studies have become feasible; however, reference values from the general population are still missing. In this study, we used an automated deep learning pipeline to estimate pancreatic volume and fat from magnetic resonance imaging (MRI) to calculate reference curves similar to growth charts known from pediatric care.

### METHODS AND MATERIALS

We used pooled MRI data from two large observational cohort studies: the UK Biobank (UKBB) and the German National Cohort (NAKO). The only input to the deep learning pipeline was a T1w dual-echo Dixon MRI scan; the output was 1) pancreas volume (ml) and 2) the pancreatic fat fraction (PFF; %). Based on these outputs, sex-stratified changes in pancreas volume and PFF were calculated across age groups. In addition, normative reference curves adjusted for age, sex, and height were generated for both measures.

### RESULTS

The final cohort comprised 66,666 individuals from the general population (mean age: 57.7±12.9 years; mean BMI: 26.2±4.5 kg/m2; 48.3 % female). Mean pancreatic volume and PFF was 73.9±23.6 ml and 19.2±9.1 % in males and 54.6±19.9 ml and 14.1±7.9 % in females, respectively. Pancreas volume showed a slight increase until the 6th age decade followed by a slow decline in both sexes. In contrast, PFF steadily increased for both sexes throughout the lifespan. For both measures, the variability was higher in males vs. females.

### CONCLUSION

This study provides MRI-derived age, sex and height adjusted normative curves for pancreas volume and PFF from a large general population. These curves may provide the basis to establish reference values and track typical and atypical changes of pancreatic phenotypes throughout the lifespan with the potential to identify individuals at risk similar to growth charts in pediatric care. As automated assessment of imaging-derived pancreatic phenotypes are increasingly accessible, this could be used for opportunistic risk estimation from routine MRI to improve personalized prevention and lifestyle interventions.

### CLINICAL RELEVANCE/APPLICATION

Fully automated imaging-based assessment of pancreatic phenotypes during routine MR imaging may provide clinicians with a tool to opportunistically identify high-risk individuals beyond currently established approaches with the potential to improve personalized prevention and decision-making without additional testing.

## M5B-SPIN-2 END-TO-END AI SEGMENTATION OF KIDNEY AND LESIONS: A DUAL-MODEL APPROACH FOR ENHANCED CT IMAGING

Nalan Karunanayake, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The main objective of this study is to develop a deep learning model for precise 3D segmentation of kidneys and renal lesions from CT scans.

### METHODS AND MATERIALS

The developed model provides an end-to-end segmentation solution across two phases. Initially, a transformer-based approach delineates kidney organs and lesions, enhancing spatial awareness. Subsequently, a deep convolutional neural network with cross-layer connections performs advanced feature abstraction, optimizing the network by improving feature propagation and depth effectiveness. This study employed two renal CT datasets in the nephrogenic phase: a public dataset with 489 scans (mean age 59.33 ± 14.39, 306 males, 182 females, 1 transgender) and a proprietary dataset with 617 scans (mean age 56.71 ± 11.18, 428 males, 189 females). Training was conducted on 389 scans from the public dataset, with internal validation on 100 scans and external validation on all 617 scans from the private dataset. Lesion sizes were categorized as small (=4 cm), medium (>4 cm to =7 cm), and large (>7 cm) for detailed performance evaluation.

### RESULTS

The initial segmentation of kidney organ achieved a compelling Dice score of 0.966 ± 0.067 and Predictive Volume Error (PVE) of 0.027 ± 0.062. In detailed lesion analysis, Dice scores for small, medium, and large lesions on the internal validation dataset were 0.896 ± 0.162, 0.897 ± 0.062, and 0.928 ± 0.156, respectively, with corresponding PVEs of 0.059 ± 0.144, 0.054 ± 0.063, and 0.045 ± 0.132. External validation further confirmed the model's effectiveness, achieving Dice scores of 0.768 ± 0.0247, 0.885 ± 0.112, and 0.917 ± 0.071 for small, medium, and large lesions, respectively, with respective PVEs of 0.172 ± 0.235, 0.071 ± 0.099, and 0.051 ± 0.067.

### CONCLUSION

The dual-phase AI model accurately segments renal lesions of varying sizes and demonstrates robust performance on unseen CT data, matching human expert precision. Its integration into clinical workflows could enhance diagnostic accuracy, especially for small or indistinct lesions, positioning it as a valuable tool in radiology.

### CLINICAL RELEVANCE/APPLICATION

The AI model's precise segmentation of kidney lesions boosts diagnostic accuracy. Its robust performance on new data indicates readiness for clinical use, potentially accelerating diagnosis and guiding clinical decisions. This marks a significant step forward in renal tumor imaging.

## M5B-SPIN-3 PANCREAS VOLUME PREDICTS MAJOR ADVERSE CARDIOVASCULAR EVENTS AND MORTALITY IN THE GENERAL POPULATION: INSIGHTS FROM THE UK BIOBANK

Jakob Weiss, MD (*Abstract Co-Author*) Nothing to Disclose
Maximilian Russe, MD (*Abstract Co-Author*) Nothing to Disclose
Fabian Bamberg, MD, MPH (*Abstract Co-Author*) Speakers Bureau, Bayer AG;Speakers Bureau, Bracco Imaging;Speakers Bureau, Siemens AG;Research Grant, Siemens AG

Marco Reisert (*Abstract Co-Author*) Nothing to Disclose
Matthias Jung, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The pancreas plays a crucial role in the pathogenesis of cardiometabolic diseases. Pancreas volume may serve as a measure to estimate pancreas function and to identify individuals at increased risk of cardiometabolic disease and mortality. Here, we used a deep learning model to automatically quantify pancreatic volume from MRI and investigated the association with major adverse cardiovascular events (MACE) and mortality in the general population.

### METHODS AND MATERIALS

This study used a large population cohort from the UK Biobank (UKBB). The only input to the deep learning model was a T1-weighted dual-echo Dixon MRI; the output was an estimate of pancreas volume in ml. The primary outcome was MACE, the secondary outcome all-cause mortality. Cumulative incidence and Kaplan-Meier survival curves were calculated (volume categories <10%; 10-90%; >90%) to investigate time to MACE and mortality, respectively. The association between pancreas volume and MACE/mortality was assessed via multivariable Cox regression analyses.

### RESULTS

Among 36,317 UKBB participants (mean age 65.1±7.8 years, 51.7% female), 2.7% [969/36,317] MACE and 1.7% [633/36,317] deaths of all cause occurred over a median follow-up of 4.8 years. Cumulative incidence and Kaplan Meier survival curves showed a higher rate of MACE and mortality for individuals with the lowest (<10%) pancreas volume. Cox regression revealed an association between pancreas volume and MACE (HR (per SD), 0.92 [95% CI, 0.85-0.99]; p=0.02) as well as mortality (HR, 0.80 [95% CI, 0.74-0.87]; p<0.001). This association remained significant after adjustment for demographics (age, sex, BMI, race) and cardiometabolic risk factors (hypertension, smoking, diabetes, lipid panel, history of cancer) (MACE; HR (per SD), 0.88 [95% CI, 0.81-0.96]; p=0.005 and mortality; HR (per SD), 0.81 [95% CI, 0.73-0.89]; p<0.001).

### CONCLUSION

MRI-derived pancreas volume is an independent predictor for MACE and all-cause mortality in the general population beyond traditional clinical risk factors.

### CLINICAL RELEVANCE/APPLICATION

Opportunistic quantification of pancreas volume from medical imaging studies may help to identify individuals at increased risk of MACE and all-cause mortality with the potential to improve personalized prevention and prognostication.

## M5B-SPIN-4 PANCREAS SUB-REGION SEGMENTATION ON CT

Abhinav Suri, BA, MPH (*Abstract Co-Author*) Nothing to Disclose

### PURPOSE

CT imaging contains useful biomarkers for detecting pancreatic pathologies. However, current approaches provide whole-organ biomarkers rather than region-specific biomarkers, which are critical to predicting disease severity such as pancreatic adenocarcinomas. The purpose of this study is to develop a

deep learning-based 3D tool to segment pancreatic sub-regions (the head, body, and tail) on CT volumes.

**METHODS AND MATERIALS**

This retrospective study used the large publicly available TotalSegmentator dataset, which contains 1228 unique CT volumes. 595 volumes were excluded because part or all of the pancreas was not included, resulting in a total number of 633 CT volumes in the final dataset. We randomly split the dataset into training (n=507) and testing (n=126) subsets. To minimize annotation burden, two graders labeled three pancreatic landmarks (i.e., the centroid of the head, body, and tail) for all 633 volumes and also created full annotations for the head, body and tail for 50 out of 126 volumes in the testing set. These sub-regional annotations were evenly verified by two radiologists (an attending w/30 yrs experience and a resident) and used for evaluation.A modified nnUNet-based model was trained to predict the head, body, and tail centroid landmarks. Given the full pancreas segmentation (which is easily obtained from prior algorithms with high accuracy), the predicted centroid landmarks assign each voxel in the pancreas mask to a subregion label based on which centroid it was closest to. The segmentation results were evaluated against the ground truth masks using the Dice similarity coefficient (DSC) and Normalized Surface Distance (NSD).

