## Plenary Session: AI’s Transformation of Medicine

Monday, Dec. 2 11:00AM - 12:00PM Room: ARIE CROWN THEATER

**COURSE DESCRIPTION**

The progress from unimodal supervised learning of medical images to multimodal, self- or unsupervised learning foundation models, has enabled marked changes in the practice of medicine. They include promoting accuracy of diagnoses, freeing up time for clinicians to provide better care for patients, and partitioning patient risk for various medical conditions that integrate many layers of patient data, including electronic health record, images, genomics, biosensors, and environmental. Not only can the objective of individualizing medicine be more likely fulfilled, but rebooting how we do cancer screening, hospital-at-home, and enhanced coaching of patients to prevent conditions they are at-risk for manifesting. Patients with large language model support will be more autonomous. However, all of this potential is contingent on dealing with the many challenges of conducting prospective clinical research, real world validation and provision of compelling evidence, transparency, regulatory oversight, minimizing bias and maximizing fairness, promoting utmost privacy and security, preventing inequities, and implementation with careful ongoing surveillance.

## Image Interpretation Session

Monday, Dec. 2 4:30PM - 5:30PM Room: ARIE CROWN THEATER

Bruce B. Forster, MD, FRCPC (*Moderator*) Stockholder, Canada Diagnostic Centres

### LEARNING OBJECTIVES

1) Identify key abnormal findings on radiologic studies that are critical to making a specific diagnosis. 2) Construct a logical list of differential diagnoses based on the radiologic findings, focusing on the most probable differential diagnoses. 3) Determine which, if any, additional radiologic studies or procedures are needed in order to make a specific final diagnosis. 4) Choose the most likely diagnosis based on the clinical and the radiologic information. 5) Have fun achieving 1-4!

### COURSE DESCRIPTION

This session will employ an expert panel to discuss unknown cases in the fields of neuroradiology, musculoskeletal radiology, breast imaging, body imaging and chest radiology. The material will include plain radiography, CT, Ultrasound, MRI, and PET imaging with an overall theme of cases with unusual appearances that can be solved by carefully analyzing the images and recognized ancillary findings in order establish the correct diagnosis. The five expert readers will provide insights into how they approach challenging clinical cases, the pearls and pitfalls during the creation of a differential diagnosis, and the keys to a final diagnosis, in a light-hearted entertaining format.

## RSNA/AAPM Symposium: Together We Can Make A Difference

Thursday, Dec. 5 11:00AM - 12:00PM Room: E450A

Lifeng Yu, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Explain how a multidisciplinary team can work together to realize the promise of AI in cancer care.

**COURSE DESCRIPTION**

The hype on artificial intelligence is highlighting our need to transform the current approach to manage the pace of technological innovation in healthcare. While these technologies are expected to have substantial impact, the reality is that healthcare is ill-prepared to assure they are safe, efficient, and impactful. Maturation of institutional data stewardship and algorithm oversight capabilities should be a priority for healthcare organizations. Growing and operationalizing this capability requires redefining the multidisciplinary and interdisciplinary team needed to successfully manage these technologies in healthcare. A broad collaborative effort to develop and deploy this transformative approach in a large cancer center will be illustrated in this presentation in the context of quantitative analysis of imaging data for cancer care and research.

**Sub-Events**

## PL01A President's Address: Building Intelligent Connections

Curtis P. Langlotz, MD, PhD (*Presenter*) Stockholder, whiterabbit.ai;Advisor, whiterabbit.ai;Stockholder, Galileo CDS, Inc;Advisor, Galileo CDS, Inc;Stockholder, Bunker Hill, Inc;Board of Directors, Bunker Hill, Inc;Stockholder, Sirona Medical, Inc;Advisor, Sirona Medical, Inc

### LEARNING OBJECTIVES

Radiology has revolutionized medicine, embracing change and fostering progress by pursuing innovation that improves our ability to diagnose and treat patients more effectively and efficiently. Now, as the pace of change rapidly accelerates in the modern medical landscape, radiology's leadership in driving health care innovation becomes increasingly important. We are experiencing transformations in all facets of patientcare, from our clinical knowledge base and technological capacities to modes of health care delivery and practice management. These transformations are happening at every level, in every country in the world, in academia and in private practice. Change is not only inevitable, but also necessary as we commit to continuous improvement for our practices and our patients. That is why leading teams through change in an uncertain healthcare environment is an essential skill for today's radiologist. To lead through change, we must first be able to identify when change is necessary. After identifying a need for change, we can form a clear strategic vision for moving forward. By effectively communicating that vision, we inspire others to join us in removing barriers to change and empowering our teams to work as one to achieve our goal. RSNA President Matthew A. Mauro, MD, will explore how radiologists, regardless of setting, can embrace and influence change among their teams and throughout the radiology community; and—in so doing—spark a renewed commitment to ingenuity and innovation among practitioners across multiple disciplines of patient care. By strengthening our foundation as leaders to address the transformative challenges of our specialty, radiologists will be well positioned to secure our future and advance health care for the good of our patients.

## PL01B Opening Session: The Only Way to Predict the Future Is to Create It

Nina E. Kottler, MD, MS (*Presenter*) Partner, Radiology Partners Stockholder, Radiology Partners (Radiology Partners owns a minority interest in Aidoc medical and an indirect minority interest in Rad AI) Employee, Radiology Partners Consultant, ES3 Consultant, W.L. Gore & Associates, Inc Consultant, Synapsica Healthcare Pvt Ltd

### LEARNING OBJECTIVES

"History never repeats itself, but if does often rhyme", is often mistakenly credited to Mark Twain. Regardless of the origin, the notion that events, discoveries and circumstances are "unprecedented", when evaluated more thoughtfully, turnout to have precedent. While the nature of disruptive events and change can be uncomfortable, it must be embraced by leaders. Is today's world more complex than the past, perhaps? But do we leaders need to thoughtfully embrace advancements such as Artificial Intelligence, I think so. And as radiologist, while many may suggest AI might lead us to irrelevancy, I would argue, like past challenges, we should be excited to continue to do what we do best, which is be agile and innovative.

**Plenary Session: Removing the Mask v. 2.0**

Tuesday, Dec. 3 11:00AM - 12:00PM Room: ARIE CROWN THEATER

**LEARNING OBJECTIVES**

1) Summarize the current state of mental health in our community. 2) Discuss the impact of cultural norms and stigma on seeking treatment. 3) Outline personal, institutional, and societal strategies to enact change.

**COURSE DESCRIPTION**

Dr. Cunningham will discuss the current mental health crisis among health care professionals. Through her own lived experience, she will discuss the current state, barriers to care, and a multifaceted approach to enacting change in mental health awareness, reducing stigma and increasing resources for those who are struggling in our community.

**Plenary Session: Social Artificial Intelligence**

Tuesday, Dec. 3 1:30PM - 2:30PM Room: ARIE CROWN THEATER

**COURSE DESCRIPTION**

Humans are naturally embedded in face-to-face social networks that obey particular mathematical and social principles. Increasingly, we are also embedding artificial agents, in the form of AI agents and physical robots, among us – giving rise to "hybrid systems" of humans and machines. These forms of AI act in humanlike ways and open up a new world of social artificial intelligence. Our lab has focused on human-human interactions in the presence of such AI. And specifically, we have focused not on super-smart AI to replace human cognition, but rather on "dumb AI" to supplement human interaction. In one experiment involving 4,000 people in 230 groups, we evaluated how adding bots to human groups improved their ability to coordinate to solve a problem. Another experiment involving 1,024 humans in 64 groups showed that cooperation within a group could be promoted when the AI intervened to rewire social connections. In still another experiment with 1,875 subjects in 125 groups, we showed how bots might enhance creativity by helping groups to avoid groupthink and optimize the diffusion of innovation. We have also done experiments with physical systems, adding humanoid and non-humanoid robots endowed with simple AI to face-to-face groups, showing how they can make it easier for groups to work together by reducing friction in their interactions. Humans have developed ethical and practical norms to address collective challenges, but such tacit understandings can break down in situations where machine intelligence is involved. Our work shows that AI can work to help humans to help themselves; but, of course, the reverse is possible, and AI can be used to harm groups. The ties between people make the whole of society greater than the sum of its parts. This is changing as AI is added.

## Plenary Session Game Show: Microbial Mayhem: The Pathogenic Party You Won't Forget!

Wednesday, Dec. 4 11:00AM - 12:00PM Room: ARIE CROWN THEATER

Linda Probyn, MD (*Moderator*) Nothing to Disclose
Lindsey M. Negrete, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review radiologic images and diagnoses of common and uncommon infectious diseases. 2) Encourage teamwork and collaboration of a diverse group of expert subspecialty radiologists from around the world. 3) Demonstrate learning through gamification with engaging radiology content. 4) Understand the impact of emerging infectious diseases and novel imaging techniques in patient care and diagnostics.

**COURSE DESCRIPTION**

COURSE DESCRIPTION

Clue: This quiz show, created by Merv Griffin, features answers and questions, where contestants must respond in the form of a question.

Answer: What is “Jeopardy!”?

At RSNA 2024, get ready for two teams of elite subspecialty radiologists to face off using this popular and timeless quiz show format. Our notable teams will compete to answer clues across various infectious imaging categories in the body, brain, bones, and beyond! The interactive course will test and expand your knowledge of clinical cases of viral, bacterial, fungal, and parasitic infections. Rounds will include infections related to contagious diseases, pandemics, and tropical medicine, to name a few. Designed for students, residents, and experts in the field, this course provides a dynamic way to reinforce learning, encourage teamwork, and make mastering radiology both fun and memorable. This battle of the bugs will surely be an exciting 60 minutes of imaging modalities from head to toe, pathology identification, and a sprinkle of radiologic physics and trivia. Are you ready to play? Come join us and see if you become a Radiology Jeopardy champion.

## RSNA Deep Learning Lab: DIY Deep Learning: Programming Setup for Beginners (Beginner Friendly) (Registration Fee Required)

Sunday, Dec. 1 12:00PM - 1:00PM Room: DEEP LEARNING LAB

Kirti Magudia, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Establishing a Programming Environment: Participants will be able to set up a robust programming environment tailored for data science and deep learning, including proficiency with command line tools, Python, and package managers. 2) Managing Dependencies with Virtual Environments: Participants will learn to create and utilize virtual environments to manage project-specific dependencies, ensuring streamlined and conflict-free workflows for various data science projects. 3) Preparing Datasets for Deep Learning: By the end of the workshop, participants will be able to download, prepare, and preprocess datasets for deep learning experiments on their own computers, providing the necessary skills for flexible and independent AI development. You will need your own laptop computer to participate in this session. For the best experience, you should have administrator privileges on your laptop computer. You will also need a Google account.

**COURSE DESCRIPTION**

In this interactive session, you'll learn how to establish a robust programming environment tailored for data science and deep learning. We'll dive into command line tools, Python, and package managers to streamline your workflow, and demonstrate the power of virtual environments for managing project-specific dependencies. By the end of the workshop, you'll be equipped to download and prepare a dataset for a deep learning experiment on your own computer, giving you the flexibility and control needed for cutting-edge AI development.

You will need your own laptop computer to participate in this session. For the best experience, you should have administrator privileges on your laptop computer. You will also need a Google account.

## RSNA Deep Learning Lab: Basics of NLP in Radiology (Beginner Friendly) (Registration Fee Required)

Monday, Dec. 2 9:00AM - 10:00AM Room: DEEP LEARNING LAB

Jae Ho Sohn, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn to build basic NLP models in radiology, discussing preprocessing and model architectures, forming the foundation for more advanced NLP courses involving transformers. 2) Learn evaluation metrics and strategies for radiological NLP models. 3) Learn various potential applications of NLP in clinical radiology with hands-on coding.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

This session will feature a lecture introducing the basic technical concepts and clinical applications of natural language processing (NLP), highlight potential uses for it in radiology. The goal is to introduce standard text preprocessing techniques, NLP model training approaches, and model evaluation strategies that would be widely applicable and would form the basis for studying more advanced courses that use neural network and/or transformer based methods. We will follow up the didactic portion with a hands-on Google Colab demo implementing discussed concepts for a text classification task. For best experience, we highly recommend attendees bring a laptop with a keyboard as well as have a Gmail account to access Google Colab.

### LEARNING OBJECTIVES

1) Understand the genesis and development of the Medical Imaging and Data Resource Center (MIDRC). 2) Experience how to build your own data cohort for AI research using the MIDRC publication platform - Gen3. 3) Explore additional MIDRC resources.

### COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

The Medical Imaging Data and Resource Center (MIDRC) provides a model for collecting and publishing data to support research that can be applied across all areas of medical imaging. This session will give an overview of the structure of the MIDRC data commons, provide a tour of the open access data portal published on the Gen3 platform and discuss interoperability with other data commons including indexing with other imaging data commons. During this session, attendees will have the opportunity to experience how to build a selected data cohort direct from the MIDRC data commons for AI research.

**Sub-Events**

## RSNA Deep Learning Lab: Data Extraction from Radiology Reports with LLMs (Beginner Friendly) (Registration Fee Required)

Monday, Dec. 2 1:00PM - 2:00PM Room: DEEP LEARNING LAB

Walter F. Wiggins, MD,PhD (*Moderator*) Advisor, Qure.ai;

**LEARNING OBJECTIVES**

1) Understand the basics of prompt engineering and its application in extracting data from radiology reports using large language models (LLMs). 2) Gain hands-on experience with LLMs using an open-source computing platform to ensure data privacy. 3) Develop the ability to create and refine prompts that can accurately classify chest radiograph reports as normal or abnormal, enhancing skills in medical data analysis with LLMs.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

In this engaging, interactive tutorial, participants will learn the fundamentals of prompt engineering using an open-source library to deploy large language models (LLMs) on any computer, preserving data privacy. Using a dataset of chest radiograph reports, we will guide you step-by-step in developing a prompt that can reliably classify reports as normal or abnormal. Attendees must bring their own laptop computer (tablets will NOT provide an optimal experience) and have an active Google account. This session offers a valuable opportunity to gain hands-on experience and practical skills in applying LLMs to medical data extraction. No prior coding or machine learning experience is necessary.

## RSNA Deep Learning Lab: NCI Imaging Data Commons - Curated Data and Reproducible AI Workflows (Advanced) (Registration Fee Required)

Monday, Dec. 2 3:00PM - 4:00PM Room: DEEP LEARNING LAB

Andriy Fedorov, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn about the functionality of NCI Imaging Data Commons (IDC) related to selection and preparation of data cohorts for developing AI workflows. 2) Introduce the basic capabilities of IDC in support of development of reproducible AI workflows. 3) Experiment with the application of open source AI tools to public imaging datasets.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

NCI Imaging Data Commons (IDC), https://imaging.datacommons.cancer.gov , is a cloud-based environment of publicly available cancer imaging data co-located with the analysis and exploration tools and resources. IDC contains over 60TB of publicly available images and image annotations spanning a variety of cancer types and modalities. Attendees of this course will learn how to search, visualize and download IDC data, and how to build reproducible and shareable analysis workflows using Google Colab. The educational format will combine a lecture followed by a hands-on component and interactive discussions to gain familiarity with this resource.

**Sub-Events**

## RSNA Deep Learning Lab: Accessing Freely Available Public Datasets from The Cancer Imaging Archive (TCIA) (Beginner Friendly) (Registration Fee Required)

Tuesday, Dec. 3 9:00AM - 10:00AM Room: DEEP LEARNING LAB

Justin Kirby (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn how TCIA makes data sharing easier for researchers and hear a summary of existing datasets that are freely available for download. 2) Practice utilizing TCIA for data exploration, cohort definition, and downloading data. 3) Learn how to access public and restricted access datasets using TCIA's REST APIs and other command line tools via Jupyter Notebooks.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

Access to large, high quality data is essential for researchers to understand disease and precision medicine pathways, especially in cancer. However HIPAA constraints make sharing medical images outside an individual institution a complex process. The Cancer Imaging Archive (TCIA) is a public service funded by the National Cancer Institute which addresses this challenge by providing de-identification and data publication services to take major burdens of data sharing off researchers. TCIA has published over 200 unique data collections containing more than 70 million images. Recognizing that images alone are not enough to conduct meaningful research, most collections are linked to rich supporting data including patient outcomes, treatment information, genomic / proteomic analyses, and expert image analyses (segmentations, annotations, and radiomic / radiogenomic features). In this course we will address basic use cases for identifying TCIA datasets of interest and downloading them via command-line tools and Jupyter Notebooks.

## RSNA Deep Learning Lab: Developing and Implementing a 3D Segmentation Model - From DICOM to Deployment (Advanced) (Registration Fee Required)

Wednesday, Dec. 4 11:00AM - 12:00PM Room: DEEP LEARNING LAB

Evan D. Calabrese, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Have a basic understanding of how to curate and preprocess DICOM data. 2) Develop segmentation models from scratch using human-in-the-loop learning. 3) Deploy pre-trained segmentation models for their task of interest.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

This session will be focused on developing and deploying an image segmentation model starting from raw DICOM data. We will use DICOM data from the publicly available CURE.ai head CT dataset. We will briefly review key data curation and preprocessing steps including series conversion and normalization. Most of the session will focus on developing segmentation models using open-source tools with minimal user coding. We will highlight a human-in-the-loop learning approach using MONAI label. Participants will get hands on experience with image annotation in 3D slicer and real-time model training using cloud resources from AWS. Finally, we will discuss model deployment using the MONAI deploy. At the end of the session, participants will understand how to curate and preprocess DICOM data, develop segmentation models using human-in-the-loop learning, and deploy trained models for their task of interest.

## RSNA Deep Learning Lab: Quantifying Uncertainty in Deep Learning (Advanced) (Registration Fee Required)

Wednesday, Dec. 4 1:00PM - 2:00PM Room: DEEP LEARNING LAB

Bradley J. Erickson, MD, PhD (*Moderator*) Board of Directors, VoiceIt Technologies, LLC;Stockholder, VoiceIt Technologies, LLC;Board of Directors, FLOWSIGMA Inc;Officer, FLOWSIGMA Inc;Stockholder, FLOWSIGMA Inc;Officer, Yunu Inc;Stockholder, Yunu Inc

**LEARNING OBJECTIVES**

1) Recognize the role of uncertainty in AI applications. 2) Recognize the difference between raw AI model output, calibrated model output, and model uncertainty value. 3) Recognize the different forms of uncertainty quantification and see examples of how to implement UQ.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

This course will focus on understanding different types and sources of uncertainty in medical imaging, learning about model calibration and exploring various uncertainity quantification techniques. PyTorch and MONAI to be used for hands-on experience and will include implementing model ensembling, applying Monte Carlo Dropout and integrating conformal prediction methods into practical applications.

## RSNA Deep Learning Lab: Best Practices for Model Training: Architectures, Hyperparameters and Optimization (Advanced) (Registration Fee Required)

Wednesday, Dec. 4 3:00PM - 4:00PM Room: DEEP LEARNING LAB

Peter Chang, MD (*Moderator*) Co-founder, Avicenna.ai;Stockholder, Avicenna.ai;Research Grant, Canon Medical Systems Corporation;Speakers Bureau, Canon Medical Systems Corporation;Research Grant, General Electric Company

### LEARNING OBJECTIVES

1) Review top-performing convolutional neural network design choices and architecture motifs. 2) Develop heuristics for customizing model design based on specific medical imaging task. 3) Identify strategies for efficient hyperparameter search. Note: This session is completely new from the topic previously presented as part of the 2022-2023 RSNA Deep Learning Labs.

### COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

Deep learning models are characterized by a constant influx of new, innovative design choices. However, for any specific medical imaging task, it remains unclear how to best choose between different training strategies, from network topology to layer implementations (activation and normalization functions) to loss objectives and other permutations. In this session, we review top-performing design choices with a particular emphasis on developing heuristics for how to best customize model architectures and hyperparameters based on task-specific characteristics (e.g., image modality, anatomy, resolution and dimensionality, size and distribution of target pathology, class imbalance, etc). To help guide experimentation, a code repository is provided including a generic framework for rapid prototyping and model comparison to enable robust hyperparameter search. Though the presented key ideas generalize to many settings, this specific session will utilize demonstrations based on optimizing semantic segmentation using convolutional neural network (CNN) based architectures.

**Sub-Events**

**DLL14B** **RSNA Deep Learning Lab: Best Practices for Model Training: Architectures, Hyperparameters & Optimization**

## Insights on AI Governance, a Health System Approach (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 2 8:00AM - 9:00AM Room: N226

Brian Fox, MBA (*Moderator*) Nothing to Disclose
Keith Chew, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Outline various methodologies for deploying AI in clinical environments. 2) Evaluate the considerations, relative costs, benefits, and risks associated with each deployment method. 3) Understand the advantages of an AI platform for scaling AI deployment within a health system.

**COURSE DESCRIPTION**

Ensuring robust cybersecurity is crucial when deploying AI. This presentation will examine the three primary deployment models—cloud, private cloud, and on-site hardware—analyzing the cybersecurity advantages and disadvantages of each approach.

## Cardiac CT Mentored Case Review: Imaging the Heart: Imaging Techniques, Anatomy, and Function

Monday, Dec. 2 8:00AM - 9:00AM Room: E353C

Jacobo Kirsch, MD, MBA (*Moderator*) Medical Advisory Board, Zebra Medical Vision Ltd

**LEARNING OBJECTIVES**

1) To review the expected appearance of normal cardiac anatomy on CTA and the appearance of coronary artery pathologies beyond coronary artery disease. To learn technical strategies for a successful coronary CT scan.

**COURSE DESCRIPTION**

This course will provide the basis for recognizing normal appearance of cardiac structures on CTA. The concept on non-atherosclerotic coronary artery pathology will be introduced with several case examples of disease on CTA. Finally, the attendees will learn techncial tips and tricks on how to obtain ideal image quality on a coronary CTA study.

## HRCT Topics

Monday, Dec. 2 8:00AM - 9:00AM Room: E451A

Brett M. Elicker, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe recent advances in our understanding of the role of antifibrotic agents in progressive fibrotic lung diseases. 2) Recognize the broad spectrum of imaging manifestations of hypersensitivity pneumonitis. 3) Distinguish recurrent malignancy from malignancy-directed pulmonary radiation and drug toxicity on imaging.

**COURSE DESCRIPTION**

This session will focus on several advanced topics in the diffuse lung disease space. First, the role of imaging in progressive pulmonary fibrosis will be presented. This topic is particularly pertinent with the expansion of the use of anti-fibrotic agents to other diseases other than idiopathic pulmonary fibrosis. Additional topics presented will include the spectrum of imaging findings in hypersensitivity pneumonitis and the typical imaging manifestations of radiation and drug-induced lung disease in the setting of treated cancer.

## Multi-Energy CT in the ER: Where Are We in 2024?

Monday, Dec. 2 8:00AM - 9:00AM Room: N228

Savvas Nicolaou, MD, FRCPC (*Moderator*) Institutional research agreement, Siemens AG;Stockholder, Canada Diagnostic Centres

**LEARNING OBJECTIVES**

1) Understand the fundamental principles and technological advancements of multi-energy CT (MECT) imaging. 2) Identify the clinical indications and benefits of utilizing MECT in the emergency room setting. 3) Explore the role of MECT in expediting patient triage and treatment decisions in emergency radiology practice. 4) Discuss strategies for optimizing MECT protocols to enhance image quality and diagnostic confidence in acute musculoskeletal presentations. 5) Assess the potential challenges and limitations associated with implementing MECT technology in the emergency room environment.

**COURSE DESCRIPTION**

In this session, leading experts in Multi-Energy CT(MECT) imaging will discuss the evolving landscape of MECT imaging and its crucial role in diagnosing acute conditions affecting the head, neck, abdomen, and musculoskeletal system. Participants will gain valuable insights into the clinical applications of MECT, uncovering their potential to revolutionize emergency radiology practice. This comprehensive discussion aims to enhance understanding of the benefits, challenges, and future directions of MECT in the ER, empowering attendees to optimize patient care and decision-making in acute settings.

**Sub-Events**

## Colorectal Imaging

Monday, Dec. 2 8:00AM - 9:00AM Room: E451B

Kevin J. Chang, MD (*Moderator*) Speaker, RELX;Speaker, Koninklijke Philips NV

**LEARNING OBJECTIVES**

1) Get updated on the latest techniques to detect pathology in CT Colonography, stage rectal cancer by MRI, and evaluate treatment response on rectal MRI. 2) Learn about what has changed in the latest version of C-RADS.

**COURSE DESCRIPTION**

Colorectal cancer is the 2nd leading cancer killer in the US with incidence skyrocketing amongst younger patients, now also the leading cancer killer of men and 2nd leading cancer killer of women under the age of 50.

This 4 lecture session will teach the basics of staging and restaging rectal cancer by rectal MRI, illustrate how CT colonography (CTC) can diagnose challenging cases, as well as update the practicing radiologist on how to classify and manage CTC findings using the 2023 update of the C-RADS classification system.

**Sub-Events**

## Hip Imaging: The Fundamentals

Monday, Dec. 2 8:00AM - 9:00AM Room: E450A

Megan K. Mills, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn the imaging findings and appropriate reporting of tendon injuries about the hip.

2) Identify expected and unexpected postoperative imaging findings of frequently encountered surgical procedures of the hip.

3) Discuss the various diagnostic imaging markers of hip dysplasia and impingement morphology in the adult patient population.

**COURSE DESCRIPTION**

Hip Imaging: The Fundamentals session is an up-to-date lecture-based review of imaging of the hip with specific emphasis on femoroacetabular impingement, hip dysplasia, gluteal tendon pathology, hamstring tendon pathology, and hip arthroplasty imaging. Attendees will have the opportunity to learn about the latest multimodality radiologic findings of hip related disease process as well as practical reporting, relevant clinical and treatment details from content experts in the field.

## IgG4-related Disease from Head to Toe

Monday, Dec. 2 8:00AM - 9:00AM Room: S502

Ichiro Ikuta, MD, MMedSc (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Participants will learn to recognize the multi-system characteristic features and pitfalls of IgG4-related disease in neuroradiology, head and neck, cardiac, thoracic, gastrointestinal (GI), and genitourinary (GU) radiology. 2) Participants will learn the complimentary nature of multimodality imaging in IgG4-related disease across multiple body systems. 3) Participants will learn an appropriate differential diagnosis when the imaging characteristics overlap with other diseases along with clinically appropriate next steps.

**COURSE DESCRIPTION**

IgG4-related disease can affect multiple body systems. This course provides insights into characteristic imaging manifestations of IgG4-related disease "from head-to-toe" including neuroradiology, head and neck, cardiac, thoracic, gastrointestinal (GI), and genitourinary (GU) radiology. Multimodality imaging provides complimentary information for this multisystem disease, and can help guide clinical testing, surveillance, and impact patient care.

## Radiation and Medical Imaging: Best Practices for Communicating Risk

Monday, Dec. 2 8:00AM - 9:00AM Room: N227B

Cynthia H. McCollough, PhD (*Moderator*) Research Grant, Siemens AG

**LEARNING OBJECTIVES**

1) To understand the difficulties in discussing radiation and identify strategies to help the audience hear the right message. 2) To describe message maps and review several examples related to the use of radiation in medical imaging. 3) To recognize best practices for communicating with the media. 4) To experience examples of effective risk communication.

**COURSE DESCRIPTION**

While medical imaging can provide lifesaving medical care, the transfer of energy into human tissue can be associated with some level of risk to the patient. Not only are healthcare providers responsible for balancing the benefits of medical imaging with the potential risks, but they must also be able to effectively exchange information about the benefits and risks of medical imaging with patients, their families, the public, and other health professionals. The American Association of Physicists in Medicine created a Radiation and Medical Imaging Communication Guide to assist healthcare providers with this essential task. The educational content and sample questions and answers provided in the guide are intended to provide health professionals with the tools necessary for effective risk communication about the use of ionizing radiation in medicine. This course will review the difficulties in discussing radiation and identify communication strategies that can help the audience hear the right message. Speakers will describe the use of message maps when communicating about risk and summarize best practices when communicating with the media. The session will conclude with a series of role plays to demonstrate effective communication about radiation and medical imaging.

## A Profession Fit for the Future: Educating the Future Imaging Technologist/Radiographer Workforce (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 2 9:30AM - 10:30AM Room: N226

Charlotte Beardmore, MBA (*Moderator*) Nothing to Disclose
Nancy McDonald, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the challenges in supporting the future growth of the imaging technologists/ radiographer workforce to meet imaging services demands. 2)Discuss solutions being developed in US and UK in relation to evolving education pathways at entry and advancing levels. 3) Consider and understand how regulators, professional bodies, accrediting bodies, education and clinical providers are supporting new models of education and training.

**COURSE DESCRIPTION**

This course is for radiological technologists / radiographers and managers wishing to learn about the development of the profession. As technologies evolve, radiological technologists /radiographers will be required to develop their skills set, continuing to efficiently provide high quality compassionate patient care and safe delivery of imaging services to patients. The course will discuss the changing skills sets within imaging services and look at these skills sets from entry to advancing levels of practice. The speakers in this session from the UK and US, will deliver interactive lectures providing attendees with learning from both countries, and consider how both education and regulatory requirements are changing in order to support the rapidly changing clinical

## Landscape of AI in Current Clinical Breast Imaging Practice and Ethical Considerations

Monday, Dec. 2 9:30AM - 10:30AM Room: S406A

Emily F. Conant, MD (*Moderator*) Research Grant, Hologic, Inc;Advisory Panel, Hologic, Inc;Research Grant, OM1, Inc;Research Grant, iCad, Inc;Advisory Panel, iCad, Inc;Speaker, WebMD LLC

**LEARNING OBJECTIVES**

1) Describe artificial intelligence (AI) applications that may be used to optimize workflow by reducing interpretation and reporting time while maintaining or improving clinical outcomes. 2) Examine ethical challenges of artificial intelligence (AI) applications including conflicts of interest among radiologists, artificial intelligence (AI) algorithm developers, and patients. 3) Critically evaluate existing regulator frameworks for artificial intelligence (AI). 4) Identify potential barriers to the clinical implementation of artificial intelligence (AI).

**COURSE DESCRIPTION**

This educational session provides an in-depth exploration of artificial intelligence (AI) in contemporary breast imaging clinical practices. AI applications that can be used to optimize clinical workflow will be described. In addition, ethical considerations and challenges that arise when implementing AI into clinical practice and strategies to overcome these challenges will be discussed. Through lectures and a Q&A session, participants will gain a comprehensive understanding of the practical and ethical dimensions of implementing AI into breast imaging practices.

**Sub-Events**

### M3-CBR13B Workflow Improvements

Manisha Bahl, MD, MPH (*Presenter*) Consultant, Lunit Inc;Expert Advisory Committee, 2nd.MD

### M3-CBR13C Hurdles and Pitfalls of Clinical Implementation

## Cardiac CT Mentored Case Review: Coronary Atherosclerotic Disease: From Straightforward to Most Complicated

Monday, Dec. 2 9:30AM - 10:30AM Room: E353C

Michelle C. Williams, MBChB, PhD (*Moderator*) Speakers Bureau, Canon Medical Systems Corporation;Speakers Bureau, Siemens AG

**LEARNING OBJECTIVES**

1) To understand the significance and how to report cardiac calcifications on CT. 2) To develop skills to apply the CAD-RADS system to coronary CT. 3) To understand the range of information available from coronary CT and its clinical significance.

**COURSE DESCRIPTION**

To understand the significance and how to report cardiac calcifications on CT.

To develop skills to apply the CAD-RADS system to coronary CT.

To understand the range of information available from coronary CT and its clinical significance.

**Sub-Events**

### M3-CCA12B All You Need to Know About Cardiac Calcifications

Rozemarijn Vliegenthart, MD, PhD (*Presenter*) Institutional Research Grant, Siemens Healthineers Speaker's Bureau, Siemens Healthineers Speaker's Bureau, Bayer

### M3-CCA12C Coronary Atherosclerosis I: Approach to Atherosclerotic Plaque Analysis and Severity of Stenosis Assessment

## Role of Imaging in Disasters

Monday, Dec. 2 9:30AM - 10:30AM Room: N228

Mehmet Ruhi Onur, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Raise awareness about preparedness strategies and requirements for radiology departments in case of a disaster. 2) Provide attendees with the knowledge to contribute to disaster management plans of their hospitals. 3) Present imaging findings in natural, accidental, and violence-related disasters.

**COURSE DESCRIPTION**

Natural, accidental, and violence-related disasters are catastrophic incidents

that require accurate infrastructure capability, preparedness, and staff performance in emergency radiology units.

This course aims to present the essential requirements for a well-set-out response of emergency radiology units in various types of disasters such as earthquakes, bombings, hurricanes, and transportation accidents. Lecturers of the course will focus on the disaster preparedness planning of radiology departments including policy-making, managing imaging workup, organizing equipment and staff, and implementing interim processes to overcome challenges.

Attendees of the course will learn about the injury types and imaging findings related to disaster-related injuries, which are crucial for emergency radiologists in diagnosing and managing disaster victims.

## Mastering Imaging of Urothelial Cell Carcinoma

Monday, Dec. 2 9:30AM - 10:30AM Room: E353B

Antonio C. Westphalen, MD, PhD (*Moderator*) Shareholder, ScanMed, LLC;Research funded, BotImage, Inc
Danielle E. Kruse, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify and describe the imaging features of atypical and aggressive histology in urothelial cell carcinoma, enhancing their diagnostic capabilities. 2) Evaluate gaps in current imaging guidelines for urothelial cell carcinoma and apply expanded imaging utilization practices to improve patient outcomes. 3) Understand the diagnostic accuracy and potential pitfalls of VI-RADS and will explore new applications of imaging techniques in the management of urothelial cell carcinoma.

**COURSE DESCRIPTION**

This educational session provides a comprehensive overview of the latest advancements and challenges in imaging urothelial cell carcinoma. The session will cover imaging features of atypical and aggressive histologies, the expanding role of imaging in clinical practice, and the diagnostic accuracy and pitfalls of VI-RADS. Additionally, new applications of imaging techniques will be discussed. Through a combination of lectures and discussions led by experts in the field, attendees will gain valuable insights and practical knowledge to improve diagnostic accuracy and patient outcomes. This session is essential for radiologists and clinicians seeking to stay updated on cutting-edge imaging practices in urothelial cell carcinoma.

## Cranial Nerve Deficits - A Symptom Based Session

Monday, Dec. 2 9:30AM - 10:30AM Room: E352

Nikdokht Farid, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Select the appropriate imaging algorithm for patients presenting with diplopia, trigeminal neuralgia, and facial weakness. 2) Identify the common causes of diplopia, trigeminal neuralgia, and facial weakness.

**COURSE DESCRIPTION**

In this clinical correlation didactic head and neck imaging session, speakers will review the imaging evaluation and common causes of diplopia, trigeminal neuralgia, and facial weakness. Speakers will emphasize search patterns, pitfalls of interpretation to avoid, and relevant clinical management considerations with which radiologists should be familiar. This session offers attendees the opportunity to refine their interpretation of complex head and neck imaging studies by incorporating tips from world experts.

M3-CIR03

## Musculoskeletal Interventions – Fixation and Augmentation Procedures

Monday, Dec. 2 9:30AM - 10:30AM Room: S405

Ernesto G. Santos Martin, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understanding of pathologic fractures of the pelvis and patient selection for percutaneous approach. 2) Importance of combined therapies in patients with pathologic fractures of the pelvis: ablation, RT, augmentation and screw fixation. 3) Learn about complications and their management after MSK interventions.

**COURSE DESCRIPTION**

In this educational session, participants will dive into the world of the percutaneous treatment in patients with pathologic fractures of the pelvis. These fractures pose a unique challenge for orthopedic surgery and traditional open approaches may not be possible in patients with bone metastases. IR should be a key component of multidisciplinary bone metastases team. Percutaneous treatments can offer a minimally invasive alternative with promising outcomes. Learners will be familiar with the current minimally invasive percutaneous options and how to combine different techniques, including ablation, embolization, cement augmentation and screw fixation.

This session will combined lectures and interactive discussions to provide a comprehensive understanding of augmentation and screw fixation and their combination with radiation therapy. Participants will also have the opportunity of discussing indications, contraindications and potential complications and review the current research and future directions in the field.

By the end of the course, participants will:

- Gain proficiency in the field of minimally invasive image-guided interventions in patients with pathologic fractures of the pelvis

- Advantages and disadvantages of this approach

- Review evidence-based conceptual and technological paradigm shifts in percutaneous treatment strategies for this patient population

- Integration of augmentation and percutaneous fixation into clinical practice.

Join us for an engaging and informative course on advance percutaneous interventions in patients with pathologic fractures of the pelvis

## Musculoskeletal Tumor Imaging: Current Trends and Recent Advances

Monday, Dec. 2 9:30AM - 10:30AM Room: E450A

Shivani Ahlawat, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Discuss key diagnostic features of imaging of musculoskeletal malignancies to differentiate benign vs malignant etiologies and to distinguish tumor mimics. 2) Explain current trends and recent advances in musculoskeletal tumor imaging evaluation to assist in accurate diagnosis and management.

**COURSE DESCRIPTION**

This session discusses benign and malignant features of musculoskeletal malignancies including differentiating tumors from tumor mimics. Important features to distinguish lipoma vs ALT/WDL, encondroma vs chondrosarcoma and benign vs malignant PNST will be described during and key features of SoftTissue-RADS will be reviewed during the lectures. The expected outcome is for participants to gain a better understanding of the current trends and advances in musculoskeletal tumor imaging.

**Sub-Events**

## Planetary Health and Radiology: Actionable Steps to Decrease Our Environmental Impact (Sponsored by the RSNA Professionalism Committee)

Monday, Dec. 2 9:30AM - 10:30AM Room: S501

Kate Hanneman, MD, MPH (*Moderator*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Reed A. Omary, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe the intersection of planetary health and radiology including energy and non-energy related environmental impacts. 2) Discuss key actionable strategies to reduce electricity and energy use in radiology and potential impact. 3) Discuss of key actionable strategies to reduce our environmental impact beyond energy in radiology including reducing waste and environmental waterbody contrast contamination. 4) Explore the impact of climate change on patient outcomes and the delivery of radiology services and describe the need to prepare for these effects including infrastructure upgrades, disaster management protocols, and education on changing disease patterns.

**COURSE DESCRIPTION**

The overarching purpose of this course is to discuss the intersection of planetary health and radiology and describe actionable steps we can take to decrease the environmental impact of radiology.

**Sub-Events**

## Pediatric Neuroimaging: You Don't Want To Miss This!

Monday, Dec. 2 9:30AM - 10:30AM Room: E350

Thierry Huisman, MD, PhD (*Moderator*) Nothing to Disclose
Birgit B. Ertl-Wagner, MD, PhD (*Moderator*) Spouse, Employee, Siemens AG

### LEARNING OBJECTIVES

1) Know the pearls and pitfalls of interpreting imaging of children with suspected spine trauma and identify critical injuries outside the CNS associated with spinal trauma. 2) Differentiate focal cerebral arteriopathy of childhood and understand the use of vessel wall imaging in these conditions. 3) Explain the typical neuroimaging features of important metabolic disorders in children.

### COURSE DESCRIPTION

This session will provide an overview of some of the most important and challenging topics in pediatric neuroimaging, with an emphasis on practical and clinical implications. The speakers will share their expertise and experience in the following areas: Spine trauma in children: how to avoid missing critical injuries and complications; pediatric stroke and focal cerebral arteriopathy of childhood; metabolic disorders affecting the brain: how to recognize and differentiate them on neuroimaging. The session will include case-based presentations and key take-home messages for the attendees. Attendees will gain confidence in making diagnoses in pediatric neuroimaging that they really don't want to miss.

## Empowering Health: Bridging the Gap with Population Health, Patient Advocacy and Quality Access in Medical Imaging (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 2 11:00AM - 12:00PM Room: N226

Napapong Pongnapang, BSc, PhD (*Moderator*) Nothing to Disclose
Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Examine key strategies and challenges integral to ensuring equitable access to healthcare, with a specific emphasis on the dynamics of population health. 2) Discuss the crucial role of patient advocacy and describe actionable strategies for community empowerment. 3) Identify opportunities to enhance professional capabilities for quality access in the specific context of low-resourced regions.

### COURSE DESCRIPTION

This session will explore the vital realm of patient advocacy, unravelling its significance in shaping the landscape of medical imaging practices. The speakers will examine contributing factors to health disparities both within the United States and on a global scale and highlight the transformative role of strategic patient advocacy in fostering community engagement and empowerment. The speakers will also consider professional capabilities, quality access, and the specific context of low-resourced regions. Through a discussion of real-world initiatives that have successfully addressed and mitigated health disparities, this session will help participants identify concrete solutions aimed at enhancing access to care for diverse communities, fostering a more inclusive and responsive healthcare landscape.

## Vision-Language Generative Models for Radiology: A Quick Introduction and Current State-of-the-Art

Monday, Dec. 2 11:00AM - 12:00PM Room: E450B

Amara Tariq, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Introduce fundamental concepts of vision-language modeling. 2) Explain current applications of vision-language modeling in the domain of radiology. 3) Discuss future directions for vision-language modeling for radiology data.

**COURSE DESCRIPTION**

In this session, the audience will be introduced to state-of-the-art vision-language models (VLM) and their application in the field of radiology through a series of lectures from four experts. VLMs are designed to jointly process visual and textual data and have shown astounding performance for challenging tasks like information retrieval and generation such as caption or image generation. Such models tend to outperform image-only models for zero-shot detection and diagnosis using radiology images. Expert speakers will introduce the fundamentals and describe their latest work in VLM.

## What Happened to the Radiology Department: Exploring the Relationship of People, Place and Performance (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 2 1:30PM - 2:30PM Room: N226

Meena Amlani, PhD, MBA (*Moderator*) Nothing to Disclose
Morris A. Stein, BArch (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Discuss the impact and opportunity for radiology design from physical, social and digital perspectives. 2) Understand the advantages and disadvantages of centralizing vs. decentralizing imaging while embracing new technologies. (Digital Health, AI, Model Guided Medicine) to futureproof imaging designs. 3) Participants will be able to understand how a Central Command Suite for a "Hospital of the future" can improve multidisciplinary coordination and personalized care.

**COURSE DESCRIPTION**

As healthcare delivery trends continue to evolve rapidly, so must our approach for imaging planning and functional expectations. Historical patterns and relationships may no longer be most effective or efficient. New models provide a timely opportunity to rethink the how and where we connect patient experience and radiologist/staff performance.

## Thoracic Multidisciplinary Tumor Board Meeting

Monday, Dec. 2 1:30PM - 2:30PM Room: E451A

Jane P. Ko, MD (*Moderator*) Research collaboration, Siemens AG

### LEARNING OBJECTIVES

1) Review current therapies for thoracic malignancy treatment related to surgery, radiation, and thoracic oncology.

2) Emphasize challenges in diagnosis and treatment of thoracic malignancy and important imaging features that aid in clinical management decisions.

3) Discuss expected imaging manifestations after therapy and identify complications.

### COURSE DESCRIPTION

This session will cover management decisions that are encountered in the multidisciplinary care of patients with thoracic malignancy, including lung cancer. Evaluation of thoracic malignancy patients span multiple modalities and organ systems and is a crucial contributing determinant for diagnostic and therapeutic decisions. Awareness of the radiology consultant of current techniques and potential complications associated with treatment of thoracic malignancy pertaining to surgery, radiation, and thoracic oncology is important. Emphasis will also be placed on important information on chest imaging that aids referring clinicians in the diagnosis, planning for therapy, and surveillance. The attendee will gain knowledge that they would be able to apply through participation in tumor boards and in daily clinical practice.

## Non-Traumatic Thoracic Emergencies

Monday, Dec. 2 1:30PM - 2:30PM Room: N228

Nupur Verma, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the role of CCTA in evaluation of patients with acute chest pain, parameters for use of CCTA, and limitations. 2) Review acute aotic syndrome diagnosis as they may present in patients with chest pain symptoms and describe imaging classification for radiology reporting. 3) Describe findings in chest infections of fungal pathology, considering endemic and special populations as well as associated risk factors.

**COURSE DESCRIPTION**

The lectures in the session will focus on crucial diagnoses in non-traumatic acute aortic syndromes, fungal infections, and CCTA in the emergency department. Concepts of critical imaging features, accurate and clinically relevant reporting, and strategies to overcome diagnostic challenges in the emergency setting will be emphasized.

**Sub-Events**

## Case-Based Imaging Review

Monday, Dec. 2 1:30PM - 2:30PM Room: E451B

Douglas S. Katz, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) To review several emergency diagnoses which can be identified on abdominal and pelvic ultrasound, with differential diagnoses if appropriate. 2) To discuss the differential diagnosis of peritoneal disease on cross sectional imaging. 3) To review current imaging findings of pancreatic tumors including with dual energy CT. 4) To understand the incidence of common and less common liver tumors and their imaging findings.

**COURSE DESCRIPTION**

Case-based abdominal imaging session with 4 topics covering acute diagnoses of miscellaneous etiologies in the abdomen and pelvis, liver tumors which are uncommon and more common, peritoneal disease, and pancreatic tumors. The experienced faculty will make relevant teaching points sharing cases from their institutions, with briefs reviews of the relevant literature.

## Best Practices for AI Model Creation (Multi-modal (image+text) AI Model Development and Interpretation)

Monday, Dec. 2 1:30PM - 2:30PM Room: E450B

Hari Trivedi, MD (*Moderator*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;

### LEARNING OBJECTIVES

1) Develop robust AI models that integrate multi-modal data (image and text) for enhanced clinical decision-making. 2) Understand the role of public-private partnerships in the validation and deployment of AI models within healthcare settings. 3) Implement advanced evaluation techniques to assess the performance, trustworthiness, and clinical applicability of AI models beyond traditional metrics.

### COURSE DESCRIPTION

This course is designed to attendees with insights into the development and interpretation of multi-modal AI models. Topics include practical approaches to building robust AI models, the latest advancements in vision-language generative models for radiology, advanced evaluation metrics for AI performance and trustworthiness, and the validation of commercial AI models through public-private partnerships. Participants will gain a deeper understanding of the best practices for creating and implementing ethical, reliable, and clinically useful AI models in healthcare.

**Sub-Events**

**M6-CIN14B** **Public-Private Partnerships in AI Validation: A Comprehensive Review of Evidence from Commercial Models**

## Management of Portal Hypertension

Monday, Dec. 2 1:30PM - 2:30PM Room: E352

David C. Madoff, MD (*Moderator*) Advisory Board, Zimmer Biomet Holdings, Inc;Consultant, General Electric Company;Consultant, Guerbet SA;Consultant, Merck & Co, Inc;Consultant, Sirtex Medical Ltd;Consultant, Boston Scientific Corporation;Consultant, Johnson & Johnson;Consultant, Siemens AG

### LEARNING OBJECTIVES

1) Understand the Etiology and Pathogenesis of Portal Hypertension: Grasp the underlying causes and mechanisms of portal hypertension. Review current medical management strategies for portal hypertension. 2) Explore the Role of Interventional Radiology (IR): Identify the options and indications for IR in the management of portal hypertension. Discuss the benefits and limitations of various IR techniques. 3) Learn Advances in TIPS/DIPS Procedures: Understand the latest techniques for access and guidance in TIPS/DIPS. Manage postprocedural care and complications associated with TIPS/DIPS. 4) Management of Non-TIPS Portosystemic Shunts: Review the techniques and indications for mesocaval shunts and variceal embolization. Compare and contrast these methods with TIPS/DIPS procedures. 5) Handle Complications in Portal Hypertension Interventions: Identify potential complications during portal hypertension interventions. Develop strategies for managing complications, including prevention and treatment approaches.

### COURSE DESCRIPTION

This course offers an in-depth exploration of portal hypertension, a common and serious condition in patients with liver cirrhosis and other liver diseases. It provides a comprehensive understanding of the disease's etiology, pathogenesis, and medical management, followed by a detailed examination of the role of Interventional Radiology (IR) in treating this condition. Attendees will gain insights into various IR techniques, including Transjugular Intrahepatic Portosystemic Shunt (TIPS) and Direct Intrahepatic Portocaval Shunt (DIPS), as well as the management of other portosystemic shunts and variceal embolization. The course will also cover the complications that can arise during these interventions, providing strategies for managing both successful outcomes and potential disasters.

**Sub-Events**

### M6-CIR09B Disease Etiology, Pathogenesis and Medical Management

Abhishek Kumar, MD (*Presenter*) Speaker, Boston Scientific Corporation

### M6-CIR09C Role of IR in the Management of Portal Hypertension - Options and Indications

## RSNA Hands-On Lab: Musculoskeletal Ultrasound Workshop: Ankle and Foot (Registration Fee Required)

Monday, Dec. 2 2:00PM - 3:30PM Room: S504CD

Linda Probyn, MD (*Moderator*) Nothing to Disclose
Viviane Khoury, BSc, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review anatomy and ultrasound imaging techniques for evaluation of the ankle and foot. 2) Describe useful dynamic imaging techniques to enhance assessment of the ankle and foot. 3) Discuss ultrasound imaging of common pathologic musculoskeletal conditions at the ankle and foot.

**COURSE DESCRIPTION**

This session will review an approach to ultrasound of the ankle and foot.

Part 1: There will be a hands-on demonstration by an instructor showing an approach to ultrasound examination of the ankle and foot. This will include assessment of the tibiotalar joint, extensor, flexor, peroneal tendons, Achilles tendon, ligaments (ATFL, PTFL, calcaneofibular ligament, deltoid ligament, spring ligament), subtalar joint, plantar fascia, neurovascular structures with dynamic maneuvers.

This will be followed by a brief presentation highlighting common pathologic musculoskeletal conditions about the ankle and foot that are seen on ultrasound.

Part 2: Participants will be divided into small groups and will practice an approach to ultrasound of the ankle and foot on a model with an instructor teaching the participants.

Proper patient positioning will be shown. Tips on how to optimize ultrasound imaging to best evaluate the area of concern will be reviewed and discussed. Participants will have an opportunity to practice these skills and techniques.

Time is allocated for questions and answers.

## Masterclass in the Multidisciplinary Management of Gliomas

Monday, Dec. 2 1:30PM - 2:30PM Room: S406B

Suyash Mohan, MD (*Moderator*) Research Grant, NovoCure Ltd;Research Grant, Galileo CDS, Inc;Consultant, Northwest Biotherapeutics, Inc;Consultant, AIRS Medical Inc;Consultant, Qynapse SAS

**LEARNING OBJECTIVES**

1) Review the progress in the war on cancer with impact of tumor treating fields, new/targeted therapies including IDH inhibitors, in the age of genomics and immuno-oncology. 2) Discuss role of extent of resection, clinically relevant molecular markers, and value of providing percentage of viable tumor in the resected specimen. 3) Illustrate role of advanced neuroimaging techniques and AI-methods to differentiate tumor progression from treatment related changes.

**COURSE DESCRIPTION**

Join us to stay at the forefront of brain tumor diagnosis and treatment - to improve patient outcomes through integrated, multidisciplinary care. Led by renowned experts in the field, this masterclass offers an interactive 'case-based' session discussing how to approach brain tumors as a team. This advanced course will showcase how radiologists can tailor their reports and imaging assessment to what is relevant for clinical decision making. Participants will also have the opportunity to network with peers and leaders, fostering collaboration and knowledge sharing.