**RESULTS**

The mean +/- std dev of DSC (%) and NSD (%) for the head, body, and tail were 90.6+/-4.5 and 94.2+/-4.7, 83.1+/-6.9 and 86.9+/-6.0, and 85.6+/-8.3 and 90.2+/-7.4, respectively.

**CONCLUSION**

The proposed method accurately segmented three pancreatic sub-regions (head, body, and tail) in a large publicly available CT dataset.

**CLINICAL RELEVANCE/APPLICATION**

This tool can extract imaging biomarkers for each pancreatic sub-region and facilitate the assessment of regional pancreatic pathologies for clinical correlation with disease status, such as diabetes, pancreatitis, and pancreatic cancer.

## M5B-SPIN-5 FACTORS IMPACTING AI-BASED CORONARY ARTERY CALCIFICATION SCORING IN NON-GATED LOW-DOSE CHEST CT: A COMPARISON TO MANUAL SCORING IN ECG-GATED CARDIAC CT

Jong H. Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Eun-Ah Park, MD (*Abstract Co-Author*) Nothing to Disclose
Baren Jeong (*Abstract Co-Author*) Nothing to Disclose
Changmin Park (*Abstract Co-Author*) Nothing to Disclose
Sihwan Kim, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate influential factors on the agreement between manual coronary artery calcification scoring (CACS) in ECG-gated cardiac CT and AI-based automated CACS in non-gated low dose chest CT using multi-vendor dataset.

**METHODS AND MATERIALS**

The study retrospectively analyzed 1083 and 851 patients from the two different CACS CT protocols with multi-vendor CT dataset. Manual CACS in ECG-gated cardiac CT was set as the reference standard using commercial semi-automatic CACS program. AI-based automated CACS was performed in different CACS CT protocols using a dedicated AI software. A Pearson coefficient (r) and coefficient of determination (r2) were calculated for demonstrating a linear correlation and its explainability between manual CACS and fully automated AI-CACS. The detection performance of AI-CACS was evaluated by accuracy, sensitivity, and specificity. The reliability of AI-CACS for cardiovascular disease severity categorization was assessed using linearly weighted kappa (?) statistics. The agreement between manual CACS for ECG-gated cardiac CT and AI-CACS for two different CACS CT protocols were evaluated with intraclass correlation coefficient (ICC).

**RESULTS**

Pearson coefficient (?) was less than one for both ECG-gated cardiac CT and non-gated low dose chest CT. Coefficient of determination (R2) was at the estimated level of 0.98 and 0.92 for each CT protocol. While the AI-CACS in ECG-gated cardiac CT was almost perfect (at least 99.3%), the AI-CACS in non-gated low dose chest CT yield scores of 86.4-100%, 74.0-100%, and 76.7-100% for accuracy, sensitivity, and specificity, respectively. The ? for CVD risk categorization was 0.91-0.96 for ECG-gated and 0.68-0.9 for non-gated low dose chest CT. The ICC between manual CACS and AI-CACS for each CT protocol were 0.988 [95%CI 0.985-0.991] and 0.959 [95%CI 0.945-0.968], respectively. Among the CVD risk categories, minimal- to low-risk range (1=CAC<10) showed largest errors.

**CONCLUSION**

Image distortion by unwanted motion blurring and quantum noises from reduced radiation dose were the main factors for subtle CACS discrepancy. Nevertheless, AI-based CACS in low dose chest CT shows promising reliability in risk management of future cardiovascular event; One thing should be cautious is the underestimation of CAC score compared to that of ECG-gated cardiac CT.

**CLINICAL RELEVANCE/APPLICATION**

The CACS remains limited to manual or semi-automatic measurements in ECG-gated cardiac CT, which takes a large amount of human labor and time. What factors influence a clinical usage of the automated AI-CACS in non-gated low dose chest CT compared to the manual CACS in ECG-gated cardiac CT? In this paper, we aim to analyze the findings regarding this matter.

## M5B-SPIN-6 A DUAL-ENERGY CT-BASED NOMOGRAM FOR IDENTIFYING AXILLARY LYMPH NODE WITH MACROMETASTASES IN CLINICAL T1/2N0 INVASIVE BREAST CANCER

Suping Chen (*Abstract Co-Author*) Nothing to Disclose
Lin Lin, MBBS (*Abstract Co-Author*) Nothing to Disclose
Fang Zeng, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a prediction model based on spectral CT to evaluate axillary lymph node (ALN) with macrometastases in clinical T1/2N0 invasive breast cancer.

**METHODS AND MATERIALS**

A total of 217 clinical T1/2N0 invasive breast cancer patients who underwent spectral CT scans were retrospectively enrolled and categorized into a training cohort (n = 151) and validation cohort (n = 66). These patients were classified into ALN non- macrometastases (stage pN0 or pN0[i+] or pN1mi) and ALN macrometastases (stage pN1-3) subgroups. The morphologic criteria and quantitative spectral CT parameters of the most suspicious ALN were

measured and compared. Least absolute shrinkage and selection operator (Lasso) was used to screen predictive indicators to build a logistic model. The receiver operating characteristic (ROC) curve and decision curve analysis (DCA) were used to evaluate the models.

**RESULTS**

The combined arterial-venous phase spectral CT model yielded the best diagnostic performance in discrimination of ALN non-macrometastases and ALN macrometastases with the highest AUC (0.963 in the training cohort and 0.945 in validation cohorts). Among single phase spectral CT models, the venous phase spectral CT model showed the best performance (AUC = 0.960 in the training cohort and 0.940 in validation cohorts). There was no significant difference in AUCs among the three models (DeLong test, P > 0.05 for each comparison).

**CONCLUSION**

A Lasso-logistic model that combined morphologic features and quantitative spectral CT parameters based on single phase contrast enhanced spectral imaging potentially be used as a non-invasive tool for individual preoperative prediction of ALN status in clinical T1/2N0 invasive breast cancers.

**CLINICAL RELEVANCE/APPLICATION**

The prediction model has a favorable discriminating ability between patients with ALN non-macrometastases (stage pN0 or pN0[i+] or pN1mi) and patients with ALN macrometastases (stage pN1-3), showing potential for serving as a non-invasive imaging biomarker to predict ALN status and develop individualized treatment strategies.

## M5B-SPIN-7 DEEP LEARNING-BASED FULLY AUTOMATED DETECTION AND SEGMENTATION OF PELVIC LYMPH NODES ON DIFFUSION-WEIGHTED IMAGES FOR PROSTATE CANCER: A MULTICENTER STUDY

Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Kexin Wang (*Abstract Co-Author*) Nothing to Disclose
Wenpeng Huang (*Abstract Co-Author*) Nothing to Disclose
Zhaonan Sun (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate identification and evaluation of lymph nodes (LNs) in prostate cancer (PCa) patients is crucial for effective staging but can be time-consuming. We utilized a 3D V-Net model to improve the efficiency and accuracy of LN detection and segmentation.

**METHODS AND MATERIALS**

Utilizing pelvic diffusion-weighted imaging (DWI) scans, the 3D V-Net framework underwent training on a dataset comprising data from a hospital with 1,151 patients, encompassing 32,507 annotated LNs, following data augmentation procedures. Subsequently, external validation was conducted on data from 401 patients across three additional hospitals, encompassing 7,707 LNs. The segmentation performance was evaluated using the Dice similarity coefficient (DSC). The comparison between automated and manual segmentation regarding the short diameter and volume of LNs was conducted using Bland-Altman plots and correlation analysis. The performance for suspicious metastatic LN detection (short diameter > 8 mm) was evaluated using sensitivity, positive predictive value (PPV), and per-patient false-positive rate (FP/vol) at the LN level and sensitivity, specificity, and PPV at the patient level.

**RESULTS**

In the external validation test dataset, the model achieved a DSC of 0.77-0.82 for all, suspicious, and largest LNs. The model achieved a sensitivity, PPV, and FP/vol of 60.1% (95% confidence interval (CI), 57.6%-62.6%), 79.2% (95% CI, 76.6%-81.5%), and 0.56 at the LN level, respectively. At the patient level, the model achieved a sensitivity, specificity, and PPV of 81.1% (95% CI, 76.5%-85.0%), 75.6% (95% CI, 65.1%-83.8%), and 93.2% (95% CI, 89.7%-95.6%), respectively. The model achieved a strong correlation and good consistency between the short diameter and volume of the automatically segmented and manually annotated LNs.

**CONCLUSION**

This 3D V-Net model can segment LNs effectively based on pelvic DWI images for PCa and holds great potential for facilitating N-staging in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

This study showcases the clinical potential of a 3D V-Net model in accurately segmenting LNs in patients with PCa, offering promising prospects for enhancing N-staging in clinical settings.

## M5B-SPIN-8 THE ARTIFICIAL INTELLIGENCE MODEL AUTOMATICALLY QUANTIFIES MULTIPLE MYELOMA LESIONS ON WHOLE-BODY LOW-DOSE CT SCANS

Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Zhaonan Sun (*Abstract Co-Author*) Nothing to Disclose
Wenpeng Huang (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to assess the feasibility of utilizing deep learning technology for the automatic detection of osteolytic lesions in multiple myeloma (MM) on Whole Body Low Dose CT (WBLDCT) scans.

**METHODS AND MATERIALS**

WBLDCT images were retrospectively collected from inpatients at Peking University First Hospital between June 2020 and July 2023. Exclusion criteria encompassed postoperative bone quality, poor image quality, and the presence of other bone tumor lesions. The dataset comprised 106 image sets, including 34 MM patients with 9638 osteolytic lesions and 75 non-MM patients without osteolytic lesions. Data were divided into training (n=84), tuning (n=11), and testing (n=11) sets at an 8:1:1 ratio. Following preprocessing, a 3D V-Net deep learning network was employed for whole-body bone structure segmentation, followed by a 2D U-Net deep learning network for osteolytic lesion segmentation. Evaluation metrics included Dice similarity coefficient (DSC), Jaccard index (JACRD), volume similarity (VS), Hausdorff distance (HD), and average distance (AD), with lesions smaller than 5 mm filtered out at the lesion level.

**RESULTS**

In the testing set, 397 osteolytic lesions were manually annotated by physicians. The model detected 169 lesions accurately, missed 228 lesions, and identified 794 additional lesions, yielding a sensitivity of 42.5% and a positive predictive value of 17.5%. The overall segmentation results were DICE=0.31±0.13, JACRD=0.19±0.09, VS=0.74±0.13, HD=141.3±40.7mm, and AD=13.0±4.39mm. Bland-Altman analysis demonstrated high

consistency between the model-predicted and physician-annotated volumes, long diameters, mid diameters, and short diameters, with most data points falling within the 95% confidence interval.

## CONCLUSION

Deep learning technology holds promise for detecting osteolytic lesions in MM on WBLDCT scans, though further improvement in accuracy is warranted.

## CLINICAL RELEVANCE/APPLICATION

The model shows promise in facilitating the quantitative assessment of tumor burden in multiple myeloma.

Keivan Daneshvar Ghorbani, MD (*Abstract Co-Author*) Nothing to Disclose
Alois Komarek, MD (*Abstract Co-Author*) Nothing to Disclose
Wolfram Bosbach, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The future demand for interventional radiology services is predicted to grow substantially. Administration and documentation consume a substantial amount of working time already and can be expected to increase equally. This study tested the possibility of the large language model ChatGPT to perform those tasks.

### METHODS AND MATERIALS

The reporting template of the Radiological Society of North America (RSNA) for peripherally inserted central catheters (PICC) was iterated in three predefined cases. ChatGPT had to produce appropriate reports in text. ChatGPT output was assessed by radiologist by score card, as well as by a Python code calculating similarities between output texts.

### RESULTS

Overall, reception of the score card assessment was positive. Participating radiologists expect potential time savings for clinical operations from large language models.

### CONCLUSION

In the future, large language models might well find their way into clinical application. Our study has been able to highlight potential productivity improvements which would appeal to patients, doctors, and hospital administrators.

### CLINICAL RELEVANCE/APPLICATION

Time savings on documentation / administration are highly welcome. Large language models might provide those. Freed time could be spend on increased doctor-patient interaction.

## M5B-SPIR-3 AUTOMATIC AUGMENTED REALITY OVERLAY OF CT WITHOUT FIDUCIALS USING SKIN TRACKING WITH A SMARTPHONE

Bradford J. Sheng Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Nicole Varble (*Abstract Co-Author*) Nothing to Disclose
Tabea Borde, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Laetitia Saccenti, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Augmented reality (AR) can enhance standard visualizations by overlaying internal 3D images or objects onto external surfaces through goggles or smartphones. An overlay of CT imaging is possible on a body for percutaneous applications. One of the main limitations has been the necessity to include fiducials in the pre-procedural imaging, to assure correct registration of the AR objects to the real body. To overcome this limitation, we evaluated the use of a skin tracking tool, to recognize and track physical objects in the real environment and compared it to conventional registration using fiducial

### METHODS AND MATERIALS

An AR smartphone application was developed using Unity and Vuforia SDK platforms. For skin tracking registration, a CT scan of a torso phantom was acquired, and its surface model was generated. The AR app detected and tracked the skin of phantom according to its surface model. For conventional fiducial registration, an image reference box with embedded radio opaque fiducials was placed on the torso phantom and was included in the preoperative CT scan. The AR app then tracked the phantom by tracking this reference box. Accuracy of the overlay using skin tracking registration was assessed and compared to conventional registration by measuring the gap distance between 7 skin marks on the physical body and the AR model, on scaled pictures (ImageJ). Pictures were taken at different distances from the skin (10cm, 30cm) and different angles (0°, 45°, 90°)

### RESULTS

Using skin tracking registration, the median accuracy from 30 measurements was 1.75mm [IQR 0.73-3.18mm]. There was no difference of accuracy according to the distance of the smartphone (at 10cm: 2.30 [IQR 1.50-3.15mm], at 30cm: 1.10mm [IQR 0.30-5.65mm], p=0.18), neither according to the angle of the smartphone (0°: 2.45mm [IQR 1.40-3.80mm], 45°: 1.05mm [IQR 0.63-2.03mm], 90°: 5.05mm [IQR 2.83-7.28mm], p=0.1). Skin tracking registration matches conventional registration accuracy (3.2mm, [IQR1.3-4.6mm], p=0.07). Using conventional registration, there was no difference according to the distance or angle of the smartphone, but there was a difference according to skin mark location, with greater error the further away from fiducial marker. Surface tracking has the advantage over conventional registration of not losing accuracy with distance from fiducial to phantom

### CONCLUSION

Automatic registration using a skin tracking tool has an accuracy of 1.75mm on a torso phantom, which is as accurate as conventional registration with fiducial

### CLINICAL RELEVANCE/APPLICATION

Skin tracking on a smartphone can be used to recognize and track a body for augmented reality applications. This overlay technique is accurate while it is no longer necessary to perform pre-procedural imaging to include fiducial.

## M5B-SPIR-4 INTERPRETABLE MACHINE LEARNING FOR MANAGEMENT OF ABDOMINAL AND PELVIC INJURIES CAUSED BY BLUNT TRAUMA: A PROOF-OF-CONCEPT STUDY WITH THE TRAUMA QUALITY IMPROVEMENT PROGRAM REGISTRY

Arrix Ryce, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To demonstrate interpretable machine learning’s capacity to support comparisons of therapeutic strategies for blunt abdominal and pelvic traumas.

### METHODS AND MATERIALS

Patients 18 years and older with abdominal and pelvic injuries registered via the Trauma Quality Improvement Program (2007-19) were identified and grouped by management strategy initiated within 24 hours of presentation: non-operative management (NOM), embolization, or surgery. Given a management strategy and set of clinical characteristics, gradient boosting classifiers predicted in-hospital mortality. Each classifier’s performance was described via area under the receiving operating characteristic curve (AUC) and F1 score. Characteristics with the greatest contributions to predicted mortality were identified via mean absolute SHAP value. The top 5 contributors to predicted mortality were compared visually across management strategies via SHAP partial dependence plots.

### RESULTS

Classifiers of in-hospital mortality were associated with AUC's from 0.73 to 0.85 and F1 scores from 0.74 to 0.92. The 5 characteristics with the highest mean absolute SHAP values and, thus, greatest impact on predictions were GCS score, body temperature, blood oxygen saturation, respiratory rate (RR), and pulse. These did not vary across management strategies.Across all management strategies, GCS scores’ contributions to predicted mortality were lower among patients with scores = 7 than those with scores < 7. Blood oxygen saturation’s contributions decreased monotonically with increasing oxygen saturation. RR’s contributions decreased with RR < 20 breaths/min but increased with RR > 20 breaths/min.Body temperature’s contributions decreased with temperatures < 37 C and increased with those >37 C among NOM and surgery patients but decreased monotonically with increasing body temperature among embolization patients. Pulse’s contributions decreased with pulses < 80 beats/min and increased with pulses > 80 beats/min among NOM patients, decreased with pulses < 100 beats/min and increased with pulses > 100 beats/min among surgery patients. However, no clear trend between pulse and predicted mortality was visualized among embolization patients.