**Sub-Events**

### M6-CNR11B TMZ to TTFields and Beyond: Progress in "The War on Cancer"

Roger Stupp, MD (*Presenter*) Research Consultant, Carthera;Research Grant, Carthera;Scientific Advisory Board, Alpheus Medical Inc;Scientific Advisory Board, Hemispherian AS;Consultant, GT Medical Technologies, Inc;Consultant, Triact Therapeutics Inc;Research Consultant, AstraZeneca PLC;Research Consultant, Boston Scientific Corporation

## Endometriosis 2024 Updates

Monday, Dec. 2 1:30PM - 2:30PM Room: E353B

Myra K. Feldman, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe US scanning maneuvers recommended by the SRU consensus to improve sensitivity of routine pelvic US for detection of endometriosis. 2) Analyze augmented ultrasound images for direct and indirect imaging findings of endometriosis. 3) Evaluate pelvic MR studies and report high-yield findings that impact surgical decision-making. 4) Identify common pitfalls and mimics of endometriosis on pelvic imaging studies.

**COURSE DESCRIPTION**

This course will review important concepts in endometriosis imaging including a summary of the recently published Society of Radiologists in Ultrasound (SRU) consensus paper on routine pelvic ultrasound for endometriosis detection, important findings to report on pelvic MR studies for endometriosis that will impact treatment planning, and common pitfalls and endometriosis mimics on both ultrasound and MR.

## Emerging Technologies Integrating Imaging into Radiotherapy

Monday, Dec. 2 1:30PM - 2:30PM Room: S404

Tokihiro Yamamoto, PhD (*Moderator*) Nothing to Disclose
Gregory C. Sharp, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Recognize the rationale, opportunities, and challenges of the current and emerging technologies integrating imaging into radiotherapy. 2) Identify the current and emerging applications of these technologies to treatment planning, delivery, adaptation, and response assessment. 3) Promote collaboration among radiologists, radiation oncologists, and medical physicists in research and clinical applications of these technologies.

**COURSE DESCRIPTION**

Imaging plays a crucial role in radiotherapy (RT) and various imaging technologies, methods, and biomarkers have been increasingly integrated into RT for investigational and clinical use in treatment planning, delivery, adaptation, and response assessment. Photon RT delivery systems combined with x-ray imaging systems have become widespread and critical for i mage-guided RT. The recent advent of MR-guided RT (MRgRT) systems, combining an MRI system with an RT delivery system, has provided new capabilities, including real-time image guidance and treatment adaptation. Biology-guided RT (BgRT) system, combining a PET system with an RT delivery system, has enabled synchronizing PET signals from tumors with RT delivery to direct treatment with sub-second latency. Imaging is also a topic of growing importance in particle RT for accurate prediction of stopping-power ratios and for in-vivo verification of treatment delivery. Moreover, functional/biological imaging has been increasingly utilized to guide RT (for example, to selectively increase dose to subvolumes within the target exhibiting a specific phenotype or to selectively avoid irradiating radiosensitive subvolumes or substructures within the organ at risk) and to assess therapy response in cancer patients. This educational course seeks to bring together a diverse group of experts in radiology, radiation oncology, and medical physics to review and discuss the current and emerging technologies integrating imaging into RT, with a view to promote and accelerate collaboration in this rapidly evolving field.

## AAPM/RSNA Basic Physics Lecture for the RT: MRI Safety

Monday, Dec. 2 1:30PM - 2:30PM Room: N227B

Samuel A. Einstein, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify strategies to investigate and characterize foreign bodies in a patient who is scheduled to have an MRI exam. 2) Understand the risks associated with exposing patients with foreign bodies to static magnetic fields, time-varying gradient fields, and time-varying radiofrequency fields in MRI.

**COURSE DESCRIPTION**

Ferromagnetic implants and foreign bodies are known to pose a potential risk for MRI system-related accidents and injuries to patients. However, the magnitude of the risk of performing an MRI exam is not always clear when a poorly characterized foreign body is discovered during patient screening or, in some cases, once the exam has begun. This lecture will discuss how to assess risks of imaging patients with foreign bodies. Following this session, participants will be familiar with strategies to characterize foreign bodies and assess the risks they pose in an MRI environment. This knowledge will aid participants in communicating risk to help determine whether a patient with a foreign body should proceed with their MRI exam and if additional precautions are necessary.

**Sub-Events**

**M6-CPH15B** **Assessing Risks for Patients with Foreign Bodies in MRI**

## Independent Clinical Practice and Quality of Care in Interventional Oncology

Monday, Dec. 2 1:30PM - 2:30PM Room: S401

Andreas Adam, FRCR, DSc (*Moderator*) Institutional research support, Boston Scientific Corporation;Institutional research support, Siemens AG;Institutional research support, Medtronic plc

### LEARNING OBJECTIVES

1) To learn how quality assurance improves patient care in interventional oncology. 2) To understand how radiation oncology raised its standards of care by applying quality assurance principles and the lessons applicable to interventional oncology. 3) To understand how the application of quality assurance principles can help to make interventional oncology a mainstream oncological discipline.

### COURSE DESCRIPTION

This session will demonstrate how the application of quality assurance principles can raise standards of patient care and help interventional oncology to become a mainstream discipline in cancer care.

**Sub-Events**

### M6-RCP22B How Quality of Care Is Assured in Radiation Oncology and Why This Is Also Applicable to IO

Lizbeth Kenny, MD, FRANZCR (*Presenter*) Consultant, GenesisCare

## Contrast Enhanced Mammography Development and Implementation (Supported in part by an Unrestricted Medical Education Grant from GE Healthcare, Inc.)

Monday, Dec. 2 3:00PM - 4:00PM Room: S406A

Janice S. Sung, MD (*Moderator*) Research Grant, General Electric Company

**LEARNING OBJECTIVES**

1) Review how to perform contrast enhanced mammography (CEM) and considerations when starting a CEM program. 2) Discuss the emerging roles of contrast enhanced mammography in both the screening and diagnostic settings.

**COURSE DESCRIPTION**

Contrast enhanced mammography (CEM) is an FDA approved technique that is emerging as an alternative vascular based technique to conventional breast imaging and MRI in both the screening and diagnostic settings. This session will review considerations in beginning a CEM program and review data supporting the use of CEM in both the screening and diagnostic settings.

## Emergency Radiology Practice Management 2024: Managing Productivity and Wellness: Dialectical Dilemma or Zero Sum Game?

Monday, Dec. 2 3:00PM - 4:00PM Room: N228

Suzanne T. Chong, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Discuss the physiology of nocturnal and diurnal work. 2) Describe features and staffing benefits of a successful overnight radiology service. 3) Understand the importance of real time objective operational data in structuring and monitoring an emergency radiology service. 4) Review key performance indicators which can be useful for the management of an emergency radiology practice and help inform staffing decisions. 5) Understand wellness and impact on individual and organizational success. 6) Discuss evidence-based burnout mitigation strategies.

**COURSE DESCRIPTION**

Optimizing the value chain of emergency radiology while also attending to radiologists' wellbeing can result in maximal performance and productivity. In this practice management session, we explore physiological reasons behind why some radiologists find enhanced job satisfaction working overnight and discuss practice features that attract night radiologists. We familiarize you to inward and outward facing data, dashboards, and key performance indicators to assist in the creation and maintenance of a successful emergency radiology practice. We discuss evidence-based burnout mitigation strategies that can be implemented in your practices to re-energize your emergency radiologists who may be struggling with job satisfaction in the face of relentless shift intensity and imaging volumes. At the conclusion of this session, you will feel a sense of renewed optimism and vigor for managing your emergency radiologists and have discrete tools to help you manage your emergency radiology practice for both productivity and enhanced wellness.

## Sinus Pressure: All About Those Painful Paranasal Sinuses

Monday, Dec. 2 3:00PM - 4:00PM Room: E352

Kristen L. Baugnon, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review sinonasal anatomy as relevant to imaging. 2) Understand the imaging algorithm and search patterns for patients presenting with sinus disease and how to differentiate benign from malignant entities. 3) Understand the clinical and surgical implications of imaging findings in the paranasal sinuses.

**COURSE DESCRIPTION**

In this Head and Neck session devoted to the paranasal sinuses, attendees will review the imaging approach and will be presented with clinical case examples of patients with benign and malignant sinus disease. Attendees will also review the imaging anatomy as well as how to identify and convey key imaging information to the sinus surgeons. Speakers will emphasize pearls for imaging evaluation and differentiating each entity from common mimics, pitfalls of interpretation to avoid, and relevant clinical management considerations with which radiologists should be familiar. This session offers attendees the opportunity to refine their interpretation of complex head and neck imaging studies by incorporating tips from world experts.

**Sub-Events**

### M7-CHN06B Anatomy

Marin A. McDonald, MD, PhD (*Presenter*) Speakers Bureau, Canon Medical Systems Corporation

### M7-CHN06C Benign Sinus Disease

Greg D. Avey, MD (*Presenter*) Research Consultant, General Electric Company

## Best Practices for AI Model Regulation and Human-AI interaction (Supported in part by an Unrestricted Medical Education Grant from Siemens Healthineers of Siemens Medical Solutions, USA, Inc)

Monday, Dec. 2 3:00PM - 4:00PM Room: N227B

Susanne Gaube, PhD, MSc (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn how the FDA views clear communication regarding the design and limitations of a product as an essential component of its safe and effective use. 2) Understand different paradigms to study human-AI interaction and identify appropriate evaluation methods. 3) Know about the different options of how AI results may be returned in the workflow and understand the implications of the choice of integration.

**COURSE DESCRIPTION**

This session provides an overview of regulatory considerations for AI/ML-enabled radiological devices and showcases the importance of understanding how users interact with these types of products. First, we will provide a brief overview of the FDA authorization process for AI/ML-enabled products and discuss the role human factors play in the premarket review and regulation of these types of devices, as well as their importance across the product lifecycle. We will then examine key radiologist-specific considerations, such as automation bias, deskilling, and education, and how these factors influence both user experience and performance & safety in AI/ML-enabled medical devices. Next, examples of different paradigms and methodologies that can be used to investigate various aspects of human-AI interaction and how AI/ML-generated advice affects clinical decision-making will be explored. Then, we will see how AI algorithms are brought to clinical routine use and how they impact clinical operations, what challenges were observed, and what lessons have been learned from projects in recent years. This session equips participants with practical knowledge for navigating AI model regulation from a human factors perspective, the role of and best practices for evidence-based user testing, and provides examples of AI-enabled products to help participants better understand how users interact with these technologies in clinical settings.

**Sub-Events**

**M7-CIN09B** **Artificial Intelligence in Radiology: Transparency in Design and Use of Medical Devices**

## Shoulder Imaging in the Athlete

Monday, Dec. 2 3:00PM - 4:00PM Room: E450A

Reto Sutter, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe how to best evaluate sports injuries of the rotator cuff, the labrum and the articular cartilage of the shoulder. 2) Identify the key imaging findings seen in shoulder instability. 3) Know how to evaluate imaging of the shoulder after rotator cuff surgery and instability surgery.

**COURSE DESCRIPTION**

State-of-the-art imaging is crucial for assessing shoulder injuries in athletes, and in recent years there have been many new insights and technological developments on how to image the shoulder. This course covers both the basics and new knowledge about imaging the rotator cuff, the labrum and articular cartilage, as well as imaging of shoulder instability. In addition, post-operative imaging will be discussed with lectures on the post-operative rotator cuff and shoulder instability surgery.

**Sub-Events**

## The Future of DEI: A Leadership Perspective to Challenges and Opportunities (Sponsored by the RSNA Health Equity Committee and the RSNA Committee on Diversity, Equity and Inclusion)

Monday, Dec. 2 3:00PM - 4:00PM Room: S402

Efren J. Flores, MD (*Moderator*) Speaker, WebMD LLC;Speaker, Consulting Medical Associates, Inc
Lucy B. Spalluto, MD, MPH (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Prioritize DEI values and goals are infused across the organization and identify areas of needs. 2) Using evidence-based practices address diversity gaps and the impact of unconscious bias across our radiology profession. 3) Collaborate with historically and currently marginalized groups to bolster pipeline efforts and deliver equitable care. 4) Establish a leadership vision and foster collaborations with national organizations to promote sustainability in DEI efforts. This session will include a 15-minute Q&A session with the audience.

### COURSE DESCRIPTION

Diversity, Equity & Inclusion (DEI) are key priorities to the future of our radiology practices aimed to deliver the best care to all patients, while fostering a sense of belonging among all patients and radiology professionals at all levels. Although new opportunities have risen over the past few years to advance the DEI goals and mission, the current environment has resulted in unexpected challenges that may impact the commitment to advance these goals. In alignment with RSNA's commitment to advancing Diversity, Equity, Inclusion & Belonging (DEIB), it is paramount that radiologists are equipped with the necessary knowledge toolkit to navigate emerging challenges and foster opportunities that advance the DEIB goals. The goal of this session is to provide radiologists with a leadership perspective on how to successfully advance DEI goals in the current environment and to overcome emerging barriers in the future.

**Sub-Events**

### M7-CNPM06C Supporting the DEI Mission at the National and Organizational Level

Maureen P. Kohi, MD (*Presenter*) Nothing to Disclose

### M7-CNPM06D Developing a DEI Vision for Sustained Commitment at an Integrated Health System

Matthew D. Bucknor, MD (*Presenter*) Nothing to Disclose

## Emergencies in Pediatric Radiology

Monday, Dec. 2 3:00PM - 4:00PM Room: E350

Ali Pourvaziri, MD, MPH (*Moderator*) Nothing to Disclose
Francisco A. Perez, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn appropriate imaging indications for pediatric emergencies. 2) Identify important imaging findings in the pediatric emergency setting.

**COURSE DESCRIPTION**

This course will provide an overview of pediatric emergencies, including neck, gonadal and abdominal emergencies through four lectures. The presentations will include key diagnoses to know in the emergency setting, as well as appropriate imaging modalities based on clinical scenarios. The outcome of the session will be improved understanding of pediatric emergency imaging.

**Sub-Events**

## Best of AAPM Summer School: Chicago Fireside Chat - Radiopharmaceutical Therapy

Monday, Dec. 2 3:00PM - 4:00PM Room: S404

Vrinda Narayana, PhD (*Moderator*) Nothing to Disclose
Robert Hobbs, PhD (*Presenter*) Nothing to Disclose
Roger W. Howell, PhD (*Presenter*) Nothing to Disclose
Joseph O'Donoghue, PhD (*Presenter*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Develop and implement a comprehensive radiopharmaceutical therapy program. 2) Understand the principles and applications of radiopharmaceutical dosimetry in patient care. 3) Recognize and utilize QA tools to maintain high standards in radiopharmaceutical therapy programs.

### COURSE DESCRIPTION

Radiopharmaceutical therapy is an increasingly significant field in medical treatment, offering targeted solutions for various conditions. This interactive course, modeled on the AAPM Summer School curriculum, is designed to educate both new and experienced practitioners on the essential components of establishing and maintaining an effective radiopharmaceutical therapy program.

Participants will engage in dynamic Q&A sessions, allowing for a deeper understanding and practical application of key concepts. The course will cover:

• Program Setup: Step-by-step guidance on developing and implementing a comprehensive radiopharmaceutical therapy program, including infrastructure, regulatory compliance, and safety protocols.

• Dosimetry: An exploration of radiopharmaceutical dosimetry principles, enabling participants to analyze dosimetric data, optimize treatment plans, and enhance therapeutic outcomes.

• Quality Assurance (QA): Identification and utilization of QA tools, adherence to standardized protocols, and alignment with International Commission on Radiation Units and Measurements (ICRU) guidelines to ensure high standards in therapy delivery.

Enhance your knowledge and skills in radiopharmaceutical therapy, and stay at the forefront of this rapidly evolving field. This course promises an engaging and informative experience for all participants, fostering both professional growth and improved patient care.

## Vascular Access Imaging for Structural Heart Practices

Monday, Dec. 2 3:00PM - 4:00PM Room: N229

Dominika Sucha, MD, PhD (*Moderator*) Nothing to Disclose
Nicholas S. Burris, MD (*Moderator*) Royalties, ImBio, LLC

**LEARNING OBJECTIVES**

1) Understand unique image acquisition protocols to optimize evaluation of the vasculature in the setting of surgical repairs and ECMO. 2) Define important imaging findings that differentiate normal and expected post-operative changes from unexpected and concerning features among patients that have undergone aortic surgery. 3) Review a variety of key findings and descriptors that are important to include in diagnostic imaging reports for best patient management from the perspective of surgeons and interventionalists.

**COURSE DESCRIPTION**

Vascular imaging in the setting of extracorporeal circulatory support and in the post-operative setting after aortic surgery can be challenging for diagnostic radiologists for a variety of reasons related to determining optimal imaging acquisition protocols and differentiating normal/expected versus potentially problematic findings. Such determinations can rely on detailed knowledge of the surgical procedure and/or devices used in the operation, which may not be familiar to the imager or readily available in the patient's history. This course will focuse= on practical aspects of imaging the central vasculature (primarily the aorta) in the setting of a patient who has recently undergone or planned to undergo major cardiovascular surgery. Additionally, there will be a review of endovascular and open aortic repair techniques and relevant imaging findings that are important to surgeons and interventionalists who are managing the patient.

**Sub-Events**

## The Academy's Annual Imaging Shark Bait Session

Monday, Dec. 2 1:30PM - 3:00PM Room: E351

Scott A. Penner, JD (*Moderator*) Spouse, Research Grant, General Electric Company;Spouse, Consultant, Human Longevity, Inc;Spouse, Stockholder, CureMetrix, Inc;Spouse, Stock options, Cortechs.ai

**LEARNING OBJECTIVES**

1) Identifying strategies for bringing research to the competitive marketplace. 2) Presenting a proposal in a way that elicits interest from potential investors. 3) Taking steps to secure investor funding while developing and protecting their intellectual property. 4) Identifying ways to generate business value through licensing and collaborations.

**COURSE DESCRIPTION**

The Academy for Radiology & Biomedical Imaging Research's Shark Tank/Shark Bait program will welcome an expert panel composed of a venture capitalist, intellectual property attorney, leaders of industry & academia, and a pitcher/entrepreneur who has successfully obtained funding. In this session, attendees will learn what experts look for and expect when deciding to invest in an innovative idea, providing tips, shared experiences, and an opportunity to ask questions. If you have ever wondered how to pitch your idea or if you wish to consider alternative funding resources, do not miss this fun, educational, and interactive session!

## Curing Burnout: Optimizing Radiologist Well-Being Through Local and National Approaches

Monday, Dec. 2 4:30PM - 5:30PM Room: S402

Jay R. Parikh, MD, FRCPC (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe practical workflow solutions to improve radiologist burnout. 2) Understand how leadership can help cause or cure radiologist burnout. 3) Become aware of a national approach in the United Kingdom to improve radiologist well-being.

**COURSE DESCRIPTION**

Previous studies have demonstrated a high prevalence of burnout amongst radiologists. The conversation needs to now shift from demonstrating prevalence to actually addressing it. Specifically, since physician resilience is amongst the highest in the population, operational and cultural solutions are required. In this session, three predominant levels at which burnout can be Improved will be described: improved informatics workflow, leadership, and system approaches.

## Photon Counting CT

Monday, Dec. 2 4:30PM - 5:30PM Room: S404

Shuai Leng, PhD (*Moderator*) License agreement, Siemens AG

**LEARNING OBJECTIVES**

1) Understand the basic principles of photon counting detector (PCD). 2) Explore the benefits of PCD-CT in comparison with energy-integrating detector CT. 3) Identify potential applications of PCD-CT in various clinical areas.

**COURSE DESCRIPTION**

Photon counting detector (PCD) has been an active research area in recent years. Commercial PCD-CT has been available for routine clinical use since the FDA cleared the first PCD-CT in late 2021, representing a major imaging device advancement for CT. In this lecture, we will discuss the fundamental principles of PCD and explain major benefits of this technology relative to energy integrating detectors which are used on most commercial CT scanners. The history and current status of PCD-CT will also be discussed, including both FDA-cleared scanners and prototype/research systems. Potential applications in various clinical areas will be demonstrated using sample phantom and patient images. Challenges and opportunities will also be discussed.

## Multi-institutional Collaboration for Artificial Intelligence - Best Practices

Thursday, Dec. 5 8:00AM - 9:00AM Room: E450B

Nishith Khandwala, MS (*Moderator*) Founder, Bunkerhill Health

**LEARNING OBJECTIVES**

1) Understand how to implement and manage prospective multi-site randomized controlled trials (RCTs) for validating AI algorithms across various institutions. 2) Apply effective data sharing strategies and understand international patient perspectives on AI in radiology. 3) Learn how expertly-annotated datasets are built and understand the importance of global AI challenges like the RSNA AI Challenges.

**COURSE DESCRIPTION**

Join us for an essential educational session focused on best practices for multi-institutional collaboration in AI. As AI continues to revolutionize radiology, the need for effective collaboration across institutions is paramount. This session will address critical issues such as running prospective multi-site RCTs, data sharing strategies, and building expertly-annotated datasets. Additionally, we will explore international patient perspectives on AI in radiology. Participants will leave with practical knowledge and skills to drive forward multi-institutional AI collaborations successfully.

## MSK Intervention: How I Do It

Thursday, Dec. 5 8:00AM - 9:00AM Room: E450A

MK Lowry, MD (*Moderator*) Faculty, Medtronic plc

**LEARNING OBJECTIVES**

1) To understand the place of image guided intervention in the patient pathway for various common MSK conditions. 2) Learn about new and emerging techniques from experts in image guided intervention. 3) Review cases where image guided intervention has been used successfully for treatment.

**COURSE DESCRIPTION**

This session is an overview of image guided musculoskeletal intervention. This will start with an overview of the injectable substances available and the evidence behind their use in common musculoskeletal conditions. New techniques in neuromodulation will then be reviewed and discussed followed by lectures on several anatomical areas where MSK image guided intervention is common.

**Sub-Events**

**R1-CMK15B** **Neuromodulation for Pain Management of OA**

Paul I. Mallinson, MBChB (*Presenter*) Nothing to Disclose

## Arthridities and Systemic Diseases with Dermatologic Manifestations

Thursday, Dec. 5 8:00AM - 9:00AM Room: E353A

Stacy E. Smith, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review dermatologic manifestations of the systemic diseases. 2) Review the role of imaging in the assessment of soft tissue necrosis. 3) Identify key imaging characteristics of phacomatoses and systemic diseases with dermatologic manifestations.

**COURSE DESCRIPTION**

Developments and improvements in knowledge are rapid and ongoing in both the radiologic and rheumatologic /neurologic/dermatologic fields. During the past decade, the roles of imaging and the radiologist in the assessment and management of many inflammatory arthritidies and phakomatoses and soft tissue necrosis have undergone several changes. To remain effective in-patient care, the radiologist needs to be aware of these changes when recommending and interpreting imaging examinations for the referring physician. The session will provide an update on various systemic presentations and dermatological manifestations of main inflammatory arthritidies and phakomatoses as well as discuss imaging of soft tissue necrosis

**Sub-Events**

### R1-CMS05B Dermatologic Manifestations of Systemic Diseases

Clarissa C. Moraes Do Carmo, MD (*Presenter*) Nothing to Disclose

### R1-CMS05C Phacomatoses/Systemic Diseases with Dermatologic Manifestations

Majid Chalian, MD (*Presenter*) Grant, The Boeing Company

## Errors in Radiology: The Human Factor is the X-Factor (Sponsored by the RSNA Professionalism Committee and RSNA Quality Improvement Committee)

Thursday, Dec. 5 8:00AM - 9:00AM Room: S402

Kate Hanneman, MD, MPH (*Moderator*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Michael K. Atalay, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe the role of human factors in radiology, including increasing safety, error avoidance and learning from errors and how communication can be crucial in safety critical environments. 2) Discuss error in radiology and the application of Human Factors - including personal factors (workload, stress, RVUs) as well as organizational issues (interruptions, workload) and communication. 3) Describe classification of errors, describe their prevalence, and review why and how they occur. 4) Review strategies to reduce error in radiology, including de-biasing, noise audits, quality assurance, standardization, self-improvement, improved workplace environments and others.

**COURSE DESCRIPTION**

This session will review the role of human factors (HFs) in radiology. Broadly, job-related HFs describe workplace interactions of humans with our environments and with other individuals. They include such concerns as: organizational culture; the nature, scope and intensity of the job; system processes and procedures; communication between team members (including interruptions); decision-making strategies and execution; ergonomics; and psychological and physiological factors (rested-state, fed-state, etc). Primary goals of human factors research in medicine are 1) to identify and reduce or eliminate causes of human error, 2) to enhance productivity and system efficiency, and 3) to improve safety, health, and well-being of both patients and care providers.

The goals of this course will be to understand the salient features of human factors, why they occur, how they lead to errors in radiology, and strategies for managing them and reducing their adverse effects.

**Sub-Events**

### R1-CNPM04C Human Factors: How Radiology Can Learn From Aviation

Niall Downey, MD (*Presenter*) Nothing to Disclose

### R1-CNPM04D Human Factors in Radiology

## CSF Imaging in Clinical Practice - What You Need to Know

Thursday, Dec. 5 8:00AM - 9:00AM Room: S406B

Lubdha M. Shah, MD, MSc (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review CSF circulation throughout the CNS in normal and abnormal states. 2) Evaluate effect of CSF alterations on brain and spine parenchyma. 3) Discuss the advances in imaging of CSF flow.

**COURSE DESCRIPTION**

Cerebrospinal fluid (CSF) is a plasma ultrafiltrate in the extra axial compartment of the cranium and spine, providing hydromechanical protection, nourishment, and waste removal. Another role of the CSF is to maintain a stable environment. CSF is propelled along the neuroaxis from the site of secretion to the site of absorption, mainly by the rhythmic systolic pulse wave within the choroidal arteries and to a lesser degree by respiration, venous pressure, physical effort, and time of day. This didactic session will be a comprehensive review of CSF circulation throughout the CNS in normal physiologic conditions and the alterations that are observed in pathologic disorders. The participant will gain an in-depth understanding the role of CSF flow in maintaining homeostasis and of the imaging advances to identify abnormalities.

**Sub-Events**

### R1-CNR01B Role of Glymphatics in Normal and Abnormal CSF Flow

Christopher G. Filippi, MD (*Presenter*) Research Consultant, Syntactx, LLC Minority stockholder, Avicenna.ai Research consultant, Sana Biotech, Inc.

## 360 Assessment of Contrast in Children: Looking at the Bowel, at the Liver, at Bubbles, and at the Environment (Partially supported by an Unrestricted Educational Grant from Guerbet LLC.)

Thursday, Dec. 5 8:00AM - 9:00AM Room: N226

Maria Navallas, MD (*Moderator*) Nothing to Disclose
Alex El-Ali, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Gain a comprehensive understanding of pediatric liver and biliary tree diseases, and improve diagnostic skills using various imaging modalities and specific contrast media. 2) Demonstrate the utility and encourage the use of contrast-enhanced ultrasound in children. 3) Describe enteric and gadolinium-based intravenous contrast agents used in MR Enterography (MRE). 4) Discuss iodine contrast shortage and the need to implement strategies to reduce the administration and waste of contrast materials such as the use of photon counting CT.

**COURSE DESCRIPTION**

This course deals with the use of contrast in pediatric imaging through four different lectures:

1) Presentation on the use of ultrasound and MRI in pediatric liver and biliary diagnostics. Tips on optimizing imaging techniques for pediatric patients.

2) Utility, indications and add-on values of contrast-enhanced ultrasound in diagnostic imaging in children, as well as its usefullness in pediatric interventional radiology.

3) Enteric and gadolinium-based intravenous contrast agent used in MR Enterography (MRE), including options and alternatives; standard MRE protocol, and patterns of bowel inflammation and damage in pediatric inflammatory bowel disease.

4) Principles of improved contrast resolution on a photon counting detector platform with illustrative case examples of reduced contrast usage on a photon counting CT, and opportunities in the radiology department and manufacturing process to reduce contrast use.

**Sub-Events**

**R1-CPD12C** **Looking at the Liver and Biliary Tree**

Lisa Suzuki, MD, PhD (*Presenter*) Nothing to Disclose

## Cone Beam Breast CT: CBCT Principles: Technology, Image Quality, and Dose (Supported in part by an Unrestricted Medical Education Grant from GE Healthcare, Inc.)

Thursday, Dec. 5 8:00AM - 9:00AM Room: S404

Mahadevappa Mahesh, PhD, MS (*Moderator*) Nothing to Disclose
Ioannis Sechopoulos, PhD (*Moderator*) Research Grant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation;Research Grant, Sectra AB;Research Grant, ScreenPoint Medical BV;Research Grant, Volpara Health Technologies Limited

### LEARNING OBJECTIVES

1) To learn the principles of CBCT and cone beam breast CT systems. 2) To understand image acquisition and dose measurement in cone beam breast CT. 3) To become familiar with clinical application of cone beam breast CT.

### COURSE DESCRIPTION

Cone-beam CT (CBCT) is increasingly used in diagnostic imaging and image-guided procedures, ranging from interventional radiology to breast imaging, radiation therapy and surgery. The proliferation of CBCT systems that are used as standalone or as part of the fluoroscopy systems are used not only in radiology but in surgery, pain clinic, dental clinics, etc. Even though the fundamentals of cone beam breast CT are similar to CBCT, there are distinct differences between the two technologies, in terms of acquisition, image processing and radiation dose estimation. This course is aimed to cover the general principles of CBCT and Cone Beam Breast CT systems, along with the challenges of quality control evaluation, radiation dose measurements and clinical applications. The course has three presentations with first two aimed at describing the physics principles of CBCT and cone beam breast CT, while the final presentation will focus on clinical applications of breast CT.

**Sub-Events**

### R1-CPH10C Overview of Cone Beam CT and The Challenges in Quality Control

Mahadevappa Mahesh, PhD, MS (*Presenter*) Nothing to Disclose

### R1-CPH10D Breast Cone Beam CT Imaging System - Technology, Image Quality & Dose

## Where are all the Women Physicists? (Sponsored by the RSNA Committee on Diversity, Equity and Inclusion)

Thursday, Dec. 5 8:00AM - 9:00AM Room: E350

Gayle E. Woloschak, BS, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) To discuss reasons why women are avoiding careers in Radiation Physics. 2) To develop approaches to help remedy the problem. 3) To facilitate communication among those women in the radiation physics community.

**COURSE DESCRIPTION**

This session will provide a panel discussion on why women are not pursuing careers in radiation physics. Discussants will talk about their own experiences as well as those that they have observed among colleagues and friends in the community. Each panelist will present their own views, and then questions from the audience will be entertained related to the topics. The goal is to provide discussion on this difficult topic in hopes of developing solutions.

**Sub-Events**

## Essentials of Breast Imaging

Thursday, Dec. 5 9:30AM - 10:30AM Room: S406A

Paola Clauser, MD, PhD (*Moderator*) Speaker, Siemens AG

**LEARNING OBJECTIVES**

1) To understand applications, advantages and limitations of x-ray-based breast imaging, particularly digital breast tomosynthesis. 2) To understand the role of ultrasound in the screening and diagnostic setting. 3) To have a basic understanding of breast magnetic resonance imaging techniques, indications, reporting and consequent management recommendations.

**COURSE DESCRIPTION**

This educational course will review the basis of image acquisition and evaluation with digital breast tomosynthesis (DBT), ultrasound (US) and magnetic resonance imaging (MRI). The current indications of the methods will be reviewed and discussed. Upon completion of this course participants will understand the current clinical applications and limitations of the methods.

**Sub-Events**

### R3-CBR06B Evaluation With DBT Techniques Include Synthetic Digital Mammography, and DBT Biopsy

Paola Clauser, MD, PhD (*Presenter*) Speaker, Siemens AG

### R3-CBR06C Evaluation with US Include US Biopsy

## An Introduction to GU Specific Diagnostic Classification Systems

Thursday, Dec. 5 9:30AM - 10:30AM Room: E350

Silvia D. Chang, MD, FRCPC (*Moderator*) Nothing to Disclose
Bahar Mansoori, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) To become familiar with the classification systems used in GU imaging for the kidneys, bladder and prostate, specifically Bosniak, Clear Cell RCC Likelihood Score, VI-RADS and PI-RADS.

2)To be able to apply these GU classification systems in clinical practice.

### COURSE DESCRIPTION

This lecture-based educational course will introduce the audience to specific diagnostic classification systems used in GU imaging of the kidneys, bladder and prostate. Diagnostic classification systems guide the assessment and interpretation of disease processes on imaging exams. This promotes standardization in terminology and interpretation enabling uniform data for monitoring of outcomes and refining quality assurance. The following systems will be presented: 1. PI-RADS in assessing for clinically significant prostate cancer on MRI, 2. VI-RADS in local assessment of bladder cancer on MRI, 3. Bosniak classification in assessing renal cysts and 4. the clear cell RCC likelihood score in assessing renal masses.

## Preparing Your Radiology Residents for Academic Research Careers (Sponsored by the RSNA Research Development Committee)

Thursday, Dec. 5 9:30AM - 10:30AM Room: S402

Janie M. Lee, MD, MSc (*Moderator*) Research Grant, General Electric Company;Investigator, General Electric Company
Jeffrey G. Jarvik, MD, MPH (*Moderator*) Royalties, Mannheim Media;Co-editor, Mannheim Media;Travel support, General Electric Company;Author with royalties, Wolters Kluwer nv

### LEARNING OBJECTIVES

1) To describe the impact of RSNA's Fellow Research Grant on academic career paths. 2) To describe how T32 Research Training grants can develop high potential residents. 3) To explain how departments can leverage resources for successful research mentorship.

### COURSE DESCRIPTION

Current radiology residents are the future physician-scientists who will conduct studies that generate evidence to improve clinical care and patient outcomes. This course will provide insight as to how current training programs can identify and train radiology residents in preparation for careers in academic research. Speakers will focus on how RSNA Fellow grants, Federal T32 training grants, and internal departmental resources can all be used to train the next generation of radiology physician scientists.

## CNS Tumors: Case-Based Multidisciplinary Tumor Board Review

Thursday, Dec. 5 9:30AM - 10:30AM Room: S401

Christina I. Tsien, MD (*Moderator*) Advisory Board, Blue Earth Diagnostics Ltd;Speakers Bureau, Agilent Technologies, Inc;Consultant, Carl Zeiss AG
Soonmee Cha, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Discuss key imaging modalities to differentiate recurrent tumor and treatment effect. 2) Discuss the role of each modality including surgery, radiotherapy, and chemotherapy in managing the major malignant adult primary CNS tumors
3) Describe the new updates of the 5th edition of the WHO Classification of Tumors of the CNS 2021. Discuss the prognostic and predictive variables that allow for the selection of the appropriate therapy.

### COURSE DESCRIPTION

Recent updates of the 5th edition WHO Classification of CNS tumors will be summarized. Significant progress has been made in the treatment of diffuse gliomas with an emphasis on prognostic and predictive biomarkers that allow for appropriate treatment selection. The role of neuroimaging to help clinicians improve the diagnosis, treatment and response assessment for CNS tumors will be emphasized. This session highlights the need for a multi-disciplinary treatment approach for primary CNS tumors in a rapid-fire tumor board format.

**Sub-Events**

## Visceral Vascular Imaging

Thursday, Dec. 5 9:30AM - 10:30AM Room: N229

Daniel Vargas, MD (*Moderator*) Nothing to Disclose
Iain D. Kirkpatrick, MD, FRCPC (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify key imaging findings and diagnostic criteria for mesenteric ischemia, pelvic congestion syndrome, renal artery stenosis and causes of gastrointestinal bleeding. 2) Understand where radiology fits within the diagnostic pathway of these four conditions and how it can guide management. 3) Describe how to optimize imaging protocols for these conditions.

**COURSE DESCRIPTION**

Abdominal visceral vascular diseases can be challenging for many radiologists as they involve multiple organ systems and cross the boundaries between subspecialty vascular and abdominal expertise. Abdominal radiologists may have less experience creating and interpreting 3D angiographic reconstructions, and vascular radiologists may be less comfortable with parenchymal solid or hollow organ changes in these diseases. As CT and MR technology evolves, our ability to diagnose these diseases early with angiographic techniques improves steadily and radiologists must be aware of a spectrum of imaging findings that have only been described in the era of multidetector CT and accelerated MRI/MRA.

This session will review the vascular and visceral findings that can be seen in a number of diseases, including mesenteric ischemia, renal artery stenosis, pelvic congestion syndrome and gastrointestinal bleeding. Techniques, diagnostic criteria, and imaging findings will all be discussed as well as the role of radiology in guiding the management of these conditions.

**Sub-Events**

## Jeopardy! Tournament of Editors: Tips to Get Your AI Paper Published

Thursday, Dec. 5 9:30AM - 10:30AM Room: S406B

Ali S. Tejani, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the key elements of a manuscript on imaging AI. 2) Apply components of the Checklist for Artificial Intelligence in Medical Imaging (CLAIM) 2024 Update for imaging AI manuscript submissions. 3) Identify and correct errors in example imaging AI manuscripts and abstracts. 4) Understand appropriate use of AI performance metrics.

**COURSE DESCRIPTION**

It can be daunting to draft a concise, yet detailed manuscript about radiology artificial intelligence (AI) projects. Manuscripts about radiology AI should incorporate key information that enables reviewers to determine the quality and reproducibility of the submitted work, as well as how the submitted work adds to a rapidly evolving field. This session will help attendees improve the quality of their AI manuscripts for submission to the RSNA Journal Suite and guide them as effective peer-reviewers for AI-related submissions. The session will follow a "game show" format based on "Jeopardy!" featuring a panel composed of editorial board members from Radiology and Radiology: Artificial Intelligence. Categories and questions will facilitate discussion on experiences from the editorial board members, including thoughts on best practices for AI-related submissions and frequently seen errors. Topics will include highlights from the CLAIM 2024 Update and general recommendations for effective medical writing. Questions will include examples inspired by manuscript submissions encountered by the editorial review board.

**Case Based Review of Challenging Cases (CEM and Multimodality Biopsy) (Supported in part by an Unrestricted Medical Education Grant from GE Healthcare, Inc.)**

Thursday, Dec. 5 11:00AM - 12:00PM Room: S406A

Maxine S. Jochelson, MD (*Moderator*) Speaker, General Electric Company

**LEARNING OBJECTIVES**

1) Understand the principals and limitations of ultrasound correlation with other modalities. 2) Identify lesion criteria that benefit most from MRI directed ultrasound correlation. 3) Familiarize learners with options for using Contrast Enhanced Mammography both in diagnostic scenarios and biopsy situations to reduce the use of MRI when possible.

**COURSE DESCRIPTION**

During this course we will discuss challenging cases involving the most commonly used modalities in breast imaging including Digital Breast Tomosynthesis (DBT), Ultrasound (US), Magnetic Resonance Imaging (MRI), and Contrast Enhanced Mammography (CEM). We will address how we correlate the images among these modalities to better characterize breast lesions and to be able to chose the best possible modalities to perform percutaneous biopsies when necessary- taking into consideration that MRI guided and Contrast Enhanced Mammography biopsy availability may be limited in many practices. We will stress the importance of accurate lesion correlation in this setting. This session aims to provide participants with valuable knowledge and skills to deal with these scenarios effectively in various breast imaging practices.

## Abdominopelvic Trauma: Core Concepts and Advances

Thursday, Dec. 5 11:00AM - 12:00PM Room: N228

Scott D. Steenburg, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the indications and diagnostic features for CT imaging in non-traumatic acute aortic syndromes, CCTA in the emergency department for acute chest pain, and the imaging features of fungal infections across different body systems. 2) Identify key imaging characteristics and provide a focused, clinically relevant review of non-traumatic acute aortic syndromes, CCTA in acute chest pain, and fungal infections, including protocols and patient criteria. 3) Analyze the limitations, potential pitfalls, and diagnostic challenges associated with CT and CCTA in acute aortic syndromes and emergency chest pain evaluation, as well as the epidemiology, risk factors, and differential diagnosis of fungal infections.

**COURSE DESCRIPTION**

The series of lectures will deliver key diagnostic pointers in liver trauma, bowel and mesenteric injuries on trauma CT, and renal trauma. Strategies will be focused on overcoming diagnostic challenges and ensuring effective patient management in trauma settings.

## Post-Operative Imaging

Thursday, Dec. 5 11:00AM - 12:00PM Room: E451B

Lauren M. Burke, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the common GI surgical interventions. 2) Be able to identify typical post-surgical imaging findings and complications.

**COURSE DESCRIPTION**

This course is designed to be an "all you need to know" course that covers the typical post-surgical findings following common hepatic, pancreatic, bariatric and gastrointestinal surgeries. Topics will be discussed through a multimodality approach with CT, MR, US, and fluoroscopy findings highlighted throughout the session.

With continued advances in surgical interventions and institutional variations in surgical technique, radiologists are expected to have a broad understanding of the post-surgical abdomen. Throughout the four didactic lectures, participants should be familiar with common gastrointestinal surgical interventions and the typical post-surgical findings and complications.

## Reading MSK Radiographs: An Art that Should Not be Lost (Supported by an Unrestricted Medical Education Grant from Carestream Health, Inc.)

Thursday, Dec. 5 11:00AM - 12:00PM Room: N227B

Andrew J. Grainger, MD (*Moderator*) Speakers Bureau, General Electric Company

**LEARNING OBJECTIVES**

1) To review and recognize radiographic features, patterns and variants, that can help and hinder our interpretation of peripheral skeletal radiographs in clinical practice.

**COURSE DESCRIPTION**

Conventional radiographs remain a fundamental part of the radiologist's workload but beyond initial training, teaching and learning radiographic interpretation is often neglected. This course brings together renowned experts in the field of musculoskeletal radiology who share a passion for the importance and teaching of conventional radiograph reading skills. Whether you have been reading radiographs for many years, or are just setting out on your radiology career, this course will offer tips and tricks that will refresh and help develop your interpretative skills.

## Is Whole Body MRI a Net Positive or Negative for Society? A Debate

Thursday, Dec. 5 11:00AM - 12:00PM Room: S402

Ruth C. Carlos, MD, MS (*Moderator*) In-kind support, RELX;Editor, RELX;Travel support, General Electric Company

**LEARNING OBJECTIVES**

1) Understand the advantages of screening whole body MRI. 2) Appreciate how the state of the art in screening MRI. 3) Identify the drawbacks of screening.

**COURSE DESCRIPTION**

Screening Whole Body MRI has been adopted in certain health-conscious constituencies. The gains touted include catching potentially fatal diseases early in their presentation and better preventive health. Skeptics question the potential for false positives and overdiagnosis. This debate will expose the pros and cons of whole body MRI at an individual and societal level.

## Controversial Topics in Neuroradiology

Thursday, Dec. 5 11:00AM - 12:00PM Room: S406B

Brent D. Weinberg, MD, PhD (*Moderator*) Research Consultant, Canon Medical Systems Corporation

**LEARNING OBJECTIVES**

1) Understand specific challenges facing neuroradiology in the next five to ten years. 2) Reflect on controversial topics in neuroradiology and how they may affect current and future radiology practice. 3) Discuss pros and cons of paradigm shifts in imaging techniques and reporting in neuroradiology.

**COURSE DESCRIPTION**

Presenters will discuss several controversial topics in neuroradiology, including how changes in imaging techniques and reporting patterns may affect current and future practice. Specific topics addressed will include ongoing and upcoming developments in nuclear medicine brain imaging, quantitative brain imaging, cerebrovascular imaging, and structured reporting. Likely future advantages will be discussed alongside potential pitfalls and challenges.

## Career Pivots in Radiology: Thriving in New Roles (Sponsored by the RSNA Professionalism Committee)

Thursday, Dec. 5 11:00AM - 12:00PM Room: E352

Carl C. Flink, MD (*Moderator*) Nothing to Disclose
Richard E. Heller III, MD (*Moderator*) Consultant, Gerson Lehrman Group, Inc;

**LEARNING OBJECTIVES**

1) Identify different types of career pivots. 2) Understand the challenges that can be faced when making a career transition. 3) Discuss strategies for achieving a successful career pivot.

**COURSE DESCRIPTION**

Career transitions have increased in frequency motivated myriad factors including values, purpose, aspirations, job security, job satisfaction, long term goals and wellness. Whether the pivot is carefully charted, or an unplanned career change strategic planning, a growth mindset and strong relationships are critical to success. This session will discuss common career change pathways as well as the opportunities, challenges and keys to success of each.

## PET-CT in Thoracic Malignancy

Thursday, Dec. 5 1:30PM - 2:30PM Room: E451A

David M. Naeger, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe the imaging findings used to stage lung cancer. 2) Evaluate imaging findings that are seen in the response to cancer treatment.

**COURSE DESCRIPTION**

This course will review the use of PET/CT in evaluating malignancies of the chest. We will review how the modality is used to stage lung cancer, how it can provide insights into the response of tumors to treatment, and how it is used to evaluate masses in the mediastinum.

**Sub-Events**

### R6-CCH11B Technical Update: Recent Innovations in Thoracic PET-C

## T-Bone Central: High Yield Topics in Temporal Bone Imaging

Thursday, Dec. 5 1:30PM - 2:30PM Room: E351

Mohit Agarwal, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn salient features of temporal bone anatomy. The session will also review the anatomy using images from photon counting CT. 2) Learn about strategies to approach cases of hearing loss on imaging. 3) Learn to develop an imaging approach in cases of tinnitus.

**COURSE DESCRIPTION**

Temporal bone anatomy and pathology is challenging for radiologists at all levels - from first year residents to practicing physicians. This session has been designed to tackle this difficult topic where Dr Bruno Policeni will teach about the complex anatomy of the temporal bone with review of photon counting CT images, Dr Paul Bunch will take us through an imaging approach to patients presenting with hearing loss and Dr Katherine Reinshagen will teach about strategies to approach cases of tinnitus.

**Sub-Events**

## Novel Breast MRI Techniques

Thursday, Dec. 5 3:00PM - 4:00PM Room: N227B

Ritse M. Mann, MD, PhD (*Moderator*) Researcher, Siemens AG;Consultant, Siemens AG;Researcher, Bayer AG;Consultant, Bayer AG;Researcher, Medtronic plc;Consultant, Medtronic plc;Researcher, Becton, Dickinson and Company;Consultant, Becton, Dickinson and Company;Researcher, ScreenPoint Medical BV

### LEARNING OBJECTIVES

1) To understand the goal of the use of various sequences in breast MRI, and define indications where it is appropriate to use a full protocol. 2) Identifying solutions to shorten breast MRI protocols in order to increase capacity and reduce costs. 3) To gain as much information as possible from abbreviated breast MRI protocols using ultrafast imaging.

### COURSE DESCRIPTION

This course aims at all interested in breast MRI from a technical and clinical perspective. The course aims to review the components of breast MRI protocols and discuss their use in clinical practice. It provides insight in various options to reduce the length of standard breast MRI protocols without decreasing their diagnostic capacity. The course will also highlight when the value of true multi parametric protocols is still strong. After following this session you should be able to adapt your MRI protocols to scan indications and build a highly efficient practice, while simultaneously providing high quality assessments.

## What Cardiac Device is That? Interactive Session on Imaging Heart Failure Patients

Thursday, Dec. 5 3:00PM - 4:00PM Room: N226

Byoung Wook Choi, MD, PhD (*Moderator*) Nothing to Disclose
Carole J. Dennie, MD, FRCPC (*Moderator*) Research Consultant, AstraZeneca PLC

**LEARNING OBJECTIVES**

1) Identify and describe the X-ray and CT appearances of different cardiac devices used in heart failure patients. 2) Recognize and overcome technical challenges in CT imaging of severe heart failure to optimize image quality and diagnostic accuracy. 3) Understand the imaging considerations, protocols, and potential complications associated with left ventricular assist devices (LVAD) and right ventricular assist devices (RVAD).

**COURSE DESCRIPTION**

This educational session is a comprehensive exploration of cardiac devices and their imaging appearances in heart failure patients. The session consists of three lectures that cover essential aspects of cardiac device imaging, including X-ray and CT appearances, technical challenges in CT imaging of severe heart failure, and imaging of left ventricular assist devices (LVAD) and right ventricular assist devices (RVAD). The session aims to enhance participants' knowledge and proficiency in imaging heart failure patients with various cardiac devices, ultimately improving patient care and diagnostic accuracy

## Understanding Thoracic AI/Radiomics: Where Are We and Where We Are Going?

Thursday, Dec. 5 3:00PM - 4:00PM Room: E451A

Carol C. Wu, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the fundamentals of AI and radiomics in thoracic imaging. 2) Assess AI and radiomics tools for clinical implementation in thoracic imaging. 3) Identify challenges and potential pitfalls of implementing AI tools in thoracic imaging.

**COURSE DESCRIPTION**

The course is designed to provide a basic overview of the current status and future directions in the fast evolving field of thoracic imaging artificial intelligence (AI) and radiomics. Through the lectures and discussion, participants will learn about principles and pitfalls of AI and radiomics and considerations required for successful clinical implementation and utilization of these advance tools in thoracic radiology.

## LI-RADS

Thursday, Dec. 5 3:00PM - 4:00PM Room: E451B

Jeong Min Lee, MD, PhD (*Moderator*) Grant, Bayer AG Grant, Canon Medical Systems Corporation Grant, Koninklijke Philips NV Grant, General Electric Healthcare Grant, Guerbet SA Grant, Samsung Electronics Co, Ltd Grant, Bracco Group Grant, Dongkuk Pharma Grant, Starmed Ltd Grant, RF medical Grant, Siemens AG Speakers, Bayer AG Speakers, Philips Healthcare Speakers, Samsung Medison Speakers, GE Healthcare

### LEARNING OBJECTIVES

1) Understand the Latest Updates in LI-RADS treatment response algorithms (TRA) and CEUS LI-RADS TRA, and learn their practical applications for HCC management. 2) Identify Prognostic Imaging Features and Pathomolecular Subtypes of HCC, aiding in better diagnosis and treatment planning. 3) Learn how to effectively evaluate the treatment response to systemic therapy in HCC, with a focus on practical case-based learning to manage challenging clinical scenarios.

### COURSE DESCRIPTION

This session will offer a comprehensive overview of the latest updates and clinical applications of the Liver Imaging Reporting and Data System (LI-RADS). Topics will include the newest updates on the LI-RADS Treatment Response Algorithm (TRA) and the pathomolecular subtypes and prognostic imaging features of hepatocellular carcinoma (HCC). The session will also cover clinical applications of LI-RADS TRA and Contrast-Enhanced Ultrasound (CEUS) LI-RADS-TRA for HCC management. Additionally, a case-based approach to systemic therapy of HCC will be featured, focusing on challenging cases to provide practical insights and enhance participants' understanding of complex clinical scenarios. This session aims to enhance participants' understanding of LI-RADS and its pivotal role in liver cancer management.

## Automatic Report Generation by Image-based AI

Thursday, Dec. 5 3:00PM - 4:00PM Room: E450B

Eduardo M. Farina, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand Current Technologies: Participants will be able to describe the latest approaches in automatic report generation and their applications in radiology. 2) Evaluate Performance Metrics: Learners will be able to identify and apply key metrics for assessing the quality and accuracy of automatically generated reports. 3) Analyze Ethical Implications: Attendees will gain insights into the ethical considerations and potential challenges associated with the implementation of automatic report generation in clinical practice.

**COURSE DESCRIPTION**

The rapid evolution of automatic report generation in radiology is reshaping the landscape of medical imaging. This educational session, titled "Automatic Report Generation by Image-based AI" will provide a comprehensive overview of the latest advancements and future directions in this dynamic field. Attendees will gain insights into the practical implementation of these technologies, the metrics used to evaluate their effectiveness, and the ethical implications surrounding their use. The session will feature expert presentations, followed by a panel discussion, enabling participants to engage with thought leaders and explore critical issues from multiple perspectives. This course is essential for radiologists, data scientists, and healthcare professionals interested in harnessing the power of AI to enhance diagnostic accuracy and efficiency. Expected outcomes include an improved understanding of current technologies, the ability to assess their performance critically, and a deeper awareness of ethical considerations.