### CONCLUSION

In-hospital mortality can be predicted with fidelity from clinical characteristics available upon hospital arrival. Additionally, SHAP values can facilitate global, visual comparisons of risk.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrates a novel approach to interpretable machine learning in trauma care that can support real-time patient selection by interventional radiologists. Risk profiles with greater specificity and clinical utility may be ascertained in future work by evaluating SHAP interaction effects.

## M5B-SPIR-5 UNVEILING THE IMMUNOMODULATORY EFFECTS OF TRANSARTERIAL CHEMOEMBOLIZATION: INSIGHTS INTO LOCAL T CELL INFILTRATION IN HEPATOCELLULAR CARCINOMA

Bernhard Gebauer, MD (*Abstract Co-Author*) Speaker, PAREXEL International Corporation;Speaker, Becton, Dickinson and Company;Speaker, Sirtex Medical Ltd;Speaker, Abbott Laboratories;Speaker, Cook Group Incorporated;Speaker, AngioDynamics, Inc;Speaker, PharmCept;Speaker, ewimed GmbH;Speaker, Novartis AG;Speaker, F. Yubei he (*Abstract Co-Author*) Nothing to Disclose
Robin Schmidt (*Abstract Co-Author*) Nothing to Disclose

Emine Yaren Yilmaz Ince, MD (*Abstract Co-Author*) Nothing to Disclose
Luisa Heidemann (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate local immunomodulatory effects of conventional transarterial chemoembolization (cTACE) in patients with hepatocellular carcinoma (HCC).

**METHODS AND MATERIALS**

This interim analysis of a prospective study included 66 patients with unresectable HCC undergoing ablation alone using interstitial brachytherapy (iBT) or cTACE followed by iBT (10/20-08/23). IRB approval and informed consent were obtained. Biopsies were acquired prior to iBT under CT-guidance from treatment-naļve HCC (iBT group) or 24h after cTACE (cTACE/iBT group), respectively. Biopsies were stained for CD8+ T cells using immunohistochemistry. Following whole slide scanning, the entire sample on the digitalized slides was quantitatively assessed using QuPath software and a machine-learning based approach to distinguish tumor cells, hepatocytes, CD8+ T cells, and stroma. CD8+ T-cell infiltration was quantified in percentage of all counted cells and compared between untreated and post-cTACE HCC. Biopsies were then categorized as low (= median) or high (> median) immune response to evaluate associations with overall survival (OS) and tumor response assessed on MRI at 8 weeks according to mRECIST. Statistics included unpaired t-test, Kaplan-Meier, and Log Rank test.

**RESULTS**

This interim analysis included 31 untreated and 35 post-cTACE biopsies. CD8+ T-cell infiltration was similar in treatment-naļve (mean 3.532±2.734%) and post-cTACE (3.158±2.881%, p=0.592) biopsies. The median percentage of tumor-infiltrating CD8+ T-cells was 2.569%. Patients with high (>2.569%) immune response following cTACE exhibited better OS than those classified low T-cell infiltration (p=0.813), although median OS was not reached. Untreated HCC yielded slightly longer survival with low (median 749 days) compared to high immune response (709 days, p=0.95). Responders (n=50) showed more T-cell infiltration (3.192±2.612%, p=0.934) compared to non-responders (n=11; 3.118±3.075 %, p=0.335) but a low odds ratio of 0.487 for having a low (= median) immune infiltration.

**CONCLUSION**

These preliminary findings show comparable CD8+ T-cell infiltration in HCC biopsies before and after cTACE. T cell counts were generally low indicating a rather immunologically cold tumor microenvironment. Results from further characterizations of T cell sub-populations and functions are still pending. Patients with high post-cTACE immune response showed slightly improved survival, and responders tended to have higher T-cell infiltration, suggesting a potential link between intratumoral T cell response and treatment efficacy.

**CLINICAL RELEVANCE/APPLICATION**

Understanding the role of T-cell infiltration in HCC and changes induced by cTACE may aid prognosis and treatment decisions in HCC patients.

## M5B-SPIR-6 FEASIBILITY AND SAFETY OF TEGUS TELEPROCTORING OF MECHANICAL THROMBECTOMIES PERFORMED BY GENERAL INTERVENTIONAL RADIOLOGISTS IN A NON-COMPREHENSIVE STROKE CENTER

**PURPOSE**

Mechanical thrombectomy (MT) is usulally performed in comprehensive stroke centers by experienced neurointerventional radiologists. However, logistical and geographic limitations often hinder access to rapid MT, especially in remote areas.The purpose of this presentarion is to explore the use of remote teleproctoring to support MT conducted by general interventional radiologists (IR) at thrombectomy capable centers, compared to on-site proctoring outcomes.

**METHODS AND MATERIALS**

The Arnau de Vilanova Hospital in Spain, serving 500,000 people over 12,000 km2, used to transfer stroke patients requiring MT to a comprehensive stroke center 160 km away. To overcome COVID-19 mobility restrictions, the Tegus Teleproctoring System was installed. From April 2021 to May 2023, general IR conducted MT either with on-site proctor supervision or teleproctoring support. We aim to compare clinical outcome of patients receiving MT according to proctoring method.

**RESULTS**

During the study, 51 MTs were performed: 17 with TEGUS teleproctoring and 34 with on-site proctoring. Both groups had similar baseline characteristics, except for NIHSS scores (Tegus 9 (IQR 6- 20) v/s 18 (IQR 12-22), p: 0,034). No significant differences were found in door-to-revascularization time (82 (SD 28.2) v/s 84 (SD 26.4) min, p: 0.895). The final mTICI distribution and 90-day mRS scores were comparable. There were no reports of symptomatic intracranial hemorrhage in either group.

**CONCLUSION**

This study shows the feasibility of remote teleproctoring during emergent cases of MT in a remote hospital.

**CLINICAL RELEVANCE/APPLICATION**

Teleproctoring tools may help to improve initial learning curves of interventional radiologists with limited experience in MT, and lower the territorial inequity associated to MT.

## M5B-SPIR-9 UNRAVELING SHIFTS IN PRO- AND ANTI-INFLAMMATORY CYTOKINE PATTERNS AFTER CONVENTIONAL TRANSARTERIAL CHEMOEMBOLIZATION FOR HEPATOCELLULAR CARCINOMA

Ornela Sulejmani (*Abstract Co-Author*) Nothing to Disclose
Andreas Wilhelm (*Abstract Co-Author*) Nothing to Disclose

Emine Yaren Yilmaz Ince, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The Emerald-1 trial sought to exploit the immunomodulatory benefits of transarterial chemoembolization (TACE) combined with immunotherapies in hepatocellular carcinoma (HCC). To better understand potential synergistic mechanisms and predict tumor response, this study analyzed cytokine levels longitudinally before and after conventional (c)TACE.

**METHODS AND MATERIALS**

This subgroup analysis of a prospective study included 23 patients with unresectable HCC undergoing cTACE followed by ablation using interstitial high dose-rate brachytherapy after 24h (02/22-05/23). IRB approval and informed consent were obtained. Serum samples were collected from peripheral blood 1 day before and after cTACE. Samples were analyzed using Mesoscale discovery validated V-Plex assays for proinflammatory (interferon-gamma (IFN-?), interleukin (IL)-1ß, -2, -6, -8, -17A, monocyte chemoattractant protein (MCP)-1, macrophage inflammatory protein (MIP)-1a, tumor necrosis factor (TNF)-a), anti-inflammatory (IL-4, -5, -10, -13), and pro-angiogenic factors (vascular endothelial (VEGF)-A and basic fibroblast growth factor (bFGF)). Additionally, tumor response at 8 weeks was assessed using mRECIST. Statistics included Wilcoxon- and Mann-Whitney test.

**RESULTS**

The cohort comprised 22 men and 1 woman (73.2±8.7 years), with 20 patients classified as Child-Pugh A and 3 as B, 10 as Barcelona Clinic Liver Cancer stage A and 13 with B, and a mean tumor size of 51.3±24.1 cm. All anti-inflammatory cytokines had decreased after cTACE compared to baseline, with IL-5 ($p=0.0006$) and IL-4 ($p=0.0019$) reaching statistical significance. However, also IFN-? ($p<0.0001$), IL-2 ($p=0.5202$), IL-8 ($p=0.0049$), IL-17 ($p=0.0049$), TNF-a ($p=0.0003$), MIP-1a ($p<0.0001$), and MCP-1 ($p=0.0003$) decreased, while only IL-1ß ($p=0.3333$) and IL-6 ($p = 0.0043$) increased following cTACE. Stratification by mRECIST (available in n=22) revealed higher baseline MCP-1 levels ($p = 0.1537$) in responders (n=15) and elevated bFGF levels ($p=0.0449$) in non-responders (n=6) post-cTACE, respectively.