## Small Joints: Big Problems

Thursday, Dec. 5 3:00PM - 4:00PM Room: E450A

Bruce B. Forster, MD, FRCPC (*Moderator*) Stockholder, Canada Diagnostic Centres

**LEARNING OBJECTIVES**

1) Determine the most effective imaging modality to evaluate common small joints. 2) Describe key normal anatomic features of these joints. 3) Categorize the imaging findings and treatment options in traumatic and non-traumatic pathologies.

**COURSE DESCRIPTION**

This one hour lecture series, using concise 10 minute presentations by MSK experts, will provide the attendee with a synopsis of the key multimodality imaging features of pathology of the acromioclavicular joint, the sternoclavicular joint, the tibio-fibular joint, the symphysis pubis and the sub-talar joint. These small joints are often under-represented in educational curricula, but can be a significant source of pain and dysfunction for patients, which attendees will be better able to diagnose and treat by the end of the session.

**Sub-Events**

### R7-CMK13B AC Joints in All Their Glory

Bruce B. Forster, MD, FRCPC (*Presenter*) Stockholder, Canada Diagnostic Centres

### R7-CMK13C Sternoclavicular Joint: Small but Mighty

## Therapeutic and Sociocultural Cosmetical Modifications and Related Complications

Thursday, Dec. 5 3:00PM - 4:00PM Room: N229

Nariman Nezami, MD (*Moderator*) Consultant, CAPS Medical Ltd

**LEARNING OBJECTIVES**

1) Describe a wide variety of common and rare therapeutic cosmetical procedures. 2)Introduce radiologists to the sociocultural phenomenon of "Image is everything " including historical context and evolution of the plastic surgery practice. 3) Familiarize the radiologist with the diversity of plastic surgeries performed for enhancement of physical appearance, with particular focus on implants, including typical and atypical locations and their appearances on medical imaging examinations. 4) Describe potential complications of cosmetic surgeries and implant procedures and the imaging findings associated with "botched" procedures. Discuss management of "botched" and otherwise complicated procedures.

**COURSE DESCRIPTION**

Therapeutic and Sociocultural Cosmetical Modifications and Related Complications" is an advanced course that explores the intersection of therapeutic interventions, sociocultural practices, and their cosmetic modifications. This course provides a comprehensive understanding of various cosmetic procedures, the sociocultural factors influencing them, and the potential complications that may arise. Participants will learn about the latest advancements in cosmetic treatments and imaging findings of complications. The course integrates theoretical knowledge with practical applications, preparing radiologists for real-world scenarios in clinical and sociocultural contexts.

**Sub-Events**

### R7-CMS04B Image is Everything: Plastic and Cosmetic Surgery as a Sociocultural Phenomenon

Nadia Solomon, MD, MSc (*Presenter*) Nothing to Disclose

### R7-CMS04C The Aftermath of Cosmetic Injectables: Imaging for Surgical Planning and Post-surgical Follow Up

Jonathan S. Luchs, MD (*Presenter*) Nothing to Disclose

### R7-CMS04D A Primer on Imaging Findings in Cosmetic Procedures and Associated Complications in the Abdomen/Pelvis

## Chest Imaging: When Molecular Imaging Helps

Thursday, Dec. 5 3:00PM - 4:00PM Room: S405

Ryan J. Avery, MD (*Moderator*) Research Consultant, Konica Minolta, Inc

**LEARNING OBJECTIVES**

1) A case-based review discussing the emerging of Molecular Imaging techniques, which can improve detection of ischemic heart disease, infiltrative cardiomyopathies, and inflammatory cardiomyopathies, with a focus on sarcoidosis. 2) Provide a discussion of new Molecular Imaging techniques that are available for routine clinical diagnosis of pathologies related to coronary artery disease and infiltrative/inflammatory cardiomyopathies. Further, the rationale of the examinations will be provided by explaining the medical and imaging sciences that necessitate when and how to perform these examinations. 3) The case-based approach will discuss the key imaging findings that can be used to improve diagnosis of cardiothoracic diseases. Given the novelty of these exams, a review of important incidental findings and imaging pitfalls will also be provided to improve examination implementation and interpretation.

**Sub-Events**

### R7-CNMMI05B Multimodality Perspective of Cardiac Sarcoidosis - Hybridizing FDG-PET and Cardiac MR Imaging

Ryan J. Avery, MD (*Presenter*) Research Consultant, Konica Minolta, Inc

### R7-CNMMI05C Complementary Roles of PET, MRI, and CT in Cardiac Ischemia, Small Vessel Disease, and COVID

Pamela K. Woodard, MD (*Presenter*) Researcher, Siemens AG;Consulting, Medtronic plc;Researcher, Bayer AG;Patent, Washington University

## Advancing Justice Oriented Innovation in Radiology (Sponsored by the RSNA Health Equity Committee)

Thursday, Dec. 5 3:00PM - 4:00PM Room: S402

Efren J. Flores, MD (*Moderator*) Speaker, WebMD LLC;Speaker, Consulting Medical Associates, Inc
Lucy B. Spalluto, MD, MPH (*Moderator*) Nothing to Disclose
Jacob A. Blythe, MA, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Discussing the implementation of a practical framework to justice oriented innovation. 2) Identifying and accelerating the justice-oriented pipelines. 3) Articulating the business case for commercialization of justice-oriented innovation. This session will include a 15-minute Q&A session with the audience.

### COURSE DESCRIPTION

Radiology is a continuously evolving field driven by technological healthcare innovations. Innovation and new technologies in our clinical radiology practices lead us to deliver better care. The shape that these technologies take, while in part unpredictable, can be guided by our shared values. In recent years, radiology has increasingly recognized its role in health disparities, many of which may be rooted in the innovative spirit without an equity lens that has motivated radiologic practice since its inception. This creates a fresh opportunity to reconsider innovative activities in radiology through a justice-oriented lens. In an effort at incorporating responsible innovation into radiology, justice-oriented innovation in radiology is concerned principally with reducing imaging disparities and leverages novel technologies as an opportunity to achieve this goal. The rapid implementation and growth of AI and theranostics in radiology provide an opportune window to set a foundation for justice-oriented innovation in radiology.

**Sub-Events**

### R7-CNPM07D Defining Key Performance Indicators for Accelerating Justice-Oriented Innovation

Marc D. Succi, MD (*Presenter*) Inventor, Frequency Therapeutics

### R7-CNPM07E The Role of Reciprocal Innovation to Achieving Equity in Global Health

Farouk Dako, MD, MPH (*Presenter*) Nothing to Disclose

## Crash Course! Imaging of Neurodegenerative Diseases and ARIA

Thursday, Dec. 5 3:00PM - 4:00PM Room: S406B

Timothy M. Shepherd, MD, PhD (*Moderator*) Co-founder, MICroStructure Imaging

**LEARNING OBJECTIVES**

1) Describe the key features of Alzheimer's disease and related diseases on clinical exam, MRI and PET imaging. 2) Explain the potential complications of anti-amyloid immunotherapy, their appearance on MRI and the role for imaging in treatment monitoring. 3) Identify near-future developments that may change how MRI and PET are used to diagnose or monitor treatment in patients with Alzheimer's disease.

**COURSE DESCRIPTION**

Alzheimer’s disease is an important clinical problem with high societal costs as US and global populations both age and live longer. MRI and PET imaging have become a more important part of clinical diagnosis and management over the past 5 years – this emerging new radiology role should grow with recently FDA-approved anti-amyloid immunotherapy. This educational session will provide the audience with a background understanding of Alzheimer’s disease pathology, prevalence and clinical presentation. We will review the specific roles for MRI and PET in shaping the diagnosis for Alzheimer’s disease and related diseases. We will review the potential benefit and complications of anti-amyloid immunotherapies, with a specific focus on how imaging contributes to clinical management. These changes are placing new demands on radiology and the situation is currently dynamic – the last presentation will preview how the radiology role may change over the next 5 years as more therapies, novel imaging methods and potential robust serum biomarkers for Alzheimer’s disease emerge. The session will conclude with a panel discussion by speakers that addresses both current controversies in this field and questions from the audience.

**Sub-Events**

### R7-CNR05B Introduction to Alzheimer's Disease and Imaging of Dementia

Gloria C. Chiang, MD (*Presenter*) Advisory Board, Biogen Idec Inc;Consultant, Life Molecular Imaging;Speaker, Horizon CME

### R7-CNR05C Role of PET for Alzheimer's Dementia

Ana M. Franceschi, MD, PhD (*Presenter*) Consultant, Biogen Idec Inc

### R7-CNR05D Imaging for Ant-Amyloid Therapy and ARIA

R7-COB05

## Acute Pelvic Pain in a Reproductive Age Female

Thursday, Dec. 5 3:00PM - 4:00PM Room: E351

Alyssa K. Kirsch, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Recognize the findings of adnexal torsion. 2) Understand the commonest cause of pelvic pain in pregnancy. 3) Perform tailored evaluation of pelvic pain in reproductive age females using US, CT, and MRI.

**COURSE DESCRIPTION**

Acute pelvic pain in a reproductive age female patient is a common imaging indication that radiologists often encounter. It is imperative that radiologists be familiar with imaging findings associated with pathologies of acute pelvic pain which may require more urgent attention and management. This session will be a lecture case-based review of US, CT, and MR imaging findings associated with acute pelvic pain in the reproductive age patient including pregnant and non-pregnant patients. This will include a review of common entities such as ovarian torsion, and less common and challenging pathology such as ectopic pregnancy, complications following pregnancy, and placenta accreta spectrum.

**Sub-Events**

**R7-COB05B** **Acute Pelvic Pain: + Pregnancy Test**

Tara A. Morgan, MD (*Presenter*) Nothing to Disclose

**R7-COB05C** **Acute Pelvic Pain: - Pregnancy Test**

## Optimizing the Use of Radiation in Fluoroscopy: Technological and Behavioral Approaches

Thursday, Dec. 5 3:00PM - 4:00PM Room: S404

David Borrego, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Discuss the impact of emerging angiography technologies on patient dose and safety. 2) Illustrate the usefulness of contributing to dose index registries and identify opportunities for incorporating their results into your clinical practice. 3) Describe radiation safety principles and opportunities for clinicians with fluoroscopy-privileges to engage in active learning. 4) Understand strategies for integrating novel technologies, leveraging powerful databases, and advanced learning methods with the goal of improving radiation safety and patient care.

**COURSE DESCRIPTION**

During this session we explore topics that are helping drive the practice of radiation protection in both occupational and medical exposures. This session, with a special emphasis on fluoroscopic imaging, will provide an overview of emerging dose saving technologies, national registries of dose indices, and perspectives from a physicist on how to integrate effective radiation safety training. These topics are presented with the goal of improving radiation protection and patient care in the clinic. Attendees will leave the course with an understanding of technological and behavioral changes contributing towards dose optimization and, more importantly, how they can play a key role in contributing towards improvements in radiation protection.

## Management of High-Risk Breast Lesions

Sunday, Dec. 1 9:00AM - 10:00AM Room: S406A

Sarah J. Vinnicombe, FRCR, MRCP (*Moderator*) Consultant, Bayer AG

**LEARNING OBJECTIVES**

1) Gain a greater understanding of the nature of high risk lesions. 2) Appreciate how the level of risk varies according to pathologic subtype 3) Recognize how strategies to manage these lesions are evolving, and how they vary internationally.

**COURSE DESCRIPTION**

This educational session will consist of three talks and discussion on elevated or high risk breast lesions, diagnosed on core needle biopsy. The session will highlight the challenges in pathologic diagnosis of these lesions and explore the differing management strategies of these lesions.

**Sub-Events**

### S1-CBR09B USA Perspective

Vilert A. Loving, MD, MMM (*Presenter*) Nothing to Disclose

### S1-CBR09C European Perspective

## Efficient and Focused Cardiac MRI

Sunday, Dec. 1 9:00AM - 10:00AM Room: E353C

Karen G. Ordovas, MD, MS (*Moderator*) Nothing to Disclose
Jens Bremerich, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) To review accelerated techniques for cardiac MRI. 2) To identify essential diagnostic information required in specific clinical scenarios and to focus imaging protocols.

**COURSE DESCRIPTION**

Cardiac MRI is a powerful tool for imaging myocardial structure, function, perfusion, and flow. The role of the radiologist is to taylor concise acquisition protocols focused on specific clinical situations. Lectures and discussions in this course aim to enhance knowledge on accelerated MRI techniques, patient physiology and contribution of imaging to management of specific cardiac diseases.

**Sub-Events**

### S1-CCA07C Fast & Focused: Cardiac MRI in 20 Minutes

Chiara Bucciarelli Ducci, MD, PhD (*Presenter*) Consultant, Circle Cardiovascular Imaging Inc

## Non-Traumatic Musculoskeletal Emergencies

Sunday, Dec. 1 9:00AM - 10:00AM Room: N228

Adnan M. Sheikh, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify common non-traumatic musculoskeletal conditions affecting the shoulder, hip, and pediatric populations. 2) Describe the essential imaging features associated with different patterns of non-traumatic musculoskeletal conditions. 3) Develop proficiency in interpreting imaging results to aid in timely and accurate diagnosis of musculoskeletal emergencies.

**COURSE DESCRIPTION**

This session focuses on non-traumatic musculoskeletal emergencies, emphasizing the pivotal role of imaging in diagnosis. Participants will explore common conditions affecting the shoulder, hip, and pediatric infections, gaining insights into the essential imaging features. By the end of the session, attendees will be equipped to recognize and articulate key imaging characteristics associated with various non-traumatic musculoskeletal conditions.

## Communication Errors in Radiology and How to Avoid Them: From Actionable Reports to AI (Sponsored by the RSNA Quality Improvement Committee)

Sunday, Dec. 1 9:00AM - 10:00AM Room: E450B

Bettina Siewert, MD (*Moderator*) Editor, Wolters Kluwer nv;Reviewer, Wolters Kluwer nv

**LEARNING OBJECTIVES**

1) Describe the etiology of communication errors in radiology and their impact on patient outcomes. 2) Explain measures to ensure closed loop communication in actionable reports and in verbal communication in the radiology department supported by human factors engineering and AI tools. 3) Discuss the value of a radiology consult service for communication with referring physician.

**COURSE DESCRIPTION**

Communication errors contribute to serious adverse events in 65% of cases. In malpractice cases, this increases to 80%. Communication errors in radiology adversely affect the patient in 38%. Potential impact has been noted in an additional 52% of reported near miss events. Awareness among radiologists regarding the nature of communication errors in radiology and how to avoid them is therefore critical.

This course will discuss root causes of communication errors in radiology, where in the diagnostic process communication errors most frequently occur, and which staff pairings are most vulnerable to communication errors. Countermeasures on how to avoid errors in direct communications with other staff and in radiology reports will be described. The benefit of human factors engineering and artificial intelligence tools will be discussed.

**Sub-Events**

**S1-CIN03B** **Communication Errors in Radiology: Where, When, Why, What**

## Accelerating Patient Care Through the Electronic Medical Record: Case Studies in Learning Health Systems (Sponsored by the RSNA Research Development Committee)

Sunday, Dec. 1 9:00AM - 10:00AM Room: S402

Janie M. Lee, MD, MSc (*Moderator*) Research Grant, General Electric Company;Investigator, General Electric Company
Stella Kang, MD, MSc (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Review processes for integrating and evaluating artificial intelligence applications into routine clinical practice workflows. 2) Discuss electronic medical record tools to support peer learning in the clinical setting. 3) Identify actions that clinical practices can use to leverage the electronic medical record to increase cancer screening rates.

### COURSE DESCRIPTION

Clinical data is available in electronic medical record (EMR) systems and is underutilized, or can be used in ways that introduce bias. Preparing raw data from the EMR for clinical analytics, quality improvement projects, or clinical research involves curation and transformation of raw data and variables into a dataset which can be used to analyze data, inform meaningful interventions, and assess outcomes. This session will highlight how radiology learning health systems can leverage electronic medical record (EMR) data for operational, peer learning, and clinical research goals. Using case studies, we will review strengths and important pitfalls of EMR data analysis.

## RSNA Hands-On Lab: Pediatric Musculoskeletal Ultrasound (Registration Fee Required)

Sunday, Dec. 1 9:30AM - 11:30AM Room: S504CD

Andrea S. Doria, MD, PhD (*Moderator*) Baxalta-Shire (Research Grant), Novo Nordisk (Research Grant), Terry Fox Foundation (Research Grant), PSI Foundation (Research Grant), Society of Pediatric Radiology (Research Grant), Garron Family Cancer Centre (Research Grant)

**LEARNING OBJECTIVES**

1) Review the anatomy and common pediatric pathologic musculoskeletal conditions in three pediatric joints: the shoulder, elbow and nerves of the lower extremity. 2) Use dynamic scanning of the joints to better demonstrate the anatomy of soft tissue and osteochondral components of three pediatric joints and will point out the distinction of soft tissue structures by a compression technique. 3)Discuss pathologies in the aforementioned joints as an overview of common pediatric pathologic musculoskeletal conditions.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This 120-min pediatric musculoskeletal hands-on session is targeted to general radiologists who aim to get an overview of technical and clinical application perspectives on ultrasound scanning and interpreting pathology of elbows, hands and ankles of children and adolescents.

The information provided in this session adds value to the diagnostic tools that can be used for assessment of musculoskeletal disorders that affect growing joints, particularly in young children who may require general anesthesia for MRI assessment of their joints.

The session has two parts, a 60-min hands-on part where pre-assigned radiologists scan teenager models' joints in real time and a second 60-min knowledge application part where the audience has the opportunity to scan models' joints by themselves.

## Pediatric MDC Review

Sunday, Dec. 1 9:00AM - 10:00AM Room: S401

Hesham Elhalawani, MD, MSc (*Moderator*) Nothing to Disclose
Camilo Jaimes Cobos, MD, MPH (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Engage in a multidisciplinary discussion concerning three complex pediatric oncology cases, focusing on their clinical and imaging characteristics. 2) Present recommendations from the COG/SPR consensus papers pertaining to image acquisition and interpretation. 3) Examine the role of radiation therapy in these cases, emphasizing strategic planning and delivery considerations.

**COURSE DESCRIPTION**

This interactive panel discussion will delve into three complex pediatric oncology cases. The panel, composed of two pediatric radiologists, a radiation oncologist, and a medical oncologist, will guide the conversation. Each case will be introduced through its clinical presentation and initial imaging. The medical oncologist will provide insights into the biology of the tumor, its staging, and the standard medical management. Following this, the radiation oncologist will discuss treatment alternatives, intricacies of radiation planning, and crucial aspects of delivery. The discussion will emphasize key aspects of medical imaging for each case, drawing on the recent recommendations from the Children's Oncology Group (COG)/Society for Pediatric Radiology (SPR) guidelines.

**Sub-Events**

### S1-CRO04C Pediatric MDC Review

Jessica Clymer, MD (*Presenter*) Nothing to Disclose

## Peripheral Vascular Imaging

Sunday, Dec. 1 9:00AM - 10:00AM Room: N226

Jeffrey D. Jaskolka, MD (*Moderator*) Nothing to Disclose
Kacie Kuykendall, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review CT and MR techniques for evaluating the peripheral vasculature. 2) Discuss findings on imaging examinations of the peripheral vasculature that radiologists must be able to identify. 3) Learn to use imaging findings to make diagnoses and help direct patient management.

**COURSE DESCRIPTION**

This RSNA course is geared towards providing the listener with an overview of current imaging of the peripheral vascular system. CT and MR angiogrpaphic techniques will be reviewed. Attention will be directed towards using these exams to identify findings that affect medical decision making and patient management. One particularly important disease, thoracic outlet syndrome, will be presented in detail. In addition, there will be a specific presentation addressing the role of noninvasive imaging on interventional radiology techniques and management.

**Sub-Events**

## Imaging Innovations in Obesity and Weight Loss: Shaping Patient Care from Weight Loss to Ethical Screening (Sponsored by the RSNA Public Information Committee)

Sunday, Dec. 1 9:00AM - 10:00AM Room: N227B

Vijay M. Rao, MD (*Moderator*) Nothing to Disclose
Jennifer L. Kemp, MD (*Moderator*) Stockholder, Scanslated, Inc

### LEARNING OBJECTIVES

1) Have a greater understanding of incidental imaging findings and appropriate screening in obese and overweight patients. 2) Know more about changes in body composition after weight loss and how those changes are reflected in imaging studies. 3) Grasp how medical images enhanced with cinematic rendering can aid in informing diagnoses and treatment decisions in the context of obesity, as well as improve communication with patients.

### COURSE DESCRIPTION

According to the World Health Organization, worldwide 43% of adults over 18 years old are overweight, and 16% are obese. Worldwide adult obesity has more than doubled since 1990, and adolescent obesity has quadrupled. It is critical that radiologists understand the challenges and findings associated with imaging this patient population. This course consists of three integrated lectures focused on imaging of obese or overweight patients, including those who have had weight loss from either surgery or medication. The first lecture examines appropriate screening for obese patients and touches on common incidental findings that may occur when imaging these patients. The second talk delves into changes in body composition after weight loss and impact on imaging results. Lastly, cinematic rendering has emerged as an innovative tool in diagnosis, treatment planning and communication. This talk will focus on how cinematic rendering of medical images can be utilized to help patients visualize their health and make informed decisions with their care team.

**Sub-Events**

## Strategic Career Moves Beyond Clinical Practice (Sponsored by the American Association for Women in Radiology)

Sunday, Dec. 1 9:00AM - 10:00AM Room: E350

Meridith J. Englander, MD (*Moderator*) Medical Director, Capital District Physicians' Health Plan, Inc
Catherine J. Everett, MD, MBA (*Moderator*) Shareholder, Radiology Partners;Officer, Radiology Partners;President, Eidetico Radiology Solutions;Medical Director, MSN Healthcare Solutions

### LEARNING OBJECTIVES

1) Understand Non-Clinical Career Paths: Identify and describe various non-clinical career opportunities available to radiologists and radiation oncologists, including roles in practice and hospital leadership, professional societies, and industry. 2) Analyze Career Success Stories: Consider the career paths of the featured speakers to gain insights into how they transitioned from clinical roles to significant non-clinical achievements. 3) Explore Personal Insight: Evaluate the role of professional coaching in achieving career goals. Learn strategies to identify professional interests and how to navigate the challenges of family and self-care. Explore how non-clinical roles can help mitigate burnout. 4) Assess the Impact of Mentorship: Discuss the importance of mentorship in professional development and career progression and identify strategies for seeking and benefiting from mentorship relationships. 5) Develop Strategic Career Planning Skills: Learn how to create and implement a strategic career plan, including setting realistic goals, identifying opportunities, and navigating potential challenges in pursuing non-clinical roles.

### COURSE DESCRIPTION

As radiologists and radiation oncologists progress through their careers, non-clinical roles offer opportunities to learn and use new skills. Whether it is leadership within your practice or hospital system, professional society or industry, there are many paths to career fulfillment. This session will feature speakers who have achieved significant professional successes outside of their clinical roles. Moderators will guide the panelists through a discussion of their career journeys with an emphasis on understanding the roles of personal insight, mentorship, coaching and strategic planning in reaching professional goals.

## Lung Cancer Screening (1) - US/International Perspectives and Directions (Supported by an Independent Medical Education Grant from Merck Sharp and Dohme LLC)

Sunday, Dec. 1 10:30AM - 11:30AM Room: E451A

Mark M. Hammer, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Discuss current state of lung cancer screening in the United States, Europe, and East Asia. 2) Compare and contrast eligibility for lung cancer screening across different countries. 3) Discuss challenges with increasing uptake of lung cancer screening around the world.

**COURSE DESCRIPTION**

This course will be a panel-based session with 3 speakers discussing United States and International perspectives on CT lung cancer screening. Each speaker will offer a perspective, after which we will have a lively discussion of the similarities, differences, and challenges moving forward.

**Sub-Events**

### S2-CCH01B US Perspective: Current Status and Directions

## Prostate MRI and Molecular Imaging: Core and Advanced Applications

Sunday, Dec. 1 10:30AM - 11:30AM Room: E353B

Spencer C. Behr, MD (*Moderator*) Grant, Cancer Targeted Technology;Scientific Advisory Board, Novartis AG;Research Consultant, GenVivo
Aytekin Oto, MD (*Moderator*) Research Grant, Koninklijke Philips NV;Medical Advisory Board, Profound Medical Inc;Consultant, IBM Corporation;Co-founder, Qmis LLC;Co-owner, Qmis LLC

### LEARNING OBJECTIVES

1) Explore the latest advancements in prostate imaging, with a particular focus on MRI and PET imaging techniques. 2) Analyze the clinical performance expectations and limitations of AI in Prostate MRI, aiming to set realistic benchmarks for clinical application. 3) Prepare for the integration of MRI in routine prostate cancer screening protocols, including considerations for technology, workflow, and patient selection.

### COURSE DESCRIPTION

This educational session aims to provide a comprehensive update on the latest developments on prostate imaging with a special focus on MR and PET imaging. The presentations cover a well-balanced, broad scope from practical, updated tips for optimized prostate MR acquisition and interpretation to new techniques such as PET MRI and PSMA PET imaging. There will be a critical examination of the use of artificial intelligence in Prostate MRI, discussing both its potential and its limitations to establish realistic clinical expectations. The session will guide attendees on how to effectively incorporate MRI into routine prostate cancer screening protocols, considering technological needs, workflow integration, and patient selection criteria. Finally, the course will address healthcare disparities in prostate imaging by identifying existing inequities and proposing strategies to mitigate them.

**Sub-Events**

### S2-CGU01C Prostate MR Update: What is in the Horizon?

## Telemammography: Success Stories, Tools for Troubleshooting, and Embracing Innovation

Sunday, Dec. 1 10:30AM - 11:30AM Room: E351

Mindy L. Yang, MD (*Moderator*) Clinical Advisory Board, Solutionreach, Inc

**LEARNING OBJECTIVES**

1) Identify benefits and challenges of telemammography. 2) Understand the current status of telemammography in various practice settings. 3) Identify specific troubleshooting tips and solutions for optimizing telemammography in the real world.

**COURSE DESCRIPTION**

Telemammography, including remote screening and diagnostic mammography, while sparsely utilized in the past, has gained significant traction in recent years, offering several potential advantages including improved patient access to high level fellowship-trained breast radiologists as well as efficient turnaround from screening to diagnosis and subsequent downstream treatment of breast cancer. Given the unique challenges of evaluating a breast patient remotely, a hybrid didactic and interactive discussion of the pearls and pitfalls by experts in the field will help breast imagers gain confidence and improve problem-solving in the telemammography setting.

**Sub-Events**

**S2-CIN01B** **Discussion of Innovative Strategies Including Possible Incorporation/Impact of AI Tools in this Practice**

## Emerging Topics in AI: Trustworthiness, Safety, Ethics and Bias

Sunday, Dec. 1 10:30AM - 11:30AM Room: E450B

Shandong Wu, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the importance of the trustworthiness, bias, and ethics in advancing AI for clinical translation and practice. 2) Learn about the key factors that are associated with gaining trust to, mitigating biases of, and incorporating ethical considerations in medical AI. 3) Identify challenges and opportunities to improve clinical implementation and adoption of AI in clinical settings.

**COURSE DESCRIPTION**

Artificial intelligence (AI) is gaining rapid evolvement and showing early success in radiology for clinical translation and applications, with great potential to increase diagnosis accuracy, optimize workflow efficiency, reduce unnecessary procedures, and save costs. To achieve scaled impact of radiology AI in operational clinical settings, it is critical for medical AI to be trustworthy for clinicians, informaticists, providers, and patients. This indicates challenges and opportunities in ethical design, rigorous evaluation, bias mitigation, secure/safe deployment, practical acceptance, human-AI synergy, and equitable access. The speakers of this course will discuss important pillars of trustworthy AI and important considerations on bias and ethics, which will help the attendees understand the importance of trust for AI's utilities, learn insights on advancing AI translation, and identify opportunities for research, practice, and collaboration.

## State-of-the-Art Management of Hepatocellular Carcinoma

Sunday, Dec. 1 10:30AM - 11:30AM Room: S402

Julius Chapiro, MD, PhD (*Moderator*) Research Grant, Guerbet SA;Consultant, Guerbet SA;Research Grant, Boston Scientific Corporation;Consultant, AstraZeneca PLC;Consultant, Bayer AG

### LEARNING OBJECTIVES

1) To understand the current landscape of HCC imaging and image-guided interventions including staging, treatment algorithms and therapy combinations. 2) To learn about novel developments and evolution of combination therapies in intermediate-advanced stage HCC and the role of image-guided therapies. 3) To learn about novel technologies, including AI, virtual reality, robotics and personalized staging systems. 4) To refresh on available percutaneous and transarterial therapy options and their advanced utilization in the multi-modal therapy of HCC.

### COURSE DESCRIPTION

The course will feature an update on advanced imaging and image-guided interventions in primary liver cancer, highlighting recent updates on imaging guidelines, therapy recommendations as well as an update on novel technologies and therapeutics. The course will highlight recent developments involving prospective clinical trials that combine locoregional therapy and immunotherapy of HCC and touch on new developments in AI facilitating image-guidance, imaging standardization and patient workflows.

**Sub-Events**

## Optimization of MSK Imaging: Pitfalls and Workarounds (Supported by an Unrestricted Medical Education Grant from Carestream Health, Inc.)

Sunday, Dec. 1 10:30AM - 11:30AM Room: E450A

Robert D. Boutin, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Recognize particularly important pitfalls encountered in MSK imaging that can adversely affect accuracy and efficiency. 2) Identify practical strategies to address pitfalls, with actionable tips for optimizing MSK imaging.

**COURSE DESCRIPTION**

This course provides essential insights and expert advice for optimizing effectiveness in musculoskeletal radiology. Participants will gain practical knowledge by effectively recognizing common pitfalls and identifying how to implement effective workarounds with valuable tips and tricks. By attending this course, radiologists can enhance their diagnostic accuracy, improve patient care, and stay up-to-date with the latest advancements in musculoskeletal imaging.

**Sub-Events**

## MRI and Ultrasound Elastography: Where Do We Stand?

Sunday, Dec. 1 10:30AM - 11:30AM Room: N226

Margarita V. Revzin, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Discuss pros and cons of Ultrasound versus MRI elastography in evaluation of liver fibrosis. 2) Discuss pros and cons of Ultrasound versus MRI elastography in evaluation of musculoskeletal pathologies. 3) Discuss pros and cons of Ultrasound versus MRI elastography in the evaluation of various other vascular and abdominal/pelvic pathological processes, including but not limited to kidneys, spleen, transplants, scrotum, ovaries and more.

**COURSE DESCRIPTION**

Elastography is gaining popularity in the assessment of various solid and hollow organs and structures, and pathological processes, including but not limited to liver disease, thyroid nodules, breast lesions, vascular clot pathology, scrotal masses and more.

The session provides a detailed review of various applications of elastography using MRI and Ultrasound, with emphasis on benefits and limitations of each modality in the assessment of different pathological conditions. Specifically, elastography applications in the Abdomen/Pelvis, Musculoskeletal, and Vascular Systems will be discussed. The session's format is panel discussion.

**Sub-Events**

### S2-CMS01B MR Elastography in GI, GU, MSK

Richard L. Ehman, MD (*Presenter*) CEO, Resoundant, Inc;Stockholder, Resoundant, Inc;

## Epilepsy Imaging - Pearls, Pitfalls and the Misses

Sunday, Dec. 1 10:30AM - 11:30AM Room: S406B

Dhairya Lakhani, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify the range of hippocampal abnormalties in temporal lobe epilepsy. 2) Understand potential pitfalls in interpretation of FDG-PET in epilepsy. 3) Learn the role and potential challenges of epilepsy imaging at 7T.

**COURSE DESCRIPTION**

Epilepsy is a common and debilitating neurological condition, with imaging playing a crucial role in patient evaluation and outcome prediction. This multi-part lecture series will delve into the complexities of epilepsy imaging, covering four key modalities: MRI, PET, fMRI, and ultra-high field MRI. Speakers will share essential insights for evaluating epilepsy patients and highlight common pitfalls in interpreting cases across each modality. By the end of the session, attendees will be better equipped to navigate the challenges of epilepsy imaging and identify common mistakes made in imaging interpretation.

## Virtual Clinical Trial

Sunday, Dec. 1 10:30AM - 11:30AM Room: S404

Ehsan Samei, PHD (*Moderator*) Research Grant, General Electric Company;Advisory Board, General Electric Company;Research Grant, Siemens AG;Advisory Board, Siemens AG;Advisory Board, medInt Holdings, LLC;Advisory Board, Metis Health Analytics;Research Consultant, Nanox Imaging Ltd;Royalties, General Electric Company;Royalties, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Mirion Technologies, Inc;Royalties, Cambridge University Press;Royalties, John Wiley & Sons, Inc

### LEARNING OBJECTIVES

1) Understand the role of virtual trials in medicine and in radiology. 2) Understand the components of virtual imaging trials. 3) Understand the research, clinical, and regulatory potentials of virtual trials.

### COURSE DESCRIPTION

The complexity and diversity of medical imaging technologies have continued to accelerate, outpacing our ability to optimize their use. This has become a significant challenge across the spectra of scientific inquires, product designs, and clinical applications. New imaging technology has been traditionally evaluated through clinical trials. However, such trials are often not feasible or even definitive due to ethical limitations, expense, time requirements, difficulty in accruing enough subjects - especially with low prevalence conditions, or the fundamental lack of ground truth. Virtual Clinical Trials (VCT) provide a new paradigm to assess the impact of medical imaging innovations on patient care. VCTs offer a new disease-known approach to conduct medical trials that can be clinically relevant, timely, and accurate while reflecting the variabilities of human subjects and disease, as well as the complexities of technologies, providing answers that would otherwise be impractical to obtain or simply unattainable. A VCT consists of 1) realistic populations of computational patients spanning ages and a range of phenotypical characteristics including sex and race with realistic models of disease, 2) detailed models of clinical imaging systems, and 3) computational models of the image interpretation processes. This session offers a summary of VCT methods and processes in the field of radiology and highlights applications in clinical practice and in the regulatory assessment of imaging products.

## DCIS Non-Traditional Treatment and Management

Sunday, Dec. 1 1:00PM - 2:00PM Room: S406A

Nisha Sharma, MBChB, FRCR (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Have a clear understanding of the current challenges with DCIS from an imaging and oncological perspective. 2) Recognize the need for change. 3) Understand the barriers to change.

**COURSE DESCRIPTION**

DCIS Non-Traditional Treatment and Management

This is an important and challenging topic for all of us. The three speakers will discuss this topic from the perspective of population data, imaging perspective and advances in imaging techniques and from an oncological perspective - the shifts in traditional treatment to evidence based need for treatment. The speakers will highlight the challenges we face and how do we move forward in a collaborative way

**Sub-Events**

### S4-CBR02B Radiology Perspective on DCIS

Lars J. Grimm, MD (*Presenter*) Advisor, Hologic, Inc;Consultant, Hologic, Inc;Editorial Advisory Board, WebMD Health Corp (WebMD, Inc)

### S4-CBR02C Oncology Perspective

## Essentials of Mapping Targets for Ablation: Imaging Guidance for Electrophysiology Procedure Planning

Sunday, Dec. 1 1:00PM - 2:00PM Room: E353C

Jamie L. Schroeder, MD, DPhil (*Moderator*) Nothing to Disclose
Jiayin Zhang, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Realize the significance of interactive 3D modeling in guiding EP procedure. 2) Explain the value of advanced CT imaging in EP planning. 3) Identify the role of CMR biomarkers in EP Planning.

**COURSE DESCRIPTION**

The course aims to provide insights into the role of multi-modality imaging for electrophysiology procedure planning. CT is helpful for 3D mapping of left atrium and excluding thrombus. In addition to the anatomical evaluation, the imaging of AF substrate is also essential. This course will provide a general view of the essentials of mapping targets for ablation.

## A Case-Based Review of Pediatric Trauma

Sunday, Dec. 1 1:00PM - 2:00PM Room: N228

Summer L. Kaplan, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe common mechanisms of trauma in children. 2) Discuss how developmental changes in the body predispose children to unique injuries. 3) Explore common and easily missed features of pediatric trauma. 4) Explain features of non-accidental trauma apparent on imaging. 5) Understand "Do Not Miss" imaging findings in pediatric trauma.

**COURSE DESCRIPTION**

An intensive series of lectures focused on essential diagnoses in pediatric abdominal trauma, musculoskeletal trauma, neurological trauma, and chest trauma. The focus will be identifying critical imaging features, producing accurate and clinically relevant reports, developing strategies to address diagnostic challenges, and ensuring effective patient management in pediatric trauma settings.

**Sub-Events**

## RSNA Hands-On Lab: Liver Elastography (Registration Fee Required)

Sunday, Dec. 1 1:30PM - 3:30PM Room: S504CD

Richard G. Barr, MD, PhD (*Moderator*) Consultant, Siemens AG;Speakers Bureau, Siemens AG;Research Grant, Siemens AG;Consultant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Consultant, Canon Medical Systems Corporation;Advisor, Hologic, Inc;Research Grant, Hologic, Inc

**LEARNING OBJECTIVES**

1) To review the protocol required for accurate liver stiffness measurements. 2) To discuss the confounding factors needed to be considered when interpreting results. 3) Identify the various quantitative ultrasound methods for liver fat quantification.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

Chronic Liver disease is a world-wide health problem. The use of multiparametric ultrasound can assess the presence of disease, severity of the disease, and monitor treatment. This course will review how to perform and interpret liver elastography. For accurate measurements a strict protocol is required. The protocol will be reviewed, and potential acquisition errors will be discussed. Confounding factors will be discussed as they can significantly affect the interpretation of the results. The course will also review the state-of-the-art for quantitative ultrasound assessment of liver fat content which is critical in making the diagnosis of non-alcoholic fatty liver disease. The combination of these techniques will be discussed on how to evaluate chronic liver disease.

**Sub-Events**

## Is it a TUMOR? Case Based Review of Common Mimics in the Brain, Spine, Head and Neck (Joint Session with Neuroradiology)

Sunday, Dec. 1 1:00PM - 2:00PM Room: E352

Ian T. Mark, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify cross-sectional imaging findings of malignancies in the brain, spine, and head and neck. 2) Distinguish the imaging appearances of malignancy from their non-malignant mimics. 3) Learn common imaging pitfalls related to the diagnose of malignancy.

**COURSE DESCRIPTION**

This case-based imaging review will show a series of examples to highlight how to distinguish malignancies in the head, neck, brain and spine from their mimics, with a focus on don't miss diagnoses and imaging pitfalls. This is a DO NOT MISS session for radiologists who read cross-sectional imaging of the brain, spine, or head & neck!

## Contract Review and Negotiation (Sponsored by the RSNA Resident and Fellow Committee)

Sunday, Dec. 1 1:00PM - 2:00PM Room: S402

Heba Albasha, MD (*Moderator*) Nothing to Disclose
Jocelyn Cheng, MD (*Moderator*) Nothing to Disclose
Megan K. Mercer, MD (*Moderator*) Nothing to Disclose
Aishwariya S. Vegunta, MD (*Moderator*) Nothing to Disclose
Brandon K.K. Fields, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Identifying the key elements of a contract. 2) Defining and explaining common contract terms. 3) Comparing and contrasting different compensation models. 4) Assessing the fairness of benefits and compensation packages. 5) Identifying and understanding the business and legal consequences of contracts. 6) Highlight contract negotiation strategies.

### COURSE DESCRIPTION

The ability to negotiate and understand contracts is one of the most challenging aspects of the job search. This session will provide participants at all career levels with tips and strategies for understanding and negotiating contracts. During this session, the various elements of a contract will be broken down and reviewed. In this process, the speakers will also explain common contract language. Key differences between contracts in private practice versus academics will be discussed. Sample academic and private practice contracts will be dissected in detail. Additionally, the speakers will describe the elements of a contract that may be negotiated and strategies for negotiation. Furthermore, options to add value to a contract with non-compensation-related benefits will be suggested.

## Hot Topics in Pediatric Imaging: Molecular Biomarkers and AI

Sunday, Dec. 1 1:00PM - 2:00PM Room: E350

Safwan Halabi, MD (*Moderator*) Advisor, Change Healthcare
Teresa Chapman, MD, MA (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Summarize the current status of imaging biomarkers in pediatric abdominal imaging, their value and current clinical applications. 2) Explore various clinical examples of radiomics applied to enhance diagnosis of intracranial tumors in children. 3) Discuss value-added and clinical indications of PET-CT and PET-MRI in the children. 4) Discuss available AI algorithms currently approved for the pediatric population and the appropriateness of using algorithms originally designed for the adult population in children.

**COURSE DESCRIPTION**

In this hour-long pediatric imaging-focused session, four lectures will summarize past, present and upcoming topics surrounding molecular biomarkers and artificial intelligence. The audience members will gain improved understanding of advancements in pediatric care as they relate to neuro-oncology, abdominal imaging, positron-emission tomography advances, and AI.

**Sub-Events**

### S4-CPD10C Biomarkers: PET-CT/PET-MRI Indications

Helen R. Nadel, MD, FRCPC (*Presenter*) Consultant, ICON plc;;

### S4-CPD10D Imaging Biomarkers in the Pediatric Body: What They Are and Where We Are in the Field Now

## AAPM/RSNA Physics Tutorial 1: Tutorial on Basics of Flat Panel C-Arm CT and Its Use in Interventional Radiology

Sunday, Dec. 1 1:00PM - 2:00PM Room: N226

Thaddeus A. Wilson, PhD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Flat panel technologies: this section explains the fundamental structure and different designs of the flat panel detector, covering both the direct and indirect conversion approaches. Characteristics of different flat panels often lead to different CT designs.

2) Flat panel CT: this section describes how CT data are acquired and how images are generated. The goal is not to dive deep into the mathematics, but to provide an intuitive explanation of the image reconstruction process. Similarities and differences between flat panel CT and the x-ray computed tomography are discussed.

3) Applications and future development: this section provides a brief survey of major clinical applications of the flat panel CT. The session concludes with a brief discussion on the future technology development and applications.

### COURSE DESCRIPTION

Flat panel-based CT has been used extensively in many clinical applications. The goal of this course is to provide an introductory overview of the technology, a brief survey of major clinical applications, and a quick exploration of the future.

**Sub-Events**

**S4-CPH13B** **Basics of Flat Panel C-Arm CT and Its Use in Clinical Applications**

## Early Interstitial Lung Abnormality - Categorization and Management

Sunday, Dec. 1 2:30PM - 3:30PM Room: E451A

David A. Lynch, MBBCh (*Moderator*) Research Consultant, CALYX Inc;Research Consultant, Boehringer Ingelheim GmbH;Research Consultant, Veracyte, Inc;Research Consultant, DAIICHI SANKYO Group;Research Consultant, AstraZeneca PLC;Consultant, Polarean, Inc;Consultant, Bristol Myers Squibb Company

### LEARNING OBJECTIVES

1) Define interstitial lung abnormalities (ILAs) and identify important subtypes. 2) Differentiate between ILAs and early/subclinical interstitial lung disease (ILD). 3) Understand the clinical significance and management of ILAs.

### COURSE DESCRIPTION

This session will provide the most recent imaging and clinical information on interstitial lung abnormalities (ILAs). Topics for this rapidly evolving area will include defining ILAs and their specific CT patterns, understanding smoking related interstitial abnormalities, the clinical significance of ILAs from a pulmonologist's perspective, and the significance of early ILA in higher risk individuals such as those with connective tissue disease.

## Multisystem Diseases Jeopardy

Sunday, Dec. 1 2:30PM - 3:30PM Room: N229

Margarita V. Revzin, MD, MS (*Moderator*) Nothing to Disclose
Stacy E. Smith, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Learn with the contestants various signs and pathognomonic imaging findings of diseases involving multiorgan multisystem. 2) Challenge yourself with answering the questions for the audience. 3) Support Contestants and Have Fun!

### COURSE DESCRIPTION

This session will help attendees to improve the quality of their interpretations of the findings specific to a particular multisystemic disease.

The session will follow a “gameshow” format based on “Jeopardy”, featuring a panel composed of experts specializing in various fields of Radiology. Categories and questions will facilitate discussion on experiences from the panelists, including main differentiating features of certain diseases that aid in differentiation of various diagnostic multisystemic entities. The cases will be divided into 5 categories with topics including congenital, immune, oncology, infection, vascular, and metabolic multisystemic diseases. Questions will include examples inspired by the panelists’ suggested diagnoses.

The “gameshow” format will help deliver the content through targeted discussion, while offering an opportunity for the audience to interact with panelists throughout the session. Participants will be familiarized with presentations of various multisystemic diseases and learn decision algorithms which will help in making an accurate diagnosis.

## The Radiologist and the Patient

Sunday, Dec. 1 2:30PM - 3:30PM Room: S402

Colbey W. Freeman, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the payment policies and regulations that impact radiologists' ability to bill for patient consults. 2) Describe how frequently patients utilize available tools and systems to speak directly to radiologists. 3) Legal implication of communicating radiology results directly to the patient: Should we do it? If so, when? 4) Understand the impact of the 21st Century Cures Act outside of Radiology.

**COURSE DESCRIPTION**

This session will focus on a number of important aspects of patient-radiologist interactions, including consultations with patients and the economic considerations, the legal ramifications of communicating directly with patients, and the impact of the 21st Century Cures Act.

**Sub-Events**

### S5-CNPM18B Do Patients Want to Speak to Radiologists? What Does the Evidence Say?

Colbey W. Freeman, MD (*Presenter*) Nothing to Disclose

### S5-CNPM18C 21st Century Cures Act. The Opinion of Referring Clinicians on Early Disclosure of Results to Patients

## Practical Use of AI in Daily Neuroradiology Practice: Challenges and Opportunities

Sunday, Dec. 1 2:30PM - 3:30PM Room: S406B

Amish H. Doshi, MD (*Moderator*) Speaker, Becton, Dickinson and Company;Consultant, Siemens AG

**LEARNING OBJECTIVES**

1) Gain a comprehensive understanding of the current utilization of artificial intelligence (AI) in clinical neuroradiology practice. 2) Explore and articulate practical applications of AI within neuroradiology, highlighting how these technologies are integrated into diagnostic and treatment workflows. 3) Describe the challenges and opportunities presented by existing AI applications in neuroradiology, assessing their impact on clinical decision-making, patient outcomes, and operational efficiency.

**COURSE DESCRIPTION**

This course will feature lectures that explore the contemporary applications of artificial intelligence (AI) in Neuroradiology, focusing on practical implementations. Lecturers will use real-life examples to underscore the challenges facing AI adoption in clinical settings. Additionally, they will discuss opportunities to enhance patient care, safety, and radiology diagnostic interpretation and efficiency.

**Sub-Events**

### S5-CNR07B AI Powered MRI Acceleration of the Brain and Spine - Speed vs. Quality

Lawrence N. Tanenbaum, MD (*Presenter*) Speaker, General Electric Company;Speaker, Siemens AG;Speaker, Guerbet SA;Speaker, Koninklijke Philips NV;Consultant, icoMetrix NV;Consultant, Subtle Medical, Inc;Consultant, Columbo;Consultant, iMedis;Consultant, Agamon;Consultant, FUJIFILM Holdings Corporation

### S5-CNR07C Clinical Implementation of AI in Brain Tumor Imaging

Mariam S. Aboian, MD, PhD (*Presenter*) Researcher, Blue Earth Diagnostics Ltd;Researcher, Fusion Pharmaceuticals;Research collaboration, Pro Medicus Limited

### S5-CNR07D Report Automation in Neuroimaging

Jason F. Talbott, MD, PhD (*Presenter*) Nothing to Disclose

## Zooming In - FAST MRI Imaging: Imaging with the Wiggles (Partially supported by an Unrestricted Educational Grant from Guerbet LLC.)

Sunday, Dec. 1 2:30PM - 3:30PM Room: N227B

Teresa Chapman, MD, MA (*Moderator*) Nothing to Disclose
Ting Y. Tao, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Recognize the strengths and limitations of motion reduction methods to enable selection of the appropriate techniques for pediatric abdominal MRI. 2) Apply a structured program to minimize the potential risks of intravenous contrast in pediatric MRI. 3) Highlight barriers/challenges in implementation of a rapid MRI appendicitis program with guidance on potential solutions. 4) Learn methods for reduced imaging time and improved image quality of diffusion weighted imaging (DWI) in the abdomen and pelvis.

**COURSE DESCRIPTION**

In this session of four separate lectures, learners will have the opportunity to pick up new skills and ideas for protocol optimization allowing for fast MR imaging of the abdomen and pelvis in our pediatric patients. Our expert faculty presenters will cover aspects of pediatric abdominal imaging including synthetic MRI- and AI deep learning-based reconstruction methods, clinical indications for intravenous contrast agents in pediatric abdominal MRI, the medical evidence supporting a need for fast pediatric MRI to diagnosis appendicitis, and a review of the current and potential future applications of diffusion weighted imaging in the pediatric abdomen.

**Sub-Events**

### S5-CPD05C MRI Sequences for Pediatric Imaging: The Old and The New

Suraj D. Serai, PhD (*Presenter*) Nothing to Disclose

### S5-CPD05D Indications for Intravenous Contrast in Pediatric MRI and Strategies to Minimize Its Use

Michael S. Gee, MD, PhD (*Presenter*) Researcher, General Electric Company Researcher, Siemens AG Researcher, Motilent LLC

## Total Body PET/CT Imaging: Current and Future Status of this Technology Innovation

Sunday, Dec. 1 2:30PM - 3:30PM Room: S404

Osama R. Mawlawi, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn about the various commercial TB system offerings and their performance characteristics. 2) Learn about the potential clinical and research applications of TB PET/CT systems. 3) Develop an in-depth understanding of the advantages and challenges of TB PET/CT systems.

**COURSE DESCRIPTION**

Total body (TB) PET/CT is one of the major recent innovations in the field of PET imaging. This is evidenced by the introduction of several TB systems from various manufacturers such as General Electric, SIEMENS, and United imaging. With total body PET there are potential advantages of reduced scan duration, decreased patient radiation dose, new clinical/research applications and quantitative outcome measures. This session will discuss the design and performance characteristics of these various systems as well as their potential clinical and research applications in oncology. A moderated debate centered around the need for TB systems in nuclear medicine is also included in this session and will cover the advantages/need for these systems versus their challenges.

**Sub-Events**

### S5-CPH12B Commercial TB PET/CT Systems and their Performance Characteristics

Ramsey Badawi, PhD (*Presenter*) Research Grant, Shanghai United Imaging Healthcare Co, Ltd;Institutional research agreement, Shanghai United Imaging Healthcare Co, Ltd

### S5-CPH12C Clinical and Research Applications of TB PET/CT Systems

Brian J. Burkett, MD, MPH (*Presenter*) Nothing to Disclose

### S5-CPH12D Moderated Debate/Discussion: Should or Shouldn't We Buy a TB PET/CT System

Osama R. Mawlawi, PhD (*Presenter*) Nothing to Disclose

### S5-CPH12E Moderated Debate/Discussion: Should or Shouldn't We Buy a TB PET/CT System

Ramsey Badawi, PhD (*Presenter*) Research Grant, Shanghai United Imaging Healthcare Co, Ltd;Institutional research agreement, Shanghai United Imaging Healthcare Co, Ltd

## AAPM/RSNA Physics Tutorial 2: Tutorial on Yttrium-90 Microspheres in Interventional Radiology Practices

Sunday, Dec. 1 2:30PM - 3:30PM Room: N226

Thaddeus A. Wilson, PhD (*Moderator*) Nothing to Disclose

**COURSE DESCRIPTION**

As Y-90 has increased significantly and falls presently under the purview of interventional radiologist and radiological physicists this course is intended to give a broad overview of the implementations and use of the new device. It is also going to cover the safety and dosimetry of these high energy beta particle based therapies.

**Sub-Events**

### S5-CPH14B The Nuts and Bolts of Yttrium-90 Radioembolization

Osmanuddin S. Ahmed, MD (*Presenter*) Speaker, Canon Medical Systems Corporation;Research Grant, Canon Medical Systems Corporation;Speaker, Becton, Dickinson and Company;Speaker, Cook Group Incorporated;Advisory Board, Boston Scientific Corporation;Advisory Board, Argon Medical Devices, Inc;Speaker, Koninklijke Philips NV;Speaker, Argon Medical Devices, Inc;Advisory Board, Argon Medical Devices, Inc;Consultant, Asahi Kasei Medical Co, Ltd;Consultant, Medtronic plc;Speaker, Penumbra, Inc;Speaker, Inari Medical, Inc

### S5-CPH14C Dosimetry and Safety Considerations for Yttrium-90

## GI Multidisciplinary Review

Sunday, Dec. 1 2:30PM - 3:30PM Room: S401

Ann Raldow, MD, MPH (*Moderator*) Consultant, ViewRay, Inc

**LEARNING OBJECTIVES**

1) Review the anatomy and physiology of the liver, biliary tract, and surrounding structures relevant to the diagnosis and management of hepatobiliary malignancies. 2) Discuss the various treatment modalities available for hepatobiliary malignancies, including surgical resection, liver transplantation, locoregional therapies, systemic chemotherapy, targeted therapy, and immunotherapy. 3) Discuss the challenges and controversies in the management of hepatobiliary malignancies, including surveillance strategies, treatment sequencing, and the integration of emerging therapies into clinical practice.

**COURSE DESCRIPTION**

This course offers a comprehensive review of hepatobiliary malignancies, focusing on the anatomy, diagnosis, and management of these complex and challenging diseases. Participants will explore the latest advancements in treatment modalities, including surgical techniques, systemic therapies, and emerging immunotherapies. Through interactive discussions and case-based learning, attendees will gain insights into the multidisciplinary approach necessary for optimal patient care and address the challenges and controversies in the management of hepatobiliary malignancies.

**Sub-Events**

**S5-CRO03B** **GI Multidisciplinary Review**

S5-RCP15

## Growing Green Radiology: Building Teams, Engaging Stakeholders, and Defining Measurements (Sponsored by the RSNA Professionalism Committee)

Sunday, Dec. 1 2:30PM - 3:30PM Room: E352

Kate Hanneman, MD, MPH (*Moderator*) Speaker, Groupe Sanofi;Speaker, Amicus Therapeutics, Inc
Maura J. Brown, MD (*Moderator*) Synthesis Health Inc - research collaboration, no financial relationship at this time ( Nov 2022).

**LEARNING OBJECTIVES**

1) Discuss a practical approach to creating a green radiology team in radiology departments, including key stakeholders to engage, and an action plan to implement changes. 2) Describe key measurements and metrics, define short- and long-term goals, highlight the role of dashboards, key performance indicators, and AI to improve environmental sustainability in radiology. 3) Explore the need for collaboration and engagement with industry partners to support environmental sustainability in radiology and align technical development with the goal of reducing emissions and reliance on finite resources. 4) Discuss the need for advocacy and the role of regulators and other professional organizations in improving environmental sustainability in radiology.

**COURSE DESCRIPTION**

The overarching purpose of this course is to discuss the intersection of environmental sustainability and radiology and provide a practical roadmap to establishing local green teams, engaging key stakeholders, collaborating with industry and vendor partners, and defining key measurements and metrics.

**Sub-Events**

### S5-RCP15C Building Environmental Sustainability Green Teams in Radiology

Benjamin E. Northrup, MD (*Presenter*) Nothing to Disclose

### S5-RCP15D Green Radiology Teams: Outcomes, Metrics, and Measurements

Katherine E. Maturen, MD, MS (*Presenter*) Nothing to Disclose

### S5-RCP15E Vendor and Industry Engagement to Improve Environmental Sustainability in Radiology

## Economics of Imaging (Sponsored by the RSNA Associated Sciences Consortium)

Tuesday, Dec. 3 8:00AM - 9:00AM Room: N226

Catherine Gunn, MBA, RT (*Moderator*) Nothing to Disclose
Keith Chew, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Important forecast updates, along with how top trends and new developments will impact the growth outlook. 2) How factors such as technology advances, industry landscape, and other market trends are intersecting to impact Diagnostic Imaging. 3) Considerations for strategic planning.

**COURSE DESCRIPTION**

The increased demand for imaging services is being met with continued workforce challenges and reimbursement pressures. Delayed capital investments, which have left many providers with aged equipment, now require proactive asset management and strategic planning to meet future demand with the appropriate technology. Challenging system-wide management strategies, imaging volumes are expected to continue to shift to lower-cost outpatient facilities as the industry landscape evolves. To improve cost, quality, access to care, and patient/clinician experience, radiology providers should consider the forecasting and trends impacting the industry.

## Breast AI in Clinical Practice...Are We There Yet?

Tuesday, Dec. 3 8:00AM - 9:00AM Room: S406A

Linda Moy, MD (*Moderator*) Grant, Siemens AG Advisory Board, Lunit Inc Advisory Board, iCad, Inc

**LEARNING OBJECTIVES**

1) Update the roles of artificial intelligence (AI) for breast imaging into clinical practice. 2) Explain the current clinical applications of AI such as standalone AI, triage and risk prediction.

**COURSE DESCRIPTION**

AI for breast imaging is evolving quickly. This course will the hurdles to clinical implementation to AI. Issues such as the pearl and pitfalls of AI in breast imaging will be reviewed. The important issue of what we have learned from clinical trials of AI and breast imaging will be highlighted. Regulatory concerns for AI and procurement framework that will incentivize the adoption of AI in clinical care while keeping our patients safe will be addressed.

**Sub-Events**

### T1-CBR01B Pearls and Pitfalls of AI in Clinical Practice Implementation

## RSNA Hands-On Lab: Breast US Biopsy (Registration Fee Required)

Tuesday, Dec. 3 8:30AM - 10:30AM Room: S504CD

Stamatia V. Destounis, MD (*Moderator*) Medical Advisory Board, iCad, Inc

**LEARNING OBJECTIVES**

1) Identify the different types of biopsy devices and understand the ultrasound biopsy process as to obtain tissue for diagnosis. 2) Explain the current clinical applications of needle biopsy devices in daily breast practice.

**COURSE DESCRIPTION**

Identify and review the multiple biopsy devices whether spring loaded or vacuum and how to utilize for breast biopsy with guidance and support from expert breast faculty.

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

## Cardiac Imaging in Private Practice: Maximizing Efficiency With Quality

Tuesday, Dec. 3 8:00AM - 9:00AM Room: E353C

Whitney B. Edmister, MD, PhD (*Moderator*) Consultant, McKesson Corporation
Michael F. Morris, MD (*Moderator*) Educator, Medtronic plc

**LEARNING OBJECTIVES**

1) Identify strategies for improving workflow and patient throughput in cardiac MRI and CT. 2) Understand how AI can assist with cardiac MRI and CT, and which AI tools can be used in current practice. 3) Learn how a 3D post processing lab can help improve efficiency, standardization, and quality.

**COURSE DESCRIPTION**

This course covers methods for improving efficiency in cardiac MRI/CT, which is applicable to imagers in private practice and academic/employed settings. Topics include techniques for improving efficiency via high throughput workflows, how to use AI/which AI programs to use, and the utility of a virtual or in-person 3D lab.

## Multimodal Imaging in Urogenital Cancers: Integrating PET, MRI, and CT

Tuesday, Dec. 3 8:00AM - 9:00AM Room: E353B

Devaki Shilpa S. Surasi, MD (*Moderator*) Research support, Blue Earth Diagnostics Ltd
Garvit D. Khatri, MBBS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the principles, protocols and imaging techniques in the evaluation of urogenital cancers. 2) Identify key imaging features and patterns across imaging modalities to improve detection, characterization, and staging of urogenital cancers. 3) Develop strategies for interdisciplinary collaboration among radiologists, oncologists, and urologists to optimize the use of PET, MRI, and CT imaging in urogenital cancer management. 4) Recognize common pitfalls and limitations associated with PET, MRI, and CT imaging in urogenital cancer assessment and develop strategies to overcome them.

**COURSE DESCRIPTION**

Course description:

This case based interactive session will delve into the imaging, comprehensive evaluation and management of urogenital cancers. Through a series of engaging cases, participants will explore the synergistic advantages of multimodality imaging in enhancing diagnostic accuracy, treatment planning, and patient outcomes in urogenital cancer care. Session will be divided into four case based sessions including the adrenals, kidneys, bladder and prostate.

Advantages :

Cutting-Edge Insights: Discover the latest advancements and techniques in multimodality imaging for urogenital cancers, providing attendees with cutting-edge insights into latest developments.

Interactive Case Studies: Engage in interactive case discussions led by experts, offering attendees a unique opportunity to apply theoretical knowledge to real-world scenarios and refine their diagnostic skills.

Practical Strategies: Acquire practical strategies and solutions for overcoming challenging cases to enhance clinical decision-making in their practice.

CME Credits: Earn valuable continuing medical education (CME) credits by participating in this educational session, enhancing your professional development while staying up-to-date with the latest advancements in urogenital cancer imaging.

T1-CMS08

## Paraneoplastic Syndromes: Head to Toe

Tuesday, Dec. 3 8:00AM - 9:00AM Room: S402

Margarita V. Revzin, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review pathophysiology and clinical presentations of paraneoplastic syndromes. 2) Discuss neurologic imaging findings in paraneoplastic syndromes associated with malignancies. 3) Discuss paraneoplastic manifestations of chest, abdominal and pelvic malignancies. 4) Discuss musculoskeletal and dermatologic manifestations of paraneoplastic syndromes and associated malignancies.

**COURSE DESCRIPTION**

Recent advances in medicine have improved the understanding of the pathogenesis of paraneoplastic syndromes (PNSs) and enhanced their diagnosis and treatment. Knowledge of various PNSs is necessary, as these syndromes may precede tumor development, complicate the patient's clinical presentation, indicate tumor prognosis, or be mistaken for metastatic spread.

The session provides a review of paraneoplastic manifestations involving neurologic, musculoskeletal, dermatologic, endocrinologic, gastrointestinal, and cardiovascular systems. The attendees will learn characteristic imaging findings associated with paraneoplastic syndromes and various tumors responsible for their development. Clinical manifestations of PNSs will also be discussed. Emphasis will be made on the role of surveillance for reoccurrence of PNSs as a measure to evaluate tumor treatment response.

**Sub-Events**

## Case-based Review of PET/CT: Brain, Dementia and Tumors

Tuesday, Dec. 3 8:00AM - 9:00AM Room: S405

Cristina S. Matushita, MD, MSc (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Understand best clinical practices for the use and interpretation of PET imaging in the diagnosis of dementia. 2) Understand best clinical practices for the use and interpretation of PET imaging for central nervous system tumors. 3) Identify common pitfalls and effective strategies for interpreting PET/CT scans in complex CNS cases.

### COURSE DESCRIPTION

This course will delve into the complexities of PET/CT imaging for the brain, focusing on dementia and tumors. Attendees will gain valuable insights from clinical cases presented by experts in the field, highlighting the best clinical practices for the use and interpretation of PET imaging. The session will cover the essential fundamentals, as well as the common pitfalls and pearls that can improve diagnostic accuracy. This lecture-based session aims to equip attendees with practical knowledge that can be directly applied in clinical practice, ultimately enhancing patient outcomes in diagnosing and managing CNS conditions.

**Sub-Events**

### T1-CNMMI09B Amyloid and Tau PET for Dementia

Phillip H. Kuo, MD, PhD (*Presenter*) Consultant, Konica Minolta, Inc;Consultant, Amgen Inc;Consultant, Blue Earth Diagnostics Ltd;Research Grant, Blue Earth Diagnostics Ltd;Consultant, Novartis AG;Speaker, Novartis AG;Consultant, Chimerix, Inc;Consultant, Fusion Pharmaceuticals Inc;Consultant, Bayer AG;Consultant, General Electric Company;Speaker, General Electric Company;Research Grant, General Electric Company;Speaker, Digital Science Press, Inc;Consultant, Radionetics;Former Employee, Konica Minolta, Inc

## The Spinal Cord in Hot Water - Compression, Demyelination, and Inflammation

Tuesday, Dec. 3 8:00AM - 9:00AM Room: S406B

Wende N. Gibbs, MD, MA (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review the intrinsic spinal cord pathologies that produce myelopathy. 2) Recognize the primary processes that disfigure the cord and post treatment appearances. 3) Identify key features of cord infarction and hemorrhage. 4) Understand the acute and chronic causes of extrinsic cord compression and their treatments.

**COURSE DESCRIPTION**

Patients with pathology involving the spinal cord may present acutely in the emergency setting, or may present with subacute to chronic symptoms. An approach to imaging spinal cord pathology is therefore an essential skill to master for radiologists of a wide variety of backgrounds and practice types. This session will review acute and non-acute presentations of spinal cord compression, the most common cause of spinal cord pathology, and will also discuss the most common pathologies intrinsic to the spinal cord itself, including demyelinating and inflammatory lesions.

**Sub-Events**

**T1-CNR02B** **Acute Cord: Infarct and Hemorrhage**

T1-COB02

## All You Need to Know About Fibroids

Tuesday, Dec. 3 8:00AM - 9:00AM Room: E351

Nicole M. Hindman, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review FIGO staging of fibroids and the different surgical methods of approach by the gynecologists. 2) Review adenomyomas versus fibroid differentiation and importance. 3) Cover updates in MR imaging for prediction of leiomyosarcoma and other tumors when imaging the symptomatic patient with fibroids.

**COURSE DESCRIPTION**

Fibroids are a common cause of symptoms in female patients, including bleeding, bulk symptoms, infertility or recurrent pregnancy loss and pain. These patients often present to gynecologists for these symptoms and typically are then imaged by ultrasound and sometimes MRI. Radiologists have a central role in the description of these fibroids (or fibroid mimickers) to best guide appropriate treatment and inform the gynecologist about any atypical features that may affect management.

**Sub-Events**

## MRI in Chest Imaging

Tuesday, Dec. 3 9:30AM - 10:30AM Room: E451A

Rachna Madan, MBBS, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the problem-solving value of MRI for more definitive characterization of indeterminate intrathoracic (mediastinal, pleural, pulmonary) masses on CT and appreciate how various MR pulse sequences help achieve the above objectives. 2) Understand the rationale, physical basis and clinical applications of advanced functional MR techniques used to characterize focal and diffuse lung abnormalities. 3) Understand the rationale and clinical applications of vascular MR/MRA.

**COURSE DESCRIPTION**

MRI in Chest Imaging session includes lectures by 4 experienced speakers and clinical practitioners in this subspecialty. This session will provide learners with a quick recap of nuts and bolts of non-vascular and vascular thoracic MRI as well as recent significant updates to protocols and sequences to enhance the problem-solving capability of MRI. Using multiple case studies and examples speakers will illustrate how the soft tissue contrast, tissue characterization, multiparametric and dynamic functional imaging capabilities of MRI adds to diagnostic specificity, preventing unnecessary and sometimes hazardous diagnostic intervention.

Attendees will also learn about sequences used and clinical applications of functional MRI as well as vascular thoracic MR/MRA.

**Sub-Events**

### T3-CCH05B Chest MRI: Update your Protocols/Sequences

## Best Practices for AI Education

Tuesday, Dec. 3 9:30AM - 10:30AM Room: E450B

Katherine P. Andriole, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Know why Radiologists whether in training or beyond should have an understanding of Artificial Intelligence/Machine Learning (AI/ML) technologies at least at a high level. 2) Learn example curricula and ways in which Radiologists and residents can be trained in AI/ML. 3) Become familiar with ways to educate care team members and patients about AI.

**COURSE DESCRIPTION**

Clinical Radiology will be practiced using Artificial Intelligence/Machine Learning (AI/ML) tools. Multiple steps are involved in developing and deploying machine learning models and artificial intelligence applications and clinical radiological expertise and input is required throughout the development and translation pipeline. In order to contribute to the process, Radiologists should have at a minimum, knowledge of AI/ML technology at a high level, understanding of technology limitations and recognition of error, the ability to converse and collaborate with a multidisciplinary team, capability to critically read the literature, and the ability to evaluate and properly use an AI/ML product or application. Example educational activities for residents are discussed. Other health care team members as end-users and patients as consumers must be educated as well. This session will present best practices for educating each of these constituents.

## Medicolegal Issues and Hot Topics in Radiology

Tuesday, Dec. 3 9:30AM - 10:30AM Room: S402

Jonathan Mezrich, MD, JD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand how the legal system may address liability for errors which occur when using artificial intelligence in radiology. 2) Learn about recent litigation results which could impact future malpractice exposure. 3) Learn about recent medicolegal developments involving radiology litigation.

**COURSE DESCRIPTION**

Malpractice and other medico-legal issues are commonplace in radiology, and risks of liability are often underappreciated. Many radiologists would benefit from a greater understanding of legal issues they may face in the current landscape. This course will feature four lectures on medico-legal topics, along with an opportunity for audience questions, and will provide an overview of several “hot topics” in radiology. In this thought provoking session we will address potential medico-legal implications and liability risks relating to artificial intelligence liability in radiology generally, and generative AI more specifically. Lectures will also include a case based analysis of a recent malpractice lawsuit involving stroke diagnosis, as well as a discussion of use of functional neuroimaging in the courtroom. It is expected that attendees will have a greater understanding of a number of medico-legal issues affecting radiologists in current practice, and some insight on evolving topics to keep tabs on in the future.

## AI in Ultrasound Imaging

Tuesday, Dec. 3 9:30AM - 10:30AM Room: S404

Karen Drukker, PHD (*Moderator*) Royalties, Hologic, Inc

**LEARNING OBJECTIVES**

1) To learn about incorporating imaging physics into AI models for ultrasound image reconstruction and beamforming, and to examine a practical example of AI in ultrasound image reconstruction that integrates imaging physics. 2) To understand the current challenges in ultrasound-guided interventions and discover how AI and robotics can enhance these procedures. 3) To understand how AI in medical ultrasound image analysis can assist radiologists and clinicians in the detection, diagnosis, and prognosis of disease.

**COURSE DESCRIPTION**

This course features 3 expert speakers and is essential for professionals seeking to understand the cutting-edge advancements in artificial intelligence (AI) medical ultrasound imaging and their practical applications. Attendees will gain valuable knowledge on three key topics: the use of AI in detecting and imaging targeted microbubbles, the role of AI and robotics in ultrasound-guided interventions, and the application of AI in medical image analysis for disease detection, diagnosis, and prognosis. Each lecture will provide in-depth exploration of these areas, equipping participants with the skills to leverage AI technologies in enhancing ultrasound imaging practices.

**Sub-Events**

### T3-CPH01B Incorporating Ultrasound Imaging Physics into Artificial Intelligence: Example in the Detection and Imaging of Targeted Microbubbles

## Aortic Dissection

Tuesday, Dec. 3 9:30AM - 10:30AM Room: S502

Kacie Kuykendall, MD (*Moderator*) Nothing to Disclose
Dominik Fleischmann, MD (*Moderator*) Research Grant, Siemens AG;Stockholder, iSchemaView, Inc;Stockholder, Segmed, Inc

**LEARNING OBJECTIVES**

1) Review the role of imaging in patients presenting with an acute aortic syndrome. 2) Explain the spectrum less common lesions such as PAU and limited tears. 3) Identify the imaging features which are most important for surgical or endovascular treatment planning. 4) Review the rationale and techniques for surveillance imaging in survivors of aortic dissection.

**COURSE DESCRIPTION**

This course provides a selection of high-yield topic related to imaging of aortic dissection. After a thorough overview of pathologies that can present clinically as an 'acute aortic syndrome', several less common entities of this spectrum will be reviewed, such as penetrating atherosclerotic ulcers, and limited tears of the aorta.

The course will highlight imaging features and new classifications to support surgical and endovascular treatment planning. Finally, the rationale and measurement techniques required for surveillance imaging in patients with chronic dissection will be presented.

## Fostering Culturally Aware Mentoring in Radiology (Sponsored by the RSNA Health Equity Committee and the RSNA Committee on Diversity, Equity and Inclusion)

Tuesday, Dec. 3 9:30AM - 10:30AM Room: S501

Efren J. Flores, MD (*Moderator*) Speaker, WebMD LLC;Speaker, Consulting Medical Associates, Inc
Ashley E. Prosper, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Define culturally aware mentorship (CAM) and best ways to identify belief and perceptions that influence mentoring relationships. 2) Navigate barriers and facilitators to incorporating CAM into your mentorship practices in radiology. 3) Use relational meetings to navigate cultural differences and promote career advancement for mentees. This session will include a 15-minute Q&A session with the audience.

### COURSE DESCRIPTION

Radiology efforts to address health equity require the investment of meaningful resources to diversify the radiology workforce. However, diversity efforts often may fall short without mentorship that considers the mentees sociocultural background to ensure a sense of belonging. Culturally Aware Mentoring (CAM) seeks to address this gap in the mentor-mentee relationship, by forming a bidirectional relationship that takes into consideration their sociocultural background and uses this approach to create new pathways for career advancement. To effectively mentor radiology faculty and trainees across radiology among all practice settings, it is paramount that culturally aware mentoring (CAM) is included in efforts to improve successful mentoring in radiology.

**Sub-Events**

## Best Practices for AI Model Continuous Monitoring

Tuesday, Dec. 3 11:00AM - 12:00PM Room: E450B

Walter F. Wiggins, MD,PhD (*Moderator*) Advisor, Qure.ai;

**LEARNING OBJECTIVES**

1) Understand Regulatory Compliance and Best Practices: Gain a comprehensive understanding of the regulatory landscape and requirements/best practices for AI model performance monitoring post-product approval. 2) Evaluate Real-World AI Deployment: Analyze practical experiences and lessons learned from deploying AI in large academic medical centers, focusing on continuous monitoring and performance validation. 3) Address Post-Deployment Challenges: Develop strategies for effective post-market validation, comparative performance analysis of commercial AI tools, and ongoing surveillance to identify and mitigate biases in AI applications.

**COURSE DESCRIPTION**

This course will delve into the continuous monitoring of AI models in Radiology, covering regulatory compliance, real-world deployment insights, and post-market validation. Participants will learn from deployments in large practices and academic medical centers, explore the comparative performance of commercial AI tools, and gain strategies for effective post-deployment surveillance. The session will also address the critical issue of evaluating and mitigating bias, ensuring the ethical and effective use of AI in clinical practice.

**Sub-Events**

## Role of Nonphysician Providers (NPP) in Radiology: Existential Threat or Unforeseen Opportunity? (Sponsored by the RSNA Professionalism Committee)

Tuesday, Dec. 3 11:00AM - 12:00PM Room: N227B

Monica M. Sheth, MD (*Moderator*) Nothing to Disclose
R. Paul Guillerman, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Identify and differentiate the types of radiology NPPs. 2) Discuss current utilization trends of NPPs in academic and private practice. 3) Understand how state and federal regulations impact the role of NPPs in radiology practice.

### COURSE DESCRIPTION

The use of nonphysician providers (NPPs) is a potential strategy to mitigate the shortfall of radiologists to cover increasing work volume in the setting of declining reimbursement. The lectures and discussions in this session will inform attendees of the rules and regulations regarding the scope of practice of NPPS in radiology, the operational and budgetary impact of NPPs, and the potential quality and safety issues related to the practice of NPPs.

## ASRT@RSNA: Artificial Intelligence in Radiology: Exploring the Radiologic Technologist's Role

Tuesday, Dec. 3 11:00AM - 12:00PM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Define and differentiate between clinical informatics, imaging informatics, artificial intelligence and machine learning in radiology. 2) Clearly interpret informatics' impact on radiology and develop a deeper understanding of the use of AI in radiology. 3) Discuss current and future applications of informatics and AI in medical imaging.

**COURSE DESCRIPTION**

The integration of informatics and imaging significantly impacts how radiologic technologists care for patients. This session provides an overview of artificial intelligence and how it is impacting radiology and radiologic technologists. Attendees will learn why it is imperative to understand informatics applications and AI's role and function in health care's daily operations. The speaker will discuss current innovations and forthcoming applications of informatics and AI, including a look into the future of informatics and its impact on patient-centered care.

## Localization and Biopsy Techniques

Tuesday, Dec. 3 1:30PM - 2:30PM Room: S406A

Sarah M. Friedewald, MD (*Moderator*) Consultant, Hologic, Inc;Research Grant, Alphabet Inc

**LEARNING OBJECTIVES**

1) Identify different ways to optimize imaged guided biopsies

2) Understand the advantages and disadvantages of upright versus prone biopsies

3) Appreciate different methods of image guided localizations, and understand their strengths and limitations

**COURSE DESCRIPTION**

In this course, the attendee will learn the basics of tomosynthesis guided biopsies, ultrasound guided biopsies, MRI guided biopsies and image guided localizations. The most recent literature supporting these techniques will be reviewed. Additionally, through imaging examples, different scenarios will be presented that the radiologist may encounter during these procedures. A practical guide on how to troubleshoot various issues that might arise will be presented.

**Sub-Events**

### T6-CBR11B Pearls and Pitfalls of Challenging Mammo and DBT Biopsies and Localizations

Sarah M. Friedewald, MD (*Presenter*) Consultant, Hologic, Inc;Research Grant, Alphabet Inc

### T6-CBR11C Challenging Biopsies With Breast MRI and Targeted US

## RSNA Hands-On Lab: MRI-Guided Breast Biopsy (Registration Fee Required)

Tuesday, Dec. 3 2:00PM - 4:00PM Room: S504CD

Roberta M. Strigel, MD, MS (*Moderator*) Research support, General Electric Company

**LEARNING OBJECTIVES**

1) Define indications for MRI-guided breast biopsy and appropriate patient selection including relative and absolute contraindications to MRI-guided breast biopsy. 2) Describe and understand the steps of a MRI-guided breast biopsy procedure, including protocol and requirements for appropriate coil, needle, and approach selection. 3) Identify the benefits and limitations of MRI-guided breast biopsy and understand tips for handling challenging biopsy locations and patient anatomy.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

This course is intended to provide both didactic and hands-on experience performing MRI-guided breast biopsy. Those with experience and those who do not have experience with this procedure are welcome and will find this course beneficial. The course begins with a 45-minute lecture covering patient selection criteria, contraindications, appropriate biopsy positioning and troubleshooting, steps of the procedure, lesion targeting using both manual and computer aided techniques, post-biopsy care, radiologic/pathologic concordance, and potential challenges and strategies. The final 75-minutes is a hands-on workshop with 11 stations, each with a breast coil, targeting options (computer and manual), biopsy device and two expert faculty members to teach the performance of an MRI-guided biopsy with live coaching, tips, techniques, and advice, with opportunities for questions.

## Emergency Radiology Challenge: Jeopardy

Tuesday, Dec. 3 1:30PM - 2:30PM Room: N228

Christina A. LeBedis, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand and differentiate the imaging features of traumatic and non-traumatic conditions commonly encountered in the emergency room. 2) Provide accurate and clinically relevant radiologic reports highlighting critical findings for effective ER management. 3) Exposure to a panel discussion to analyze and discuss common diagnostic challenges, limitations, and potential pitfalls in emergency radiology imaging for traumatic and non-traumatic conditions and develop strategies to improve diagnostic accuracy and patient outcomes.

**COURSE DESCRIPTION**

Join us for an engaging Jeopardy-style session where multiple non-traumatic and traumatic cases presented to emergency radiology will be discussed. This interactive format will encourage audience participation, challenging attendees to solve cases and learn about critical findings. Participants will gain valuable insights into making accurate and timely emergency radiology diagnoses, ultimately improving patient outcomes. This session promises to be both educational and entertaining, significantly impacting your emergency radiology practice.

## Pancreatic Tumor Imaging

Tuesday, Dec. 3 1:30PM - 2:30PM Room: E451B

Avinash R. Kambadakone, MD, FRCR (*Moderator*) Advisory Board, Bayer AG Research Grant, General Electric Company Research Grant, Koninklijke Philips NV Research Grant, PanCAN Research Grant, Bayer

### LEARNING OBJECTIVES

1) To describe the key updates in the imaging diagnosis of pancreatic cancer. 2) To explain the current role of imaging in assessment of therapeutic response in pancreatic cancer. 3) To discuss the importance of structured reporting in pancreatic cancer and implications for patient management. 4) To review the current and emerging applications of artificial intelligence in pancreatic cancer. 5) To explain recent advances in pancreatic neuroendocrine tumor imaging.

### COURSE DESCRIPTION

This course will review the current state-of-the-art and recent advances in imaging of pancreatic cancer and pancreatic neuroendocrine tumors. The attendees will also learn the role of structured reporting and emerging applications of artificial intelligence in pancreatic cancer.

**Sub-Events**

### T6-CGI11B Diagnosis and Staging of Pancreatic Cancer: State of the Art

Avinash R. Kambadakone, MD, FRCR (*Presenter*) Advisory Board, Bayer AG Research Grant, General Electric Company Research Grant, Koninklijke Philips NV Research Grant, PanCAN Research Grant, Bayer

## RSNA Radiology Reimagined Demo and IHE: Facilitating the Future of AI-Enabled Radiology

Tuesday, Dec. 3 1:30PM - 2:30PM Room: E450B

Mohannad Hussain (*Presenter*) Consultant, Techie Maestro Inc
Namita S. Gandhi, MD, MSc (*Presenter*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Recognize the future of AI applications throughout the entire radiology workflow. 2) Understand how semantic and interoperability standards enable clinical implementation of AI. 3) Consider how standards were specifically applied to an example RSNA Imaging AI in Practice demo.

**COURSE DESCRIPTION**

The Imaging AI in Practice (IAIP) demonstration project was started in 2020 to demonstrate the utility of AI applications throughout the radiology workflow. Partnering radiologists, technical experts and vendors developed clinically relevant scenarios highlighting the use of integration and semantic standards. Integrating the Healthcare Enterprise (IHE) is an initiative by health care professionals and industry to improve the way computer systems in healthcare share information. Relevant integration and semantic standards will be reviewed. We will take a detailed look at one of the demonstration cases presented at IAIP this year. This will be followed by a panel discussion responding to questions from the audience with particular emphasis on lessons learned and what the future may hold.

If you're interested in this session, we recommend you visit the Radiology Reimagined demo booth (5104 South Hall Level 3) to observe the live demos that run Sunday-Wednesday 10am - 5pm.

**Sub-Events**

## Management of Early-Stage Lung Cancer

Tuesday, Dec. 3 1:30PM - 2:30PM Room: E352

Florian J. Fintelmann, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Explain the current non-surgical options for the diagnosis and treatment of stage I and II NSCLC. 2) Identify selection criteria for CT-guided percutaneous biopsy and ablation. 3) Identify selection criteria for navigational biopsy and transbronchial ablation.

**COURSE DESCRIPTION**

Lectures will cover state-of-the-art thoracic interventions for the diagnosis and treatment of stage I and II non-small cell lung cancer, including percutaneous and transbronchial approaches. Awareness of non-surgical management options enhances care for patients with lung cancer.

**Sub-Events**

**T6-CIR01B** **Percutaneous Lung Needle Biopsy and Fiducial Placement**

## Musculoskeletal Ultrasound: Normal Appearances, Pathologic Conditions and Hands-On Demo (Shoulder, Wrist, Knee)

Tuesday, Dec. 3 1:30PM - 3:00PM Room: E450A

Robert S. Campbell, MBChB, FRCR (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Learn the US scan techniques to be able to perform studies of US of the Shoulder, Wrist & Knee. 2) Understand the normal US appearances of the relevant anatomical structures related to US of the Shoulder, Wrist & Knee. 3) Apply that knowledge to be able to interpret pathologic conditions around the Shoulder, Wrist & Knee.

**COURSE DESCRIPTION**

This Course is focused in 3 parts on US of the Shoulder, Wrist & Knee. Each section will include a live demonstration of scanning technique and the normal US anatomical appearances, followed by a powerpoint oration discussing the important pathologic conditions that may be diagnosed by US, and discuss any diagnostic limitations and in what circumstances other imaging techniques such as MRI may be required.

Please use the following links to follow along with the presenters in the session:

Shoulder

Knee

Wrist and Hand

## Case-based Review of PET/CT: Infection/Inflammation and Gastrointestinal Malignancies

Tuesday, Dec. 3 1:30PM - 2:30PM Room: S405

Emily S. Nia, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand best clinical practices for use and interpretation of PET for infection and inflammation. 2) Understand best clinical practices for use and interpretation of PET for gastrointestinal malignancies.

**COURSE DESCRIPTION**

FDG-PET is a uniquely suited modality for the imaging of infection and inflammation, both as the primary indication or as an important secondary finding. PET for gastrointestinal malignancies is as complex and varied in presentation as the pathologies are. In this session, PET experts will use clinical cases to demonstrate fundamentals of interpretation, as well as pearls and pitfalls to help improve interpretation.

## Radiologists' Role in LGBTQIA+ Health Equity (Sponsored by the RSNA Health Equity Committee)

Tuesday, Dec. 3 1:30PM - 2:30PM Room: S402

Vaz A. Zavaletta, MD, PhD (*Moderator*) Nothing to Disclose
Huber David Jaramillo Gil, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify Barriers and Challenges in Radiology for LGBTQIA+ Individuals 2) Evaluate how increased awareness and education on LGBTQIA+ healthcare can positively influence various facets of radiological practice, including advancements in imaging techniques for cancer diagnosis. 3) Learn to effectively engage with LGBTQIA+ patients, tailor treatment approaches, and make well-informed medical decisions to improve overall patient care in radiological settings.

**COURSE DESCRIPTION**

There is a need for education about the specific barriers and challenges faced by LGBTQIA+ individuals in radiology settings. This includes awareness of the social determinants of health that disproportionately affect this community and how these determinants can impact radiological care and outcomes. By delving into the intricacies of LGBTQIA+ health, societal attitudes, policy landscapes, familial dynamics, educational contexts, and economic factors, radiologists can develop a nuanced understanding aimed at mitigating provider misinformation, instances of medical mistreatment, barriers to gender-affirming care, and misconceptions regarding transgender individuals' bodies. A deeper understanding will allow radiologists to effectively engage with patients, tailor treatment approaches, and make well-informed medical decisions. Moreover, the panelist will uncover ways that increased awareness and education surrounding LGBTQIA+ healthcare can positively influence various facets of radiological practice. For instance, advancements in imaging techniques for cancer diagnosis, especially concerning breast and cervical cancer screenings, stand to benefit significantly and immediately from in-depth education in LGBTQIA+ health. All in all, the exploration of LGBTQIA+ health, and the advancement of the field of transgender radiology in particular, offers a pathway to broader improvements in interventional radiology and medical imaging.

## Pediatric Neuroimaging: White Matter Disease Simplified

Tuesday, Dec. 3 1:30PM - 2:30PM Room: N227B

Rupa Radhakrishnan, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review typical imaging findings and diagnostic challenges in common white matter diseases in the pediatric age group. 2) Understand the role of imaging in early diagnosis, disease monitoring and prognosis of these conditions.

**COURSE DESCRIPTION**

This session will be a didactic lecture series from expert pediatric neuroradiologists. Topics will cover a wide variety of pediatric white matter diseases including autoimmune and demyelinating diseases, leukodystrophies, and hypomyelinating disorders. The talks will highlight the characteristic radiological features and diagnostic challenges in these conditions, as well as brief clinical-radiological. Advanced imaging techniques, including the use of MR spectroscopy will be discussed. At the end of the session, participants will understand the characteristic imaging findings of common pediatric white matter diseases and imaging tips to arrive at a diagnosis.

## Head to Toe Pitfalls in Pediatric Imaging: Don't fall for These Errors in Interpretation!

Tuesday, Dec. 3 1:30PM - 2:30PM Room: E350

Amy R. Mehollin-Ray, MD (*Moderator*) Nothing to Disclose
Yumin Zhong, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review the normal imaging anatomy of the growing pediatric patient to recognize variants that may be confused with pathology. 2) Present both common pathologies and mimics that might be mistaken for pathology, with focus on the pediatric abdomen, head and spine, and skeleton.

**COURSE DESCRIPTION**

This course is designed for both early career and experienced radiologists who may encounter pediatric patients in their clinical practice, with a focus on differentiating pathology from the normal, varying appearance of the developing pediatric patient. Information will be presented in a case-based format and include a variety of imaging modalities.

**ASRT@RSNA: The Radiographer's Role in Patient Pathways: Facilitator or Passenger?**

Tuesday, Dec. 3 1:30PM - 2:30PM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Consider how imaging fits into patient pathways. 2) Discuss how radiographers can be influential in pathway improvement. 3) Learn from examples in practice to optimize the radiographer’s contribution.

**COURSE DESCRIPTION**

Imaging is a critical component in elective, acute and emergency pathways. Although radiographers are often bystanders in pathway redesign, they can take a proactive role to ensure patients receive the optimal diagnosis in a timely manner. This session explores examples from practice to examine how radiographers can lead in improving patient care and services.

## Staging Updates in Thoracic Malignancy (TNM 9)

Tuesday, Dec. 3 3:00PM - 4:00PM Room: E451A

Mylene T. Truong, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review the 9th edition of the staging system for lung cancer, thymic epithelial tumors and mesothelioma. 2) Review the rationale for changes proposed in N and M staging for lung cancer. 3) Review the rationale for changes proposed in T staging for thymic epithelial tumors and mesothelioma.

**COURSE DESCRIPTION**

Staging classification provides universal, well-defined nomenclature to describe the anatomic extent of tumor: T for the primary tumor, N for nodal involvement and M for distant metastases. Updates in staging are needed to optimize tailored patient treatment. The proposed changes in TNM 9th edition are based on data collected by the International Association for the Study of Lung Cancer database.

## Case-based Review of PET/CT: Lung Cancer and Lymphoma

Tuesday, Dec. 3 3:00PM - 4:00PM Room: S405

Giuseppe Esposito, MD (*Moderator*) Medical Advisory Board

**LEARNING OBJECTIVES**

1) Understand best clinical practices for use and interpretation of PET in patients with lung cancer. 2) Understand best clinical practices for use and interpretation of PET for lymphoma.

**COURSE DESCRIPTION**

PET has revolutionized the staging and monitoring of response for lung cancer and lymphoma and thus accurate reads are of the utmost importance for patient management. In this session, experts in PET will use clinical cases to demonstrate fundamentals of interpretation, as well as pearls and pitfalls to help improve interpretation of PET studies involving lung cancer and lymphoma.

**Sub-Events**

## Imaging Ovarian Cancer: Radiologists as Partners in Cancer Care

Tuesday, Dec. 3 3:00PM - 4:00PM Room: S502

Atul B. Shinagare, MD (*Moderator*) Consultant, VirtualScopics, Inc;Consultant, Imaging Endpoints

**LEARNING OBJECTIVES**

1) Understand role of CT in assessment of incidental adnexal masses. 2) Discuss role of imaging in the initial staging of advanced ovarian cancer.

**COURSE DESCRIPTION**

Incidental adnexal lesions are commonly detected on CT but there is confusion about the role of CT in guiding further management of these lesions. Ovarian cancer is one of the leading causes of cancer deaths in women. Radiologists play an important role in the initial staging and guiding the management of advanced ovarian cancer. While CT is the most common modality used for staging, role of MRI for this purpose is evolving. This didactic refresher course will address various imaging considerations around detection and staging of ovarian cancer.

**Sub-Events**

### T7-COB08B Incidental Ovarian Lesions on CT: When is it Cancer

Atul B. Shinagare, MD (*Presenter*) Consultant, VirtualScopics, Inc;Consultant, Imaging Endpoints

### T7-COB08C Ovarian Cancer Staging: Pretreatment Imaging Evaluation (CT, MRI, PET)

## ASRT@RSNA: Patient Partnerships – Journey to Implementation in Academic Programs

Tuesday, Dec. 3 3:00PM - 4:00PM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Summarize the importance of patient partnerships in health care education. 2) Share insights on implementing patient partnerships into academic programs. 3) Discuss current patient partnership activities in imaging programs.

**COURSE DESCRIPTION**

In diagnostic imaging, the patient is at the center of what we do and why we do it. Technology continues to advance and improve care; however, the human element will always be the most critical part of our role. In the past 20 years, there has been a greater focus on patient and family-centered care in our health care systems and that is filtering into education programs as well. Traditionally, postsecondary education programs focus on students and their needs. However, the re-emphasizing of the patient voice has shifted the culture in our programs. This session looks at the journey a postsecondary education program in Canada is taking to implement the patient voice and perspective into its curriculum. The speaker will discuss the importance of the patient voice in education and how to balance that with students' needs. Attendees will learn about the framework, tools and committees created to provide structure and guidance for the faculty during implementation. The speaker will describe patient partnership models in health care and how those models were used as a foundation to develop patient partnerships in education. Attendees will discover ways to work with patients through co-learning, co-creating, co-developing and sharing.

## Practical Applications of Advanced Vascular Imaging

Tuesday, Dec. 3 3:00PM - 4:00PM Room: N229

Michael Markl, PhD (*Moderator*) Research support, Siemens AG Research Grant, Circle Cardiovascular Imaging Inc
Jeremy D. Collins, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review the applications of advanced imaging technologies including photon counting CT, 4D flow MRI and PET imaging in non-coronary vascular disease. 2) Consider opportunities for AI to improve imaging evaluation of non-coronary vascular disease.

**COURSE DESCRIPTION**

Cross-sectional imaging methods have advanced our capabilities in the in-vivo assessment of vascular disease. This course will review the current clinical applications of advance vascular imaging techniques including photon counting CT, 4D flow MRI, and PET imaging. Additionally clinical applications of Artificial Intelligence methods will be discussed in the context of advanced vascular imaging applications.

## Japan Presents: Unique Evolution and Global Influence of Japanese Radiology

Tuesday, Dec. 3 3:00PM - 4:00PM Room: E352

Noriko Aida, MD, PhD (*Moderator*) Nothing to Disclose
Noriyuki Tomiyama, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the unique evolution and current state of radiology in Japan, even in challenging circumstances, which may serve as a reference for other countries. 2) Share insights into the diverse global landscape of radiology.

**COURSE DESCRIPTION**

Japan is in a unique situation, having the highest number of CT and MRI units per capita in the world despite having far fewer radiologists compared to North America. Despite this challenging situation, radiology in Japan has achieved remarkable development. In this session, we will introduce our struggles, efforts, achievements, current status, and future prospects in various fields.

**Sub-Events**

## The New Era of Performance Evaluation (Sponsored by the RSNA Quality Improvement Committee)

Tuesday, Dec. 3 3:00PM - 4:00PM Room: N227B

Nadja Kadom, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Use KPI for specific goals. 2) Describe examples of patient care KPI. 3) Implement a new approach to performance evaluation. 4) Implement personalized feedback for radiologists.

**COURSE DESCRIPTION**

This course differentiates between various uses for key performance indicators (KPI), and focuses on KPI that can lead to better patient care. The session describes a new approach to KPI for technologists. Rad-Path correlation is described as an example of personalized and private performance feedback.

**Sub-Events**

## BI-RADS 6th Edition Updates and Challenging Cases

Tuesday, Dec. 3 4:30PM - 5:30PM Room: S406A

Stamatia V. Destounis, MD (*Moderator*) Medical Advisory Board, iCad, Inc

### LEARNING OBJECTIVES

1) Identify the updates and additions in the mammography, ultrasound, MRI and Audit and outcomes sections of the 6th Edition BI-RADS Atlas. 2) Explain the clinical applications and utilization of the updated descriptors and audit processes.

### COURSE DESCRIPTION

This course will provide standardized breast imaging terminology, report organization, assessment structure and a classification system for mammography, ultrasound and MRI of the breast.

Through a medical audit and outcome monitoring, the system provides important mechanisms for peer review and quality assurance data to improve the quality of patient care.

**Sub-Events**

## Fundamentals of Cardiac MRI for Nonischemic Cardiomyopathies - A Case-Based Review

Tuesday, Dec. 3 4:30PM - 5:30PM Room: E353C

Bradley D. Allen, MD, MS (*Moderator*) Consultant, Circle Cardiovascular Imaging Inc;Speaker, WebMD LLC
Jadranka Stojanovska, MD, MS (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Review current best-practices for CMR evaluation of non-ischemic cardiomyopathy. 2) Discuss CMR interpretation and reporting in non-ischemic cardiomyopathy to provide accurate diagnosis and risk-stratification. 3) Highlight areas of uncertainty in the current diagnostic approach and when other tools and modalities can be helpful.

### COURSE DESCRIPTION

Cardiac MRI (CMR) is an important tool for providing accurate diagnosis and risk-stratification for non-ischemic cardiomyopathies. In this course, learners will be presented with a broad overview of the current state-of-the-art for CMR evaluation of multiple non-ischemic cardiomyopathies. Topics will be presented in a case-based lecture format highlighting relevant CMR acquisitions and interpretation approaches, with a data-driven focus on current best-practices for providing optimal patient care.

**Sub-Events**

## Fundamentals of HRCT

Tuesday, Dec. 3 4:30PM - 5:30PM Room: E451A

Smita Patel, MBBS, FRCR (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Evaluate HRCT images for the presence of key imaging features, including lung cysts, pulmonary fibrosis and micronodules. 2) Define key imaging features used to characterize pulmonary fibrosis. 3) Formulate a differential diagnosis based on the presence of cysts and micronodules in the lungs.

**COURSE DESCRIPTION**

This course will review three important topics needed to evaluate HRCT of the lungs and is intended for radiologists re-reviewing the fundamentals of this important aspect of chest radiology. We will use didactic and case-based material to review how to evaluate cystic and micronodular lung disease and how to categorize pulmonary fibrosis.

**Sub-Events**

## It’s a Full Moon: A Nightmare on Night Float, Trauma Cases

Tuesday, Dec. 3 4:30PM - 5:30PM Room: N228

Laura L. Avery, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Improve your speed for diagnosing various traumatic injuries in hopes of achieving a state of Zen during the trauma STAT. 2) Develop mastery and confidence in communicating imaging findings quickly and gracefully; establish dominance over trauma surgeons.

**COURSE DESCRIPTION**

As your grandmother said, “Nothing good happens after midnight; the only thing open is the 7-11 and trouble”. Unfortunately, you are spending Saturday night in a dark room overwhelmed by trauma CT scans- just another night of saving people from their own bad ideas. Spend an hour reviewing rapid-fire trauma cases with an emphasis on tricky traumatic injuries.

## Horse or Zebra? Case-Based Review of High Yield Head and Neck Topics

Tuesday, Dec. 3 4:30PM - 5:30PM Room: E351

Elizabeth George, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Recognize typical and atypical imaging features of thyroid, parathyroid, odontogenic, salivary and vascular lesions.

2) Differentiate thyroid, parathyroid, odontogenic, salivary and vascular lesions from relevant mimics.

**COURSE DESCRIPTION**

In this case-based Head and Neck session, attendees will be presented with frequently and rarely seen thyroid, parathyroid, odontogenic, salivary and vascular lesions. Speakers will emphasize imaging pearls that distinguish the common diagnoses from the unusual and infrequent, as well as how not to get fooled by mimics and pitfalls. This session offers attendees the opportunity to refine their interpretation of complex head and neck imaging studies by incorporating tips from world experts.

## Artificial Intelligence Empowered Radiology: Unleashing the Power of Language Models for an Intelligent Future

Tuesday, Dec. 3 4:30PM - 5:30PM Room: E450B

Zi Zhang, MD, MSc (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Address the educational need for integrating advanced artificial intelligence (AI) Language Models into the radiology field. 2) Equip radiologists, radiology residents, medical educators, and healthcare IT professionals with the knowledge to harness AI in enhancing the quality and efficiency of radiological services. 3) Explore the impact of AI on medical imaging, research, and education, learning to translate complex data into insightful narratives. 4) Offer a unique journey into the future of radiological practice, where advanced AI tools and human expertise converge to create new standards in medical imaging, research, education, and presentation effectiveness.

**COURSE DESCRIPTION**

This course includes four lectures as listed below:

1. Transforming Current Practices with AI Language Models in Radiology:

In this session, attendees will discover how AI language models like Google's Gemini and custom ChatGPTs can improve radiology practices. We will demonstrate the practical applications of these tools in enhancing report generation and communication. Participants will learn how Google's Gemini can simplify complex imaging results for patients, and how ChatGPT can be utilized to create clear and concise radiology reports. This session will highlight the role of AI in improving workflow efficiency, report accuracy, and communication between radiologists, referring physicians, and patients, thereby advancing patient care and collaboration within the healthcare system.

2. Tailored AI Language Models for Personalized Radiology Education:

Participants in this session will be introduced to the concrete applications of AI language models in radiology education. We will dissect how AI language models analyze learner performance data to create a customized educational experience that identifies individual learning gaps and tailors' content accordingly. The session will provide a walk-through of an AI-powered module that adjusts the complexity of cases and questions based on the learner's progress, thereby supporting radiologists in mastering nuanced diagnostic skills.

3. AI Language Models in Radiological Research Innovation:

In this session, participants will explore the use of AI language models, including Google's NotebookLM, in radiological research. We will demonstrate how NotebookLM acts as a virtual research assistant, summarizing literature, clarifying complex concepts, and stimulating creative thought based on the user's uploaded documents. Custom ChatGPTs, designed for specific medical domains, will also be covered, highlighting their utility in synthesizing data and enhancing research output.

4. Creating Radiology Presentations and Patient Education Materials with AI language models:

In this workshop, attendees will be guided on leveraging AI language models to craft dynamic radiology presentations and engaging patient education content. Radiologists will acquire skills for the efficient production of lecture slides and educational materials. Through practical demonstrations, the session will showcase the potential of AI language models in enhancing presentation effectiveness and enriching patient education.

**Sub-Events**

## Imaging of Infection: Patterns, Complications and Things not to Miss

Tuesday, Dec. 3 4:30PM - 5:30PM Room: E353B

William B. Morrison, MD (*Moderator*) Co-founder, Trace Orthopedics;Patent agreement, Trace Orthopedics;Consultant, AprioMed AB;Patent agreement, AprioMed AB;Consultant, Centinel Spine, LLC;Consultant, Medical Metrics, Inc

**LEARNING OBJECTIVES**

1) Discuss key diagnostic features of multimodal imaging of infection including osteomyelitis, joint, soft tissue and spine infection. 2) Explain complications and important features to be included in the imaging report to assist with patient management.

**COURSE DESCRIPTION**

This session focuses on imaging of infection and includes important information on imaging of acute and chronic osteomyelitis, joint, soft tissue and spine infection. The lectures will provide essential pearls and pitfalls relating to the diagnostic assessment and multimodal imaging evaluation of infection. The expected outcome is for participants to review and understand patterns of infection, complications and essential features not to miss.