**CONCLUSION**

Our study revealed significant cytokine changes post-cTACE for HCC, including decreases in anti-inflammatory and some pro-inflammatory cytokines. Notably, IL-1ß and IL-6 increased, suggesting an acute inflammatory reaction to treatment. These findings highlight the intricate immunological responses to cTACE and their potential impact on treatment outcomes.

**CLINICAL RELEVANCE/APPLICATION**

Understanding cTACE-induced immunological effects in HCC can help tailor treatment strategies and predict outcomes. Humoral factors, alongside cellular immune responses, could serve as prognostic markers, but further longitudinal research is needed to understand the underlying mechanisms.

## M5B-SPMK-1 FOUR-DIMENSIONAL COMPUTED TOMOGRAPHY-DERIVED INTEROSSEOUS PROXIMITIES DURING FOREARM PRONOSUPINATION

Kristin D. Zhao, MA (*Abstract Co-Author*) Nothing to Disclose
Sanjeev Kakar, MD (*Abstract Co-Author*) Nothing to Disclose
Thor Andreassen (*Abstract Co-Author*) Nothing to Disclose
Andrew Thoreson (*Abstract Co-Author*) Nothing to Disclose
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Cesar Lopez (*Abstract Co-Author*) Nothing to Disclose
Taylor Trentadue, BS (*Presenter*) Nothing to Disclose

### PURPOSE

The distal radioulnar joint (DRUJ) transmits load through the wrist and facilitates forearm pronosupination (PS). Limited osseous congruency of the radius and ulna contributes to intrinsic DRUJ instability, with volar-dorsal translation occurring during PS. Dynamic imaging-derived biomarkers may improve DRUJ instability diagnosis. 4DCT (3DCT + time) captures wrist mechanics during functional tasks. We seek to relate DRUJ interosseous proximities to PS angle using statistical parametric mapping (SPM), which quantifies variability in spatiotemporal data. We hypothesized that PS angle influences DRUJ proximity, particularly along the volar-dorsal axis of the sigmoid notch.

### METHODS AND MATERIALS

Following IRB approval and written consent, 4DCT data during PS were collected in 12 female participants with unilateral DRUJ injury (median (IQR) age: 28 (24-46) years). Participants moved in a motion-guiding device at 70 bpm (pronation to supination) while 4DCT volumes were captured using a commercial dual-source photon-counting detector CT (NAEOTOM Alpha, Siemens; temporal resolution: 66 ms). A total of 725 CT volumes were collected over all 4DCT acquisitions. The radius and ulna were segmented from static CT using semi-automated pipelines. Static-to-dynamic bone registration was performed using custom algorithms; 686 (95%) volumes were free from motion artifact and included. A multi-domain statistical shape model was used to generate a canonical DRUJ. Participant meshes were morphed to the canonical DRUJ using a generalized regression neural network. PS angle was calculated as the finite helical axis. The relationship between PS angle and interosseous proximities was analyzed with an SPM general linear model. The test statistic, SPM{t}, was calculated on the sigmoid notch. The critical threshold (t*), which a% of smooth random proximity maps would traverse, was used for hypothesis testing (a=0.05, 0.01, 0.001, 0.0001 in sensitivity analyses).

### RESULTS

As hypothesized, there was a significant relationship between PS angle and DRUJ sigmoid notch proximities, particularly along the volar-dorsal axis. Vertex-specific coefficients ß quantify that 10° increased pronation is associated with a ß [range: -0.18 - 0.30] mm change in proximity.

### CONCLUSION

Increased pronation is associated with increased volar and decreased dorsal sigmoid notch proximities. This demonstrates a novel application of SPM to 4DCT data, allowing quantitative spatial analysis of articular surface interactions during motion.

### CLINICAL RELEVANCE/APPLICATION

4DCT is an emerging technique to quantify and localize changes in wrist mechanics during functional tasks. SPM can be applied to paired datasets to determine regions demonstrating injury-related patterns.

## M5B-SPMK-2 THE APPLICATION OF CONTRAST-ENHANCED MAGNETIC RESONANCE NEUROGRAPHY IN DIAGNOSIS AND GRADING OF CARPAL TUNNEL SYNDROME

Wenjun Wu (*Abstract Co-Author*) Nothing to Disclose
Youzhi Wang (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the diagnostic accuracy and grading value of carpal tunnel syndrome (CTS) with contrast-enhanced magnetic resonance neurography (ceMRN).

### METHODS AND MATERIALS

Thirty-one patients with confirmed carpal tunnel syndrome (CTS) and 30 healthy controls were prospectively collected, and evaluated using ceMRN to record the information below the median nerve: nerve width, nerve-to-muscle T2 signal intensity (nT2), which are identified as CTS patients, also need to

measure the length, area of nerve entrapment, negative enhancement (percentage reduction of nerve signal at entrapment compared to higher signal from adjacent nerve) and ceMRN nerve entrapment grade of CTS patients. Clinical data were retrospectively extracted from the medical records of patients diagnosed with CTS (Boston carpal tunnel questionnaire, symptoms and signs, and clinical severity grading).

**RESULTS**

Compared with clinical evaluation, ceMRN had a sensitivity of 0.97 and specificity of 0.90 in detecting nerve entrapment. When distinguished according to clinical severity levels, the sensitivities were 0.63, 0.5, and 0.56 for I, II, and III injuries, and the specificities were 0.83, 0.59, and 0.86, respectively. The areas under the curve for predicting CTS using nerve width and nT2 were 0.89 and 0.87 ($p<0.05$), respectively, and the AUC for predicting CTS using the above two parameters combined was 0.94. In the ceMRN nerve entrapment grading, there were significant differences in nerve length, area of nerve entrapment, negative enhancement, and nT2 ($p<0.05$). There was a positive correlation between clinical severity and ceMRN nerve entrapment grading (correlation coefficient = 0.64; $p<0.0001$).

**CONCLUSION**

Contrast-enhanced MRN of the median nerve in the wrist can improve the diagnostic efficacy of CTS and has great potential for grading patient severity.

**CLINICAL RELEVANCE/APPLICATION**

The ceMRN significantly improves the visualization of peripheral nerves and pathology in the wrist and palm by robustly suppressing the signals of fat, bone marrow, and especially vessels in patients, which can significantly improve readers' confidence in identifying nerves, and improve the detection of lesions.

## M5B-SPMK-3 PRELIMINARY EXPERIENCE WITH NEW TRACTION DEVICE ON NON-ARTHROGRAPHIC WRIST MRI

David Yeung (*Abstract Co-Author*) Nothing to Disclose
James F. Griffith, MD (*Abstract Co-Author*) Nothing to Disclose
Miaoru Zhang, MMEd (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the distraction effect and wearability of a new wrist traction device in healthy subjects during wrist MRI examinations.

**METHODS AND MATERIALS**

17 healthy subjects (11 males, 6 females; mean age 29 years, range 24-43 years) underwent wrist MRI (Philips Ingenia Elition X 3.0T MRI system) between November 2023 and April 2024. A new traction device was applied to the wrists during MR examination. All subjects first completed the wrist MRI without traction and then with traction, lying supine with the examined wrist and traction device at the side (Fig. 1).A 10-point analog scale pain-severity questionnaire was completed by each subject within 15 minutes of MRI completion (1). Joint space width and articular cartilage visibility at five radiocarpal and intercarpal joints were evaluated on proton-density weighted fat-suppressed coronal images before and after traction. Joint space width was defined as the minimal distance between opposing cortical bone surfaces (2,3). Articular cartilage visibility was graded as poor (<25%), moderate (25-75%), or good (>75%) visibility depending on the percentage visibility of articular cartilage (4).

**RESULTS**

12 (71%) of 17 subjects had no pain during or after the MRI with traction, while 5 (29%) subjects had a slight increase of wrist pain with traction (mean 2 points, range 1-4 points). Joint space width of the radioscaphoid, radiolunate, scaphocapitate and lunocapitate joints was increased after traction (all p values = 0.001), with an average increase of 0.74 mm (Fig. 2, Table.1). Articular cartilage visibility was improved at the radiolunate and lunocapitate joints (p values < 0.05). More than half of radiolunate, scaphocapitate and lunocapitate joints were graded as 'good' visibility after traction (Table 2).