**Sub-Events**

### T8-CMK09B Chronic Osteomyelitis: Pearls and Pitfalls

## What Test is the Best: Point Counterpoint Debate on CEUS vs MRI

Tuesday, Dec. 3 4:30PM - 5:30PM Room: E353A

John S. Pellerito, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Discuss pros and cons of CEUS versus MRI in evaluation of liver neoplasms. 2) Discuss pros and cons of CEUS versus MRI in evaluation of pediatric pathologies. 3) Discuss pros and cons of CEUS versus MRI in the evaluation of vascular and abdominal/pelvic pathological processes, including but not limited to aorta and post EVAR, kidney neoplasms, solid organ transplants, organs of reproduction and more.

**COURSE DESCRIPTION**

The session provides a review of various applications of CEUS vs MRI in a point counterpoint format, where the speakers have a chance to debate about the benefits and limitations of each of these modalities when applied to a specific organ assessment. Discussion will involve comparison of CEUS vs MRI in evaluation of liver and renal lesions, solid organ transplants, gastrointestinal tract, gyn, pediatrics, and vascular systems with emphasis on ease to perform these studies, skill set needed for interpretation of the findings, associated reimbursement issues, as well as sensitivity and accuracy of these modalities in making a correct diagnosis.

**Sub-Events**

## Essential Updates in Ischemic Stroke Imaging and Treatment

Tuesday, Dec. 3 4:30PM - 5:30PM Room: N227B

Arindam R. Chatterjee, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify the latest clinical trial developments in large core and distal vessel ischemic stroke therapy. 2) Explain standard-of-care neuroimaging in ischemic stroke and the latest changes in 2024. 3) Understand the expanding frontier of ongoing ischemic stroke trials and neuroimaging implications that are likely to report results in 2025.

**COURSE DESCRIPTION**

Ischemic stroke therapy has undergone a paradigm shift in the last decade with a flurry of groundbreaking randomized clinical trials expanding eligibility criteria. Developments in neuroimaging acquisition, processing, and interpretation have been critical in the design and implications of the latest clinical trials. Learn from neuroradiology and neurointerventional experts working at the frontier as we discuss the latest and ongoing ischemic stroke clinical trials focusing on large core infarctions and distal vessel occlusions and their implications for neuroimaging expectations. The standard-of-care in ischemic stroke is changing – catch up with the latest in 2024. The educational formal will be lectures.

Larry A. Binkovitz, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the use of imaging techniques to evaluate the most common pediatric soft tissue sarcomas, identifying key imaging features by advanced MRI (DC-MRI and DWI) for diagnosis and re-assessment. 2) Describe the role of imaging, the diversity of imaging findings and unique features in pediatric lymphoma and its mimickers which may help guide imaging protocols. 3) Review anatomic (CT and MRI) and functional (PET) imaging techniques, including AI and deep learning; identify updated COG recommendations for imaging and surveillance as well as those that apply to patients with cancer predisposition syndromes.

**COURSE DESCRIPTION**

This pediatric imaging course aims to provide the learner with methods to diagnose and evaluate soft tissue sarcomas using advanced MRI techniques as well as novel functional PET and deep learning approaches. In addition to reviewing the most common pediatric sarcomas and their look alikes, this session will cover pediatric lymphoma, diagnosis, staging and restaging using advanced imaging techniques. This will be a high yield course for all radiologists with interest in pediatric sarcoma, lymphoma and cancer predisposition syndromes.

**Sub-Events**

**T8-CPD03C** **Soft Tissue Sarcomas in Children: The Better, The Bad and The Ugly**

Emilio Inarejos Clemente, MD (*Presenter*) Nothing to Disclose

## Tales from the Bedside: Clinical Experiences with AI in Medical Imaging (Supported in part by an Unrestricted Medical Education Grant from Siemens Healthineers of Siemens Medical Solutions, USA, Inc)

Tuesday, Dec. 3 4:30PM - 5:30PM Room: S404

Lubomir M. Hadjiiski, PhD (*Moderator*) Nothing to Disclose
Samuel G. Armato III, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the FDA requirements for the approval of CAD-AI tools prior to clinical adoption. 2) Describe the role of clinical acceptance testing from the perspectives of generalizability, efficiency in a clinical workflow, output explainability, and performance stability over time. 3) Identify practical considerations for the translation of CAD-AI tools to the clinic, including the human-machine interface, user training, and prospective surveillance. 4) Discuss challenges and opportunities of large-scale implementation of radiology AI systems, including the quantitative evaluation of their real-world usefulness in clinical practice.

**COURSE DESCRIPTION**

Artificial intelligence (AI) and machine learning techniques are finding their way into a wide variety of applications across the healthcare enterprise. These techniques have advanced the computer-aided diagnosis (CAD) paradigm by incorporating newer deep-learning-based approaches to achieve an expanded clinical decision support environment referred to as "CAD-AI." It is of paramount importance to ensure that a clinical decision support tool undergoes proper training and rigorous validation of its generalizability and robustness before adoption for patient care. Ongoing QA after clinical installation is also essential. An AAPM task group developed recommendations on practices and standards for the development and performance assessment of CAD-AI decision support systems. With CAD applications expanding to new stages of the patient care process, this educational session will explore the broader issues common to the translation of CAD-AI applications from the bench to the clinic. The goal of this lecture-based session (followed by discussion) is to bring attention to the advantages and challenges associated with the adoption of CAD-AI systems for clinical decision support. The presentations will focus on (1) the FDA approval process of CAD-AI tools, (2) clinical acceptance (generalizability, efficiency of use in a clinical workflow, explainability of the output, and performance consistency over time), (3) translation of CAD-AI tools to the clinic (the human-machine interface, user training, acceptance testing, and prospective surveillance), and (4) challenges and opportunities of large-scale implementation of radiology AI systems, including the quantitative evaluation of their real-world usefulness in clinical practice.

**Sub-Events**

### T8-CPH04C FDA Approval of CAD-AI Tools: Necessary but Not Sufficient for Clinical Adoption

## Musculoskeletal MDC Review

Tuesday, Dec. 3 4:30PM - 5:30PM Room: S401

Edward Y. Kim, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Expose the attendees to multidisciplinary discussion when treating sarcomas and other musculoskeletal malignancies. 2) Demonstrate specific imaging findings that directly affect staging and treatment decisions. 3) Provide the audience with specific information they should include in their reports that directly after prognosis and management.

**COURSE DESCRIPTION**

This multidisciplinary panel will discuss a series of challenging soft tissue and bone sarcoma cases. The session will highlight the importance of imaging in the diagnosis and treatment of these rare tumors. Panelists will represent radiology, orthopedic oncology, medical oncology, and radiation oncology.

**Sub-Events**

## MIDRC: Engaging the Cancer Imaging Research Community (Sponsored by the RSNA Radiology Informatics Committee)

Tuesday, Dec. 3 4:30PM - 5:30PM Room: N226

Adam E. Flanders, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand the purpose of the Medical Imaging and Data Repository (MIDRC). 2) Review metrics describing the progress in data dissemination and AI research so far. 3) Examine possible futures for MIDRC as it expands to other disease areas, including cancer.

**COURSE DESCRIPTION**

The Medical Imaging and Data Resource Center (MIDRC), initially funded through the National Institute of Biomedical Imaging and Bioengineering (NIBIB) under the National Institutes of Health (NIH) special emergency COVID-19 process, is an open-access platform for medical images and associated data. After collecting more than 300,000 imaging studies on COVID-19 patients, the initiative is expanding to engage the cancer imaging research community. This session will describe the purpose of MIDRC, its progress so far, and how it is expanding its scope.

**Sub-Events**

### T8-RCP19B Role of MIDRC Within the ARPA-H Structure

## Breast Cancer Screening and Risk for Intermediate Risk Patient

Wednesday, Dec. 4 8:00AM - 9:00AM Room: S406A

Elizabeth A. Morris, MD (*Moderator*) Scientific Advisory Board, Bracco Group;Speaker, Bayer AG;Scientific Advisory Board, Bayer AG;Speaker, Guerbet SA;Researcher, Guerbet SA;Stockholder, Revel Transit Inc;Stockholder, Kheiron Medical Technologies Ltd

**LEARNING OBJECTIVES**

1) Understand how to identify the intermediate risk patient. 2) Describe the current imaging modalities that may benefit the intermediate risk patient. 3) Review current risk assessment algorithms.

**COURSE DESCRIPTION**

Guidelines on how to screen are clear for high-risk and average-risk patients however there are limited guidelines for the intermediate-risk patient. Identifying the intermediate-risk patient is challenging and not uniformly agreed upon. This course will address the current thinking on risk assessment and how to screen these important patients.

**Sub-Events**

## Cardiac CT Updates 2024

Wednesday, Dec. 4 8:00AM - 9:00AM Room: N227B

Jill E. Jacobs, MD (*Moderator*) Nothing to Disclose
Pamela K. Woodard, MD (*Moderator*) Researcher, Siemens AG;Consulting, Medtronic plc;Researcher, Bayer AG;Patent, Washington University

**LEARNING OBJECTIVES**

1) Understand the current benefits and limitations of cardiac CT perfusion and CT FFR based on decades of experience. 2) Identify the importance of quantitative atherosclerotic plaque imaging and reporting. 3) Recognize the utility of cardiac CT for planning minimally invasive cardiac surgery.

**COURSE DESCRIPTION**

This Cardiac Updates 2024 session will provide attendees with the state-of-the-art information on cardiac CT perfusion, CT FFR, quantitative atherosclerotic plaque imaging and reporting, and utilization of cardiac CT for planning minimally invasive cardiac surgery.

**Sub-Events**

### W1-CCA09C Truth and Myths About Cardiac CT Perfusion - Two Decades of Experience

Michelle C. Williams, MBChB, PhD (*Presenter*) Speakers Bureau, Canon Medical Systems Corporation;Speakers Bureau, Siemens AG

### W1-CCA09D Truth and Myths about CT FFR - A Decade of Experience

## Imaging Pulmonary Infection - An International Perspective

Wednesday, Dec. 4 8:00AM - 9:00AM Room: E451A

Jeffrey P. Kanne, MD (*Moderator*) Research Consultant, PAREXEL International Corporation;

**LEARNING OBJECTIVES**

1) State the difference in endemic infections in the Americas, India, and Oceania. 2) Describe how travel history affects the differential diagnosis of infections. 3) Describe thoracic imaging findings of North American fungal infections, infections prevalent in South America, Mycobacterial infections in India, and infections prevalent in Oceania.

**COURSE DESCRIPTION**

This course will cover the thoracic imaging findings of North American endemic fungal infections, infections prevalent in South America, Mycobacterial infections in India, and infections in Australia and New Zealand. Learners will become familiar with infections that they may not normally encounter in their routine daily practice.

**Sub-Events**

### W1-CCH08B North American Fungal Infections

Jeffrey P. Kanne, MD (*Presenter*) Research Consultant, PAREXEL International Corporation;

## What Do You Worry About and Know Less of in the ER?

Wednesday, Dec. 4 8:00AM - 9:00AM Room: N228

Sameer B. Raniga, MD, FRCR (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify key diagnostic challenges and strategies in emergency radiology cases that overlap with other subspecialties such as neuro, head-neck, and nuclear medicine. 2) Explain the complexities and nuances involved in acute care settings through case studies, expert insights, and interactive discussions. 3) Enhance diagnostic acumen in emergency radiology by uncovering hidden complexities and improving understanding of lesser-exposed areas.

**COURSE DESCRIPTION**

Emergency radiology often intersects with other radiology subspecialties, presenting unique diagnostic challenges to emergency radiologists. This session, "What Do You Worry About and Know Less of in the ER?" is crucial for radiologists seeking to enhance their expertise in emergency radiology by delving into lesser-known areas that overlap with neuro, head-neck, and nuclear medicine.

Participants will engage in an interactive educational format featuring a mix of case studies, expert insights, and discussions that will guide attendees through real-world scenarios, highlighting the nuances and intricacies of emergency radiology.

The expected outcome is for learners to gain a deeper understanding of the diagnostic challenges in emergency radiology, develop enhanced diagnostic acumen, and be better prepared to manage complex cases that span multiple subspecialties. This session promises to be an invaluable resource for those looking to elevate their skills and confidence in the ER.

## Multi-Energy & Photon Counting CT

Wednesday, Dec. 4 8:00AM - 9:00AM Room: E451B

Benjamin M. Yeh, MD (*Moderator*) Grant, Koninklijke Philips NV;Grant, General Electric Company;Consultant, Canon Medical Systems Corporation;Speaker, Canon Medical Systems Corporation;Royalties, Oxford University Press;Shareholder, Nextrast, Inc;Board Member, Nextrast, Inc

**LEARNING OBJECTIVES**

1) Describe the clinical benefits of multi-energy CT of the abdomen and pelvis. 2) Identify methods to introduce multi-energy CT to clinical practice. 3) Describe photon counting CT technology and the advantages of this technology for clinical diagnosis. 4) Review ways in which photon counting CT can be used to improve evaluation of the abdomen and pelvis. 5) Explain how multi-energy CT may influence the way we use contrast agents now and in the future.

**COURSE DESCRIPTION**

Multi-energy CT has opened new diagnostic possibilities for abdominopelvic imaging. Benefits of multi-energy CT include increased reader confidence for a range of clinical diagnoses, increased sensitivity for subtle lesions, improved detection of iodine enhancement, and reduction of common CT artifacts. The recent introduction of photon counting CT further augments our ability to obtain crisp high resolution imaging of the abdomen and pelvis with improved iodine detection and reduced radiation dose. Multi-energy CT allows unprecedented accuracy in the delineation of otherwise subtle or ambiguous contrast agent enhancement. Conversely novel non-iodine contrast agents promise to unlock information-rich capabilities of our modern multi-energy CT scanners.

**Sub-Events**

### W1-CGI13B Interpretation of Abdominal Pelvic Dual Energy CT in Daily Practice

Bari Dane, MD (*Presenter*) Nothing to Disclose

## RSNA Hands-On Lab: Contrast Reaction Management (Registration Fee Required)

Wednesday, Dec. 4 8:30AM - 10:30AM Room: E265

Carolyn L. Wang, MD (*Moderator*) Research Grant, General Electric Company

**LEARNING OBJECTIVES**

1) Recognize various types of contrast reactions and the proper management of various types of contrast reactions through hands-on simulation-based training. 2) Learn with hands-on practice the proper administration of various routes of epinephrine as well as other medications to treat the more common hypersensitivity contrast reactions. 3) Recognize and manage a contrast reaction in a sedated patient and pediatric patient.

**COURSE DESCRIPTION**

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. Through hands-on high-fidelity simulation scenario training, learners will practice recognizing and managing various types of contrast reactions. Following a brief lecture, learners will rotate through multiple stations during the course to gain individual hands-on experience. To enhance the learner's experience and allow for more time in the hands-on stations, we ask all learners for the course to watch this short 15 min. video on contrast reaction management prior to the course: https://www.youtube.com/watch?v=9r-_E8dmJ0A

Hediyeh Baradaran, MD, MS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify appropriate imaging in patients with embolic stroke of undetermined source. 2) Develop an approach for interpreting intracranial vessel wall imaging and evaluating risk of extracranial carotid plaque. 3) Identify markers of heightened stroke risk on standard neuroimaging.

**COURSE DESCRIPTION**

This lecture-based session will review imaging markers of heightened stroke risk frequently encountered in neuroimaging in both emergent and non-emergent settings. The session will be comprised of individual talks from both a vascular neurologist and neuroradiologists discussing critical imaging findings which may aid in stroke risk classification and future stroke mitigation. Talks will focus on imaging of embolic stroke of undetermined source from a neurologist's perspective, utilizing intracranial vessel wall imaging for ischemic stroke, extracranial carotid plaque classification and stroke risk, and other imaging findings of heightened stroke risk.

**Sub-Events**

### W1-CNR10B Changing Landscape of ESUS: When and Why We Image: A Neurologist's Perspective

## Endometrial and Cervical Cancer: Imaging Before and After Treatment

Wednesday, Dec. 4 8:00AM - 9:00AM Room: E351

Jeanne M. Horowitz, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Explain what radiologists need to know about the new 2023 Endometrial Cancer FIGO Guidelines to add value in their reports for their ordering physicians, featuring interactive cases. 2) Review how to optimize and interpret cervical cancer MRI exams for staging, with interesting case examples. 3) Learn pearls and pitfalls of imaging endometrial and cervical cancer after treatment with practical take home points.

**COURSE DESCRIPTION**

"Endometrial and Cervical Cancer: Imaging Before and After Treatment" will feature three lecturers using interactive imaging case examples and giving practical take home points focusing on the new 2023 Endometrial Cancer FIGO Guidelines, Cervical Cancer staging with MRI, and Imaging of Endometrial and Cervical Cancer after treatment.

## Clinical Implementation and Standardization of Proton Magnetic Resonance Spectroscopy

Wednesday, Dec. 4 8:00AM - 9:00AM Room: S404

Yuxiang Zhou, PHD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review the physical principles of magnetic resonance spectroscopy (MRS) and MRS pulse sequences. 2) Describe strategies to effectively acquire, analyze, and quantify the quality of MRS data. 3) Discuss emerging applications of MRS in clinical practice. 4) Provide MRS reporting standards and discuss future perspectives in clinical reality.

**COURSE DESCRIPTION**

Magnetic resonance spectroscopy (MRS) permits the quantification of metabolites within a diverse range of tissues and pathologies. This metabolic information has been shown to enable better diagnoses, personalized treatments, and rapid assessment of treatment response. However, implementation of MRS remains challenging and consistent acquisition of high-quality data remains difficult due to the lack of technical standardization. This session will provide experts' advice, consensus recommendations, standardization of MRS acquisition, analysis and reporting to improve MRS quality in routine clinical practice. First, this educational course will introduce the physical principles of MRS and describe the latest clinically available MRS pulse sequences. Next, this course will present strategies to effectively and consistently acquire high-quality MRS data, robustly analyze this data, and perform MRS quality management in routine clinical practice. Finally, this session will discuss established and emerging applications of MRS, reporting standards and future perspectives in clinical reality.

## ASRT@RSNA: Thriving in an Environment of Accelerating Change: A Survival Guide for Breast Imaging Teams

Wednesday, Dec. 4 8:00AM - 9:00AM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand how breast imaging technologies and tools have changed over the last several years, bringing challenges, opportunities and growth to breast imaging teams. 2) Discover methods for minimizing burnout and stress caused by a physically and emotionally demanding environment. 3) Identify steps in the Guide to Thrive toolkit to overcome challenges and embrace opportunities in an environment of accelerating change.

**COURSE DESCRIPTION**

This session provides an overview of how breast imaging technologies have changed over the

last several years, bringing challenges, opportunities and growth to breast imaging teams across

the globe. The speaker will share methods for minimizing burnout and stress in a physically

and emotionally demanding environment, using new technologies, focusing on proper

ergonomics and enhancing communication skills.

## RSNA/ESR Symposium: Advances in Prostate Cancer Imaging and Therapy - Early Detection and Organized Testing in US and Europe

Wednesday, Dec. 4 8:00AM - 9:00AM Room: E353B

Katarzyna J. Macura, MD, PhD (*Moderator*) Author with royalties, RELX;Research Grant, Profound Medical Inc
Ivo Schoots, MD,PhD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Discuss the evolution of diagnostic pathway and role of MRI in improving the detection and localization of life-threatening prostate cancer. 2) Describe the MRI-pathway for early detection of prostate cancer based on the North American and European guidelines and discuss how practice patterns of MR-informed prostate biopsy may differ between the US and Europe. 3) Learn about the basis for the European screening recommendations from the Europe Union's Beating Cancer Plan and discuss the challenges and controversies of prostate cancer screening vs. early detection, based on guidelines (EAU/AUA/NCCN).

### COURSE DESCRIPTION

This course highlights advancements in imaging for prostate cancer diagnosis and treatment. In this educational session, presenters will focus on early detection of prostate cancer and discuss the role of MR imaging and MR-informed prostate biopsy. Other topics will include practice patterns and guidelines in US and Europe, and controversies surrounding prostate cancer screening.

**Sub-Events**

## Re-Imagining Academia

Wednesday, Dec. 4 9:30AM - 10:30AM Room: S402

Saurabh Jha, MBBS, MRCS (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Appreciate the non-traditional methods of academic trajectory. 2) Understand how to become domain experts in global health and education. 3) Identify how success in non-traditional endeavors can be measured.

**COURSE DESCRIPTION**

Traditionally academic success has been rooted in the "publish or perish" sentiment. Much deference has been given to hypothesis-driven research work. As academia has evolved, what it means to be an academic scholar, a domain expert, and create impact has changed. This panel discussion will explore non-traditional routes to academic success, such as by advancing education, advancing imaging in resource-poor settings, and science communication, to give aspiring academic radiologists options for a fulfilling career.

**Sub-Events**

## Liver Disease Imaging in Children

Wednesday, Dec. 4 9:30AM - 10:30AM Room: E350

Gary R. Schooler, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review ultrasound techniques, particularly liver shear wave elastography, and how they can be adapted to and optimized for pediatric patients in the evaluation of liver disease. 2) Summarize AI and non-AI-based MRI methods for detecting and characterizing chronic liver diseases in children. 3) Apply ultrasound and MRI techniques in the evaluation of chronic liver disease in children through case-based review.

**COURSE DESCRIPTION**

Imaging is an important component in the diagnosis and longitudinal care of many pediatric patients with liver disease. This lecture-based course will provide a review of imaging-based techniques used in the evaluation of pediatric liver diseases. Techniques ranging from quantitative ultrasound to artificial intelligence aided MRI will be reviewed and discussed by pediatric radiology content experts.

**Sub-Events**

### W3-CPD02C US Techniques for Evaluation of Diffuse Hepatic Disease: From Contrast-enhanced Sonography to Elastography

## Updates to MRI Safety Guidance for Varied MR Environments and Devices

Wednesday, Dec. 4 9:30AM - 10:30AM Room: N227B

Michael N. Hoff, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe unique MRI safety considerations and corresponding guidance in radiation oncology environments. 2) Describe unique MRI safety considerations and corresponding guidance in low field, high field, and alternate layout MR environments. 3) Understand unique concerns of implants and devices within the context of new MR environments.

**COURSE DESCRIPTION**

MRI safety guidance is continually evolving to keep pace with the changing MRI landscape. Recent years have seen the introduction of novel clinical MR environments, including those with the MR/LINAC and ultra-high and low field systems, challenging the abilities of institutions, governing bodies, and regulators to stay abreast of the wave of change. It is not only essential that new safety standards for these diverse environments are established, but it is also necessary to clearly communicate new guidance to radiological personnel in a timely fashion. These lectures will outline key MRI safety considerations involving radiation oncology, variable magnetic fields, and patients with implants and devices, with special attention paid to the unique challenges in each environment, how radiologists, physicists, and technologists can address them.

## ASRT@RSNA: Managing the Pediatric Patient

Wednesday, Dec. 4 9:30AM - 10:30AM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Recognize the pediatric patient's feelings through facial expressions. 2) Understand the role of the child life specialist. 3) Recognize tips and tricks to avoid procedure sedation. 4) Identify how to increase pediatric patient satisfaction.

### COURSE DESCRIPTION

Although health care encompasses all ages, the pediatric population often feels afraid and anxious in the health care environment. White coat syndrome is when the patient experiences anxiety around physicians and the patient's blood pressure subsequently rises. Pediatric patients can feel anxious and scared because they don't know what is going to happen or the procedure that's going to take place, and they may fear pain from the needle placement. This session provides education on how to interpret the patients' feelings through their facial expressions and understand their age specific needs. Attendees will learn about the child life specialist role, patient education and distraction techniques, and how teamwork can support the best experience possible for pediatric patients.

**Sub-Events**

## RSNA/ESR Symposium: Advances in Prostate Cancer Imaging and Therapy - Management Strategies for Monitoring Prostate Cancer

Wednesday, Dec. 4 9:30AM - 10:30AM Room: E353B

Tristan Barrett, MBBS, MD (*Moderator*) Nothing to Disclose
Andrei S. Purysko, MD (*Moderator*) Contract, Profound Medical Inc;Research support, Blue Earth Diagnostics Ltd;Consultant, KOELIS;

### LEARNING OBJECTIVES

1) Discuss the implications of overdiagnosis and overtreatment in prostate cancer management, with a focus on how biopsy regimens contribute to these challenges. 2) Review the indications, adoption, and risk assessment in active surveillance in North America and Europe, and discuss differences. 3) Describe the scenarios for abbreviated prostate MRI and discuss the pros and cons of contrast-enhanced imaging and how the omission of MR sequences may impact the diagnostic accuracy.

### COURSE DESCRIPTION

This session will cover the impact of various biopsy strategies on early detection and active surveillance in the US, and compare active surveillance approaches between Europe and the US, highlighting key differences in indications and definitions. Additionally, participants will assess the pros and cons of contrast-enhanced imaging and the indications for abbreviated prostate MRI. This session will provide critical insights and practical strategies to enhance prostate cancer management through a combination of informative lectures and interactive discussions.

**Sub-Events**

## AI that Knows When it Doesn’t Know – Uncertainty Quantification and Safe Clinical Integration of AI Algorithms

Wednesday, Dec. 4 11:00AM - 12:00PM Room: E450B

Natalia Alves, MSc (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand and explain the importance of uncertainty quantification (UQ) in AI predictions and its impact on clinical decision-making. 2) Describe the latest UQ methods and their applications in medical imaging to enhance the reliability of AI-generated outcomes. 3) Apply practical UQ strategies in daily work as radiologists, AI vendors, or AI scientists to improve the trustworthiness of AI predictions in clinical settings.

**COURSE DESCRIPTION**

Artificial Intelligence (AI) has shown remarkable promise in medical imaging applications, yet a significant gap remains between technological advancements and clinical integration. For AI algorithms to be truly beneficial in real-world settings, it is crucial that their confidence, or uncertainty, in individual predictions is effectively communicated to clinicians. Uncertainty quantification (UQ) enhances AI outputs by adding a layer of trustworthiness to predictions, such as cancer likelihood or survival rates. This layer informs end-users about the reliability of AI outcomes, making predictions without UQ methods generally less reliable.

In this course, we delve into the fundamentals and latest developments in UQ from technical, clinical, and application perspectives. The course features three presentations by leading experts, each focusing on different aspects of UQ: technical details, clinical implications, and practical implementation. Interactive components will be included in all talks, culminating in a round-table discussion where speakers will address audience questions. By the end of the course, participants will have a robust understanding of UQ fundamentals and recent advancements, equipped with practical insights to apply in their daily work as radiologists, AI vendors, or AI scientists.

## Success for Mid-Career Radiologists Across the Board: Research, Education, Leadership (Sponsored by the RSNA Research Development Committee)

Wednesday, Dec. 4 11:00AM - 12:00PM Room: S402

Jadranka Stojanovska, MD, MS (*Moderator*) Nothing to Disclose
Ahuva Grubstein, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify strategies for balancing clinical, research, and educational responsibilities: Participants will learn to create a sustainable plan for integrating these three critical aspects into their professional lives, ensuring continuous growth and impact in each area. 2) Develop a plan for securing research funding and managing successful research projects: Attendees will gain insights into the grant application process, project management, and how to produce high-quality, publishable research that advances the field of radiology. 3) Enhance leadership skills to effectively lead teams and drive innovation within radiological departments: This objective focuses on building leadership capabilities, including communication, decision-making, and team-building skills, to foster a collaborative and innovative work environment.

**COURSE DESCRIPTION**

As radiologists progress to the mid-career stage, they often encounter a unique set of challenges and opportunities that require a balance of clinical expertise, research innovation, educational commitment, and leadership skills. This session at the Radiological Society of North America (RSNA) conference is designed to empower mid-career radiologists with the knowledge and tools needed to excel in these multifaceted roles. In this comprehensive course, participants will explore strategies to enhance their professional development across three critical areas: research, education, and leadership. Expert speakers will address issues such as securing research funding, developing impactful educational initiatives, and cultivating effective leadership skills. The session will also cover practical approaches to managing time and resources efficiently while maintaining a high standard of clinical care. Through a blend of lectures, interactive discussions, and case study analyses, attendees will gain actionable insights and practical skills to navigate the complexities of mid-career advancement. This course is essential for radiologists looking to make significant contributions to their field and achieve a balanced, fulfilling career.

## ASRT@RSNA: Understanding Imaging for Patient Selection in Mechanical Thrombectomy

Wednesday, Dec. 4 11:00AM - 11:45AM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Understand the clinical and imaging criteria for selecting patients for mechanical thrombectomy. 2) Analyze clinical data to identify suitable candidates for the different imaging modalities. 3) Understand recent advancements in imaging that aid in patient selection. 4) Apply this knowledge to clinical scenarios.

### COURSE DESCRIPTION

The criteria for selecting patients for mechanical thrombectomy has changed significantly in recent years due to the evolving landscape of evidence and imaging techniques. This session provides radiographers with information regarding the latest imaging techniques and standards for mechanical thrombectomy patient selection. The speaker will use selected clinical cases to illustrate the different imaging modalities and established protocols. The session aims to bridge the gap between theoretical knowledge and practical application, providing radiographers with the tools to improve patient care in acute ischemic stroke.

## DWI Clinical Applications and Future Directions

Wednesday, Dec. 4 1:30PM - 2:30PM Room: S406A

Katja Pinker-Domenig, MD, PhD (*Moderator*) Speakers Bureau, European Society of Breast Imaging;Speakers Bureau, Siemens AG;Speakers Bureau, IDKD;Speakers Bureau, Canon Medical Systems Corporation;Consultant, F. Hoffmann-La Roche Ltd;Consultant, Merantix Healthcare;Consultant, AURA Health

### LEARNING OBJECTIVES

1) Explain the clinical application of DWI in breast imaging. 2) Identify the current technical advances. 3) Understand the future directions and recommendations.

### COURSE DESCRIPTION

DWI is a non-contrast MRI technique that measures the diffusion of water molecules within biologic tissue and is increasingly incorporated into routine breast MRI examinations. Main applications of DWI are breast cancer detection and characterization, prognostication, and prediction of treatment response to neoadjuvant chemotherapy and might be a non-contrast alternative for breast cancer screening. Problems with suboptimal resolution and image quality have restricted the mainstream use of DWI for breast imaging, but these shortcomings are being addressed through several technologic advancements. In this review, we present a summary of the implementation of breast DWI in clinical practice, discuss technical advances and present future directions including standardization.

**Sub-Events**

Jeremy D. Collins, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Review the naming conventions and how to setup standard cardiac MR imaging planes. 2) Learn the cardiac MR imaging pulse sequences used across imaging protocols including flow imaging. 3) Review techniques for myocardial tissue characterization including late gadolinium enhancement. 4) Review pulse sequences and techniques for magnetic resonance angiography. 5) Learn common cardiac MR imaging applications in clinical practice.

### COURSE DESCRIPTION

Cardiac MRI is an established technique to evaluate myocardial structure and function. When combined with MR angiography and flow imaging Cardiac MRI offers a comprehensive assessment of both cardiac and vascular pathology in a single exam. In this educational course we will review the basics of performing cardiac MRI and MR angiography including imaging planes and pulse sequences. Techniques and applications of flow imaging will be reviewed. Finally, common clinical applications of cardiac MR will be reviewed.

**Sub-Events**

### W6-CCA10C ABC of Cardiac Planes and Sequences

## Pearls and Pitfalls in Chest Radiography

Wednesday, Dec. 4 1:30PM - 2:30PM Room: E451A

Mark S. Parker, MD (*Moderator*) Co-author, Thieme Medical Publishers, Inc

**LEARNING OBJECTIVES**

1) List definitions, types, and etiologies of atelectasis. 2) Recognize classic radiographic signs of atelectasis and volume loss. 3) Identify cases of atelectasis requiring additional imaging assessment for exclusion of a central obstructing lesion. 4) Understand the mechanism of pneumomediastinum formation. 5) How to detect pneumothorax in a supine patient. 6) Distinguish benign mediastinal gas from those conditions associated with pneumomediastinum requiring urgent evaluation and management. 7) Acknowledge some of the diagnostic challenges associated with accurate interpretation of single view and 2-view chest radiographic exams. 8) Provide case-based examples highlighting various potential and or unrecognized radiographic findings, iatrogenic injuries, and or disease processes. 9) Emphasis radiographic tips to avoid potential interpretative errors that can adversely impact patient care.

**COURSE DESCRIPTION**

I. "The Many Faces of Atelectasis": Course will review protean radiographic manifestations of atelectasis and volume loss. Various types of atelectasis will be defined and described including obstructive, non-obstructive, and postoperative atelectasis. Direct and indirect radiographic signs of atelectasis will be illustrated classic radiographic signs of atelectasis and volume loss highlighted. Morphologic and radiographic features of lobar atelectasis will be presented. Special situations leading to atelectasis and volume loss will be presented including rounded atelectasis and middle lobe syndrome.

II. "Anormal Intrathoracic Gas Collections": This course will review the radiographic detection of abnormal intrathoracic gas collections, with a focus on the detection of pneumothorax on portable radiography. We will review the radiographic findings in pneumothorax, pneumomediastinum, pneumopericardium and extrapleural gas collections and their radiographic mimics. While most abnormal intrathoracic gas collections are innocuous, there are specific situations, such as pneumomediastinum in a patient with esophageal perforation or tracheobronchial injury, that require urgent management.

III. "Radiographic Misses and Mysteries": Despite widespread clinical use, accurate chest radiographic interpretation is challenging. Even good quality single view portable and standard 2-view chest radiographic exams are simply 2-dimensional imaging modalities used to assess a complex 3-dimensional organ system with multiple superimposed anatomic structures and often complex disease processes. As a result, abnormal iatrogenic and pathologic disease processes are often subtle, obscured by overlapping anatomic structures, and nonspecific, contributing to potential diagnostic errors. This course will highlight some of these diagnostic challenges and potential ways to improve diagnostic interpretations and avoid potential diagnostic errors.

**Sub-Events**

### W6-CCH10B Radiographic Misses and Mysteries

## GI Emergencies: Core Concepts and Advances

Wednesday, Dec. 4 1:30PM - 2:30PM Room: N228

Douglas S. Katz, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) To demonstrate a series of recent challenging cases of the acute abdomen and pelvis on CT. 2) To show a set of important diagnoses of acute conditions of the abdomen and pelvis with ultrasound. 3) To review the role of cross-sectional imaging for demonstrating expected and unexpected findings in the findings related to interventional abdominal procedures, with an emphasis on emergency conditions and subsequent appropriate patient management.

**COURSE DESCRIPTION**

Three very experienced emergency and abdominal radiologists will conduct case-based practice reviews of three topics of relevance to emergency and general abdominal radiology. The first presentation will be on recent challenging CT cases of the abdomen and pelvis in the emergency setting. The second presentation will be on emergency imaging using ultrasound of the abdomen and pelvis. The third presentation will be using cross-sectional imaging to demonstrate findings related to expected and unexpected findings related to procedures before and after interventional abdominal procedures. Brief relevant reviews of the literature will be performed, differential diagnoses - if any - will be discussed, and patient management will be emphasized.

**Sub-Events**

### W6-CER06B Challenging Recent CT Cases of the Acute Abdomen and Pelvis

## Abbreviated and Accelerated MRI

Wednesday, Dec. 4 1:30PM - 2:30PM Room: N227B

Hersh Chandarana, MD, MBA (*Moderator*) Institutional research agreement, Siemens AG;Equipment support, Siemens AG;Software support, Siemens AG
Ivan Pedrosa, MD, PhD (*Moderator*) Scientific Advisor, Health Tech International;Scientific Advisor, Merck & Co, Inc

**LEARNING OBJECTIVES**

1) Describe and compare strengths and weaknesses of different methods for performing abbreviated MRI for Hepatocellular Carcinoma (HCC) screening. 2) Describe the current evidence for abbreviated protocol for pancreatic cyst surveillance. 3) Examine the latest technological advancements and innovations in Prostate MRI (such as AI-assisted image reconstruction /acquisition and intelligent scanning) that support the use of abbreviated protocols.

**COURSE DESCRIPTION**

With increasing healthcare costs and challenges with staffing and access to MR imaging, it is important to consider focused indication-based abbreviated scanning and reporting of MRI to maximize efficiency and address above mentioned challenges. In this course, we will review current evidence for abbreviated MRI protocol for liver cancer, pancreatic cysts, and prostate cancer as well as opportunities and challenges in implementing abbreviated protocols in busy clinical practice. Furthermore, we will have a lively panel discussion to dive deeper into the opportunities and challenges and share experiences of how one can get started and measure the utility, efficacy, and cost savings with implementation of abbreviated protocols.

**Sub-Events**

## A Debate on the Future of Radiology Reporting: Semantic vs Large Language Models

Wednesday, Dec. 4 1:30PM - 2:30PM Room: E450B

Namita S. Gandhi, MD, MSc (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Introduction of structured report, semantic standardization and large language models in context of radiology report Discuss opportunities and challenges with semantic standardization in radiology reports. 2) Discuss opportunities and challenges with large language models in radiology reports.

**COURSE DESCRIPTION**

Data from radiology reports not only contributes to clinical care, but can be used for facilitating downstream workflows like clinical decision support, clinical registries and AI development.

Structured reports provide the benefit of structured data and semantic standardization which facilitates these downstream workflows. With the recent advancements, large language models can be applied to radiology reports and can potentially facilitate similar downstream workflows. This session will focus on this evolving landscape of radiology reporting, juxtaposing the structured, semantically standardized reports against the burgeoning capabilities of large language models, discussing the opportunities and challenges with both these models and envisioning the future of radiology reports.

**Sub-Events**

## The Rules of Engagement: Regulatory Perspectives on Healthcare AI on Reducing Bias and Discrimination

Wednesday, Dec. 4 1:30PM - 2:30PM Room: E352

Alex Towbin, MD (*Moderator*) Author, RELX;Consultant, Anderson Publishing, Ltd;Advisory Board, KLAS Enterprises LLC;Travel support, Merative LP

**LEARNING OBJECTIVES**

1) Describe key U.S. federal regulations, including Section 1557 of the ACA, addressing AI bias and healthcare discrimination. 2) Participants will gain an understanding of the ONC HTI-2 Final Rule and its implications for AI bias reduction. 3) Participants will learn about Canada's AIDA and how it influences AI development and deployment in medical imaging.

**COURSE DESCRIPTION**

Artificial intelligence (AI) is rapidly advancing in radiology, offering significant potential to improve diagnostic accuracy and efficiency. However, the risk of perpetuating bias within data and algorithms poses a severe challenge, potentially leading to discriminatory outcomes in healthcare. This session provides a comprehensive review of the regulatory frameworks of the United States and Canada that aim to mitigate these risks. The session will cover overviews and specific discussions of federal and state-level regulations in the U.S. that have significant implications for healthcare AI and algorithm-based bias. Additionally, it will explore Canada’s approach through the Artificial Intelligence and Data Act (AIDA). The discussions will highlight the complexities of implementing these regulations in clinical practice and their impact on AI development and deployment in radiology.

**Sub-Events**

### W6-CIN24B Overview of the U.S. AI Regulatory Landscape: Section 1557 of the ACA and Beyond

Nina E. ## Imaging of Muscle Injury: Diagnosis and Reporting

Wednesday, Dec. 4 1:30PM - 2:30PM Room: E450A

Christopher F. Beaulieu, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Improve understanding and reporting on myotendinous injuries across the age spectrum and in various anatomic locations. 2) Learn to recognize abnormal muscle signal intensity patterns as they pertain to myopathy and its mimics. 3) Appreciate differential diagnostic tips that help distinguish muscle injury from malignancies.

**COURSE DESCRIPTION**

This five part session focuses on common and clinically important disorders of muscle. Attendees will hear from experts on key issues in assessment of myotendinous injury including tips on radiological reporting, imaging of pediatric and adolescent patients, and how to distinguish injury from neoplasia. Special focus will be given to uncommon but important injuries along the chest wall, including pectoralis and latissimus doors injuries. Diffuse patterns of muscle abnormality will also be addressed during the presentation on myopathy and its mimics.

**Sub-Events**

### W6-CMK11B Myotendinous Injuries in Pediatric and Adolescent Patients

## Conquering 2024 Radiologist Workforce Challenges

Wednesday, Dec. 4 1:30PM - 2:30PM Room: S402

Jay R. Parikh, MD, FRCPC (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) To understand the current radiologist job market within the United States. 2) To describe how understanding diversity can be leveraged to improve retention of radiologists. 3) To describe strategies to help recruit and retain radiologists in the current job market.

**COURSE DESCRIPTION**

The last five years have demonstrated an unprecedented radiologist job market within the United States. Radiology practices across the country are having challenges both retaining and recruiting radiologists. The purpose of this session is to update the attendees with respect to the current job market, understand the implications regarding diversity in the job market, and describe strategies to help retain slash recruit radiologists in this current job market.

**Sub-Events**

### W6-CNPM10B Cultural Solutions to Increase Radiologist Retention

Eric M. Rubin, MD (*Presenter*) Nothing to Disclose

## Can I Call a Consult Please? This is a Weird Case!

Wednesday, Dec. 4 1:30PM - 2:30PM Room: S406B

Carlos H. Torres, MD, FRCPC (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identify key imaging findings, including pertinent positive and negative findings, that can help narrow the differential diagnosis in the provided clinical context. 2) Develop an approach and organized thought process when faced with difficult unknown cases.

**COURSE DESCRIPTION**

This will be a case-based session focused on complex and challenging neuroradiology cases. The goal is not necessarily nailing the diagnosis, but rather to develop an approach and organized thought process when encountering complex cases. It will include brain, spine, head & neck and pediatric neuroradiology cases.

**Sub-Events**

**W6-CNR13B** **Can I Call a Consult Please? This is a Weird Spine Case!**

## ASRT@RSNA: Breaking down the Barriers of Quality Control

Wednesday, Dec. 4 1:30PM - 2:30PM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Explain changes in required imaging equipment quality control before ACR accreditation and Joint Commission-required testing. 2) Learn how to interpret quality control data and demonstrate how to apply working knowledge in quality control across multiple imaging modalities. 3) Present rationale for changes in radiology departments. 4) Discuss future directions in quality control and continuous quality improvement.

**COURSE DESCRIPTION**

Quality control requirements for radiologic imaging equipment have changed significantly over the past 20 years. The advent of new imaging systems and hybridized imaging equipment now requires competency in multiple imaging modalities. This session discusses how quality control has evolved over the past 20 years, including quality control before American College of Radiology accreditation and Joint Commission-required testing, machine- and modality-specific quality control, the benefits of quality control standards, regulatory and accrediting body requirements, and continuous quality improvement strategies for radiologic imaging equipment.

Attendees will learn how to incorporate what they know about their modality's principles in accuracy, constancy, geometry, linearity and reproducibility and apply that knowledge to hybridized systems and new technology. The speaker will provide data on how to improve quality control, offer continuous quality improvement resources and rationale for future process improvement, and give strategies for ACR and Joint Commission compliance.

**Sub-Events**

**W6-CRT07B** **Breaking down the Barriers of Quality Control**

Ryan Misseldine, MBA, BS (*Presenter*) Nothing to Disclose

## Case Based Review of Vascular Imaging

Wednesday, Dec. 4 1:30PM - 2:30PM Room: N229

Christopher J. Francois, MD (*Moderator*) Nothing to Disclose
Prachi P. Agarwal, MD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Explain the radiographic and cross-sectional imaging findings essential for diagnosis of congenital thoracic vascular diseases, pulmonary arterial and venous vascular diseases, and challenging thoracic aortic diseases. 2) Identify advanced imaging techniques for use in patients with congenital thoracic vascular diseases, pulmonary arterial and venous vascular diseases, and challenging thoracic aortic diseases.

### COURSE DESCRIPTION

After this course, attendees will be more comfortable in the diagnosis of congenital thoracic vascular diseases, pulmonary arterial and venous vascular diseases, and challenging thoracic aortic diseases. In addition, attendees will be able to explain the rationale for recommending and using advanced imaging techniques in patients with thoracic vascular diseases. The format of this course will be case-based presentations.

## RSNA/ESR Symposium: Advances in Prostate Cancer Imaging and Therapy - Developments on Accreditation, Certification, Quality Control and AI

Wednesday, Dec. 4 1:30PM - 2:30PM Room: E353B

Katarzyna J. Macura, MD, PhD (*Moderator*) Author with royalties, RELX;Research Grant, Profound Medical Inc
Ivo Schoots, MD,PhD (*Moderator*) Nothing to Disclose

### LEARNING OBJECTIVES

1) Discuss the importance of quality control and assurance measures in maintaining the accuracy and reliability of prostate MRI within diagnostic centers, including the role of radiologists and frontline staff in ensuring adherence to best practices. 2) Review the criteria, standards, and procedures required for prostate cancer MRI center designation in US, and outline the framework with key learnings from ACR Prostate MRI Quality Improvement Collaborative. 3) Discuss radiologists' certification and MR imaging quality control initiatives in Europe. 4) Learn about developments in artificial intelligence (AI) for prostate cancer imaging and detection, as well as applications of AI methods to increase efficiency and improve accuracy.

### COURSE DESCRIPTION

This course highlights advancements in imaging for prostate cancer diagnosis and treatment. In this educational session, presenters will discuss the accreditation of imaging centers, certification of radiologists, quality control in MR imaging, and emerging applications of artificial intelligence for the improvement of diagnostic accuracy and workflow efficiency.

**Sub-Events**

## Head and Neck Cancer: Read Like the Experts and Tumor Board Discussion

Wednesday, Dec. 4 3:00PM - 4:00PM Room: E352

Ashley H. Aiken, MD (*Moderator*) Nothing to Disclose
Luke N. Ledbetter, MD (*Moderator*) Royalties, RELX

**LEARNING OBJECTIVES**

1) Review the key imaging findings in evaluation of head and neck cancer patients, including at staging, treatment response and surveillance time points.
2) Recognize the important imaging findings that impact clinical management of patients with head and neck cancer.

**COURSE DESCRIPTION**

In this "Best of" head and neck imaging session, attendees will hear short talks from experts focusing on the key information the multidisciplinary tumor board (surgeons, radiation oncologists and oncologists) needs to know from the imaging at diagnosis and follow-up of tumors in the head and neck. Speakers will emphasize imaging pearls and important clinical management considerations with which radiologists should be familiar. These talks will be followed by a case-based discussion by a panel of experts in a simulated tumor board session. Sample cases will be presented and discussed by radiologists, a head and neck cancer surgeon and a radiation oncologist. This session offers attendees a real world glimpse into how imaging interpretation impacts decision-making in the clinical management of head and neck cancer patients.

W7-CIN20

## Cybersecurity in Healthcare: Implications of Generative AI and Large Language Models (LLMs)

Wednesday, Dec. 4 3:00PM - 4:00PM Room: E450B

Benoit Desjardins, MD, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand which aspects of generative AI and LLMs relate to cybersecurity. 2) Understand how these can be used for good or nefarious purposes. 3) Describe how generative AI and LLMs can help offensive cybersecurity. 4) Describe how generative AI and LLMs can help defensive cybersecurity.

**COURSE DESCRIPTION**

Cybercrime against healthcare institutions has exploded in recent years. Five years ago, the Hollywood Presbyterian Medical Center paid a $17,000 ransom to regain access to its medical records blocked by ransomware. In 2021, more than 1 in 3 healthcare organizations reported being hit by ransomware. The Russia-tied Ryuk group hit over 235 healthcare facilities, raking in more than $100 million in ransoms. Although paying ever-increasing ransoms can be costly for medical centers, refusing to pay them often leads to even bigger losses. The University of Vermont Health system lost $50 million and Universal Health System lost $67 million for refusing to pay ransoms in 2020. The situation has been considerably worsened by the pandemic, which produced a triple threat for healthcare systems: (1) a rapid expansion of internet-connected technologies and services causing an expanded attack surface, (2) an increase in many types of cyberattacks, and (3) fewer available resources to defend against cyberattacks. Recently, the zero-day vulnerability Log4j in Apache software has been leading to hundreds of cyber-attacks around the world since December 2021. Cybersecurity has become an important part of healthcare, and we must address this topic at RSNA since every radiology practice can become a victim of a cyber-attack. This explosion in cyber-attacks against medical centers is the result of (1) the US Justice System penalizing cyber-attack victims, rather than going after the perpetrators, (2) the commoditization of cyber-attack tools, and (3) the increased use of artificial intelligence (AI) to fine-tune cyber-attacks. The latest developments in generative AI and LLMs is truly changing the game, both from an offensive and a defensive point of view. AI is now extensively used by both attackers (“Offensive AI”) and defenders (“Defensive AI”). In this refresher course, we will explore the latest developments in generative AI and LLMs from a cybersecurity point of view. 1- Overview of generative AI and LLMs for cybersecurity: After providing a quick overview of the latest developments in generative AI and LLMs, Dr Benoit Desjardins, a leader in cybersecurity and artificial intelligence, will discuss not only how these techniques are helpful in general, but also how they can be used for good or nefarious purposes in the context of cybersecurity. 2- Cybercriminals are weaponizing generative AI and LLMs against healthcare: how cybercriminals are weaponizing artificial intelligence to improve their attacks against medical institutions. This will be discussed by Brett Strassner (Archangel), a leader in cybersecurity. He will provide a cutting-edge picture of how cyber-criminals are currently using generative AI and LLMs to improve success of different types of attacks, such as phishing, scanning, and intrusions of medical centers. 3- Generative AI and LLMs are transforming healthcare cybersecurity: how cyber-defense teams at medical centers are using artificial intelligence to supplement the limited capabilities of humans to detect and defend against cyberattacks, especially now that many of those cyberattacks are controlled by artificial intelligence. This will be discussed by Ty Greenhalgh, a top leader in the cybersecurity industry, who will provide many current examples of how generative AI and LLMs are used to defend against attacks against medical centers and healthcare personnel. This refresher course will bring the radiology community up to date on the latest interaction between artificial intelligence and cybersecurity involving generative AI and LLMs, affecting healthcare, including recent attacks, and techniques of defense. The course will be presented by radiologists and top cybersecurity and artificial intelligence experts. The information technology issues will be addressed at a technical level appropriate for the radiology community at large, to make the community aware of this growing era of digital warfare and its implicatio

## State-of-the-Art Management of Biliary Disease

Wednesday, Dec. 4 3:00PM - 4:00PM Room: E353A

Nariman Nezami, MD (*Moderator*) Consultant, CAPS Medical Ltd

**LEARNING OBJECTIVES**

1) Understand the Principles of Percutaneous Biliary Stenting

**COURSE DESCRIPTION**

"State-of-the-Art Management of Biliary Disease" is a specialized course designed to provide an in-depth understanding of the latest advancements in the diagnosis, treatment, and management of biliary diseases. This course covers the comprehensive spectrum of biliary pathology, including benign and malignant conditions, and highlights the role of radiology and interventional radiology in patient care. Through a combination of lectures, case studies, and hands-on training, students will gain expertise in state-of-the-art imaging techniques, minimally invasive procedures, and multidisciplinary approaches to biliary disease management.

## Dos and Don'ts of Whole Body MR: Evaluation of Oncologic and Congenital Diseases versus Celebrity Screening

Wednesday, Dec. 4 3:00PM - 4:00PM Room: N227B

Yuliya Lakhman, MD (*Moderator*) Stockholder, Y-mAbs Therapeutics Inc;Consultant, Perceptive Informatics, LLC

**LEARNING OBJECTIVES**

1) Describe how to perform the state-of-the-art whole-body MRI and how to tailor the protocol to different clinical settings. 2) Illustrate the important of proper patient selection for various applications of whole-body MRI. 3) Highlight the value of whole-body MRI in different clinical settings. 4) Emphasize the importance of quality-control measures.