**CONCLUSION**

This new traction device can effectively distract the wrist joints, improving cartilage surface visibility in all subjects with a minimal increase in discomfort in about one-third of subjects.

**CLINICAL RELEVANCE/APPLICATION**

Wrist MRI with traction, using the standard weight and pulley system, has high accuracy for detecting intrinsic ligaments and other injuries, though it is limited by the cumbersome traction method. With this new traction device, patients can lie comfortably in a supine position with the wrist examined by the side. This new device provides good wrist joint distraction and cartilage visibility, which may reduce the need for wrist arthrography.

## M5B-SPMK-4 MUSCULOSKELETAL IMAGING COMPLICATIONS OF RECREATIONALLY INJECTED XYLAZINE

Amber C. Simmons, MD (*Abstract Co-Author*) Nothing to Disclose
Noah Wasserman, MD (*Abstract Co-Author*) Nothing to Disclose
Alvaro Ordonez, MD (*Abstract Co-Author*) Nothing to Disclose
Nogah Shabshin, MD (*Abstract Co-Author*) Consultant, Active Implants;Consultant, CartiHeal Ltd;Consultant, Nanox;Consultant, Greenbone;
John D. Karp, MBBCh (*Presenter*) Nothing to Disclose

**PURPOSE**

Xylazine is an increasingly misused non-opioid sedative that is often recreationally injected with Fentanyl for enhanced effects. Xylazine is now found as an adulterant in >90% of illegal drug samples tested in Philadelphia and has been detected in samples nationwide. Xylazine causes vasoconstriction of peripheral blood vessels and decreased skin perfusion, causing tissue necrosis and impaired wound healing. Despite the surge in xylazine use, there is limited information regarding the associated soft tissue and bone complications on imaging. Therefore, we provide the first imaging evaluation of Xylazine-related musculoskeletal (MSK) complications.

**METHODS AND MATERIALS**

An IRB-approved retrospective analysis was conducted in a multicenter institution in Philadelphia, PA. Adult patients were identified through Nuance mPower and included if injected xylazine was documented (self-reported and/or positive drug test) and had received MSK imaging. Demographics, clinical and imaging characteristics were evaluated and correlated with inflammatory and microbiological results.

**RESULTS**

A total of 44 patients were included with a median age of 38 years (range 29-52), 27% female and 91% Caucasian. The site of injection-related MSK complications was predominantly in the lower extremities (52%), followed by upper extremities (48%), and the neck (7%). All patients had extensive open wounds. Imaging included radiographs (89%), CT (70%), ultrasound (23%), and MRI (20%). Radiographic and CT findings included soft-tissue obliteration and marginal undulations, exposed fascia and muscles, and extensive periosteal reaction along the involved bone. Despite the similarity to

osteomyelitis (OM) and the severity of the wounds, acute and chronic OM were confirmed with multimodality imaging in 20% and 9% of the cases, respectively. One pathological fracture on acute OM was noted. In 7% of cases, findings were indeterminate for OM. Additional imaging features included abscess formation (19%) and subcutaneous emphysema (11%). A lack of a robust systemic inflammatory response was also observed (mean white blood cell count = 8.4 ± 4.9 103 cells/uL). Positive blood cultures were reported in only 18% of cases.

**CONCLUSION**

The increased recreational use of injected xylazine is leading to a rise in severe MSK complications observed on imaging. Our analysis showed that the severity of wounds was not commensurate with the degree of bone involvement and systemic inflammatory response.

**CLINICAL RELEVANCE/APPLICATION**

The emerging xylazine abuse as an illicit substance is associated with severe MSK complications. Detailed characterization of the imaging findings observed in this population can guide radiologists to optimize resources and improve patient care.

## M5B-SPMK-5 ASSOCIATIONS OF THREE MAGNETIC RESONANCE IMAGING CLASSIFICATIONS WITH TREATMENT OPTIONS FOR PATIENTS WITH LATERAL EPICONDYLITIS: SURGICAL OR CONSERVATIVE TREATMENT

Huili Zhan, MMed (*Abstract Co-Author*) Nothing to Disclose
Ping Wang (*Abstract Co-Author*) Nothing to Disclose
Heng Zhang (*Abstract Co-Author*) Nothing to Disclose
Qian Zhanhua (*Abstract Co-Author*) Nothing to Disclose
Bai Rongjie (*Abstract Co-Author*) Nothing to Disclose
Ye Wei (*Abstract Co-Author*) Nothing to Disclose
Jianing Cui (*Presenter*) Nothing to Disclose

**PURPOSE**

The study aimed to analyze the magnetic resonance imaging (MRI) features of patients with lateral epicondylitis (LE) who underwent conservative or surgical treatment and to evaluate the significance of MRI characteristics in deciding treatment management. Furthermore, three MRI-based LE classifications were introduced to investigate the best classification that can be used to refine predictive models for surgical treatment.

**METHODS AND MATERIALS**

374 LE patients comprised the operative(n = 261) and non-operative (n = 113) groups. All patients received conservative treatment for at least 6 months. If elbow pain persisted or elbow movement was limited, conservative treatment had failed, and surgery was required. The covariance of parameters was checked using Spearman's correlation analysis, and variables with correlation coefficients greater than 0.7 were excluded. The predictors of surgical treatment were analyzed using the logistic regression method. Furthermore, based on previous studies, we selected three MRI classifications to classify the pathologies of the origin of ECT. Specific details of the three MRI classifications are summarized. Finally, four models were developed. Model 1 included all meaningful parameters in the multivariate analysis, and models 2 to 4 were model 1 plus MRI classifications 1 to 3, respectively. The Net Reclassification Improvement (NRI) index was employed to evaluate the enhanced prediction capabilities of models 2 to 4 relative to model 1 regarding patient management strategies. Of the whole samples, 70% were randomly chosen to train the models, while 30% were applied for the test.

**RESULTS**

There were significant differences in age, CET tear size, LCL complex, synovial plica(SP), muscle edema, and ulnar nerve. The factors of sex, CET tear size, LCL complex, SP, muscle edema, and ulnar nerve were correlated with surgical treatment. The AUC of predicted probabilities for model 1 in the training and testing sets were 0.824 and 0.728. In the test set, the NRI values for Models 2 to 4 were 4.2, 1.3, and 11.8, respectively; however, only Model 4 achieved significance with a P-value of 0.012.

**CONCLUSION**

The severity of the LE was greater in the surgical group. The combination of MRI and baseline characteristics can assist doctors in making prompt decisions regarding surgical treatment for patients. MRI classification 3, which further categorizes tendinopathy into subtypes, enhances the accuracy of traditional predictive models.

**CLINICAL RELEVANCE/APPLICATION**

MRI classification of subdivided tendinopathy improves the ability of the conventional model to assess which LE patients require surgical treatment.

## M5B-SPMK-6 THE RADIOHUMERAL SYNOVIAL PLICA: ANATOMY, HISTOLOGY, AND IMPLICATIONS FOR CHRONIC LATERAL EPICONDYLITIS

Huili Zhan, MMed (*Abstract Co-Author*) Nothing to Disclose
Ping Wang (*Abstract Co-Author*) Nothing to Disclose
Qian Zhanhua (*Abstract Co-Author*) Nothing to Disclose
Bai Rongjie (*Abstract Co-Author*) Nothing to Disclose
Ye Wei (*Abstract Co-Author*) Nothing to Disclose
Heng Zhang (*Abstract Co-Author*) Nothing to Disclose
Jianing Cui (*Presenter*) Nothing to Disclose

**PURPOSE**

Our study aimed to elucidate the relationship between synovial plica (SP) and the surrounding ligaments and tendons through the cadaveric section, histological assessment, magnetic resonance imaging (MRI), and MR angiography of elbow specimens. We then evaluated the relationship between SP and clinical symptoms as well as MRI features in patients with chronic lateral epicondylitis (LE).

**METHODS AND MATERIALS**

MRI was performed on 8 cadaveric elbows specimens. The MRI findings were compared with those in anatomic sections and histologic preparations. In addition, 99 patients with chronic LE who underwent preoperative elbow MRI and arthroscopic surgery were included and divided into 77 patients with SP and 22 without SP. The differences in clinical and MRI features between the two groups were compared. The clinical variables included age, affected side, pain duration, and elbow function. Elbow function was evaluated preoperatively and at 3-week, 6-week, and 3-month postoperatively using the visual analogue scale (VAS) score, DASH score, and range of motion. The MRI variables included common extensor tendon (CET), lateral collateral ligament(LCL) complex, muscle edema, ulnar neuropathy, and bone changes.