**COURSE DESCRIPTION**

This course provides an overview of the whole-body MRI potential. The lectures will highlight how whole-body MRI is performed, how its properly implemented, and how it can add value compared to other available tools.

**Sub-Events**

### W7-CMS07B WB MRI Screening: Celebrity Screening

## Financial Planning: From Investment to Retirement

Wednesday, Dec. 4 3:00PM - 4:00PM Room: S502

Sherwin S. Chan, MD, PhD (*Moderator*) Consultant, Jazz Pharmaceuticals plc;Research Grant, Jazz Pharmaceuticals plc;Research Grant, Hyperfine, Inc;Research Grant, General Electric Company

**LEARNING OBJECTIVES**

1) Understand how to construct an appropriate investment portfolio for retirement. 2) Understand the importance of savings and learn strategies to make it a priority. 3) Gain insight into asset protection strategies for radiologists.

**COURSE DESCRIPTION**

Many radiologists are unable to translate their high income into a high net worth. This is due to high student debt, poor financial literacy and lifestyle creep. High debt drives choices in career path for trainees and practicing radiologists and contributes to physician burnout and mental health issues. Despite the importance of personal financial health, education on finances is absent from most radiology training programs. Some highly successful and intelligent radiologists who contribute enormously to research, radiology education, and clinical care have not spent the necessary time learning about finances and preparing for retirement. This course will feature lectures on more advanced financial literacy topics. The expected outcome of the session will be that attendees will learn about some financial literacy topics and then will be inspired to learn even more and improve their personal financial health.

**Sub-Events**

## ASRT@RSNA: Milestones in CT: Past, Present, and Future

Wednesday, Dec. 4 3:00PM - 4:00PM Room: N226

Susie M. Moseley, MS, RT (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Summarize major technical developments in CT over the past five decades. 2) Describe specific changes that have occurred to decrease the radiation dose associated with CT. 3) Review key developments that enabled cardiac CT. 4) Explain what is unique about photon-counting CT.

**COURSE DESCRIPTION**

Since its invention in the 1970s, computed tomography has undergone numerous technical developments and innovations that have established it as an indispensable tool in the practice of medicine. Multiple CT scanner geometries, or generations, have existed, and with each new generation of technology, the speed and spatial resolution of CT increases, enabling new clinical applications and decreasing the required doses of radiation and iodinated contrast media. Technical developments such as shorter gantry rotation times, multiple detector rows, multisector reconstructions, and dual-source technologies have increased the quality and robustness of cardiac CT. Meanwhile, radiation doses in CT have been reduced using tube current modulation, lower tube potential, beam-shaping filters, beam collimation and iterative reconstruction algorithms. Recently, photon-counting detectors have been introduced into commercial CT systems to provide increased spatial resolution and multi-energy CT imaging from a single acquisition. This session reviews these and other major milestones in CT imaging.

## RSNA/ESR Symposium: Advances in Prostate Cancer Imaging and Therapy - Advancements in Precision Oncology and Therapy

Wednesday, Dec. 4 3:00PM - 4:00PM Room: E353B

Fiona M. Fennessy, MBBCh, PhD (*Moderator*) Consultant, Imaging Endpoints II LLC
Patrick Asbach, MD (*Moderator*) Institutional research support, Siemens AG;Institutional research support, Canon Medical Systems Corporation;Speaker, b.e.imaging GmbH;Travel support, b.e.imaging GmbH

### LEARNING OBJECTIVES

1) Review the role of imaging biomarkers in detection and characterization of prostate cancer, guidance of personalized treatment planning, prediction and assessment of response to therapy, and detection of disease recurrence. 2) Review the emerging image-guided focal therapies as methods for personalized treatment of prostate cancer based on risk criteria and optimization of oncologic and life quality outcomes. 3) Discuss the role of theranostic agents in the treatment of prostate cancer.

### COURSE DESCRIPTION

This course will provide a comprehensive lecture-format overview of latest developments in precision oncology, addressing both prostate cancer detection and treatment. It will delve into the significance of novel imaging biomarkers in detection and characterization of prostate cancer, and in tailoring personalized therapy. Furthermore, the course will review both image-guided focal therapy and theranostics in prostate cancer care, emphasizing the importance of selecting suitable candidates and strategies for optimizing treatment outcomes for these forms of precision therapy.

**AOSR-RSNA 2024 Joint Session: Acute Abdomen**

Wednesday, Dec. 4 3:00PM - 4:00PM Room: S402

Dinesh K. Varma, FRANZCR (*Moderator*) Nothing to Disclose
Judy Yee, MD (*Moderator*) Research Grant, General Electric Company

**LEARNING OBJECTIVES**

Acute abdominal pain – Right Lower Quadrant

Understand Acute Appendicitis: Gain a understanding of acute appendicitis, its commonality, and its appearances in radiology.

Master Pain Mechanism and Pathways: Learn about the mechanism and pathways of right lower quadrant (RLQ) pain, with a focus on appendicitis as the most common pathology.

Explore Imaging Techniques: Understand various imaging techniques and protocols for acute appendicitis, including MRI protocols and performance criteria.

Identify Differential Diagnoses: Learn to identify and understand the most common differential diagnoses for RLQ pain from gastrointestinal, gynecological, and genitourinary systems through imaging case examples.

Traumatic acute abdomen: hepatobiliary, pancreas and spleen

1.Importance of initial patient hemodynamic status and CT protocol with multidisciplinary management

2.Image finding with AAST injury scale according to organs

3.Organ specific traumatic conditions for diagnosis and treatment options.

**COURSE DESCRIPTION**

The talk emphasizes the importance of diagnosing acute appendicitis, a common condition encountered by radiologists.

It discusses the mechanism and pathways of right lower quadrant (RLQ) pain, with appendicitis being the most common pathology in this area.

Imaging Techniques: Various imaging techniques and protocols for acute appendicitis are outlined, including MRI protocols and performance criteria.

Differential Diagnosis: The talk provides case examples and discusses differential diagnoses for RLQ pain from gastrointestinal, gynecological, and genitourinary systems.

This talk will focus on hepatobiliary, pancreas and splenic trauma in traumatic acute abdomen.

It discusses from diagnostic methods to organ specific traumatic image findings and evaluation of traumatic injury scale. This talk also includes recent

treatment options according to injury scales and organs.

**Sub-Events**

## Pearls and Pitfalls of Challenging Cases (MMG, US, MRI, CEM) (Supported in part by an Unrestricted Medical Education Grant from GE Healthcare, Inc.)

Wednesday, Dec. 4 4:30PM - 5:30PM Room: S406A

Silvia Perez, MD (*Moderator*) Support, Becton, Dickinson and Company;Support, Bayer AG

### LEARNING OBJECTIVES

1) Identify and understand common pitfalls in the diagnosis of breast cancer using mammography (MMG), ultrasound (US), magnetic resonance imaging (MRI), and contrast-enhanced mammography (CEM). 2) Apply key diagnostic pearls to enhance the interpretation of challenging breast cancer cases across different imaging modalities. 3) Integrate multimodal imaging findings to improve diagnostic accuracy and decision-making in complex breast cancer scenarios.

### COURSE DESCRIPTION

Join us for an in-depth exploration of the complexities and nuances of breast cancer imaging in the session "Pearls and Pitfalls of Challenging Cases (MMG, US, MRI, CEM)." This course is designed to enhance the diagnostic skills of radiologists by addressing the common challenges and pitfalls encountered in mammography, ultrasound, magnetic resonance imaging, and contrast-enhanced mammography. Through a combination of lectures and interactive case discussions, participants will gain valuable insights into identifying and overcoming diagnostic obstacles, improving accuracy, and integrating multimodal imaging approaches in clinical practice. Attendees will leave with practical strategies and a deeper understanding of advanced imaging techniques, ultimately improving patient outcomes.

**Sub-Events**

Albert Hsiao, MD, PhD (*Moderator*) Co-founder, Arterys Inc;Shareholder, Arterys Inc;Co-founder, Vektor.AI;Shareholder, Vektor.AI;Research Grant, Bayer AG;Research Grant, General Electric Company;Research Grant, KA Imaging

### LEARNING OBJECTIVES

1) Understand the Role of AI in Cardiac Imaging: Gain insights into how artificial intelligence is revolutionizing cardiac MRI and CT imaging, highlighting both current applications and future advancements. 2) Identify Challenges and Opportunities of AI in Cardiac Imaging to improve diagnosis, prognosis and workflow efficiency. 3) Identify Strategies and Challenges for AI Implementation in Clinical Practice: Gain knowledge on effective strategies, tips, and potential challenges for meaningful clinical use of AI.

### COURSE DESCRIPTION

This course offers an in-depth exploration of the role of artificial intelligence in cardiac imaging. Participants will gain insights into how AI is revolutionizing cardiac MRI and CT imaging, with a focus on both current applications and future advancements. The challenges and opportunities presented by AI in cardiac imaging will be discussed. Additionally, this session will be addressing potential implementation strategies and challenges to ensure successful adoption and optimization of these technologies in a clinical setting.

## Advanced Neuroimaging Techniques- Ready for Prime Time?

Wednesday, Dec. 4 4:30PM - 5:30PM Room: S406B

Luca Saba, MD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Describe the principles and clinical applications of MR fingerprinting, and discuss its transition from theory to practice. 2) Evaluate the current and potential uses of functional MRI (fMRI) in clinical settings. 3) Understand the glymphatic system's role in neuroimaging and its implications for clinical practice. 4) Assess the advancements and current status of photon counting CT technology and its application in neuroimaging.

**COURSE DESCRIPTION**

This session will move into the cutting-edge advancements in neuroimaging techniques and their readiness for clinical application. Attendees will explore a range of topics from the practical implementation of MR fingerprinting to the clinical utility of fMRI, the role of the glymphatic system, and the current status of photon counting CT. The session aims to provide a comprehensive understanding of these advanced imaging techniques and their potential impact on clinical practice.

## Advance Radiology Practice: Generative AI and Imaging Physics

Wednesday, Dec. 4 4:30PM - 5:30PM Room: S404

Shandong Wu, PhD (*Moderator*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Understand basic generative AI techniques on how to generate synthetic imaging data and the some latest technical advances. 2) Learn representative use cases of training AI models using synthetic data and reducing uses of contrast agents by generative AI. 3) Explain how imaging physics and radiology can be augmented by generative AI and how physics knowledge can be adapted to enhance synthetic data generation.

**COURSE DESCRIPTION**

Artificial intelligence (AI) is gaining rapid evolvement in radiology for clinical translation and applications. The emergence of generative AI techniques shows impressive power in generating massive amount of synthetic data, including medical images, which not only have a large influence to AI models but also some strong indications to the physics of imaging formation. Generative AI can be an important supplement to medical physics, and meanwhile, imaging physics may play a fundamental role in ascertaining fidelity of synthetic imaging data. Currently, there is a gap in introducing the latest generative AI techniques and its clinical indications to the community of medical physics. Some of the related knowledge, such as how to generate synthetic imaging data, how to incorporate physics into data synthetization, and how synthetic data may reduce uses of contrast agents, remains to be delivered to medical physicists and radiology practitioners. In this educational course proposal, we aim to bring in the latest generative AI techniques and applications that are relevant to radiology and imaging physics to the RSNA audiences.

## Publishing Your Radiology Research: Tips From the Junior Editors of the RSNA Journals

Wednesday, Dec. 4 4:30PM - 5:30PM Room: E351

Susanna I. Lee, MD, PhD (*Moderator*) Royalties, Wolters Kluwer nv
Gary D. Luker, MD (*Moderator*) Institutional Research Grant, Polyphor, Ltd

**LEARNING OBJECTIVES**

1) Understand the manuscript submission and editorial process for trainees and early career physicians and scientists intending to publish in the RSNA journals. 2) Identify available resources and platforms useful in performing and publishing imaging research. 3) Find opportunities to contribute to the RSNA journals in non-author roles (e.g. peer reviewer, editor, etc.).

**COURSE DESCRIPTION**

Gary Luker, Editor of Radiology Imaging Cancer and Susanna Lee, Editor of Radiology Advances, will lead a panel discussion of early career editors of the RSNA journals. Each participant will present a brief talk on a focused topic related to scientific publishing. Following this, 25-30 minutes will be devoted to a question and answer session open to the audience. Sample discussion points include: "Selecting the right journal for your manuscript: how do you decide?" "Journal author information: what's in them and why?", "How to write a good title, abstract, summary statement and key results/teaching points", "Tips on creating graphics, tables and figures", "Responding to peer review comments".

### PURPOSE

To compare supplemental imaging techniques following a negative screening mammogram in women with dense breasts in a UK breast screening programme.

### METHODS AND MATERIALS

Women with BI-RADS (5th Ed.) c/d and negative 2D mammograms were randomized to either abbreviated MRI (Abb-MRI), automated whole breast ultrasound (ABUS), contrast enhanced mammography (CEM) or standard of care (SoC) at 10 UK centres. Double reading with arbitration was undertaken. Cancer detection rate (CDR) and recall rate (RR) was compared in each intervention arm together with cancer type and size.

### RESULTS

Over 9,000 women aged 50-70 years were randomized to Abb-MRI (2318), ABUS (2253), CEM (2242) or SoC (2553). Numbers undergoing supplemental imaging were 1970, 2119, and 1959, respectively. Intention to treat CDR was 10.8/1000, 4.0/1000, 13.8/1000 and RR was 9.5%, 4.1%, 9.4% in each arm respectively. There were 57 invasive cancers (with and without DCIS) and 14 DCIS alone. Median invasive cancer size was 10 mm (IQR: 8-11 mm), 9 mm (15 - 29 mm) and 12 mm (9 - 14 mm) for Abb-MRI, ABUS, and CEM respectively. All cancers detected by ABUS were invasive, while the proportions of invasive cancers in CEM and ABB-MRI were 79% and 74%, respectively. Cancers detected by all arms were predominantly grade 2.

### CONCLUSION

Supplemental imaging finds additional cancers not detected by 2D mammography. Contrast techniques (Abb-MRI and CEM) are more sensitive at the expense of higher recall rates than ABUS.

### CLINICAL RELEVANCE/APPLICATION

Earlier detection of cancers by offering supplemental screening will result in fewer late-stage cancers and improve mortality.

## M1-SSBR03-2 IMPROVING CANCER DETECTION IN DENSE BREASTS IN BREAST SCREENING PROGRAMS: THE COMPLEMENTARY STRENGTH OF AI AND HUMAN INTELLIGENCE

William Wei Lian Teh, MBChB (*Abstract Co-Author*) Speaker, Hologic, Inc;Speaker, Devicor Medical Products, Inc

Peter D. Kecskemethy, PhD (*Abstract Co-Author*) CEO, Kheiron Medical Technologies
Annie Ng, PhD (*Presenter*) Researcher, Kheiron Medical Technologies Ltd

**PURPOSE**

While women with dense breasts have a higher probability of developing breast cancer, detecting cancers in dense breast tissue is found to be more challenging in standard screening. This study investigated the use of an AI system regarding cancer detection across different density categories compared to standard human double reading.

**METHODS AND MATERIALS**

In the largest retrospective clinical study in breast screening to date (306,839 cases from 236,739 participants between 2017-2021), Sensitivity (SEN) of a commercially available AI system was compared to the first human reader (HR) in double reading, using the McNemar test at a significance level of 0.05 and reported with 95% CIs. Cancer cases were pathology proven, including screen-detected (SD) and interval cancers (IC). Breast density was determined by an AI tool according to the 4 BIRADS categories (A-D), with A or B defined as "fatty" and C or D defined as "dense".

**RESULTS**

The breast density distribution of the cohort was 12.7% A, 45.5% B, 37.5% C and 4.3% D, resulting in subgroup proportions of 58.2% fatty and 41.8% dense. The dataset included 2588 SDs and 379 ICs.AI and HR SEN was 82.7% (81.3%-84.0%) vs 80.9% (79.4%-82.2%) (p=0.027) for the whole study population, 84.8% (83.0%-86.5%) vs 86.2% (84.4%-87.8%) (p=0.198) for participants with fatty breasts, and 80.3% (78.2%-82.3%) vs 75.1% (72.8%-77.3%) (p<0.001) for participants with dense breasts, respectively. Subgroup analysis for age 49-55 yr resulted in SEN of 81.2% (76.6%-86.1%) vs 85.8% (80.9%-89.5%) (p=0.133) in fatty breasts and 77.9% (73.9%-81.5%) vs 72.3% (68.0%-76.2%) (p=0.014) for dense breasts, for AI and HR respectively. Screening participants with age 56-71 yr showed similar results with SEN 84.1% (82.6%-86.8%) vs 85.9% (83.7%-87.8%) (p=0.420) for fatty breasts and 81.4% (78.6%-83.8%) vs 75.8% (72.9%-78.5%) (p<0.001) for dense breasts, for AI and HR respectively.

**CONCLUSION**

In this large-scale study, human readers had non-significant higher sensitivity than the AI system for cancer detection in fatty breasts but the effect was opposite in dense breasts, showing a significantly higher sensitivity of the AI system compared to HR. These results suggest that the combination of human reading and AI may achieve best overall screening performance, as they seem to complement each other in cancer detection performance across breast densities.

**CLINICAL RELEVANCE/APPLICATION**

While cancer incidence is higher in dense breasts, cancer can be masked by dense tissue. This study showed that AI performs significantly better than human readers in dense breasts, demonstrating the potential to reduce cancer misses in this group and to support equitable breast screening with the integration of AI into screening workflows.

## M1-SSBR03-3 CANCER DETECTION RATE OF BREAST-MR IN SUPPLEMENTAL SCREENING AFTER NEGATIVE MAMMOGRAPHY IN WOMEN WITH DENSE BREASTS. PRELIMINARY RESULTS OF THE MA-DETECT STUDY AFTER 200 PARTICIPANTS

Clemens G. Kaiser, MD, BA (*Abstract Co-Author*) Nothing to Disclose
Pascal A. Baltzer, MD (*Abstract Co-Author*) Nothing to Disclose
Sabrina Walter (*Presenter*) Nothing to Disclose

**PURPOSE**

Due to increased cancer detection rates (CDR), breast MR (breast MRI) can reduce underdiagnosis of breast cancer compared to conventional imaging techniques, particularly in women with dense breasts. The purpose of this study is to report the additional breast cancer yield by breast MRI in women with dense breasts after receiving a negative screening mammogram.

**METHODS AND MATERIALS**

For this study we invited consecutive participants of the national German breast cancer Screening program with breast density categories ACR C D and a negative mammogram to undergo additional screening by breast MRI. Endpoints were CDR and recall rates. This study reports interim results in the first 200 patients. At a power of 80% and considering an alpha error of 5%, this preliminary population size is sufficient to demonstrate a 4/1000 improvement in CDR.

**RESULTS**

In 200 screening participants, 8 women (40/1000, 17.4-77.3/1000) were recalled due to positive breast MRI findings. Image-guided biopsy revealed four cancers, 3 of them invasive in women presenting with ACR C breast density and one non-calcifying DCIS in a woman with ACR D breast density, resulting in a CDR of 20/1000 (95%-CI 5.5-50.4/1000) and a PPV of 50% (95%-CI 15.7-84.3%).

**CONCLUSION**

Our initial results demonstrate that supplemental screening using breast MRI in women with heterogeneously dense and very dense breasts yields an additional cancer detection rate in line with a prior randomized trial on breast MRI screening of women with extremely dense breasts. These findings are highly important as the population investigated constitutes a much higher proportion of women and yielded cancers particularly in women with heterogeneously dense breasts.

**CLINICAL RELEVANCE/APPLICATION**

Due to its significant additional cancer detection in women with dense breasts, high quality breast MRI should be considered for selected screening purposes.

## M1-SSBR03-4 COMPARATIVE ANALYSIS OF DIGITAL BREAST TOMOSYNTHESIS AND BREAST ULTRASOUND AS SUPPLEMENTAL SCREENING TOOL FOR WOMEN WITH DENSE BREAST AND NEGATIVE MAMMOGRAM: A PROSPECTIVE STUDY FROM A LOW-INCOME COUNTRY

Rashmi Sudhir, MBBS, FRCR (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the effectiveness of supplementary digital breast tomosynthesis (DBT) and breast ultrasound (US) screening among Asian women with dense breasts (ACR category C and D) and negative mammograms.

**METHODS AND MATERIALS**

A prospective study was conducted at a tertiary-level hospital in South India between November 2022 and October 2023, with approval from the Institutional Review Board. Asymptomatic women with negative and dense mammograms were offered supplemental screening for breast cancer through DBT and ultrasound. The assessments were categorized according to the 5th edition of ACR BI-RADS. Follow-up after 6 months was recommended for BI-RADS 3 cases, while biopsy was recommended for BI-RADS 4 and 5 cases. Cancer detection rates and diagnostic efficiency tests of supplemental DBT and breast US were calculated and compared.

**RESULTS**

.A total of 4,430 women were screened for breast cancer. Out of these, 2,120 women (47.8%) with a mean age of 48 ± 10.08 years (age range; 38-84 years) were found to have dense breasts (ACR category C and D). Among these women, 97 (4.6%) had positive findings on screening mammograms. The remaining 2,023 women (95.4%) with dense breasts and negative mammograms underwent additional screening with digital breast tomosynthesis (DBT) and breast ultrasound (US). Supplemental screening detected 14 additional cancers, with a cancer detection rate (CDR) of 6.9/1000 women. For women with dense breasts and negative findings at screening mammograms, the CDR was 5.9/1000 for supplemental US screening and 2.9/1000 for supplemental DBT screening.The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of supplemental DBT screening were 33.3% (95% CI: 13.3 - 59.01%), 51.3% (95% CI: 35 - 67.6%), 24.0% (95% CI: 13.2 - 39.6%), 62.5% (95% CI: 51.6 - 71.3%), and 45.6% (95% CI: 32.4 - 59.3%), respectively. For supplemental US screening, the sensitivity was 85.7% (95% CI: 57.9 - 98.2%), specificity was 9.3% (95% CI: 2.6 - 22.1%), PPV was 23.5% (95% CI: 19.6 - 28.0%), NPV was 66.7% (95% CI: 29.0 - 70.7%), and accuracy was 28.0% (95% CI: 17.7 - 41.5%).

**CONCLUSION**

Supplemental DBT and breast ultrasound screening can detect additional cancers in dense breasts which are not visible on mammograms. Breast ultrasound is more effective but has lower specificity than DBT. Larger multicentre studies are needed to validate findings.

**CLINICAL RELEVANCE/APPLICATION**

Breast cancer is a major issue in public health, especially in low and middle-income countries where access to digital breast tomosynthesis (DBT) facilities is limited. In these settings, breast ultrasound can be an effective supplementary screening tool for women with dense breasts and without exposure to additional radiation.

## M1-SSBR03-5 A DEEP NEURAL NETWORK TO REDUCE THE NUMBER OF UNNECESSARY SUPPLEMENTAL SCREENING BREAST ULTRASOUND EXAMS IN SELECT PATIENTS

Krzysztof J. Geras (*Abstract Co-Author*) Nothing to Disclose
Yiqiu Shen (*Abstract Co-Author*) Nothing to Disclose
Guan-De Wu (*Abstract Co-Author*) Nothing to Disclose
Alana A. Lewin, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study is to assess the performance of a deep neural network (DNN), the Ultrasound Benefit Predictor (UBP), in estimating the added value of supplemental screening ultrasound (US) following a negative screening mammogram.

**METHODS AND MATERIALS**

In this IRB approved study, we developed a DNN system that analyzes full-field digital mammogram (FFDM) to produce a score estimating the added value of same-day supplemental screening ultrasound. The model was trained utilizing 141,791 same-day screening FFDM and US paired exams from 2012-2020 in 82,271 patients with patient-based training/validation/test split of 84.4%/4.6%/11%. The ultrasound benefit predictor (UBP) assessed the added value of US as follows: Positive Added Value - FFDM negative, US BI-RADS 0, cancer diagnosis; Negative Added Value - FFDM negative, US BI-RADS 0, no cancer at one year; No Added Value - both FFDM and US negative. Sensitivity, specificity and PPV were calculated at varying thresholds to test optimal US reduction rate.

**RESULTS**

In a test set of 9,468 patients (15,535 same-day FFDM-US exam pairs; mean age 58.8 years, standard deviation 10.6 years), 1.81% (171/9,468) had pathology-proven cancer. Breast density was 1.3% (201/15,535) almost entirely fatty, 25.0% (3,884/15,535) scattered fibroglandular, 62.2% (9,657/15,535) heterogeneously dense, 10.1% (1,563/15,535) extremely dense, 1.5% (230/15,535) unknown. The UBP determined that when 4% (621/15535) of screening US exams are skipped, 16/2131 false positive recall exams are avoided with no missed cancers (0/171, false negative rate 0%). Breast density in skipped patients: 1.6% (10/621) almost entirely fatty, 23.8% (148/621) scattered fibroglandular, 62.0% (385/621) heterogeneously dense, 11.4% (71/621) extremely dense, 1.1% (7/621) unknown. When 9% (1398/15535) of screening US exams are avoided, 45/2131 false positive recall exams are avoided, and 1/171 cancer was missed (false negative rate 0.058%; path: invasive ductal carcinoma). Breast density: 1.7% (24/1398) almost entirely fatty, 24.8% (347/1398) scattered fibroglandular, 61.4% (858/1398) heterogeneously dense, 11.1% (155/1398) extremely dense, 1.0% (15/1398) unknown.

**CONCLUSION**

Utilizing the UBP on same-day screening mammograms potentially decreases unnecessary supplemental screening ultrasounds performed, reducing downstream diagnostic exams and biopsies.

**CLINICAL RELEVANCE/APPLICATION**

Individualized recommendations for supplemental screening that consider relative risk within breast density categories are needed. The UBP can tailor supplemental screening recommendations and limit unnecessary exams in select patients, including those with dense breasts.

## M1-SSBR03-6 IMAGE-ONLY DEEP LEARNING RISK MODEL PERFORMANCE VS BREAST DENSITY TO PREDICT FUTURE BREAST CANCER

Andrew R. Carney, MS (*Abstract Co-Author*) Nothing to Disclose
Constance D. Lehman, MD, PhD (*Abstract Co-Author*) Institutional Grant, General Electric Company;Institutional Grant, Hologic, Inc;Co-founder, Clairity, Inc.

Sarah Mercaldo, PhD (*Abstract Co-Author*) Nothing to Disclose
Leslie Lamb, MD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Mammograms contain highly predictive biomarkers of future breast cancer risk, which can be identified by deep learning (DL) risk stratification models. Traditional risk assessment models have demonstrated improved performance with the inclusion of breast density, a known risk factor for breast cancer and cancer masking agent. The purpose of this study is to assess the performance of an image-only DL risk model with and without the addition of breast density.

**METHODS AND MATERIALS**

This retrospective, multisite study included consecutive patients >30 years undergoing routine bilateral screening mammography from 01/10/2009 to 01/10/2018 at five facilities with at least five years of follow-up. A DL 5-year model was used to assess risk. No mammograms included were used for model development. Demographic data and risk factors, including qualitative visual assessment of breast density using ACR BI-RADS 5th edition guidelines, were obtained from electronic medical records. Cancer outcomes were obtained through linkage to a regional tumor registry. DL model performance with and without breast density was compared using areas under the receiver operating characteristic curve (AUCs) with DeLong test ($P<0.05$).

**RESULTS**

123,418 bilateral screening mammograms in 67,106 patients met inclusion criteria. Median patient age was 58.0y (IQR: 50.0-67.0). 101,437/123,418 (82.2%) of patients were White, 6331/123,418 (5.1%) Asian, 5975/123,418 (4.8%) Black, 5933/123,418 (4.8%) other races, and 3742/123,418 (3.0%) had an unknown race. 23,622/123,418 (19.1%) had a family history of breast cancer, 94,068/123,418 (76.2%) were post-menopausal, and 29,350/123,418 (23.8%) pre-menopausal. 11,023/123,091 (9.0%) had fatty breasts, 61,094/123,091 (49.6%) scattered fibroglandular, 45,771/123,091 (37.2%) heterogeneously dense, and 5203/123,091 (4.2%) had extremely dense breasts. The AUCs of: DL model without vs with density were 0.71 (95% confidence interval [CI]: 0.70, 0.72) vs 0.70 (95% CI: 0.69, 0.71); $P=0.084$. Density alone was signficiantly worse (0.53 [95% CI: 0.52, 0.54]) compared to DL model, $P<0.001$.

**CONCLUSION**

Breast density is a poor predictor of breast cancer. A screening mammography DL breast cancer risk assessment model has higher risk discriminatory accuracy compared to breast density and does not improve with the addition of breast density.

**CLINICAL RELEVANCE/APPLICATION**

Breast density legislation mandates that women are informed of breast density, a historic marker of breast cancer risk. A DL image-only risk model derived automatically at the time of screening mammography, provides an opportunity to improve risk discrimation beyond breast density.

## M1-SSBR04-1 IMPACT OF BREAST CANCER MODE OF DETECTION ON PATIENT OUTCOME AND MORTALITY

Cindy S. Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Steven Chen (*Presenter*) Nothing to Disclose

### PURPOSE

Screening mammography significantly reduces breast cancer deaths. Little research exists on how the mode of breast cancer detection impacts patient outcome. We aim to compare the patient outcome and factors associated with breast cancers diagnosed by screening versus clinical symptoms in TriNetX, a global research network containing real-world aggregate EMR data from 35 health institutions and 51 million patients worldwide.

### METHODS AND MATERIALS

This HIPAA-compliant, IRB-exempt retrospective cohort study queried data from 898,049 women over age 40 diagnosed with breast cancers 1/1/2000-1/1/2023 at 89 institutions. Screening-detected cohort had abnormal screening mammography within 1 year prior to breast cancer diagnosis followed by abnormal diagnostic findings and breast biopsy within 3 months of diagnosis. Clinically-detected cohort had a diagnostic mammogram within 1 year prior to diagnosis, followed by breast biopsy within 3 months of diagnosis, but didn't have screening mammography for 2 years prior to diagnosis. Age, all-cause mortality, race, ethnicity, medical history, family history, and use of preventative services were compared.

### RESULTS

Among 3,927 women with breast cancers and reported mode of detection, 3,186 (81.1%) were in screening cohort and 741 (18.9%) in clinical cohort. Age range 49-70 years, mean 59.6 ± 10. Clinically detected breast cancers were associated with higher risks of mortality (16.87% vs. 8.38%; OR 2.22, 95% CI 1.76 - 2.79, $p < 0.0001$). Screening-detected breast cancers were associated with non-Hispanic/Latino ethnicity (OR 0.57, 95% CI 0.45 - 0.72; $p < 0.0001$), family history of breast cancer (OR 0.47, 95% CI 0.38 - 0.57; $p < 0.0001$), hyperlipidemia (OR 0.67, 95% CI 0.56 - 0.81; $p < 0.0001$), postmenopausal status (OR 0.39, 95% CI 0.30 - 0.51; $p < 0.0001$), uses of cervical cancer screening (OR 0.41, 95% CI 0.33 - 0.52; $p < 0.0001$), colon cancer screening (OR 0.52, 95% CI 0.41 - 0.65; $p < 0.0001$), and immunization (OR 0.51, 95% CI 0.42 - 0.62; $p < 0.0001$). History of stroke was associated with a higher risk of clinically detected breast cancer (OR 1.68, 95% CI 1.09 - 2.58; $p < 0.0001$) (Table 1).

### CONCLUSION

Screening versus clinical mode of detection impacts the overall mortality of breast cancer patients, with higher risks of mortality associated with clinically detected breast cancers. Women of non-Hispanic ethnicity, with family history of breast cancer who participated in cervical and colon cancer screening were more likely to have breast cancers detected during routine mammographic screening.

### CLINICAL RELEVANCE/APPLICATION

Mammographic screening significantly reduces mortality by detecting cancers earlier, before clinical symptoms develop.

## M1-SSBR04-2 2D DIGITAL MAMMOGRAPHY OCCULT, DIGITAL BREAST TOMOSYNTHESIS DETECTED ARCHITECTURAL DISTORTION: PATHOLOGIC RESULTS AND FEATURES OF MALIGNANCY

Zeeshan A. Shah, MD (*Abstract Co-Author*) Nothing to Disclose
Sean D. Raj, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Architectural distortion detected on 2D digital mammography (DM) can indicate underlying malignancy and often warrants additional imaging or biopsy. 3D digital breast tomosynthesis (DBT), a more sensitive imaging modality, detects architectural distortion at higher rates than DM. There is a paucity of data on the radiologic-pathologic correlation of DM-occult, DBT-detected architectural distortion. The purpose of this study is to evaluate the rate and features of malignancy in DM occult, DBT detected architectural distortion, and provide radiologic-pathologic correlation for benign, high-risk, and malignant lesions associated with architectural distortion that proceeded to stereotactic core biopsy with tomosynthesis guidance.

### METHODS AND MATERIALS

A retrospective review of all stereotactic core biopsies with tomosynthesis guidance from June 1st, 2017, to August 31st, 2020. All 2D-occult, 3D-detected architectural distortions biopsied with tomosynthesis guidance were identified and reviewed by two fellowship-trained breast imagers and two trained medical students. Radiologic features, clinicopathologic features, and final pathologic diagnoses were documented for analysis.

**RESULTS**

Of 624 total stereotactic core biopsies with tomosynthesis guidance during the study period, 168 2D-occult, 3D-detected architectural distortions in 166 patients (average age 60.4 years) were identified. The positive predictive value (PPV) of 2D-occult, 3D-detected architectural distortion for malignancy was 22.0% (37/168 cases; 95% CI = 16.2-29.2%). DBT-guided biopsy revealed a malignant diagnosis in 37/168 (22.0%), a high-risk diagnosis in 22 /168 (13.1%), and a benign diagnosis in 109/168 (64.9%). Among the malignant biopsy results, low-grade malignancy was most common (94.6%; 35/37 cases). Radial scar was the most common high-risk finding (21/22, 95.5%), and fibrosis and fibrocystic change were the most common benign findings (73/109, 67.0%). The negative predictive value of non-malignancy for a single-view distortion (seen only on DBT mediolateral oblique or craniocaudal view) was 92.9% (26/28).

**CONCLUSION**

The final malignancy rate of 22.0% (37/168) in 2D-occult, 3D-detected architectural distortions warrants stereotactic core biopsy with tomosynthesis guidance.

**CLINICAL RELEVANCE/APPLICATION**

Architectural distortion that is 2D digital mammography occult, 3D digital breast tomosynthesis detected is worrisome for low-grade malignancy without any clear predictive factors, and stereotactic core biopsy is justified.

## M1-SSBR04-3 MAXIMIZING BREAST CANCER DETECTION: A COMPARATIVE ANALYSIS OF SCREENING STRATEGIES

Matthew Covington, MD (*Presenter*) Consultant, inviCRO, LLC

**PURPOSE**

While mammography is crucial and lifesaving, it doesn't identify all breast cancers, especially in dense breasts. The proportions of all theoretical cancers in the screening population detected through mammography and supplemental techniques like US, MBI, CEM, or MRI are unclear. This study estimates the total detectable breast cancers via mammography and the potential detection rates of supplemental techniques like ultrasound (US), molecular breast imaging (MBI), contrast-enhanced mammography (CEM), and breast MRI.

**METHODS AND MATERIALS**

This study, with IRB approval waived, uses published data to determine the cancer detection rate (CDR) of 2D mammography and dense breast prevalence from Breast Cancer Surveillance Consortium (BCSC) data (PMID: 32227180, 25217577). ICDRs from supplemental screening methods were estimated from a 2021 multi-institution expert panel literature review (PMID: 32903054). The maximum number of 2023 U.S. mammograms was estimated from Mammography Quality Standards Act MQSA data. The calculation to estimate the maximum number of detectable cancers in the 2023 screening population is: (2D Mammography CDR x Total 2023 Screening Mammograms)/1000 + (ICDR of Most Sensitive Supplemental Screening Method x (Percentage of Dense Breast Tissue x Total 2023 Screening Mammograms))/1000 To estimate the proportion of cancers detected by various screening strategies, the number of cancers detectable by each method is divided by the total number of detectable cancers.

**RESULTS**

The number of screening mammograms estimated from MQSA was 40,538,610 in 2023. BCSC data suggest a 43% prevalence of dense breast tissue and a 2D mammography CDR of 4.7 cancers/1000 exams. The ICDRs of supplemental screening per 1,000 exams are estimated at 1.7 for DBT, 2.7 for US, 8.1 for MBI, 10.7 for CEM and 16 for MRI. The maximal number of supplemental screening exams was 17,431,602. Total detectable cancers in the 2023 screening population is 469,437. Of these, 2D mammography would detect 190,531 cancers (41%). Additional supplemental screening would detect 220,165 cancers (47%) for DBT, 237,596 (47%) for US, 331,727 (71%) for MBI, 377,049 (80%) for CEM and 469,437 (100%) for MRI.

**CONCLUSION**

It is likely that 2D mammography identifies less than half of all detectable cancers within the screening population. Detection can markedly improve with supplemental screening, but effectiveness varies. Maximal breast cancer detection involves mammography with MRI for dense breast supplemental screening.

**CLINICAL RELEVANCE/APPLICATION**

Evaluating the efficacy of different breast cancer screening methods, inclusive and exclusive of supplemental dense breast screening, could offer significant insights for devising effective screening strategies.

## M1-SSBR04-4 ENHANCING MAMMOGRAPHY SCREENING: A COMPARATIVE ANALYSIS OF AI ENSEMBLE STRATEGIES

Tatiana C. Tucunduva, MD (*Abstract Co-Author*) Nothing to Disclose
Vasanth Venugopal (*Abstract Co-Author*) Nothing to Disclose
Giselle G. Mello, PhD (*Abstract Co-Author*) Nothing to Disclose
Igor R. Oliveira, MD (*Abstract Co-Author*) Nothing to Disclose
Bruno A. Rocha, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The objective of this study is to delineate the diagnostic performance spectrum of AI algorithms in mammographic analysis by comparing the efficacy of individual algorithms with ensemble approaches, which involve the simultaneous use of multiple AI algorithms in the same case. The focus is on a critical examination of the trade-offs between optimizing sensitivity and specificity.

**METHODS AND MATERIALS**

A cohort of 1,381 mammography screenings was retrospectively analyzed, including 494 positive cases confirmed via biopsy and 887 negative cases ascertained through a one-year follow-up. The study evaluated three AI solutions—Therapixel, Lunit, and Medcog—by employing tailored thresholds to generate binary classifications. For the Any-Positive Ensemble (APE) method, a study was classified as positive if any AI model yielded a score surpassing its designated threshold. The Balanced Score Ensemble (BASE) method involved normalizing each AI score by its respective threshold and computing an average; a positive classification was determined if this average exceeded the aggregate midpoint of normalized thresholds. Metrics, including accuracy, precision, recall, specificity, F1 score, MCC, and AUC, were computed alongside false positives and negatives to objectively assess each model and ensemble strategy.

**RESULTS**

The algorithms displayed distinct AUCs: Medcog (0.91), Lunit (0.92), and Therapixel (0.93). APE All, designed to prioritize sensitivity, registered an AUC of 0.72 and a sensitivity rate of 99.39%, revealing a deliberate design choice for sensitivity prioritization. BASE All reported an AUC of 0.85, reflecting a

balanced sensitivity-specificity profile. The standard Max and Average Probability Ensembles yielded AUCs of 0.75 and 0.88, respectively, each signifying a different balance in performance trade-offs.

**CONCLUSION**

The comparative analysis elucidates the heterogeneous performance landscape of AI models and ensembles in mammography, with each method exhibiting distinct trade-offs between diagnostic accuracy and false-negative reduction. The study provides an empirical foundation for the judicious selection of AI tools in mammography, guided by clinical screening objectives.

**CLINICAL RELEVANCE/APPLICATION**

This study highlights the clinical relevance of AI integration in mammography screening, offering insights into how different AI models and ensemble strategies can be tailored to improve diagnostic accuracy. Such integration could lead to more personalized, efficient, and sensitive breast cancer screening processes, potentially improving patient outcomes through earlier and more accurate detection.

## M1-SSBR04-5 PERFORMANCE OF A COMMERCIAL DIGITAL BREAST TOMOSYNTHESIS CANCER DETECTION MODEL IN A LARGE, RACIALLY DIVERSE US SCREENING POPULATION

**PURPOSE**

To investigate the standalone performance of a commercially available artificial intelligence (AI) algorithm for breast cancer detection on digital breast tomosynthesis (DBT) images in a large, racially heterogeneous US screening population, both overall and by various patient subgroups.

**METHODS AND MATERIALS**

A total of 137,460 retrospective cases with DBT images were collected from multiple screening centers associated with Emory University from 2013-2020. A commercial AI algorithm (INSIGHT DBT, Lunit, South Korea) was used to analyze each DBT exam and return an abnormality score ranging from 1-100. Scores gt; 10 were defined as positive per previously validated relevant operating point thresholds for the model. The area under the receiver operating characteristic curve (AUC), sensitivity, and specificity, were calculated in the overall cohort and further stratified by race (White, Black, Asian, Other), ethnicity (Hispanic, non-Hispanic, Unknown), age, breast density, cancer subtype (invasive, non-invasive), and imaging features (mass, calcification, architectural distortion, asymmetry, or multiple).

**RESULTS**

Of 121,995 screening DBT examinations, there were 656 biopsy-proven breast cancers. The model achieved an overall AUC of 0.920 (95% CI 0.91-0.93), with a sensitivity and specificity of 84.5% and 83.8%, respectively. The Al algorithm demonstrated robust performance with no significant differences between race, ethnicity, age groups, or breast density. There was no statistically significant difference in performance between lesion types with AUCs (95% CI) ranging between 0.88 (0.86-0.91) for calcifications and 0.97 (0.96-0.98) for architectural distortions.

**CONCLUSION**

A commercial breast cancer detection model for digital breast tomosynthesis demonstrated equitable performance across multiple patient subgroups when tested on a diverse screening population. Notably, there were no significant differences in performance for various lesion types, indicating the model performs well across various imaging findings which may be difficult for radiologists to detect.

**CLINICAL RELEVANCE/APPLICATION**

A commercially available AI algorithm for breast cancer detection based on DBT images performs equitably across multiple patient subgroups in a diverse screening population, suggesting that the model could perform well in various patient populations.

## M1-SSBR04-6 FALSE NEGATIVE BREAST CANCER DIAGNOSES AFTER DIGITAL BREAST TOMOSYNTHESIS SCREENING: RESULTS OVER 10 YEARS

Katie Jolin, MD (*Abstract Co-Author*) Nothing to Disclose
Lawrence H. Staib, PhD (*Abstract Co-Author*) Nothing to Disclose
Maryam Etesami, MD (*Abstract Co-Author*) Nothing to Disclose
Liane E. Philpotts, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Digital breast tomosynthesis (DBT) has been shown to increase cancer detection at screening compared with 2D mammography. The interval cancer rate of DBT is an important area where more data is needed. The purpose of this study was to assess the rate and types of cancers not detected at screening DBT, but detected by either interval (symptomatic) presentation or supplemental screening.

**METHODS AND MATERIALS**

An IRB-approved (consent waived) review of our breast imaging electronic database (PenRad, Inc) was performed to identify all true positive (TP) and false negative (FN) cancers over 10 years (8/1/2011-7/31/2021). FN cancers were defined as being diagnosed within 12 months of a normal DBT screening mammogram. In our practice women with dense breasts primarily undergo supplemental hand-held ultrasound (US) and many at increased risk opt for supplemental magnetic resonance imaging (MRI). The electronic medical records were reviewed to determine patient age, risk status, method of detection (symptomatic versus supplemental screening), lesion imaging features, breast density, and cancer type, size, and molecular receptor profile. Advanced cancers were defined as: Invasive cancers 2cm or larger, HER2+ or triple-negative tumors >10mm, one or more positive axillary nodes, or distant organ spread. The cancer types, molecular profiles and rate of advanced cancers were compared.

## RESULTS

Over 10 years there were 237,394 DBT screenings, 1265 TP and 132 FN cancers for a TP rate of 5.3 and a FN rate of 0.6 per 1000. The sensitivity of DBT was 90.6% (1265/1397). Of 132 FN, 57 (43%) were symptomatic interval cancers (IC), 59 (45%) supplemental US and 16 (12%) MRI. The symptomatic interval cancer rate was 0.2 per 1000. The breast density categories were: A 1%, B 14%, C 73%, D 12%. The mean size was largest for IC and smallest for US: IC 2.6 cm, US 1.1 cm, MRI 1.4 cm. The majority of cancers were invasive: IC (57/57, 100%), US (56/59, 95%), MRI (12/16, 75%). The molecular profiles differed by group with higher rates of HER2+ and TN in the IC and MRI groups (IC:ER+ 60%, HER2+TN 40%; US:ER+ 82%, HER2+TN 18%, MRI: ER+ 50%, HER2+TN 50%). The advanced cancer rate varied significantly by method of detection with highest in the IC group: IC 43/57 (75%), US 9/56 (16%), MRI 1/12 (8%) (p=0.00001).

## CONCLUSION

The sensitivity rate of DBT is high and the FN rate low, with the interval cancer rate very low. The majority of FN cancers were detected by supplemental screening. HER2+ and TN cancers account for a large percent of IC as well as those detected by MRI. US detected cancers had smallest size and most favorable molecular profile.

## CLINICAL RELEVANCE/APPLICATION

The use of DBT for screening, in conjunction with supplemental screening for women with dense breasts or high risk, optimizes interval cancer rate.

### PURPOSE

Cardiac MR (CMR) is a labor-intensive examination with long acquisition times and long breath hold requirements1. Use of CMR to characterize cardiomyopathies, infarct, scar, valvular, and congenital heart diseases is increasing2. These patients are often dyspneic and orthopneic and symptoms can worsen during the examination. We aim to show how deep learning reconstruction (DLR) of highly undersampled cine images (Sonic DL) can substantially decrease scan time while maintaining image quality and quantitative accuracy.

### METHODS AND MATERIALS

Seventy patients (ages 10-88 years) were scanned on a 1.5T with three short axis (SA) cine techniques: standard steady state free procession (SSFP), Sonic DL 3 RR (three heartbeats per slice), and Sonic DL 1 RR (one heartbeat)3. Scan times were recorded for all sequences and defined as the total scan time from the start of one sequence until the start of the following sequence, including breaks between slices and breath holds. Volumetric measurements were processed independently with Arterys software. Bland-Altman plots were performed to compare measurements between techniques. Image quality was scored on a 5-point Likert scale and scores were compared via a Wilcoxon signed rank-sum tests.

### RESULTS

Average total scan time for standard SSFP was 7.9 minutes, significantly longer (p-value <0.001) than 3 RR (2.7 minutes), and 1 RR (1.6 minutes). Scan time savings was 66% for 3R-R and 80% for 1 R-R. Conventional SSFP Cine image quality is comparable to Sonic DL 1RR and 3RR. The volumetric and function measurements demonstrated negligible differences between the three acquisition types.

### CONCLUSION

Standard SSFP cine acquisitions are the mainstay of the CMR examination and are limited by long acquisition times, data segmentation over multiple heart beats, and breath hold requirements. We demonstrated in this study the use of the novel Sonic DL method can significantly decrease scan time while maintaining image quality. While other studies have previously evaluated sequence acquisition time and volumetric assessments3,4, this study specifically evaluates the three techniques in a routine clinical setting to assess total SSFP scan time including breath holds and dead times. Future studies will evaluate the clinical impact of Sonic DL in reducing the entire exam time.

### CLINICAL RELEVANCE/APPLICATION

Use of DLR can be a powerful tool in reducing long CMR scan times, while maintaining or improving image quality and functional assessments. Such time reduction is critical, especially in patients with cardiac conditions affecting CMR quantitative accuracy. Scan time reduction will also allow for additional patient throughput, successful exam completion, and access to cardiac MR in locations with long patient back logs.

## M1-SSCA03-2 FRACTAL ANALYSIS IMPROVES INTERPRETABILITY OF CT PERFUSION ESPECIALLY IN PATIENTS WITH REDUCED REMOTE MYOCARDIAL BLOOD FLOW

Hajime Sakuma, MD, PhD (*Abstract Co-Author*) Research Grant, Eisai Co, Ltd;Research Grant, FUJIFILM Holdings Corporation;Research Grant, Guerbet SA;
Kakuya Kitagawa, MD, PhD (*Abstract Co-Author*) Chair, Siemens AG
Kaoru Dohi (*Abstract Co-Author*) Nothing to Disclose
Tairou Kurita, MD (*Abstract Co-Author*) Nothing to Disclose
Satoshi Nakamura, MD (*Abstract Co-Author*) Nothing to Disclose
Florian Michallek, MD (*Presenter*) Nothing to Disclose

### PURPOSE

When interpreting myocardial blood flow (MBF) obtained from dynamic stress CT perfusion (CTP), presence of microvascular ischemia can be a confounder by reducing overall MBF. Fractal analysis has potential in differentiating etiology of ischemia in terms of obstructive coronary artery disease (CAD) and microvascular disease. This study evaluates fractal analysis for diagnosing obstructive CAD and improving interpretation of CTP depending on absolute MBF of remote myocardium, using relative MBF measurements as comparison.

### METHODS AND MATERIALS

We investigated data from a prospective, multicenter trial (7 centers), which enrolled patients with clinical indication for invasive coronary angiography (ICA). All patients underwent ICA with fractional flow reserve (FFR) measurements in vessels with stenosis = 25% and < 90%. Obstructive CAD was defined as either stenosis = 90% on ICA, or FFR < 0.8. Vessels were excluded if hypoplastic, or if FFR was missing. Comprehensive CT evaluation was performed by calcium scan, stress CTP, CT angiography and CT delayed enhancement. We conducted fractal analysis as well as MBF calculations as previously established. We compared diagnostic accuracy of fractal analysis and MBF standardized to remote myocardium ("relative MBF") for diagnosing obstructive CAD, and we stratified patients into high, intermediate and low absolute remote MBF to reflect potential impact of microvascular ischemia. We compared areas under receiver-operating curves (AUC) by DeLong test, and sensitivity and specificity by McNemar chi2 test.

### RESULTS

We included 156 patients (high, intermediate and low remote MBF groups; n=52 patients each) with 439 vessels. On vessel level, fractal analysis outperformed relative MBF for diagnosing obstructive CAD (AUC: 0.89 vs 0.77 for fractal analysis vs relative MBF, $p < 0.01$). In patients with high remote MBF, fractal analysis performed equally well as relative MBF (AUC: 0.91 vs 0.81, $p=0.18$), however, in intermediate and low absolute remote MBF, fractal analysis outperformed relative MBF (AUC: 0.89 vs 0.78, $p=0.04$ and 0.87 vs 0.7, $p<0.01$). On patient level, sensitivity and specificity for diagnosing obstructive CAD was 87% and 92% for fractal analysis, and 76% and 78% for relative MBF ($p<0.01$).

### CONCLUSION

Diagnostic accuracy of relative MBF for diagnosing obstructive CAD is limited in patients with reduced absolute remote MBF, which can occur due to microvascular ischemia. Fractal analysis operates independently from remote MBF and maintains high diagnostic accuracy for obstructive CAD even in patients with reduced remote MBF.

### CLINICAL RELEVANCE/APPLICATION

Fractal analysis reliably identifies obstructive CAD even in patients with reduced remote MBF in whom interpretability of relative MBF is limited.