## RESULTS

The SPs were histologically divided into two categories: one with synovial epithelium externally and fibrous, fat, and vascular tissue internally, and the other solely composed of fibrous tissue. The SP was a thickening of the synovium proximal to the annular ligament (AL) that extends into the joint cavity, then moves to the radial collateral ligament, and finally attaches to the lateral epicondyle along with the CET. The SP, ligament, and tendon blend without distinct boundaries. Furthermore, in the study of patients with chronic LE, we found that the SP group had higher preoperative and 3-week postoperative VAS scores and more severe CET and LCL complex abnormalities (Table 1-2). Postoperative VAS scores decreased in both groups. However, at 3-month postoperative, the VAS score continued to show a decreasing trend in the SP group ($P < 0.001$), whereas there was no significant decrease in the without SP group.

## CONCLUSION

The SP is distinct from the AL but closely correlates with the LCL complex and CET enthesis at the lateral epicondyle. Patients with SP have more severe pain scores, LCL complex and CET abnormalities, and longer postoperative recovery times.

## CLINICAL RELEVANCE/APPLICATION

A comprehensive study of anatomy, histology, and the impact of SP on chronic LE patients could improve diagnostic accuracy, and refine therapeutic strategies.

## M5B-SPMS-1 IMPACT OF SPLEEN VOLUME AND ITS DYNAMIC CHANGE IN THE CONTEXT OF NHL TREATED WITH CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY

Jens Ricke, MD, PhD (*Abstract Co-Author*) Research Grant, Sirtex Medical Ltd;Research Grant, Bayer AG;Research Grant, Terumo Corporation;Research Grant, Boston Scientific Corporation
Peter Bartenstein (*Abstract Co-Author*) Nothing to Disclose
Viktoria Blumenberg (*Abstract Co-Author*) Nothing to Disclose
Wolfgang G. Kunz, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Marion Subklewe (*Abstract Co-Author*) Nothing to Disclose
Michael Winkelmann, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Chimeric antigen receptor T-cell therapy (CART) targeting the CD19 antigen is a powerful treatment option for later line treatment of relapsed or refractory (r/r) lymphoma. The spleen, as part of the lymphatic system, is often involved in immune response processes that could also play a role in CART efficacy. In this study, we investigate the impact of spleen volume (SV) and its dynamic change between baseline (BL) and early follow-up imaging on progression-free survival (PFS) and overall survival (OS) in the context of CART.

### METHODS AND MATERIALS

Patients with available BL and 30-days follow-up (FU1) computed tomography (CT) or 18-F fluorodeoxyglucose positron emission tomography ([18F]-FDG PET)/CT scan before CART were included. The spleen was 3D-segmented on all scans and spleen volume change (SVC) was calculated as a percentage of BL to FU1. Treatment response, overall response rate (ORR) and PFS were determined based on Lugano criteria. Mann-Whitney U test was used to test significance between responders and non-responders and between spleen involvement at BL (SIBL) and non-SIBL. Log-rank (Mantel-Cox) tests were performed to assess the significance of survival.

### RESULTS

68 out of 78 patients met the inclusion criteria. The median SV at BL was 244.5 cm3 and the median SVCBL to FU1 was -8.85 cm3. Patients of the responder group showed a significant decrease of SVCBL to FU1 compared to the non-responding group ($p = 0.001$) and patients with SIBL showed a small, but not significant difference to patients with non-SIBL ($p = 0.056$). In survival analysis, there was a significant difference between the groups in both OS ($p = 0.040$) and PFS ($p = 0.008$) for SVCBL to FU1. No significant differences were seen in SVBL and SIBL for both OS (SVBL: $p = 0.342$; SIBL: $p = 0.418$) and PFS (SVBL: $p = 0.376$; SIBL: $p = 0.577$). A subgroup survival analysis for SVCBL to FU1 in combination with SIBL showed a significant difference for PFS ($p = 0.049$) and no significant difference for OS ($p = 0.175$).

### CONCLUSION

This study demonstrated that the change in SV between baseline and 30-day follow-up (SVCBL to FU1) is associated with PFS and OS both for patients with and without involvement of the spleen and should be explored as a potential novel biomarker for survival prediction in the context of CART treated lymphoma patients.

### CLINICAL RELEVANCE/APPLICATION

Understanding the immunologic processes and involvement of the lymphatic system may be helpful in the clinical management of lymphoma patients undergoing CART.

## M5B-SPMS-2 DEEP LEARNING AUTOMATION OF SPLEEN SEGMENTATION FOR ASSESSING SPLENOMEGALY IN MYELOFIBROSIS: A REPRODUCIBLE APPROACH TO EVALUATE DISEASE PROGRESSION VERSUS RESPONSE

Vahid Bazojoo, MD (*Abstract Co-Author*) Nothing to Disclose
Hreedi Dev (*Abstract Co-Author*) Nothing to Disclose
Chenglin Zhu (*Abstract Co-Author*) Nothing to Disclose
Zhongxiu Hu (*Abstract Co-Author*) Nothing to Disclose
Martin R. Prince, MD, PhD (*Abstract Co-Author*) Patent agreement, General Electric Company;
Usama Sattar, MBBS (*Abstract Co-Author*) Nothing to Disclose
Arman Sharbatdaran, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Myelofibrosis induces splenomegaly through extra-medullary hematopoiesis. Spleen size is an increasingly important biomarker for myelofibrosis progression. This study assesses the reproducibility and accuracy of spleen volume measurements using ellipsoidal estimation, manual contouring, and model-assisted deep learning contouring.

## METHODS AND MATERIALS

In this retrospective cohort study, spleen volume measurement approaches were analyzed in 20 myelofibrosis patients using axial T1-weighted, axial T2-weighted, and coronal T2-weighted MRI imaging. Three different measurement approaches—ellipsoidal estimation (length × width × thickness × p/6), manual contouring, and model-assisted contouring—were performed by 5 experts. The model was a 3D NNU-net model trained with Axial T1, Axial T2, Coronal T2 and SSFP images from 413 subjects labeled by experts then observed and checked by board certified radiologist with 30 years' experience in abdominal MRI. We compared these methods to identify the most reproducible approach for using spleen volume as a biomarker in assessing myelofibrosis progression.

## RESULTS

Internal/external validation of the 3D nnU-net model showed a Dice of 97% compared to radiologist ground truth. Model-assisted contouring had the lowest coefficient of variation for spleen volume among the 5 expert observers, 0.37 % (± 0.84) compared to manual contouring, 3.6% (±1.7) (p=0.004) and ellipsoidal estimation (a commonly used method) from 3 measurements 16.3% (±6.7) (p=0.008). Further reduction in coefficient of variation down to 0.32% (±0.59) was achieved by averaging model-assisted segmentations across Axial T2-weighted, Axial T1-weighted, and Coronal T2-weighted MRI sequence (p=0.006).

## CONCLUSION

Utilizing a model-assisted deep learning approach substantially enhances reproducibility, reducing observer variation in measuring splenomegaly in myelofibrosis patients.

## CLINICAL RELEVANCE/APPLICATION

Spleen volume reduction (SVR) percentage is an important biomarker in evaluating myelofibrosis disease progression versus response. Additionally, SVR percentage is used as a crucial biomarker in most clinical trials assessing drug treatment efficacy in myelofibrosis. Thus, improving the accuracy and reproducibility of spleen volume measurements is critical for reliable clinical outcomes and therapeutic decision-making. Improving reproducibility decreases the time interval required to detect a meaningful change in spleen volume allowing for more frequent monitoring of patient response to treatment and earlier detection of treatment failures.

## M5B-SPNMMI-1 DOUBLE-NETWORK MAGNETIC HYDROGEL WITH INDIRECT THERMO-SENSITIVE PHASE TRANSITION FOR "OFF-ON" CHEMOEMBOLIZATION THERAPY OF HEPATOCELLULAR CARCINOMA BASED ON MAGNETIC RESONANCE NAVIGATION

Longlong Wang (*Abstract Co-Author*) Nothing to Disclose
Lei Li (*Abstract Co-Author*) Nothing to Disclose
Na Li (*Abstract Co-Author*) Nothing to Disclose
Jingwen Ma (*Presenter*) Nothing to Disclose

### PURPOSE

Transcatheter arterial chemoembolization (TACE) has become the standard of treatment for patients suffering hepatic cancer in middle/advanced stage or no surgical resection indication. Although TACE is safe, over- and off-targeted embolization must face with. Therefore, we hypothesized the efficacy of HCC embolization could be improved by achieving precise targeting of embolic agents in vivo and "off-on" embolization.