## M1-SSCA03-3 AI-ENABLED AUTOMATIC CARDIAC CHAMBER VOLUMETRY: A COMPARATIVE ANALYSIS USING CCTA, CACT, AND NCCT

Joon-Won Kang, MD (*Abstract Co-Author*) Nothing to Disclose
Dong Hyun Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Hyun Jung Koo, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jong Eun Lee, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the feasibility of AI-enabled automatic cardiac chamber volumetry inelectrocardiography (ECG)-gated calcium scoring CT (CaCT) and non-ECG-gated chest CT (NCCT) scans. This study also investigates the prognostic implications of volumetric measurements in the context of atrial fibrillation and major adverse cardiac events (MACE).

### METHODS AND MATERIALS

Participants who underwent ECG-gated coronary CT angiography (CCTA), CaCT, and NCCT either on the same day or within one month from 2008 to 2013 were retrospectively collected from a national health screening center. AI-enabled volumetry was used to compare chamber volume congruence across modalities and to assess the prognostic association of chamber volumes with atrial fibrillation diagnosis and MACE, including unstable angina requiring hospitalization or revascularization, myocardial infarction, ischemic stroke, and cardiovascular death, using Cox hazard regression models.

### RESULTS

The study included 964 participants with a mean age of 66.8 years; 67.4% were male (650 of 964). The average left ventricular (LV) and left atrial (LA) volume indices measured from CCTA, CaCT, and NCCT were 57.4 ± 10.8 mL, 63.1 ± 10.6 mL, and 68.1 ± 16.0 mL for the LV, and 52.1 ± 11.7 mL, 45.6 ± 10.8 mL, and 44.8 ± 11.0 mL for the LA, respectively, showing excellent agreement (intraclass correlation coefficient of 0.825 and 0.903, respectively). In the multivariable Cox hazard regression models, the LA volume indices measured from CaCT and NCCT were associated with an increased risk of atrial fibrillation (HR, 1.06; 95% CI: 1.03-1.10; $P < .001$ and HR, 1.09; 95% CI: 1.04-1.15; $P < .001$, respectively), and the LV volume indices measured from CaCT and NCCT were associated with an increased risk of MACE (HR: 1.03; 95% CI: 1.01-1.04; $P < .001$ and HR, 1.02; 95% CI: 1.01-1.03; $P = .028$, respectively).

### CONCLUSION

AI-enabled automatic cardiac chamber volumetry demonstrates high reliability and congruence across different CT modalities. This technology not only aids in precise volume measurement but also provides significant prognostic value in predicting atrial fibrillation diagnosis and MACE.

### CLINICAL RELEVANCE/APPLICATION

AI-enabled automatic cardiac chamber volumetry demonstrates that AI technology can accurately measure cardiac chamber volumes across different CT scans, providing crucial prognostic information for conditions such as atrial fibrillation and MACE. This advancement supports non-invasive risk stratification, offering significant potential to enhance patient care and treatment outcomes in cardiovascular health.

## M1-SSCA03-4 QUANTIFICATION OF LEFT VENTRICULAR LGE IN CARDIAC MRI USING LARGE LANGUAGE MODELS (LLMS)

Florian Schiffers (*Abstract Co-Author*) Nothing to Disclose
Santiago Lopez-Tapia (*Abstract Co-Author*) Nothing to Disclose
Aggelos K. Katsaggelos (*Abstract Co-Author*) Nothing to Disclose

Daniel Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Neda Tavakoli, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

While left ventricular (LV) scar volume derived from late gadolinium enhancement (LGE) is a proven predictor of major adverse cardiac events (MACE) and correlates with poor outcomes, it is seldom used in clinical practice due to its time-consuming, labor-intensive nature, and susceptibility to inter-observer variability. Initial deep learning (DL) methods using a U-Net to automate this image processing have been largely unsuccessful (DICE scores < 0.70). In direct response, we propose a new method using DL to automatically segment and quantify LV scars on LGE images.

### METHODS AND MATERIALS

This study utilized labeled LGE data with myocardial wall and scar contours from the DETERMINE Trial dataset. We implemented an LLM-based DL model, based on the fine-tuned MedSAM model, on a GPU workstation (NVIDIA A100-PCIE-40GB) equipped with PyTorch, to automatically segment the LV into 4 classes: background, healthy myocardium, scar, and LV blood pool. Labeled data were randomly selected from 150 patients (totaling 1415 2-D images) for network fine-tuning. The remaining labeled data from 101 patients (totaling 829 2-D images) with ischemic cardiomyopathy and LV ejection fraction (LVEF) < 50 % were reserved for testing. We utilized PyTorch's built-in cross-entropy loss combined with the DICE loss of the entire LV (i.e., myocardium outer boundary). We compared our approach to previously described methods using the 4-class U-Net, where both our and previous approaches used the same manual contour files. To evaluate the network's performance, we calculated the DICE score and scar volume for each testing subject with manual contours as the reference. Mean DICE score between LLM and 4-class U-Net was compared using Bland-Altman (BA) analysis and paired t-test.

### RESULTS

Using manual contouring as the reference standard and conducting BA analysis, LLM showed superior agreement with less variability than the 4-class U-Net (Figure 1). Mean scar DICE score for LLM was significantly better than 4-class U-Net (0.914±0.08 vs. 0.57±0.09, respectively, P<0.001). Additionally, mean myocardium DICE score differed statistically between LLM and 4-class U-Net (0.91±0.05 vs. 0.81±0.02, respectively, P<0.001).

### CONCLUSION

Statistically closer agreement of LLM segmentation with reference standard in comparison with 4-class U-Net demonstrates a promising automatic segmentation tool to accurately quantify LV scar. Using pre-trained models and fine-tuning with domain-specific datasets in the LLM model significantly enhances the performance of the DL network compared to training from scratch used in 4-class U-Net.

### CLINICAL RELEVANCE/APPLICATION

LV scar quantification from cardiac MRI can enhance prognosis and clinical outcome understanding.

## M1-SSCA03-5 FAST AND ROBUST SINGLE-SHOT CINE CARDIAC MRI USING DEEP LEARNING SUPER-RESOLUTION RECONSTRUCTION

### PURPOSE

To apply a deep-learning (DL) method to reconstruct balanced steady-state free precession (bSSFP) single-shot (SSH) cine images and to compare them to standard bSSFP cine imaging.

### METHODS AND MATERIALS

Retrospective electrocardiogram-gated breath-hold images in short-axis view were acquired using both bSSFP compressed sensing SSH cine and standard bSSFP cine techniques (1.5T MRI). SSH cine images were reconstructed using a DL super-resolution algorithm provided by Philips Healthcare that combines and integrates compressed sensing with two distinct convolutional neural networks: Adaptive-CS-Net and Precise-Image-Net. Two readers evaluated the diagnostic quality (endocardial edge definition and blood-pool to myocardium contrast) and artifact burden using a Likert scale (from 1 = non-diagnostic to 5 = excellent). For quantitative image sharpness assessment, edge rise distance was calculated. Apparent signal-to-noise ratio (aSNR) and contrast-to-noise ratio (aCNR) were calculated. Wilcoxon signed-rank test, Bland-Altman analysis, linear regression and Pearson correlation were used

### RESULTS

45 patients (mean age, 50 years ± 18; 30 men) were included. The acquisition duration of SSH cine was about 50% lower compared to standard cine (mean duration, 32 sec ± 8 vs. 67 sec ± 20; p<.0001). Image sharpness and contrast were superior in DL-SSH cine compared to standard cine (edge rise distance: 2.0 mm ± 0.3 vs. 2.6 mm ± 0.7; p<.0001; contrast: 5.0 ± 0.1 vs. 4.8 ± 0.4, p=.01). No significant difference in ratings of artifacts (4.4 ± 0.6 vs. 4.6 ± 0.8, p=.26) and the assessment of aSNR (44.3 ± 25.8 vs. 46.5 ± 16.4; p=.37) and aCNR (33.7 ± 20.9 vs. 35.5 ± 13.1; p=.41) was found. High agreement between both cine techniques was found for functional LV parameters (e.g. ejection fraction: 0.99 [0.89, 1.09], r=0.95; end-diastolic volume index: 0.98 [0.91, 1.05], r=0.97). Subgroup analysis of patients with arrhythmia or unreliable breath holding (n=14/45, 31%) showed more distinct differences between DL-SSH and standard cine (e.g., artifacts: 4.3 ± 0.6 vs. 3.9 ± 1.0, p=.06).

### CONCLUSION

DL reconstruction of single-shot bSSFP cine sequences enabled accelerated acquisition times and non-inferior diagnostic quality with excellent agreement in the quantification of functional LV parameters compared to standard cine acquisitions.

### CLINICAL RELEVANCE/APPLICATION

Clinical application of DL reconstruction can improve the limited spatial resolution of the SSH cine technique and thus provide the basis for a fast and robust ultrafast cardiac MRI protocol, improving patient comfort and compliance and diagnostic quality in challenging patients with arrhythmia or unreliable breath holding, and meeting the increasing demand for cardiac MRI examinations.

## M1-SSCA03-6 DEEP LEARNING AUTOMATED MEASUREMENT OF SHUNT SEVERITY IN 4D FLOW MRI

Kent M. Hall, MD (*Abstract Co-Author*) Nothing to Disclose
Roshun Sankaran, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Akhilesh Yeluru, MS, BS (*Presenter*) Nothing to Disclose

## PURPOSE

4D Flow MRI is increasingly used for the clinical evaluation and non-invasive quantification of hemodynamics, such as shunt severity, in patients with congenital heart disease. Unfortunately, 3D post-processing expertise is still needed to accurately measure blood flow with 4D Flow MRI. The purpose of this study was to assess the feasibility of using deep learning to fully-automate measurement of blood flow and shunt severity with 4D Flow MRI and evaluate this against an expert cardiac radiologist who served as the reference standard.

## METHODS AND MATERIALS

With HIPAA compliance, IRB approval, and waiver of informed consent, we retrospectively collected clinical cardiac 4D Flow MRI exams from 400 patients between February 2015 and January 2021 for algorithm development. Images were manually labeled with multiple landmarks and vessel contours along the aorta and pulmonary artery. MRI from 35 patients referred for simple congenital heart disease between April 2021 and December 2022 were separately collected for algorithm evaluation. Neural networks were trained to serially perform two tasks: a multichannel 3D U-Net for vessel localization and a 2D U-Net for vessel segmentation. To evaluate performance, Euclidean distance error and Dice score were used. To evaluate the end-to-end system, automatic measurements of aortic (Ao) flow, pulmonary artery (PA) flow, and shunt severity (Qp/Qs) were compared against measurements made by an expert cardiac radiologist. Statistical analysis included Pearson correlation and Bland-Altman Analysis.

## RESULTS

Across all 35 test patients, the median distance between automatically and manually localized landmarks was 7.87 mm (IQR: 5.74-10.20 mm). Across all test patients, at ten landmarks and twenty time-points, the median dice score when comparing automatic vessel segmentations with manual vessel segmentations was 0.878 (IQR: 0.826-0.913). Automatic end-to-end measurements correlated strongly with manual measurements of aortic flow (0.884, $p<0.001$), pulmonary flow (0.863, $p<0.001$), and Qp/Qs (0.928, $p<0.001$). Mean difference [95% limits of agreement] for Ao, PA, and Qp/Qs respectively were as follows: 0.26 [1.9,-1.4] L/min, 0.51 [3.9, -2.9] L/min, and 0.0 [0.61,-0.61] L/min.

## CONCLUSION

A cascaded system of U-Nets can be used to automate measurement of blood flow for quantification of shunt severity in patients with simple congenital heart disease with accuracy comparable to an expert cardiac radiologist.

## CLINICAL RELEVANCE/APPLICATION

Deep learning algorithms, based on convolutional neural networks, have the potential to improve efficiency of interpretation of 4D Flow MRI for congenital heart disease by automating routine measurements of blood flow and shunt severity.

### PURPOSE

Examining the renal parenchyma and common incidental lesions can be challenging in abdominal imaging. This study investigated a novel, deep learning (DL)-accelerated super-resolution MRI sequence compared to the standard sequence for assessing the kidneys.

### METHODS AND MATERIALS

This study prospectively enrolled patients undergoing abdominal 3T MRI for various clinical indications. Examination protocol encompassed both a standard T1-weighted sequence (T1STD: T1-volumetric interpolated breath-hold examination (VIBE) 3D with DIXON) and a prototype DL-accelerated super-resolution T1-weighted sequence (T1DL: deep learning-accelerated T1-volume VIBE 3D with DIXON) after application of contrast agent. Image data was anonymized and evaluated independently by two radiologists in the third and fourth year of residency. The qualitative assessment included overall image quality, edge sharpness, noise, and movement artifacts rated on Likert scales (5=excellent). Additionally, with regard to renal cysts, the presence and conspicuity of cysts, detection of septa or wall irregularity, and diagnostic confidence were evaluated. For quantitative analysis, the coefficient of variation was employed. Mann-Whitney-U-Test and Kruskal-Wallis-Test were used for statistical analysis.

### RESULTS

50 patients (21 women; mean=62.6y±15.2) were included. A T2w sequence confirmed cystic renal lesions in 68% (34/50). The acquisition time of T1DL (13sec) was 24% faster than T1STD (17sec). With regard to qualitative parameters, T1DL was superior in overall image quality (T1STD: Median(Mdn)=3[interquartile range=1]; T1DL: Mdn=4[1]; p=0.05), edge sharpness (T1STD: Mdn=3[1], T1DL: Mdn=4[1]; p=0.001), noise (T1STD: Mdn=4[0], T1DL: Mdn=5[1]; p=0.001) and movement artifact reduction (T1STD: Mdn=4[0], T1DL: Mdn=4[1]; p=0.001). Moreover, T1DL was significantly better in evaluation of the presence of renal cysts (p=0.02), conspicuity (T1STD: Mdn=4[0], T1DL: Mdn=5[1]; p=0.001), detection of microstructures (T1STD: Mdn=2[1], T1DL: Mdn=4[1]; p=0.001) and diagnostic confidence (T1STD: Mdn=3[1], T1DL: Mdn=4[2]; p=0.001) of renal cystic lesions. No difference between T1STD and T1DL was noted for the coefficient of variation (T1STD: 0,044 vs. T1DL: 0,044; p=n.s.).

### CONCLUSION

Our findings suggest that the DL-accelerated T1-weighted MRI sequence might improve evaluation and diagnostic confidence in imaging the kidneys and cystic lesions.

### CLINICAL RELEVANCE/APPLICATION

Accurate assessment of renal structures is crucial for patient care. Obtaining super-resolution images may improve decision-making in patients with kidney diseases.

## M1-SSGU03-2 1. POST-CONTRAST ACUTE KIDNEY INJURY ASSOCIATES WITH RENAL FUNCTION BUT NOT DOSE OF IODINE

Per Liss, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Robert Frithiof (*Abstract Co-Author*) Nothing to Disclose
Felix Berglund (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this study is to investigate if any of the two components of the injected amount of iodine contrast media (ICM) to renal function ratio is independently associated with the development of contrast-associated acute kidney injury (CA-AKI).

**METHODS AND MATERIALS**

All patients admitted to the intensive care units (ICUs) of a tertiary hospital from January 2013 to February 2020 were retrospectively identified. Those who underwent ICM-enhanced CT scans were included in this nested case-control study. CA-AKI was defined and staged based on the creatinine and urine output criteria set forth by the Kidney Disease Improving Global Outcomes guidelines. The two components of the ratio, the dose of ICM (measured in grams of iodine) and renal function estimated by plasma creatinine, were analyzed separately in relation to the odds of developing CA-AKI.

**RESULTS**

Among the 214 patients included in the analysis CA-AKI occurred in 42 of the patients (19.6%). Median age was 61.5 years (IQR 40-73) and 59.3% were of male sex. Renal function at the day of the CT-scan differed between those developing CA-AKI (eGFR 56.9, IQR 35-87) and those that did not (eGFR 81.6, IQR 58-96). However, the dose of ICM was not associated with CA-AKI development (OR 1.31 (IQR 0.49-3.47), p=0.827).

**CONCLUSION**

In this case-control study, renal function at the day of the examination but not the administered dose of iodine contrast media was associated with CA-AKI. This suggest that including injected amount of iodine contrast media as a variable to clinically predict risk of CA-AKI is futile.

**CLINICAL RELEVANCE/APPLICATION**

This study indicates that the potential nephrotoxicity of ICM is clinically negligible and that the ratio of injected amount of iodine contrast media to renal function adds no more predictive value for CA-AKI development than renal function by itself.

## M1-SSGU03-3 BODY COMPOSITION AS A POTENTIAL IMAGING BIOMARKER FOR PREDICTING THE PROGRESSION RISK OF CHRONIC KIDNEY DISEASE

Ping Liang (*Abstract Co-Author*) Nothing to Disclose
Zhen Li, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mengmeng Gao (*Abstract Co-Author*) Nothing to Disclose
Anqin Li (*Abstract Co-Author*) Nothing to Disclose
Guanjie Yuan (*Abstract Co-Author*) Nothing to Disclose
Shichao Li (*Abstract Co-Author*) Nothing to Disclose
Kangwen He (*Abstract Co-Author*) Nothing to Disclose
Zhouyan Liao (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate whether the body composition parameters can employ as potential biomarkers for predicting the progression risk of chronic kidney disease (CKD).

**METHODS AND MATERIALS**

2980 patients diagnosed as CKD were included in this retrospective study. Body composition area, the index (visceral fat index (VFI), subcutaneous fat index (SFI), skeletal muscle index (SMI), renal sinus fat index (RFI)) and the radiodensities (VATd, SATd, SMAd, RSFd) were measured on abdominal CT images. The visceral to subcutaneous fat ratio (VSR) and the abdominal fat to SMA ratio (FM) were then calculated. The demographics and comorbid conditions such as hypertension and diabetes were also assessed. Univariate and multivariate survival regression analyses were performed according to sex, diabetes and hypertension to explore the associations between body composition parameters and the prognosis of CKD.

**RESULTS**

Univariate and multivariate survival analyses showed that high risk of CKD progression had diabetes, abnormal urea and Scr, higher 24h-Upro, MAP, VATd and RSFd. The area under curve (AUC) of 1, 3 and 5 years for differentiating high progression risk from low progression risk were 0.805, 0.836, 0.781, respectively. Urea, HCO3- , NLR, MAP, diabetes and RSFd were independent predictors of males with CKD, while urea, MAP, SMI, VSR and VATd were independent risk factors for females. Time dependent receiver operating characteristics curves shown that the AUC of at 1, 3 and 5 years of nomogram for males/females were 0.831/0.816, 0.892/0.833, 0.893/0.741, respectively. The multivariate model identified urea, HCO3-, 24h-Upro, MAP, RFI, FM and RSFd as significant predictors of no-diabetic patients, while age, urea, ALB, MAP as significant predictors of diabetic patients. Urea, diabetes, VFI, VATd and SATd were independent predictors of non-hypertensive patients, while urea, uric acid, HDL, 24h-Upro, MAP, RSFd were independent risk factors for hypertensive patients.

**CONCLUSION**

Urea, Scr, diabetes, 24h-Upro, MAP, VATd and RSFd were valuable indicators for predicting CKD progression risk. VATd and RSFd were the most valuable of all body composition parameters for predicting high-risk populations with CKD.

**CLINICAL RELEVANCE/APPLICATION**

Radiodensity rather than area of adipose tissue can be used as a new biomarker of prognosis for CKD patients, providing new insights into risk assessment, stratified management and treatment for CKD patients.

## M1-SSGU03-4 UTILIZING CHEST RADIOGRAPHS (CXRS) FOR KIDNEY FAILURE PROGNOSTICATION AND EARLY RISK STRATIFICATION WITH PROSPECTIVE AND EXTERNAL VALIDATION

Bardia Khosravi, MD, MPH (*Abstract Co-Author*) Nothing to Disclose

Ulas Bagci, MSc, PhD (*Abstract Co-Author*) Ther-AI LLC
Theodorus Dapamede, MD, PhD (*Presenter*) Intern, MARS BioImaging Ltd

**PURPOSE**

The Kidney Failure Risk Equation (KFRE), a standard for predicting CKD progression to kidney failure, is limited in clinical use due to its reliance on specialized tests like urine Albumin Creatinine Ratio (ACR). We aim to develop a machine learning prognostic model using chest radiographs (CXR), a more routinely accessible test, to improve early risk assessment and prognostication for kidney failure.

**METHODS AND MATERIALS**

In this IRB-approved study, we analyzed 224,323 adult patients' initial frontal non-portable CXRs (51.5% Black, 48.5% White) from 2008 to 2021. Time-to-event was defined as the interval from the first CXR to the first ICD-10 based KF diagnosis. The dataset was divided into a development set (2008-2018) and a prospective set (2019-2021), with an 80/20 split in the development set for Train and Test sets, stratified by time-to-event. A pre-trained ICD-10 comorbidity CNN model analyzed images to predict 10 KF risk factors, which were used in an XGBoost survival model to compute risk scores. We evaluated the model on test and prospective sets, assessing prognostic performance with C-index and diagnostic performance using time-dependent AUC, PPV, and NPV. External validation was conducted on a distinct geographic dataset (AUC). Prediction scores for normal/low (stage 1 2) and high (stage 3, 4, 5) CKD stages were compared and classified by KFRE risk category. Additionally, a multivariable Cox model served as a comparative baseline, and explainability analysis was conducted (Occlusion maps, SHAP values).

**RESULTS**

Our model outperformed the baseline clinical model, achieving a higher C-Index of 0.76 (95% CI: 0.71-0.80) compared to 0.57 (95%CI: 0.57-0.57). At the 2-year mark, it showed an AUC of 0.74, a PPV of 0.23, and an NPV of 0.94. External validation confirmed an AUC of 0.78 (95%CI: 0.77-0.79). SHAP values identified diabetes and CHF as significant influencers on model decisions, aligning with known risk factors for KF. Subgroup analysis indicated that normal/low CKD patients developing KF had similar risk scores to high CKD patients not developing KF, suggesting a potential for early risk stratification.

**CONCLUSION**

This study demonstrates the potential of using deep learning and machine learning models to predict KF from CXR, enabling early risk stratification for patients otherwise ineligible for KFRE assessment. Further categorization reveals these patients can be classified as KFRE low risk, underscoring the possibility for early intervention

**CLINICAL RELEVANCE/APPLICATION**

The model's ability to perform early risk assessment for patients not screened for CKD or KF through KFRE could significantly impact strategies to prevent or slow KF progression, potentially reducing the disease burden and enhancing patient outcomes.

## M1-SSGU03-6 R2' MAPPING FOR EVALUATING THE DIRECT EFFECT OF REMOTE ISCHEMIC PRECONDITIONING: AN EXPERIMENTAL STUDY

Jinggang Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Zhangyan Bi (*Abstract Co-Author*) Nothing to Disclose
Zha Tingting, MD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of R2' mapping in evaluating the direct effects of RIPC by comparing the difference of R2' values in renal dermal medulla after distal ischemic preconditioning (RIPC) between early and late phases.

**METHODS AND MATERIALS**

Eighteen rabbits were randomly divided into 3 groups: RICP-1H group, RICP-24H group and control group (with n= 6 each group). RICP model: Two tourniquets were applied around two hind-limbs just below the level of the inguinal ligament for 3×10 minutes with 10-minute intermittent reperfusion periods. In RICP-1H group and RICP-24H group, they were performed with the GE 3.0 Telsa MRI at 1H and 24H after reperfusion respectively. The R2' values of cortex(CO), outer medulla(OM)and inner medulla(IM)in the left kidney were measured. Blood samples were taken for testing blood gas, acid-base, metabolic and hemorheological parameters. One-way ANOVA and Kruskal-Wallis test were used for statistical analysis.

**RESULTS**

Compared to the control group, the R2' values of CO, OM and IM in RICP-1H group and RICP-24H group decreased significantly (each $P < 0.05$). The R2' values of OM and IM in RICP-1H group were lower than those in RICP-24 group ($P<0.05$). Arterial blood pCO2 in RICP-1H group increased compared to the control group ($P>0.05$), and pCO2 in RICP-24H group decreased($P>0.05$), and there was statistical significance in pCO2 between RICP-1H group and RICP-24H group ($P < 0.01$). Compared to the control group, arterial blood pO2 in RICP-1H group and RICP-24H group both increased, and the difference between RICP-1H group and control group was statistically significant ($P=0.02$). Arterial blood K+ concentration in RICP-1H group and RICP-24H group was lower than that in control group, and the difference between RICP-1H group and control group was statistically significant ($P=0.027$). The serum creatinine concentration of RICP-1H group and RICP-24H group was higher than that of control group, and the difference between RICP-24H group and control group was statistically significant ($P=0.011$), the difference between RICP-1H group and RICP-24 group was statistically significant ($P=0.033$). Arterial blood cSO2 in RICP-1H and RICP-24H groups was higher than that in control group ($P < 0.05$).

**CONCLUSION**

R2' mapping MRI can directly evaluate the effect of remote ischemic preconditioning.

**CLINICAL RELEVANCE/APPLICATION**

In this paper, R2' value indirectly reflects the changes in the oxygen environment of renal medullary cortex in the early and late phases after RIPC, to explain its effect on the improvement of renal functional reserve capacity and its histopathological basis, and to establish a set of RIPC evaluation system based on R2' value in vivo.

### PURPOSE

To explore the feasibility of accurately predicting and localizing hepatic regions at high-risk for HCC development in screening MRIs.

### METHODS AND MATERIALS

This study considered 968 patients with liver cirrhosis and HCC seen at a tertiary care center between 2012 and 2023. The final cohort comprised 124 patients with negative screening MRI preceding their diagnostic MRI by up to 18 months. Additionally, 18 patients with non-progressing LR-3 lesions were included. Liver volumes were segmented on arterial-phase screening MRI. Areas which became an HCC (<=LR-3 and non-visible) and exemplary benign liver parenchyma were manually annotated with bounding boxes (bboxes) in each axial slice to create a 3D volume of interest (VOI) in MD.ai. Bboxes of different dimensions at random locations from malignant (HCC VOI) and benign (liver segmentation) regions were extracted from the screening MRI. Texture imaging biomarkers were derived from manually and randomly annotated VOIs using Pyradiomics. Machine learning models (Logistic Regression (LR), Random Forest (RF), XGBoost (XGB)) were optimized to differentiate bboxes as malignant or benign, and their performance was validated using 5-fold cross validation and four distinct "training - validation" approaches based on the annotation methods: 1. "manual - manual" (MM), 2. "manual - random" (MR), 3. "random - random" (RR), 4. "random - manual" (RM). XGB was optimized using grid search. Voxel-level heatmaps were generated to visually represent high-risk areas for HCC across the liver using the "RR" approach.

### RESULTS

The study included 186 benign and 130 malignant manual and 1240 benign and 1300 malignant random bboxes. AUC-ROCs for the "MM" approach were: LR: 0.79, RF: 0.74, XGB: 0.78. After optimization, XGB represented an AUC of 0.81. It performed better when only assessing LR-3 lesions evident in screening MRIs (AUC: 0.88) and worse (AUC: 0.65) when only predicting non-visible precursors. Training and validation on manually annotated data ("MM", AUC: 0.81) yielded the best results, followed by random bboxes for training and validating on manual ("RM", AUC: 0.74), or random data ("RR", AUC: 0.73). "MR" caused the biggest decrease in AUC (0.60).

### CONCLUSION

Four methods for HCC prediction on screening MRIs were evaluated, achieving an AUC of up to 0.88. The approaches introduce potential future applications while heatmaps add interpretable results. These promising results call for further research aiming to reproduce and improve the presented results.

### CLINICAL RELEVANCE/APPLICATION

A basis for clinicians to focus attention and strategize treatments, e.g. considering preventive ablation of LR-3 lesions, and making informed decisions on resection, ablation, transplantation (uni- vs multifocal HCC), and biopsy.

## M1-SSIR01-2 OPTIMIZING IMAGING QUALITY AND REDUCING RADIATION EXPOSURE IN PROSTATIC ARTERY EMBOLIZATION: A COMPARATIVE ANALYSIS OF DIGITAL VARIANCE ANGIOGRAPHY AND DIGITAL SUBTRACTION ANGIOGRAPHY

Thomas J. Vogl, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Christian Booz, MD (*Abstract Co-Author*) Speaker, Siemens AG
Leon D. Gruenewald, MD (*Abstract Co-Author*) Nothing to Disclose
Mirela Dimitrova (*Abstract Co-Author*) Nothing to Disclose
Ibrahim Yel, MD (*Abstract Co-Author*) Nothing to Disclose
Leona Alizadeh, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Digital Variance Angiography (DVA) has demonstrated superior image quality in retrospective trials. This prospective study aimed to evaluate DVA's performance in radiation dose-optimized protocols compared to standard Digital Subtraction Angiography (DSA) in Prostatic Artery Embolization (PAE) for benign prostatic hyperplasia.

### METHODS AND MATERIALS

Angiographic acquisitions from 53 patients (mean age 72.35, SD 10.02, range 49-87) undergoing PAE were assessed. Contrast-to-noise ratio (CNR) between DSA and DVA pairs was compared using regions of interest across standard and optimized low-dose protocols. Clinical image quality was evaluated by three experienced interventional radiologists in a randomized blinded trial using a 5-point Likert scale based on clinically relevant criteria. Fleiss' kappa test determined interrater agreement and adequate statistic means applied.

### RESULTS

Using optimized low-dose protocols a radiation-dose reduction of -27% was achieved. DVA images still provided a 1.54 times higher CNR than DSA (median value, Q1 Q3 interval was 1.32 2 13). The visual evaluation indicated that DVA-videos provided similar to higher image quality than the full dose DSA images, since in 72.9% of comparisons evaluators preferred DVA over DSA. The interrater agreement was 88.2% and Fleiss's kappa was 0.61 ($p<0.001$).

### CONCLUSION

In PAE procedures, DVA demonstrates a significant image quality advantage, enabling radiation dose reduction, addressing a significant concern in PAE interventions. DVA's improved visualization of vascular structures, coupled with its substantial CNR increase even in low-dose acquisitions, suggests potential for reducing contrast agent use in the future.

### CLINICAL RELEVANCE/APPLICATION

DVA enhances safety and procedural confidence in PAE interventions by minimizing image noise and improving the visualization of intricate vascular structures. This facilitates the reduction of radiation dose and contrast agent, addressing critical safety considerations in PAE procedures.

## M1-SSIR01-3 EVALUATION OF MAGNETIC RESONANCE NAVIGATION (MRN) AND ANALYSIS OF THE IMPACT OF MAGNETIC DRUG ELUTING BEADS (MDEBS) DISTRIBUTION ON TARGETING SUCCESS IN HEPATIC ARTERIES

Mara Vagai, MD (*Abstract Co-Author*) Nothing to Disclose
Irene Vignon-Clementel (*Abstract Co-Author*) Nothing to Disclose
Gilles P. Cyril Tous, PhD (*Abstract Co-Author*) Support, Siemens AG
Amina Hadjadj, MD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluate the performance of Magnetic Resonance Navigation (MRN) of magnetic drug eluting beads (MDEBs) for selective liver embolization in a clinical MRI using imaging gradients and the gravitational force and assess the impact of the advancement of embolization on targeting performance.

### METHODS AND MATERIALS

The efficacy of MRN was compared on 12 pigs: 4 control (no MRN), 5 left liver-targeted, and 3 right liver-targeted MRNs. A dedicated particle injector was used to inject 100 aggregates of 20-25 aggregates in the proper hepatic artery, while a blood flow control system was used to maintain a velocity under 10 cm/s. The imaging gradient was oriented to divert MDEBS aggregates toward the target lobe and the pig positioned to take advantage of gravitational forces during the procedure. 3D slicer and Meshmixer software were used for liver, segments, lobes, particles and arterial trees segmentation and fusion. MDEBs particle number was determined after 25, 50, 75 and 100 aggregate injections by manually counting aggregates on the images and applying a mathematical relationship as established before.

### RESULTS

MRN improved significantly: targeting success from 50.7 ± 12.7% for control pigs to 80.5 ± 4.0% for the right lobe ($p=0.0211$) and from 49.1 ± 11.1% to 82.8 ± 13.7% for the left lobe ($p=0.0121$). Targeting success decreased when more aggregates were injected (80.9% ± 10.1% (injection 25), 77.7% ± 14.3% (injection 50), 76.1% ± 15.6% (injection 75), 74.5 ±12.4 (injection 100) ($p=0.037$). MDEB aggregate blockages were observed in proximal arteries at the latter stage of injections. After 100 injections, the pigs were removed from the MRI and Bo field to allow aggregate to separate in individual MDEBS and reach peripheral segmental branches. After pig reinsertion in the Bo field, targeting success rebounded from 74.5 ±12.4% (injection 100 in) to 81.9 ± 11.2% (injection 100 Out) ($p=0.0119$).

### CONCLUSION

Liver and MDEBs segmentation after MRN enables straightforward assessment of targeting success. Early detection of proximal blockages will allow prompt removal of patients from MRI magnetic field, improving targeting success. Currently, an AI software is under development for automated MDEB segmentation. It will be combined with a computational flow dynamics software to prevent proximal occlusion, optimize pig positioning, gradient orientation, and monitor flow velocities to further increase MRN performance.

### CLINICAL RELEVANCE/APPLICATION

Transarterial chemoembolization (TACE) using DEB or radioembolization are more and more used in management of intermediate and advanced HCCs. MRN could offer a more selective and less invasive approach using an implantable arterial port compared to fluoroscopy guided TACE with excellent visualization of tumor coverage.

## M1-SSIR01-4 AUTOMATIC EXTRACTION OF CRITICAL DIAGNOSTIC IMAGING FINDINGS FOLLOWING INTERVENTIONAL ONCOLOGY TREATMENTS USING TWO-STAGED LARGE LANGUAGE MODEL GENERATION

Kristy K. Brock, PhD (*Abstract Co-Author*) Grant, RaySearch Laboratories AB;License agreement, RaySearch Laboratories AB;Research support, Mirada Medical Ltd
Bruno C. Odisio, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Siemens AG;Speaker, Siemens AG;Research Grant, Johnson & Johnson;
Iwan Paolucci, PhD (*Abstract Co-Author*) Stockholder, Intuitive Surgical, Inc ;Stockholder, SOPHiA GENETICS
Jessica A. Albuquerque (*Abstract Co-Author*) Nothing to Disclose
Alexander Shieh, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Collecting oncological outcomes is crucial for new treatment development and quality control in the field of interventional oncology. Reviewing follow-up imaging for specific research purposes can be time consuming. Using large language models (LLMs) to automatically extract cancer progression findings from these imaging reports may increase the efficiency of this process by prioritizing images to review and facilitate the construction of interventional oncology registries.

### METHODS AND MATERIALS

This study included 47 consecutive patients undergoing PTA for HCC during 2022-2023. Post-PTA CT, MRI and PET/CT reports were collected. Progression findings, defined as new or enlarging lesions compared to pre-PTA scan reports, were manually annotated as ground truth. The open-source Llama 2 LLM was used on internal servers to ensure information safety. We designed a two-stage prompt for Llama 2 to extract critical cancer progression findings. The first stage proposes possible findings, and the second stage determines whether the proposed findings were true progressions. The precision and recall of lesions retrieved at each stage were evaluated with sub-analysis on different types of cancer progression: local disease progression (LDP, including residual tumor), intrahepatic progression (IHP, progression within liver excluding LDPs) and extrahepatic progression (EHP). For reports using LI-RADS, we defined LR TR viable lesions as LDP, and LR4/LR5 lesions as IHP.

### RESULTS

A total of 137 reports were analyzed (96 CT, 36 MRI, 5 PET/CT). LI-RADS was utilized in 38 reports. Manual annotation found 157 cancer progression findings. Overall precision improved from 0.24 to 0.53 ($p<0.001$) and recall was minimally decreased from 0.89 to 0.85 ($p=0.50$) after the second stage. In sub-analysis, LDP, IHP and EHP all achieved better precision with recall numerically decreased (recall: LDP 0.94 vs 0.94 [NS], IHP 0.83 vs 0.85 [NS], EHP 0.78 vs 0.86 [NS]; precision: LDP 0.35 vs 0.15 [$p=0.008$], IHP 0.70 vs 0.39 [$p<0.001$], EHP 0.37 vs 0.13 [$p<0.001$]). For reports using LI-RADS, the precision and recall for LDP and IHP were numerically better when compared to non-LI-RADS results except IHP precision, which were significantly better (recall: LDP 1.0 vs 0.90 [NS], IHP 0.90 vs 0.81 [NS]; precision: LDP 0.46 vs 0.30 [NS], IHP 0.87 vs 0.65 [$p=0.02$]).

### CONCLUSION

An open-source LLM can extract cancer progression findings to flag sentinel scans. We also found extraction results can be controlled as a tradeoff between precision and recall using a two-stage strategy.

### CLINICAL RELEVANCE/APPLICATION

This system can be used to flag sentinel scans for thorough review. Utilizing LI-RADS in reports showed a trend of better extraction by LLMs, highlighting the importance of standardized reporting.

## M1-SSIR01-5 FULLY-AUTOMATED TRANSCATHETER AORTIC VALVE REPLACEMENT PLANNING ON CONTRAST-FREE CMR USING A COMPUTATIONAL AORTA UNWRAPPING METHOD

Markus Haltmeier (*Abstract Co-Author*) Nothing to Disclose
Agnes Mayr, MD (*Abstract Co-Author*) Nothing to Disclose
Christian Kremser, PhD (*Abstract Co-Author*) Nothing to Disclose
Enrique Almar-Munoz (*Presenter*) Nothing to Disclose

### PURPOSE

This study presents a fully automated pipeline for Transcatheter Aortic Valve Replacement (TAVR) surgery planning using contrast-free CMR. It addresses the challenge of accurately identifying, without contrast, the Aortic Annulus (AA) and the coronary ostia height, crucial for graft selection and positioning. The proposed automatic approach employs an innovative aorta unwrapping technique, built on the top of a deep-learning segmentation.

### METHODS AND MATERIALS

Utilizing a in-house dataset of 78 navigator-gated non-contrast 3D whole-heart CMR scans from TAVR candidates, a nnUNet architecture was employed for multiclass segmentation, aorta and coronaries arteries. It was trained on 59 scans. To detected the AA virtual plane, an angular projection method followed by contrast enhancement, creates 2D maps of the unwrapped valve leaflets' commisures. Using them as input, a 2D-UNet was trained to detect the hinge points. Those points define the virtual plane. To detect the coronary ostia heights, we measured the distance from the aorta-coronary intersection to the AA plane.

### RESULTS

The nnUNet achieved a Dice Score of 0.962 in aorta segmentation and 0.786 in coronaries segmentation, enhanced to 0.971 and 0.798 after post-processing. The inference is computationally efficient with 3.116s per CMR scan. Data Augmentation improved leaftle commisures' segmentation, with a Dice Score of 0.848 and reduced Error Mean Line (EML) to 1.0152mm. Regarding the AA plane segmentation, technical metrics showed Mean Absolute

Error (MAE) in diameter of 2.279±0.922mm, Root Mean Squared Error (RMSE) of 2.671±1.111mm, and Wasserstein Distance of 1.933±0.920mm. Blind testing confirmed comparable results between manual and automated segmentation.Regarding the ostia detection, among the 19 scans in the test set, both coronaries were correctly detected.

**CONCLUSION**

We present a fully automated TAVR planning approach using contrast-free CMR, achieving computational efficiency. Neural network architectures demonstrate reliability even in low-quality images, supported by high correlation between measurements. Further validation in diverse patient populations is suggested. This approach streamlines procedures and improves outcomes, pending broader clinical integration and refinements.

**CLINICAL RELEVANCE/APPLICATION**

TAVR planning is critical for optimal outcomes in valvular heart disease. The pipeline enhances patient safety and procedural efficiency, especially for patients with contraindications to iodinated contrast. It represents a significant advancement in interventional cardiology, contributing to personalized, patient-centered care. This paper presents the first automatic approach for TAVR planning on CMR.

### PURPOSE

Our study aimed to evaluate the clinical features and oncological outcomes for prostate cancer patients with undetectable prostate-specific antigen (PSA) and radiographic disease progression (rDP) on PSMA PET/CT imaging referred as PSA zero rDP.

### METHODS AND MATERIALS

In our retrospective study, we examined the Mayo Clinic's PSMA PET Prostate Cancer Registry to identify patients who exhibited rDP on PSMA PET/CT despite undetectable PSA level and classified them into two groups according to the castrate status (Hormone-Sensitive Prostate Cancer [HSPC] and castrate-resistant prostate cancer [CRPC]). Disease progression was confirmed either by histological analysis from tissue biopsy or by assessing the response to subsequent therapy. We calculated overall survival for the different sites of rDP using the Kaplan-Meier method and assessed intergroup differences using the log-rank test. Furthermore, a univariate Cox regression model was used to investigate factors linked to poor survival following rDP.

### RESULTS

Out of 2141 patients with rDP, we identified 257 (12%) patients with PSA zero rDP. More than 60% of those patients presented initially with localized PCa disease while the rest (39%) had de-novo metastatic disease with a median (IQR) Gleason score of 8 (7-9). The majority (95%) of these men had received at least one systemic therapy prior to PSA zero rDP. Over a median (IQR) time of 119 (30.8-368.5) months elapsed between the initial PCa diagnosis and the PSA zero rDP occurrence, 184 (72%) patients progressed to CRPC. Significant differences were observed in Gleason score, tumor staging, initial treatment, and sites of rDP between HSPC and CRPC groups (p-value $<0.05$). Over a median follow-up period of 6.7 months in HSPC and 8.9 months in CRPC from the diagnosis of PSA zero rDP, one patient in the HSPC group and 12 patients in the CRPC group died. The median biochemical progression-free survival was 9 months and the location of rDP in visceral organs was the only statistically significant indicator of poor overall survival ($p<0.001$).

### CONCLUSION

Despite undetectable PSA levels, periodic PET imaging especially in CRPC patients is critical in early detection and management of disease progression.

### CLINICAL RELEVANCE/APPLICATION

In prostate cancer management, the undetectable PSA level does not guarantee the absence of disease progression, emphasizing the ongoing need for frequent monitoring of the disease with the PSMA PET/CT technique.

## M1-SSNMMI02-2 CLINICAL UTILITY OF WHOLE-BODY SPECT/CT AFTER THE 1$^{ST}$ CYCLE OF $^{177}$LU-PSMA-617 THERAPY COMPARED TO PRE-THERAPY PSMA PET/CT

**PURPOSE**

Post-177Lu-PSMA therapy SPECT/CT in men with advanced prostate cancer (PCa) accurately verifies targeted treatment. Along with its value in dosimetry, post-therapy SPECT/CT can also suggest discrepancies from the baseline PSMA PET, especially with increasing time from PET to therapy. We assessed the clinical utility of 1st post-therapy SPECT/CT compared to the pre-therapy PSMA PET/CT in men with PCa treated with 177Lu-PSMA with the primary objective of estimating the rate of SPECT-PET discordance.

**METHODS AND MATERIALS**

We retrospectively reviewed the records of men with PCa who were treated with 177Lu-PSMA-617 at our facility and received a whole-body SPECT/CT after the 1st therapy. We recorded the time between the PSMA PET and start of treatment, and other relevant demographic/imaging data. We compared the PSMA PET/CT with the 1st post-therapy SPECT/CT to determine discordance. Discordant findings included either unequivocal appearance of new lesions on the SPECT/CT (n <5, 6-10, >10), increase in size of the previous lesions, or appearance of additional findings that would necessitate additional management (such as new hydronephrosis). A Shapiro-Wilk test test of normality was used to guide additional testing.

**RESULTS**

51 men (median age: 72 years; range: 44-89) had the pre-therapy PSMA PET/CT and post-1st cycle SPECT/CT available for review. The median duration between the PET and 1st therapy was 49 days (range: 3-294). SPECT/CT was performed at 2-6 hours after therapy in 6 men and at 24 hours in the rest. 21 (41.2%) men had a SPECT-PET discordance: 9 had enlarging lesions, 6 had new lesions, 5 had both new and enlarging lesions, while 1 had a new-onset hydronephrosis requiring ureteral stenting. The number of new lesions was <5 in 7/11 men and >10 in the rest. Kruskal-Wallis test showed significant differences in the duration from PET to therapy in men who had concordant versus discordant SPECT-PET findings (P=0.001). The median duration between PET and therapy was 77 days (IQR: 60.5) in men who had SPECT-PET discordance versus 35.5 days (IQR: 20) in those with concordance. 19/21 men with discordant disease had the 1st therapy performed at >30 days of the baseline PET.

**CONCLUSION**

The 1st post-therapy SPECT/CT showed discordance with the PSMA PET in 41% patients, the majority (90.5%) of which had over 30 days between PET and therapy.

**CLINICAL RELEVANCE/APPLICATION**

Post 1st cycle whole-body SPECT/CT highlights important differences from the pre-therapy PET, especially when the latter is more than 30 days before therapy, thus acting as a new baseline for future comparisons and can also provide adjunct information requiring additional clinical management. These results strongly support performing post-therapy SPECT/CT in patients being treated with 177Lu-PSMA.

## M1-SSNMMI02-3 DO PATIENT OR TREATMENT RELATED FACTORS ENHANCE PSMA EXPRESSION IN PATIENTS WITH PROSTATE CANCER?

Yong C. Bradley, MD (*Abstract Co-Author*) Nothing to Disclose
Turgut Bora Cengiz, MD (*Abstract Co-Author*) Nothing to Disclose

Jackson Sullivan, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Prostate-specific membrane antigen (PSMA) PET/CT has emerged as an instrumental imaging modality for the detection and staging of prostate cancer. PSMA expression in prostate cancer cells vary greatly and there is a scarcity of research on factors that lead to higher PSMA expression in prostate cancer. Some studies indicated androgen signal inhibiting agents may increase PSMA expression in animal models; however, such factors need to be thoroughly analyzed prior to application into daily practice. The purpose of this study is to analyze factors impacting minimum standardized uptake value (SUVmin), maximum SUV (SUVmax), and mean SUV (SUVmean) in a group of patients receiving PSMA PET/CT for therapeutic purposes.

**METHODS AND MATERIALS**

All patients with prostate cancer undergoing treatment with Lutetium vipivotide tetraxetan (Lu-177 PSMA-617) at a single institution who underwent PSMA PET/CT were included. Patient demographic factors, prior treatments (hormonal treatment, chemotherapy, surgical interventions), Gleason score, and initial lab values were recorded. A semi-manual software workflow was implemented to segment each lesion to analyze SUVmin, SUVmax, SUVmean, total tumor volume, total bone volume, and total soft tissue volumes. Spearman correlation and Wilcoxon rank-sum test were then used to analyze the correlations.

**RESULTS**

A total of 34 patients were identified. Patients with Gleason scores of 6, 7, or 8 had significantly higher SUVmin compared to those with Gleason scores of 9 or 10 (SUVmin Gleason: median 4.6 vs. 4, P = 0.0275). Patients who were previously treated with enzalutamide had significantly higher SUVmin values than those who were not (SUVmin enzalutamide: median 5 vs. 4.3, P = 0.0484). Patients with visceral lesions compared to those with no visceral lesions had significantly higher SUVmin (SUVmin Visceral Lesions: median 5 vs. 4.3, P = 0.0429). Patients who were previously treated with olaparib had significantly higher SUVmax than those who were not (SUVmax : median 151.5 vs. 34, P = 0.0191). Bone tumor volume had a significant correlation with SUVmax (Spearman Cor: 0.6314, P = 0.0001) and SUVmean (Spearman Cor: 0.3448, P = 0.0458). Total tumor volume had a significant correlation with SUVmax (Spearman Cor: 0.6867, P = 0.0001) and SUVmean (Spearman Cor: 0.4915, P = 0.0032).

### CONCLUSION

This study demonstrates that some prostate cancer treatments prior to PSMA PET/CT can enhance the PSMA expression and SUV. This information can be utilized for careful selection of the patients undergoing Lu-177 PSMA-617 therapy.

### CLINICAL RELEVANCE/APPLICATION

Informs physicians of prostate cancer features that may be useful in selecting candidates who will be more likely to have positive response to PSMA-mediated radioligand therapy.

## M1-SSNMMI02-4 $^{68}$GA-PSMA-11 VERSUS $^{18}$F-DCFPYL PSMA POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY OF PATIENTS WITH PROSTATE CANCER FOR ELIGIBILITY TO TREAT WITH $^{177}$LU-PSMA-617 RADIOPHARMACEUTICAL THERAPY

### PURPOSE

To compare equivalence of the molecular imaging PSMA expression (miPSMA) score between 18F-PSMA-DCFPyL and 68Ga-PSMA-11 Positron Emission Tomography/Computed Tomography (PET/CT) scans for determining eligibility for 177LuPSMA-617 therapy for patients with metastatic castrate resistant prostate cancer (PCa) who have been treated with taxane-based chemotherapy.

### METHODS AND MATERIALS

We retrospectively identified patients referred to a quaternary care center for therapy with 177Lu-PSMA-617, had undergone a 18F-PSMA-DCFPyL and a 68Ga-PSMA-11 PET/CT. Most were enrolled in a prospective trial (NCT05547386). We excluded patients with an interval greater than 90 days between their two scans. The miPSMA scores were derived from clinical reports, determined in our practice by comparison to normal tissues including the mediastinal blood pool, liver, spleen, and parotid glands, following the classification suggested by PROMISE for PSMA ligand PET/CT interpretation. Equivalence of paired ordinal miPSMA scores was assessed via two one-sided test (TOST) approach, simultaneously testing null hypotheses of 1) an effect size lower than -0.1, and 2) an effect size greater than 0.1, using one-sided Wilcoxon signed rank tests. A significant result would reject the null hypothesis of an absolute effect size (rank biserial correlation) more extreme than 0.1, supporting equivalence. Analysis used the TOSTER package 0.8.2 library in R version 4.3.3 with a = 0.05.

### RESULTS

In total, 68 patients were included for scan analyses. On 68Ga-PSMA-11, 56 scans showed miPSMA scores of 3 and 12 showed scores of 2; on 18F-PSMA-DCFPyL, 54 patients had scores of 3 and 14 scans had scores of 2. No patients within this cohort had an miPSMA score of 0 to 1. Discordant miPSMA scores between the two tracers were observed in 6 cases (8.82%). In 4 patients, the scores were higher on 68Ga-PSMA-11, while in 2 patients, they were higher on 18F-PSMA-DCFPyL. Selection of radiotracer did not impact patient eligibility for 177Lu-PSMA-617. The observed mean difference was 0.029, standard deviation of the difference was 0.30 (95% CI: [- 0.271,0.329]). TOST analysis demonstrated $p<0.001$, rejecting a rank biserial correlation more extreme than our conservative equivalence bound of 0.1.

### CONCLUSION

Our data support the equivalence of the miPSMA score between 18F-PSMA-DCFPyL and 68Ga-PSMA-11 PET/CT for eligibility for 177Lu-PSMA-617 radiopharmaceutical therapy. Further analysis, including patients with miPSMA score of 0 or 1, would be helpful.

### CLINICAL RELEVANCE/APPLICATION

Two variants of PSMA PET/CT scans are deemed equivalent for determining patient eligibility for treatment with 177Lu-PSMA-617 radiopharmaceutical therapy.