### METHODS AND MATERIALS

Magnetic dual network hydrogel based on hyaluronic acid-dopamine (HA-DA) and alginate (ALG)-Ca2+ was constructed and three components were added including thermo-sensitive liposomes (HFP@Lip) loading with hyaluronidase (HAase) and magneto-thermal FeCo magnetic nanoparticles (NPs), Doxorubicin (DOX) and iodohexanol for digital subtraction angiography (DSA), namely HFP@LipDI/HAALG. Its gelation time and rheological properties was measured. Precise internal localization of the embolic hydrogel achieved by MRN technology; HAase was triggered releasing by alternating magnetic field (AMF) heating. The internal location of hydrogel, blocking and recanalization of bloodstream could be visualized by MRI and DSA.

### RESULTS

FeCo NPs (~11 nm) were successfully prepared; HFP@LipDI/HAALG were constructed; gelation time was adjusted by altering ratio of HRP and H2O2 and control gelation time ranging 300-400 s to ensure sufficient time for MRN; it was tested that optimum gelation time achieved when the final concentration of HA-DA, ALG, HRP and H2O2 were 2 wt%, 5 wt%, 0.05 mg·mL-1 and 0.01 mmol·mL-1 respectively. HFP@LipI/HAALG was prepared by adding 20 wt% of iodohexanol, and which successfully degrading after heating within AMF. Noteworthy, FeCo NPs not only provide magnetic property essential in MRN and contrast agents in MRI, but also act as heating source to trigger HAase release in AMF. Carotid arteries were imaged using 3D-TOF sequences in MRI, and after injection of gadodiamide vessels were observed more clearly. Inserting microcatheters in carotid artery, and HFP@LipI/HAALG were injected to block blood supply of carotid artery. An AMF coil has been made. Temperature of HFP@LipI/HAALG containing 2.5 mg·mL-1 of FeCo could be effortlessly rise by 15.4°C within 30 s under the magnetic field condition of 33 KA·m-1, 115 kHz.

### CONCLUSION

The embolic agent can be precisely localized in vivo, internal degradation through extracorporeal manipulation to successfully realizing the "off-on" embolization.

### CLINICAL RELEVANCE/APPLICATION

The construction of the hydrogel embolic agent provides new technologies for improving over- and off-targeted embolization in TACE treatment of hepatic cancer, and provides the possibility to improve the prognosis and life quality of patients receiving TACE.

## M5B-SPNMMI-2 TREM-1 PET FOR THE CHARACTERIZATION OF MYELOID INFLAMMATION AFTER TBI IN MICE

Aisling Chaney, PhD (*Abstract Co-Author*) Nothing to Disclose
John G. Cooper, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Central nervous system (CNS)-infiltrating myeloid cells, namely monocytes and macrophages, have been implicated in the pathogenesis of secondary immune injury after traumatic brain injury (TBI). Importantly, the location and temporal dynamics of myeloid cells have the potential to serve as a clinically meaningful biomarker of secondary injury after TBI. Herein, we describe the successful use of a novel positron emission tomography (PET) imaging tracer for triggering receptor expressed on myeloid cells-1 (TREM1) to specifically image whole-body proinflammatory peripheral myeloid cell responses after TBI in mice. To determine the relationship between peripheral and central inflammation, we also directly compare TREM1-PET with PET imaging of translocator protein 18 kDa (TSPO) a widely used approach for measuring neuroinflammation.

## METHODS AND MATERIALS

Mild TBI was induced in C57BL/6 mice using a weight drop model. TSPO-PET using [18F]DPA-714 was performed at 9 days post-injury (DPI). [64Cu]TREM1-mAb-PET was performed in a subgroup of the same cohort of mice at 10 DPI. This time-point was chosen to maximize the specificity for infiltrating monocytes and activated microglia. Regions of interest were defined by semi-automated fitting of skull CT to a 3D brain atlas (Fig. 1C). Following TREM1-PET, mice were sacrificed, and tissues harvested for biodistribution (BioD) analysis.

## RESULTS

TSPO-PET demonstrated significantly increased signal in whole brains of TBI compared to sham mice ($p=0.002$, Fig. 1A). Cortical TSPO signal trended higher but was not significant ($p=0.08$). TREM1-PET demonstrated significantly increased signal in both whole brain and cortex ($p=0.03$-$0.04$, Fig. 1B). Ex vivo BioD demonstrated significantly increased [64Cu]TREM1-mAb signal in the bone marrow of TBI mice (vs. shams) indicating expansion of peripheral proinflammatory myeloid cells following injury (Fig. 1D).

## CONCLUSION

We demonstrate the ability of TREM1-PET to detect both brain and whole-body innate inflammation after TBI in mice and demonstrate the feasibility of this approach. Differing signals in the cortex suggest that these tracers are detecting separate aspects of the inflammatory response. Additional PET experiments to characterize the spatiotemporal dynamics of myeloid inflammation after TBI are ongoing.

## CLINICAL RELEVANCE/APPLICATION

TBI affects more than 2.5 million US residents every year, at a cost of over $40.6 billion. There is an urgent unmet clinical need to better understand the processes involved in TBI, with the long-term goal of improving diagnosis and treatment of this devastating disorder. The present work investigates a novel PET imaging biomarker (TREM1) to characterize the myeloid component of neuroinflammation.

## M5B-SPNPM-1 ENERGY SAVING STRATEGY USING OPTIMAL TUBE VOLTAGE AND TUBE CURRENT IN ABDOMINAL CT - PHANTOM STUDY

Chang Hee Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jeong Woo Kim, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study was aimed to investigative optimal tube voltage and tube current considering energy as well as radiation dose and image quality for abdominal CT using phantom.

### METHODS AND MATERIALS

A customized anthropomorphic phantom (PH-5, Kyoto Kagaku) was scanned at 20 different protocols combining 4 tube voltages (80, 100, 120, and 135 kVp) and 5 tube currents (100, 200, 300, 400, and 500 mA) using a 320-row multidetector CT scanner. In each protocol, energy consumption was measured using an energy consumption measurement sensor, and dose length products (DLPs) were recorded. The phantom contains 8 focal liver lesions (FLLs) (4 hypoattenuating nodules and 4 hyperattenuating nodules). In quantitative analysis, noise was measured by drawing regions-of-interest (ROIs) in the subcutaneous fat layer and paraspinal muscle in the phantom. Additionally, to calculate the contrast-to-noise (CNR) of the FLLs, attenuations of the FLLs and adjacent liver parenchyma were measured by drawing ROIs. The CNRs were calculated by using the following equation: CNR = | ROIL - ROIf |/SDnoise, where ROIL is the mean attenuation of liver parenchyma, ROIf is the mean attenuation of FLL, and SDnoise is the mean image noise. All measurements were repeated five times, and the average value was used. The CNRs of FLLs in different protocols were compared using the Wilcoxon signed-rank test.

### RESULTS

Energy consumption was lower for 100 kVp/300 mA (9.64 Wh), 100 kVp/200 mA (6.82 Wh), and 100 kVp/100 mA (4.4 Wh) than for 80 kVp/400 mA (10.27 Wh) and 80 kVp/500 mA (12.65 Wh). DLP for 100 kVp/200 mA (219.4 mGy·cm) and 100 kVp/100 mA (109.7 mGy·cm) was lower than 80 kVp/500 mA (239.7 mGy·cm), but 100 kVp/300 mA (329 mGy·cm) was higher than 80 kVp/500 mA. The image noise was lower at 100 kVp/100 mA than 80 kVp/50 mA, but not statistically significant (7.20 ± 0.20 vs. 7.39 ± 0.20, p = 0.132), whereas 100 kVp/200 mA was significantly lower than 80 kVp/50 mA (6.15 ± 0.21 vs. 7.39 ± 0.20, p = 0.002). The CNR for 8 FLLs was significantly lower for 100 kVp/100 mA than 80 kVp/500 mA (4.63 ± 2.59 vs. 5.64 ± 3.29, p = 0.018), but 100 kVp/200 mA did not show a statistically significant difference from 80 kVp/500 mA (5.47 ± 3.17 vs. 5.64 ± 3.29, p = 0.208).

### CONCLUSION

Compared to the protocol using 80 kVp and 500 mA, the protocol using 100 kVp and 200 mA had lower DLP and noise, and nearly 50% lower energy consumption without compromising CNR of FLLs.

### CLINICAL RELEVANCE/APPLICATION

Low tube voltage and high tube current have been reported to increase the CNR of hepatic hypervascular tumor while reducing patient radiation dose. Considering energy consumption, the combination of moderate tube voltage and moderate tube current may be a candidate for an energy saving strategy while reducing radiation dose and image noise and without compromising CNR.

## M5B-SPNPM-2 THE IMPACT OF COOLING SYSTEMS ON THE OVERALL ENERGY USE OF MRI SYSTEMS