## M1-SSNMMI02-5 THE PROGNOSTIC VALUE OF WHOLE-BODY COMPOSITION ANALYSIS IN PROSTATE CANCER PATIENTS UNDERGOING [$^{177}$LU]PSMA RADIOLIGAND THERAPY: A PROOF OF CONCEPT STUDY USING PRETHERAPEUTIC [$^{18}$F]PSMA-PET-CT

Kambiz Rahbar (*Abstract Co-Author*) Nothing to Disclose

Lucas Plagwitz (*Abstract Co-Author*) Nothing to Disclose
Philipp Schindler, MD (*Abstract Co-Author*) Nothing to Disclose
Wolfgang Roll (*Presenter*) Nothing to Disclose

### PURPOSE

This retrospective study aims to develop a deep learning-based approach to whole-body CT segmentation out of standard [18F]PSMA-PET-CT to assess body composition in metastatic castration resistant prostate cancer (mCRPC) patients prior to [177Lu]PSMA radioligand therapy (RLT). Our goal is to go beyond standard [18F]PSMA-PET-based pretherapeutic assessment and identify additional body composition metrics out of the CT-component, with predictive and prognostic value.

### METHODS AND MATERIALS

We used a deep learning segmentation model to perform fully automated segmentation of subcutaneous fat, visceral fat, skeletal muscle, and L3 vertebrae from whole-body [18F]PSMA-PET-CT scans of n=92 prostate cancer patients before RLT. The proportions of subcutaneous fat to skeletal muscle and visceral fat to skeletal muscle are compared in detail, both on a 2D slice-by-slice basis (centered at L3) and across the entire 3D CT scan. Statistical analyses were conducted to correlate the parameter ratios of the segmented fat-to-skeletal-muscle composition with patient outcomes. For this purpose, the subjects were divided into two groups based on the median value of the tissue composition.

### RESULTS

The automated segmentation model was useful for delineating subcutaneous fat, visceral fat, and skeletal muscle across diverse patient anatomies. Analyses revealed significant correlations between lower subcutaneous fat ratios and poorer therapeutic outcomes (subcutaneous fat volume / skeletal muscle volume; high: median OS: 17 months; low: median OS: 12 months; p=0.037) in the 3D model, suggesting these parameters as potential prognostic indicators. In both 2D and 3D formats, the ratio of visceral fat to skeletal muscle, as well as the ratio of subcutaneous fat to skeletal muscle in 2D, showed no significant differences.

### CONCLUSION

In this proof-of-principle study the implementation of a deep learning-based whole-body analysis provides a robust and detailed CT-based assessment of body composition in mCRPC patients undergoing RLT. Potential prognostic parameters have to be corroborated in larger prospective datasets and compared to [18F]PSMA-PET parameters.

### CLINICAL RELEVANCE/APPLICATION

Following the approval of 177Lu-PSMA therapy for mCRPC patients in the US and many other countries around the world, the number of patients taking up this new treatment option is increasing. Patient selection and response prediction are critical to providing patients with appropriate and effective treatment and reducing side effects.

## M1-SSNMMI02-6 PROGNOSTIC VALUE OF RESPONSE EVALUATION USING PSMA PET/CT IN PATIENTS WITH METASTATIC CASTRATION-RESISTANT PROSTATE CANCER (RECIP 1.0): A SYSTEMATIC REVIEW AND META-ANALYSIS

Ur Metser, MD, FRCPC (*Abstract Co-Author*) Consultant, POINT Biopharma Inc

Simone Brandao (*Abstract Co-Author*) Nothing to Disclose
Luiza G. Schmitt, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to evaluate the prognostic performance of Response Evaluation Using PSMA PET/CT in Patients with Metastatic Castration-Resistant Prostate Cancer (RECIP 1.0) in assessing treatment outcomes in metastatic prostate cancer patients. Additionally, it seeks to compare its prognostic capability with PSMA PET Progression Criteria (PPP).

### METHODS AND MATERIALS

Searches were conducted across PubMed/MEDLINE, EMBASE, and Web of Science databases through March 2024. Only studies involving patients with metastatic prostate cancer who underwent PSMA PET/CT to assess therapeutic response and who were evaluated using the RECIP 1.0 criteria were included. Pooled hazard ratios for mortality and concordance indices (c-index) of RECIP were assessed. A secondary analysis compared RECIP 1.0 with PSMA PET Progression Criteria (PPP) in head-to-head studies.

### RESULTS

From an initial 74 articles, 10 met the eligibility criteria after full-text review. Data from seven studies involving 544 patients showed that RECIP 1.0 significantly differentiated between disease progression and non-progression in terms of mortality risk (HR: 3.43; 95% CI: 2.63 - 4.48). A sub-analysis of four studies with 202 patients demonstrated a pooled c-index of 0.68 (95% CI: 0.65-0.71). Comparison involving 252 patients from four studies indicated a non-significant trend favoring RECIP 1.0 over PPP with an HR difference of 0.27 (95% CI: -0.18 - 0.72, p = 0.11). Some studies demonstrated improved performance when PSA analysis was included in RECIP criteria, although a pooled analysis was unfeasible.

### CONCLUSION

RECIP 1.0 is a robust tool for assessing prognostic outcomes in patients with metastatic prostate cancer. While it shows a trend towards superiority over PPP, this difference was not statistically significant. The addition of PSA measurements to RECIP 1.0 criteria can enhance its prognostic accuracy.

### CLINICAL RELEVANCE/APPLICATION

These findings support the integration of RECIP 1.0 into clinical practice for evaluating treatment responses in metastatic prostate cancer.

## M1-SSPD02-1 PEDIATRIC NEURO CT: RADIATION DOSE AND IMAGE QUALITY COMPARISONS BETWEEN PCCT AND EID-CT

Andres Abadia, PhD (*Abstract Co-Author*) Nothing to Disclose
Allan Thomas, PhD (*Abstract Co-Author*) Nothing to Disclose
Robert C. McKinstry III, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhongwei Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kevin Naceanceno, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Despite its potential benefits, the clinical use of photon-counting CT (PCCT) for pediatrics remains limited and poorly understood. In this work, radiation dose and image quality were compared between traditional energy-integrating detector CT (EID-CT) and PCCT in a matched group of pediatric patients across a range of ages, neuro CT protocols, and clinical indications.

### METHODS AND MATERIALS

Head CT exams were collected from EID-CT and PCCT and separated into two protocol groups used for distinct clinical indications: 1) Full Dose (head trauma, seizure, stroke) and 2) Low Dose (hydrocephalus, shunt). A total of 186 Full Dose and 51 Low Dose matched pairs between EID-CT and PCCT were created using restrictions to water equivalent diameter (?WED =2.5 mm), age (?age <1 yr), and time between exams (<2 yrs). Subgroups with five matched pairs each from age groups of <1, 1 to <5, 5 to <10, 10 to <15, and 15 to <18 yrs old were selected for detailed image quality analysis. Mean attenuation, image noise, and SNR were measured using automated methods similar to the global noise (GN) algorithm in two target regions: 1) a soft tissue mask from thresholding (0-100 HU) and 2) segmented brain. Differences in CTDIvol and GN were compared among the matched pairs. A noise-dose-metric was calculated as GN2*CTDIvol and image quality metrics were also compared after normalization of dose and slice thickness differences between EID-CT and PCCT.

### RESULTS

All patient characteristics (age, BMI, WED) showed no statistically significant differences among the 186 and 51 matched pairs in each respective protocol group (p=0.11). CTDIvol changes depended on the protocol, with PCCT maintaining median changes of -2% (p=0.018) and -14% (p<0.001) for Full Dose and Low Dose groups, respectively. In the subgroup analysis for image quality, mean HU in the brain was lower in PCCT vs EID-CT for both protocols (p=0.002). The PCCT Full Dose protocol achieved 14% lower GN (p<0.001) and 9% higher SNR (p<0.001) in the brain despite thinner slices relative to EID-CT (3 mm vs 4 mm). In the Low Dose protocol, image noise was 17% lower (p<0.001) and SNR comparable (p=0.12) at equal slice thickness despite lower doses with PCCT. After normalization for both dose and slice thickness, PCCT showed significantly improved image quality metrics over EID-CT: 46% lower noise-dose-metric, 26% lower GN, and 24% higher SNR.

### CONCLUSION

Compared to EID-CT, PCCT shows potential for improved image quality at comparable or lower dose, as well as decreased slice thickness, in pediatric head CT.

### CLINICAL RELEVANCE/APPLICATION

Relative to EID-CT, PCCT can be tailored by the end user to: 1) maintain or slightly improve image quality while reducing radiation dose, or 2) significantly improve image quality at comparable dose in pediatric neuro CT.

## M1-SSPD02-2 GLYMPHATIC CLEARANCE ANALYSIS FROM DIFFUSION TENSOR IMAGE ALONG THE PERIVASCULAR SPACE IN CHILDREN DURING THEIR FIRST FIVE YEARS OF LIFE

Camilo Calixto, MD (*Abstract Co-Author*) Nothing to Disclose
Jeremy N. Ford, MD,MBA (*Abstract Co-Author*) Nothing to Disclose
Camilo Jaimes Cobos, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Lilla Zollei (*Abstract Co-Author*) Nothing to Disclose
Maria Camila Cortes Albornoz, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluate age-related changes in glymphatic clearance using the ALPS (Along Perivascular Space) index from diffusion tensor imaging (DTI) in children during the first five years of life

### METHODS AND MATERIALS

This retrospective cross-sectional analysis of a publicly available data set was IRB-approved and HIPAA-compliant. The data utilized were acquired as part of the Lifespan Developing Human Connectome Project from the NIMH. Data were prospectively acquired on a 3T MRI Siemens scanner with a 32channel head coil. Diffusion-weighted MR images (dMRI) were acquired with 4 shells (b0 = 0 s/mm2, b1 = 400, 1000, 2600 s/mm2), in-plane resolution 1.5 × 1.5 mm, 3 mm slice thickness, TE = 90 ms, TR = 3800 ms. DTI maps were calculated using DSI Studio (https://dsi-studio.labsolver.org/). We placed four regions of interest along the association and projection fibers of both hemispheres (superior longitudinal fasciculus and superior corona radiata of the periventricular area) (Fig1A). The ALPS index was then calculated as described by Taoka T et al. (2017). To investigate the effect of age on the ALPS index, we used linear regression with age as the predictor, sex and laterality as co-variates. We also estimated the amount of subject motion (translation and rotation) during the diffusion acquisition using FSL and incorporated these two measurements as co-variates in the regression. All statistical analyses were done using R statistical software

### RESULTS

We examined 79 DTI images from children (44 females) aged 2 to 65 months (median 23 months). The mean ALPS index was 1.306 (range, 1.084 - 1.571). Age showed a significant positive association with the ALPS index, (ß-estimate: 0.0035; 95% CI: 0.0019 to 0.0051, P<001) Fig1B. We found no differences in laterality. Sex, image rotation, and translation had no statistically significant relation with the model.

### CONCLUSION

We found significant increase in ALPS index with age, which may suggest increasing glymphatic activity in the first five years of life. These findings provide a preliminary benchmark for future studies analyzing glymphatic clearance in children and suggest that it could be utilized as a biomarker in neurodevelopmental disorders.

### CLINICAL RELEVANCE/APPLICATION

Malfunction of the glymphatic system responsible for brain waste removal, is closely related to the pathophysiology of neurological disorders, such as neurodegenerative disorders, epilepsy, brain trauma, and autism, among others. This work probes normal glymphatic clearance in children for the first time. This pioneering approach holds immense promise in revolutionizing pediatric neurological care, offering invaluable insights into pathophysiology, therapeutic efficacy, and prognosis using glymphatic clearance as a surrogate of brain health.

## M1-SSPD02-4 SEGMENTATION-FREE PRETHERAPEUTIC BRAF-STATUS IDENTIFICATION OF PEDIATRIC LOW-GRADE GLIOMAS

Matthias W. Wagner, MD (*Abstract Co-Author*) Nothing to Disclose
Uri Tabori (*Abstract Co-Author*) Nothing to Disclose
Birgit B. Ertl-Wagner, MD, PhD (*Abstract Co-Author*) Spouse, Employee, Siemens AG
Farzad Khalvati, PhD, MSc (*Abstract Co-Author*) Board of Directors, MESH Scheduling Inc
Khashayar Namdar, MSc, MEng (*Abstract Co-Author*) Nothing to Disclose
Kareem Kudus (*Presenter*) Nothing to Disclose

### PURPOSE

BRAF status is currently obtained by analyzing tumor tissue and is crucial for treating pediatric low-grade gliomas (pLGG). It has been shown that BRAF status can be identified non-invasively from the tumor regions of MRIs using machine learning (ML) models. However, manual tumor segmentations are irreproducible and tedious to generate, while automatic segmentation models are unreliable. Here we introduce an ML classification pipeline that identifies BRAF status from whole MRIs, only relying on tumor segmentations for pretraining, resulting in a more reliable and thus clinically useful model.

### METHODS AND MATERIALS

In this REB-approved retrospective study, genetic status and FLAIR MRIs were collected from 455 patients with pLGG treated between 1999 and 2020 at a single hospital. Previous works suggest that automated segmentation models fail in certain cases. We tested whether this was true on our dataset by training and evaluating three popular medical segmentation models, TransBTS, MedNeXt, and MedicalNet. Next, we tested the feasibility of identifying BRAF status from whole MRIs, without segmentations, using a classification model derived from the architecture that performed best on the segmentation task. We hypothesized that if the tumor region was highlighted, classification performance would improve. Thus, we conducted another set of experiments where pretraining was employed to embed segmentation knowledge into the model before training it to classify pLGGs based on whole MRIs.

### RESULTS

The MedNeXt segmentation model (mean Dice score: 0.555) outperformed both the convolutional neural network (CNN) based MedicalNet (0.516) and the CNN-transformer hybrid TransBTS (0.449). None of these models produced reliable segmentations; each missed the tumor completely for numerous patients. The MedNeXt style classification model achieved a one-vs-rest area under the ROC curve of 0.741 using the whole MRI as an input, without any segmentation knowledge. This was improved to 0.772 through pretraining on the segmentation task. No segmentation was used in test. All differences in model performance were statistically significant (p-value <0.05).

### CONCLUSION

BRAF status can be identified non-invasively by ML models relying on whole MRIs. Dependence on inconsistent manual or automatic segmentations can be eliminated by integrating tumor region information into the model through pretraining.

### CLINICAL RELEVANCE/APPLICATION

It has previously been shown that BRAF status can be identified non-invasively from tumor regions of MRIs using ML models. Here we introduce a classification model that only relies on segmentations for pretraining, not once deployed, resulting in a more robust pipeline suitable for clinical deployment.

## M1-SSPD02-5 EXPLORING THE ASSOCIATION BETWEEN ANNULAR FISSURES AND PEDIATRIC CERVICAL SPINAL CORD INFARCTION

Richard Jones, PhD (*Abstract Co-Author*) Nothing to Disclose
Bryan Philbrook (*Abstract Co-Author*) Researcher, Eisai Co, Ltd
J. Damien Grattan-Smith, MBBS (*Abstract Co-Author*) Nothing to Disclose
Stephen B. Little, MD (*Abstract Co-Author*) Nothing to Disclose

Ashishkumar K. Parikh, MD (*Abstract Co-Author*) Nothing to Disclose
Andrew Reisner (*Abstract Co-Author*) Nothing to Disclose
Farid Hajibonabi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Spinal cord infarction is an acute, potentially lethal injury with significant morbidity among survivors. The pathologic finding of multiple microscopic emboli of nucleus pulposus material within the intrinsic spinal vasculature has been well documented following non-traumatic spinal cord infarction. Although previously thought to be rare, there is an increasing body of literature suggesting fibrocartilage embolism may be a more common cause of non-traumatic spinal cord infarction than generally accepted. We hypothesize that annular fissures may be of particular importance in the pathophysiology of non-traumatic cervical spinal cord infarction in children. In this study, we assessed the relative incidence of annular fissures in children with and without cervical spinal cord infarction.

**METHODS AND MATERIALS**

In this IRB approved retrospective study, annular fissure frequency was determined in all children with non-traumatic cervical cord infarction (2004 to 2023) alongside two control groups: children with other non-compressive cervical myelopathies (Group 1, 2004 to 2014) and children without myelopathy (Group 2, Mar to Jul 2014). The diagnosis of cervical cord infarction was confirmed by two pediatric neuroradiologists, supported by the patients' cerebrospinal fluid analysis and clinical findings. SPSS (IBM v29.0) was used for data analysis, with significance set at $p<0.05$.

**RESULTS**

A total of 156 children including 18 with cervical spinal cord infarction and 138 without (Group 1: 39 with other myelopathies; Group 2: 99 with no myelopathies) were studied. The mean (SD) age was 10.04 (5.81) years, with 48.1% (75/156) of the patients being female. Annular fissures were present in 28.8% (45/156) of patients across = 1 disc levels. 88.9% (16/18) of cervical spinal cord infarct patients had = 1 annular fissure. Age and gender showed no significant correlation with spinal cord infarct occurrence. The odds ratio of having an annular fissure was 30.06 (CI [6.53 - 138.30]) in spinal cord infarct patients compared to the total control group (Group 1+ Group 2). Furthermore, the odds ratio of having an annular fissure in the spinal cord infarct group compared to Group 1 was 26.66 (CI [5.13-138.56]) and compared to Group 2 was 31.60 (CI [6.70-148.83]).

**CONCLUSION**

Our study highlights a strong association between annular fissures and cervical spinal cord infarction in children. Further investigation is needed as to whether this could support the postulated theory of embolization of nucleus pulposus material through annular fissures into the cervical spinal cord microcirculation.

**CLINICAL RELEVANCE/APPLICATION**

Annular fissures are strongly associated with non-traumatic pediatric cervical spinal cord infarction, warranting attention from radiologists.

## M2-STCE1-1 REDUCING ENERGY CONSUMPTION IN MRI USING SHORTER SCAN PROTOCOLS, OPTIMIZED MAGNET COOLING PATTERNS AND DEEP LEARNING SEQUENCES: HOW LOW CAN WE GO?

Sebastian Gassenmaier, MD (*Abstract Co-Author*) Nothing to Disclose

### PURPOSE

The significant rise in energy costs across Europe, combined with the high energy demands of MRI scanners in radiology departments, underscores the need for strategies to optimise energy usage without compromising efficiency or image quality. This study examines MRI energy consumption and identifies methods to enhance energy efficiency, with a particular focus on musculoskeletal MRI. Three approaches to potential savings are evaluated: 1) optimising protocols, 2) integrating deep learning (DL) accelerated acquisitions, and 3) enhancing the cooling system (see Figure 1).

### METHODS AND MATERIALS

Energy consumption measurements were conducted on two MRI scanners (1.5T Aera, 1.5T Sola) at medical practices in Munich, Germany, from December 2022 to March 2023. Three levels of energy reduction measures were implemented and compared to the baseline. The Wilcoxon signed-rank test with Bonferroni correction was employed to evaluate the impact of these measures on sequence scan times and energy consumption.

### RESULTS

The results demonstrated that significant energy savings could be achieved by optimising protocol settings and implementing DL technologies. The average energy consumption across all body regions was reduced by 72% with DL and 31% with economic protocols. Furthermore, scan times were reduced by 71% with DL and 18% with economic protocols compared to the baseline (Figure 2 and 3). Optimising the cooling system during non-scanning periods resulted in a 30% reduction in energy consumption.

### CONCLUSION

The implementation of energy-saving strategies, including economic protocols, DL accelerated sequences and optimised magnet cooling, has the potential to significantly reduce the energy consumption of MRI scanners. It is recommended that radiology departments and practices adopt these measures in order to enhance energy efficiency and reduce costs.

### CLINICAL RELEVANCE/APPLICATION

The implementation of energy-saving strategies in radiology departments has the potential to reduce operating costs and minimise environmental impact, thereby contributing to greater sustainability without compromising diagnostic quality. Furthermore, the number of patients that can be examined is increased, thereby expanding the department's capacity.

## M2-STCE1-2 BREAST CANCER ARTIFICIAL INTELLIGENCE ALGORITHM IMPROVES CANCER DETECTION RATE EQUITABLY ACROSS RACE AND ETHNICITY

Edgar Wakelin (*Abstract Co-Author*) Nothing to Disclose
Bryan Haslam, PhD (*Abstract Co-Author*) Employee, RadNet, Inc

### PURPOSE

Large prospective studies in breast cancer screening have shown that AI can improve cancer detection rate (CDR). However, no studies have investigated whether these benefits are equitable across populations. Here, we perform a retrospective analysis of a prospective deployment of an AI augmented digital breast tomosynthesis (DBT) reading program across a large and diverse US population. We test the hypothesis that changes in radiologist performance when reading with vs. without the AI are equal across racial and ethnic subgroups.

### METHODS AND MATERIALS

An AI CADe/x device was run on all eligible screening mammograms at 5 practices (200 sites, 107 radiologists) from June 3, 2022 - Nov 2, 2022. Data from Aug 3 - Nov 2, 2022 was used to characterize radiologist performance with the AI (Post-AI, N=167 809). To characterize performance without the AI, data on eligible exams from Sep 1, 2021 - May 19, 2022 was collected (Pre-AI, N=419 551). The period from June 3 - Aug 3, 2022 was used as a 2 month washout period to allow radiologists to learn the new workflow. Data collected included BI-RADS interpretation, patient self-identified race and ethnicity, and biopsy outcomes up to 12 months after the screening exam. ?2 tests were used to evaluate significance of changes in CDR and recall rate (RR) for the whole population, White non-Hispanic (W), Black non-Hispanic (B), and Hispanic women (H). To test for differences between groups, a general linear model was fit with terms for the treatment (Pre-AI vs. Post-AI), demographics, and the interaction between the terms. For all tests, the significance threshold was ?<0.05.

### RESULTS

After the breast cancer AI was deployed, CDR increased across the whole population (?0.83 or 18%, 95% CI 0.44 - 1.21, p<0.01), and for all of the populations of interest (W: ?0.81 or 14%, p=0.03, B: ?0.95 or 21%, p=0.02, H: ?0.83 or 24%, p=0.02). The interaction between the AI and demographic group was not significant (B vs. W: p=0.53, H vs. W: p=0.44, B vs. H: p=0.85), indicating that the improvement in CDR with the AI did not differ between populations. RR also increased after deployment, but to a lesser extent (Pre-AI 10.9%, Post-AI 11.5%, increase of 6%, p<0.01). Recall rate Post-AI did not differ between populations (B vs. W: p=0.66, H vs. W: p=0.12, B vs. H: p=0.29).

### CONCLUSION

Radiologist cancer detection performance improved with the use of an AI augmented DBT reading program similarly across all demographics investigated. AI algorithms with robust and diverse training data can avoid the pitfalls of bias and improve radiologist clinical performance for all demographics.

### CLINICAL RELEVANCE/APPLICATION

Prospective deployment of a breast cancer AI platform on a large diverse population suggests radiologist improvement is not dependent on patient race and ethnicity.

## M2-STCE1-3 INITIAL DATA FROM A SCREENING MAMMOGRAPHY PROGRAM INSIDE SUPERWALMART

A. Gregory Sorensen, MD (*Abstract Co-Author*) Employee, RadNet, Inc;Board member, IMRIS Inc;Board member, Siemens AG;Board member, DFB Healthcare Acquisitions Corp;Board member, inviCRO, LLC;;;;

Matthew McCabe, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Many women eligible for breast cancer screening do not comply with the most recent guidelines in part because access to screening is not convenient. Reduced rates of participation are amplified in at-risk populations, leading to delayed diagnoses and ultimately poorer prognosis. We launched a pilot program to bring screening mammography (MG) to a more convenient setting: inside SuperWalmart. Here we report early observations on whether this approach improves access by comparing population demographics and recent MG history in a retail setting vs. a traditional radiology clinic.

### METHODS AND MATERIALS

A screening MG center was opened in a SuperWalmart store in a rural town in Delaware. This center was affiliated with an outpatient imaging network with 7 other "traditional" facilities in Delaware. The SuperWalmart location was selected in part to be within 20 miles of another imaging center so that women could get diagnostic follow-up at a convenient distance, but still be far enough away to enable screening access to a different group of women. We report on the self-reported demographics and our past screening records for the first 500 women screened in comparison to the 28,208 women screened at the traditional facilities during the same timeframe. Continuous variables were compared using a T-Test, and categorical variables with a Chi Squared test. A generalized linear model was used to evaluate cancer detection rate (CDR), recall rate (RR) and positive predictive value (PPV) controlling for demographics.

### RESULTS

We found that the SuperWalmart cohort had fewer patients with a prior mammogram at an affiliated location since 2021 (24.4% vs 76.3%, $p < 0.001$) compared to the traditional radiology practice. The SuperWalmart cohort was also significantly younger (57.36 SD = ±11.15 vs 60.1±11.51 years, $p < 0.001$) and had a lower proportion of White and Asian women (White: 63% vs 67%, $p = 0.04$, Asian: 2% vs 5%, $p = 0.001$), and higher proportion of Hispanic ethnicity (10% vs 5%, $p < 0.001$). RR (p=0.78), CDR (p=0.48), and PPV (p=0.60) were similar across the cohorts with the data available and up to 8 months of follow-up.

### CONCLUSION

The observed 3-fold increase in the proportion of exams in women who did not have prior mammograms at affiliated practices since 2021, younger population, and greater proportion of women who identify as Hispanic indicates the retail setting provides patient care to a new population. Retail placement of screening MG may be a valuable approach to increase equitable access to breast cancer screening.

### CLINICAL RELEVANCE/APPLICATION

Initial results suggest retail locations for breast cancer screening could extend services to populations that experience barriers to traditional healthcare.

## M2-STCE2-1 QUANTIFICATION OF LEFT VENTRICULAR LATE GADOLINIUM ENHANCEMENT FOR THE PRIMARY PREVENTION OF VENTRICULAR ARRHYTHMIAS IN ARRHYTHMOGENIC RIGHT VENTRICULAR CARDIOMYOPATHY

Shihua Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Yanyan Song (*Abstract Co-Author*) Nothing to Disclose
Zhixiang Dong (*Presenter*) Nothing to Disclose

### PURPOSE

A novel risk-prediction model based on clinical data and right ventricular imaging tests was developed to provide an individualized estimate of sustained ventricular arrhythmias (VA) in patients with arrhythmogenic right ventricular cardiomyopathy (ARVC), but it was recently shown to potentially underestimate the risk when left ventricle (LV) was involved. It remains unclear whether the quantification of LV cardiovascular magnetic resonance (CMR) late gadolinium enhancement (LGE) provides additional value in predicting arrhythmic events in ARVC. This study sought to explore whether LV LGE could serve as an independent predictor of the first episode of sustained VA, thus further improving the risk stratification of ARVC.

### METHODS AND MATERIALS

A total of 283 consecutive patients (median age, 38 [IQR, 27-49] years; 179 male) with a definite ARVC diagnosis, no history of sustained VA at diagnosis, and CMR performed at baseline were retrospectively enrolled for analysis. The novel 5-year ARVC risk score was retrospectively calculated based on the patients' baseline characteristics. The primary outcome was defined as the first episode of sustained VAs (sustained ventricular tachycardia, ventricular fibrillation/flutter, sudden cardiac death, aborted cardiac arrest, and appropriate implantable cardioverter-defibrillator intervention). Univariable and multivariable Cox regression analysis was performed to evaluate the independent predictive value of LV LGE. Restricted cubic spline was used to flexibly model the association between LV LGE volume and hazard of sustained VAs. Additional prognostic value of LV LGE beyond 5-year ARVC risk score was evaluated using Kaplan-Meier curves, calibration plot, and likelihood ratio test.

### RESULTS

Of the 283 definite ARVC patients, LV LGE was observed in 183 (64.7%) subjects. Over a median follow-up of 42.8 months, 88 (31.1%) patients experienced sustained VAs. LV LGE volume remained an independent predictor after adjusting for important clinical and CMR variables in the multivariable analysis (HR, 1.08 [1.05-1.10]; P<0.001). The restricted cubic spline analysis indicated that the risk of sustained VAs was relatively flat until LV LGE volume reached approximately 10%, after which it started to increase rapidly. At Kaplan-Meier analysis, patients with both a 5-year ARVC risk score=25% and LV LGE=10% had the highest risk of sustained VAs. Notably, even among those with a 5-yeaer ARVC risk score<25%, patients with LV LGE=10% had a worse prognosis than those with LV LGE<10% (Log-rank P=0.02). Risk estimates for sustained VAs using the 5-year risk score showed a tendency to underestimate risk in patients with LV LGE=10% and to overestimate it in those with LV LGE<10%. When both LV LGE and 5-year risk score were considered together, receiver operating characteristic analysis showed an increase in predictive accuracy at 5 years (area under the curve from 0.69 to 0.80). The likelihood ratio test also demonstrated a significantly incremental prognostic value of LV LGE when added to the existing 5-year ARVC risk model (P<0.001).

### CONCLUSION

LV LGE was an independent predictor of the first episode of sustained ventricular arrhythmias in ARVC patients and may enhance the 5-year prediction of arrhythmic outcomes when incorporated into the novel ARVC risk calculator.

### CLINICAL RELEVANCE/APPLICATION

With the increased awareness of a broader phenotypic spectrum of arrhythmogenic right ventricular cardiomyopathy, the prognostic value of left ventricular involvement has attracted intense interest. Our study demonstrated that left ventricular late gadolinium enhancement was independently associated with the first occurrence of sustained ventricular arrhythmias in definite arrhythmogenic right ventricular cardiomyopathy patients and could improve risk prediction on the basis of the proposed 5-year risk calculator, which might further refine the primary prevention strategies of the disease.

## M2-STCE2-2 CAN WE IDENTIFY PATIENTS WHO WILL NOT BENEFIT FROM [$^{177}$LU]LU-DOTATATE TREATMENT EARLY IN THEIR TREATMENT COURSE? YES, WE CAN

Joseph Steiner, PHD (*Abstract Co-Author*) Nothing to Disclose
Madeleine Hinojos, MD (*Abstract Co-Author*) Nothing to Disclose

Onur Tuncer, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Current FDA-recommended standard therapy of [177Lu]Lu-DOTATATE for gastroenteropancreatic neuroendocrine tumor (GEP-NET) patients consists of administering the drug every two months for a total of four cycles, the same for every patient. However, due to highly heterogeneous nature of GEP-NETs, patient responses vary. Our aim is to identify patients unlikely to benefit from this treatment early, enabling a timely switch to alternative therapies and thereby reducing unnecessary toxicities and financial burdens.

**METHODS AND MATERIALS**

GEP-NET patients who completed the FDA-recommended [177Lu]Lu-DOTATATE treatment schedule were retrospectively selected. All patients underwent SPECT/CT imaging at the end of each treatment session according to our institutional protocol. Initial SPECT/CT scans served as the baseline. Maximum axial tumor diameter and the number of tumoral foci were used to calculate the previously defined Tumor Burden Score. Peak counts were automatically measured in predetermined target lesions on SPECT images with commercially available Syngo.Via software and normalized using spleen peak counts. Patient overall treatment responses were evaluated using third-month follow-up CT images according to revised RECIST criteria and binarized as progressive disease (PD) or non-PD. Changes in Tumor Burden Score and normalized peak counts after each treatment session relative to baseline (?TBS2nd-1st, ?TBS3rd-1st, ?TBS4th-1st; ?nPC2nd-1st, ?nPC3rd-1st, ?nPC4th-1st) were calculated and compared between PD and non-PD groups. ROC curves were plotted to predict PD cases, Area Under the Curves (AUCs) were calculated.

**RESULTS**

27 patients were included (7 PD, 20 non-PD). Significant differences were observed in ?nPC2nd-1st, ?TBS2nd-1st, ?TBS3rd-1st, and ?TBS4th-1st between PD and non-PD ($P = 0.033$, 0.023, 0.002, and $< 0.001$, respectively). At the optimal threshold, ?TBS4th-1st exhibited AUC of 0.957, achieving 100% sensitivity and 80% specificity. ?TBS2nd-1st and ?TBS3rd-1st reached AUCs of 0.793 and 0.893, sensitivities of 71.4%, and specificities of 85% and 95%, respectively. ?nPC2nd-1st showed AUC of 0.764 sensitivity of 71.4% and specificity of 75%.

**CONCLUSION**

Patients whose Tumor Burden Scores and normalized peak counts increase or remain relatively stable throughout the treatment are less likely to benefit from [177Lu]Lu-DOTATATE therapy and may consider switching to alternative treatment strategies.

**CLINICAL RELEVANCE/APPLICATION**

[177Lu]Lu-DOTATATE therapy is promising but comes with toxic side effects and high costs. Early transition to alternative treatment strategies for patients unlikely to benefit prevents treatment delays, which can be up to eight months, avoids resource waste, and minimizes toxicities.

Sundus Lateef, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Our goals are to (1) describe the silicosis imaging phenotype in a unique patient population - engineered stone countertop workers who are exposed to higher concentrations and different mixtures of silica dust than historically described silicosis cases, (2) correlate chest computed tomography (CT) findings with clinical severity as measured by pulmonary function tests (PFTs), and (3) assess primary provider and radiologist awareness of silicosis at presentation.

### METHODS AND MATERIALS

We performed a cross-sectional pilot study at a large urban safety-net hospital with few historic cases of silicosis. The pilot analysis included 21 patients diagnosed with silicosis with available CT and PFTs. The CT images were classified as typical or atypical for chronic silicosis defined as mediastinal lymphadenopathy and upper-lobe predominant small nodularity and/or progressive massive fibrosis. Standard descriptive statistics and preliminary inferential statistics were performed. Initial clinician/radiologist impression was graded in a binary fashion for recognition of silicosis. Given pilot nature, no a priori power calculations or evaluation for interrater reliability were performed. The full cohort of 55 patients diagnosed with silicosis will be analyzed for the current presentation.

### RESULTS

Fifty-five engineered stone workers with silicosis were identified, of which 21 underwent preliminary analysis. Of these, 100% were male and Hispanic with median age of 43 years (IQR 36-49) and median exposure of 18 years (IQR 10-22). All patients were symptomatic, with dyspnea (91%, 19/21) and cough (81%, 17/21) the most common symptoms. Recognition of silicosis at the initial encounter was 19% (4/21) by the primary clinicians and 33% (7/21) by the radiologists, with alternative diagnoses (especially, mycobacterial/atypical infection) initially suggested in most cases. Upon secondary retrospective review, 52% (11/21) of cases were typical for classic silicosis. The other 48% (10/21) had atypical imaging features (e.g. diffuse nodularity, multiple cavitary lesions, ground-glass/mosaic attenuation and/or crazy paving). PFTs revealed a restrictive pattern in 85% (18/21). In addition, patients with consolidations (including large opacities >1 cm) had lower DLCO than patients without large opacities (18.1 ± 2.7 vs. 24.5 ±1.7, p=0.02). These correlative/inferential statistics should be interpreted with caution prior to the analysis of all 55 patients.

### CONCLUSION

Engineered stone countertop workers commonly present with atypical and advanced features of silicosis.

### CLINICAL RELEVANCE/APPLICATION

The unexpected resurgence of a new silicosis epidemic with atypical features may catch providers off-guard and lead to delays in diagnosis.

## M3-SSCH03-2 IMPROVING INTERREADER AGREEMENT IN CT PATTERN CLASSIFICATION FOR DIAGNOSIS OF IDIOPATHIC PULMONARY FIBROSIS USING CONTENT-BASED IMAGE RETRIEVAL

**PURPOSE**

To evaluate the effect of a proposed content-based image retrieval (CBIR) of similar chest CT images on readers' classification of CT patterns for the diagnosis of idiopathic pulmonary fibrosis (IPF).

**METHODS AND MATERIALS**

This retrospective study included patients who underwent high-resolution chest CT (HRCT) between 2013 and 2015 for the initial work-up for fibrosing interstitial lung disease. HRCT scans were independently classified into four categories according to the 2011 guideline for the diagnosis of IPF by two thoracic radiologists and discordant cases were resolved by consensus meeting with a tertiary thoracic radiologist. One-hundred patients were selected as queries from the database. The proposed CBIR retrieved the top three similar CT images with providing predetermined usual interstitial pneumonia (UIP) classifications from the database by comparing the extent and distribution of six regional disease patterns quantified by a deep-learning algorithm. Two radiology residents and two thoracic radiologists classified CT patterns of the query CT images in two reading sessions 3 weeks apart, without and with CBIR results. Inter-reader agreement was analyzed by using Fleiss k and diagnostic accuracies of two reading sessions were compared by using McNemar test.

**RESULTS**

Of 587 patients included (mean age, 63 years; 356 men), 148 were classified into UIP pattern, 155 with probable UIP pattern, 31 with indeterminate for UIP, and 253 with alternative diagnosis. Overall survival was stratified based on the CT patterns (Log-rank $P < 0.001$). Interreader agreement improved after applying CBIR (Fleiss k, 0.382 to 0.514). Diagnostic accuracies improved in all readers (reader 1: 61.0% to 64.0%, reader 2: 60.0% to 64.0%, reader 3: 62.0% to 69.0%, and reader 4: 80.0% to 84.0%), but there was no statistical significance ($P = 0.12$ to 0.73) after applying CBIR. Readers tended to classify cases into indeterminate for UIP or alternative diagnosis more frequently after applying CBIR, compared to stand-alone reading (152 before CBIR and 184 after CBIR). With CBIR results, more cases moved from UIP or probable UIP pattern to indeterminate for UIP or alternative diagnosis, compared to vice versa (sum of readers' results, 51 vs. 18).

**CONCLUSION**

The proposed CBIR system improved interreader agreement of CT pattern classification for the diagnosis of IPF in readers with varying levels of experience.

**CLINICAL RELEVANCE/APPLICATION**

This CBIR system may guide consistent work-up and treatment strategies by enhancing interreader agreement of CT pattern classifications.

## M3-SSCH03-3 UTILITY OF CT-BASED DELTA-RADIOMICS FOR PREDICTION OF PATHOLOGICAL COMPLETE RESPONSETO NEOADJUVANT IMMUNOTHERAPYIN NSCLC PATIENTS

Ying Liu (*Abstract Co-Author*) Nothing to Disclose
Qiliang Wang (*Abstract Co-Author*) Nothing to Disclose
Jingyi Yang (*Abstract Co-Author*) Nothing to Disclose
Zhao Xiang Ye, PhD (*Abstract Co-Author*) Nothing to Disclose
Fan Liu (*Abstract Co-Author*) Nothing to Disclose
Fangyuan Qu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a unified CT-based delta radiomics model to integrate serial imaging data at different time points and assess its predictive capacity of differentiate pathologic complete response (pCR) or non-pCR status in patients with resectable stage II/IIIA non-small-cell lung cancer (NSCLC) after neoadjuvant immunotherapy.

**METHODS AND MATERIALS**

209 eligible patients with histologically confirmed NSCLC between November 2018 and January 2024 were retrospectively enrolled and they were randomly divided into training and testing sets at a ratio of 7: 3 (training: 146 patients; testing: 63 patients). Absence of residual tumor cells in both tumor bed and lymph nodes was defined as pCR. CT examinations were performed at baseline (TP0) and following 3-4 cycles of neoadjuvant immunotherapy (TP1). Tumor boundary was delineated manually on nonenhanced CT images using 3D-slicer software. A total of 1688 radiomics features were extracted from the TP0 and TP1, and then Delta-radiomics feature was calculated as the relative net change in radiomics feature between TP0 and TP1. We applied PCC, Relief and analysis of variance (ANOVA) to eliminate redundant features. LASSO regression analysis was used to determine optimal radiomics features. Two machine learning models, one based on TP0 radiomics features and the other based on Delta-radiomics features, were developed for the prediction of pCR and model performance was evaluated using ROC analysis, calibration curve and decision curve analysis (DCA).

**RESULTS**

Among the enrolled patients, 93 achieved pCR (44.4%). According to RECIST 1.1, 11 patients (5.3%) had a complete response (CR), 124 (59.3%) showed a partial response (PR), and 74 (35.4%) had stable disease (SD). Radiomics signatures with a selection of the 6 and 5 optimal features were developed for baseline radiomics model and Delta-radiomics model respectively. Delta-radiomics model demonstrated satisfactory performance in distinguishing pCR from non-pCR with AUCs of 0.74 (95% CI: 0.66-0.82) and 0.71 (95% CI: 0.58-0.84) in the training and testing sets respectively, which had an obvious advantage over baseline radiomics model (AUC in training: 0.60, AUC in testing: 0.54). With the optimal cutoff value for Delta-radiomics model above 0.4064, pCR may be detected with a sensitivity of 85.7% and a specificity of 57.1%. DCA demonstrated a net benefit of using Delta-radiomics model for adjuvant treatment decision support compared to default strategies ("treat all" or "treat none") and the baseline radiomics model.

**CONCLUSION**

Delta-radiomics model showed good performance for predicting pCR to neoadjuvant immunotherapy in patients with resectable stage II/IIIA NSCLC.

**CLINICAL RELEVANCE/APPLICATION**

Delta-radiomics model allows screening for benefit.

## M3-SSCH03-4 THE ROLE OF IMAGING BIOMARKERS IN PREDICTING OUTCOMES FOR PATIENTS WITH NON-IPF FIBROTIC ILD

Katharina Abbasi Dezfouli, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Although fibrotic interstitial lung diseases (fILD) are associated with impaired prognosis, the ability to prognosticate and predict disease trajectory remains very limited. The aim of this study was to analyse baseline clinical data and computed tomography (CT) based imaging parameters of patients with non-IPF fILD as predictors for progressive pulmonary fibrosis (PPF).

**METHODS AND MATERIALS**

Records in a prospectively collected database of 399 patients with non-IPF fILD managed between January 2012 to December 2022 at the tertiary referral center for ILD at the University Hospital Heidelberg were retrospectively screened for clinical (e.g. demographics, lung function, clinical features of progression) and radiological parameters. Patients =18 years, who underwent supine, baseline, and follow-up high resolution CT (HRCT) scans (thin slice (=2mm), volumetric, axial, non-contrast enhanced) covering the complete lung at full inspiration were identified. AI-based quantification of fibrotic lung tissue was performed with e-Lung (Brainomix (Oxford, UK)), using the Weighted Reticulovascular Score (WRVS) as an imaging biomarker for pulmonary fibrosis. Based on clinical and imaging parameters, multivariate Cox models were applied to calculate predictors of death and significant decline in lung function (relative decrease in forced vital capacity (FVC) =10%).

**RESULTS**

A total of 347 patients were included in the analysis. The WRVS increased over time as an image-based sign for progressive fibrosis. Independent baseline clinical risk factors for death were advanced age (HR 1.1 CI 1.0-1.1, p<0.001) and the presence of chronic renal failure (HR 2.1 CI 1.1-4.0, p=0.02). WRVS (% of total lung volume) was a strong imaging-based predictor for death (HR 1.1 CI 1.1-1.2, p<0.001). No lung function parameters could independently predict mortality in multivariate analyses. Clinical risk factors for =10% FVC decline were the occurrence of acute exacerbations (HR 2.3 CI 1.6-3.5, p<0.001) and baseline FVC (HR 1.0 CI 1.0-1.0, p=0.002). Again, WRVS was an independent risk factor for 10% FVC decline (HR 1.1 CI 1.0-1.1, p=0.017).

**CONCLUSION**

In this studied cohort of patients with non-IPF fILD, e-Lung based imaging biomarkers applied to baseline HRCTs were a valuable predictor of progressive disease.

**CLINICAL RELEVANCE/APPLICATION**

This AI-based approach to quantify alterations in lung texture due to fibrosis might be a valuable tool to prognosticate patient outcome at an early stage of the disease. This can help to identify those patients at risk, to intensify therapy as soon as possible, and therefore improving their prognosis.

## M3-SSCH03-5 DEEP LEARNING FOR SEPARATE QUANTIFICATION OF PULMONARY ARTERIES AND VEINS ON NON-ENHANCED CHEST CT: PROGNOSTIC VALUE IN PATIENTS WITH CONNECTIVE TISSUE DISEASE

Joon Beom Seo, MD, PhD (*Abstract Co-Author*) Stockholder, Promedius Inc;Stockholder, Coreline Soft, Co Ltd;Stockholder, Anymedi Inc

Jihwan Kim, BSc, MSc (*Abstract Co-Author*) Nothing to Disclose
Jooae Choe, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Currently, accurately quantifying pulmonary arteries (PA) and veins (PV) separately on nonenhanced CT (NECT) scans in patients with fibrosing interstitial lung disease remains challenging. This study aimed to develop deep learning algorithms for separate quantification of PA and PV on NECT and to evaluate their prognostic value in patients with connective tissue disease (CTD).

**METHODS AND MATERIALS**

We conducted a retrospective study involving CTD patients who underwent NECT for interstitial lung disease (ILD) screening or follow-up from August 2012 to October 2019. A deep learning algorithm (nnU-Net) was developed to accurately quantify PA separately from PV on NECT, using a training set derived from a different cohort with enhanced CT and gold standard PA segmentation masks, which were finally converted to simulate NECT images for training. PV was quantified by subtracting PA from total pulmonary vessel masks. Quantitative analysis of PA and PV was performed, and the prognostic value of these parameters was assessed using Cox analysis.

**RESULTS**

The study included 120 CTD patients (median age 52 years; 43 males) and 55 healthy controls (median age 42 years; 24 males). 10% of CTD patients developed pulmonary hypertension, and 27% died during follow-up. Significant differences in vascular QCT metrics such as peripheral mean PA diameters, volumes of PA and PV, and PV to PA ratios for small vessels were observed between CTD patients and controls (all, P<.05). These metrics correlated significantly with pulmonary function measures, FVC and DLCO (r, 0.23-0.49; all, P<.001). For mortality, PV5/PA5 (the ratio of PV to PA with a cross-sectional area of <5mm², adjusted HR: 1.12; P<.001) was an independent predictor along with age, but BV5/TBV% (the percentage of blood vessels, aggregating both PA and PV with a cross-sectional area of <5mm²) was not. For PV5/PA5, mortality was significantly stratified based on a threshold value of 7.0 (P<.001).

**CONCLUSION**

Our study developed and validated a deep learning algorithm capable of separately quantifying PA and PV on NECT in patients with CTD. The distinct quantification of PA and PV, as opposed to a combined assessment, revealed significant predictive value for mortality outcomes.

## CLINICAL RELEVANCE/APPLICATION

Our study highlights the benefits of detailed vascular analysis for PA and PV over aggregated measures on NECT, which could enhance patient stratification in patients with CTD and ILD.

## M3-SSCH03-6 DEVELOPMENT AND MULTI-INSTITUTIONAL VALIDATION OF ESTIMATING FORCED VITAL CAPACITY IN PULMONARY FIBROSIS USING QUANTITATIVE CHEST CT DATA

### PURPOSE

To develop and validate a method for estimating forced vital capacity (FVC) from quantitative CT lung texture in participants with interstitial lung disease (ILD).

### METHODS AND MATERIALS

Linear regression was used to predict FVC from chest CT data. Training data included patients with a diagnosis of ILD comprised of both IPF (idiopathic pulmonary fibrosis) and non-IPF ILD from the Open Source Imaging Consortium with matched same day pulmonary function tests (PFTs) and high resolution CT (HRCT). Models were generated using ILD (N=498) and a subset of this data with non-IPF ILD (N= 307). This was subsequently validated in an external multi-institutional dataset from 39 centers enrolled in the Pulmonary Fibrosis Foundation Patient Registry. Prior to linear regression, 31 features were extracted from chest CT corresponding to lung texture using a commercially available, fully automated AI algorithm with a U-net architecture. Bland-Altman plots, correlation coefficients, and mean absolute error compared the estimated FVC to the actual FVC.

### RESULTS

The validation cohort (N=715) included 61% males and was 89% white. The mean actual FVC in the overall (N=715), IPF (N=411), and non-IPF ILD (N=304) cohorts were 2.63, 2.73, and 2.49 liters. The ILD estimated FVC model had an R2 of 46% with correlation coefficient of 0.68 with mean absolute error of -0.117 in the overall cohort. The non-IPF ILD estimated FVC model had an R2 of 59% with correlation coefficient of 0.77 with mean absolute error of -0.113 across both cohorts. The non-IPF ILD estimated FVC model had an R2 of 59% with correlation coefficient of 0.77 with mean absolute error of -0.166 within the non-IPF ILD cohort.

### CONCLUSION

A fully automated AI algorithm to quantify lung texture features can estimate forced vital capacity using linear regression in patients with ILD.

### CLINICAL RELEVANCE/APPLICATION

Initiation of anti-fibrotic therapy in patients with non-IPF ILD is based on a combination of symptomatic, radiographic, and functional progression. Estimating pulmonary function with CT can potentially be used to evaluate for both functional and radiographic progression. Further investigation is needed to explore the accuracy of estimated FVC for determining pulmonary function decline, progression, and mortality.

Dylan Siltamaki, MD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Patients with pancreatic ductal adenocarcinoma (PDAC) who undergo pancreatectomy have among the worst outcomes of cancer patients undergoing curative-intent treatment. This study determined the impact of pre-operative abdominal MRI on all-cause mortality for patients with resected PDAC.

### METHODS AND MATERIALS

All adult (=18 years) PDAC patients who underwent pancreatectomy between January 2011 and December 2022 in Ontario, Canada, were identified for this population-based cohort study (ICD-O-3 codes: C250, C251, C252, C253, C257, C258). Patient demographics, comorbidities, PDAC stage, medical and surgical management, and survival data were sourced from multiple linked provincial administrative databases at ICES. All-cause mortality was compared between patients with and without a pre-operative abdominal MRI after controlling for multiple covariates.

### RESULTS

A cohort of 4,579 patients consisted of 2,432 men (53.1%) and 2,147 women (46.9%) with mean age 65.2 years (standard deviation: 11.2 years); 2,998 (65.5%) died while 1,581 (34.5%) survived. Median follow-up duration post-resection was 22.4 months (interquartile range: 10.8-48.8 months), and median survival post-pancreatectomy was 25.9 months (95% confidence interval [95%CI]: 24.8,27.5). Patients who underwent a pre-operative abdominal MRI had a median survival of 33.1 months (95%CI: 30.7,37.2) compared to 21.1 months (95%CI: 19.8,22.6) for all others. A total of 2,354/4,579 (51.4%) patients underwent a pre-operative abdominal MRI, which was associated with a 17.2% (95%CI: 11.0,23.1) decrease in the rate of all-cause mortality, with an adjusted hazard ratio (aHR) of 0.828 (95%CI: 0.769,0.890). Other covariates independently associated with improved survival included higher neighborhood income quintile, residence =50 km from the surgical center, fewer comorbidities, no neoadjuvant chemotherapy, earlier stage cancer, no adjuvant chemotherapy, younger age and non-Whipple pancreatectomy.

### CONCLUSION

Pre-operative abdominal MRI was associated with improved overall survival for PDAC patients who underwent pancreatectomy, possibly due to better detection of liver metastases than CT.

### CLINICAL RELEVANCE/APPLICATION

Clinical practice guidelines and clinical trials may benefit from considering abdominal MRI as a mandatory step for the workup of patients who appear to have resectable or borderline resectable disease on CT.

## M3-SSGI05-3 18F-FDG PET/CT IN THE INITIAL STAGING OF SQUAMOUS CELL CANCER OF THE ANAL CANAL: RESULTS OF A PROSPECTIVE MULTICENTER REGISTRY

Aruz Mesci (*Abstract Co-Author*) Nothing to Disclose
Andres Kohan, MD (*Abstract Co-Author*) Nothing to Disclose
Jelena Lukovic, BS (*Abstract Co-Author*) Nothing to Disclose
Deanna L. Langer, PhD (*Abstract Co-Author*) Nothing to Disclose

Victor Mak, MSc (*Abstract Co-Author*) Nothing to Disclose
Lisa Avery, PhD (*Abstract Co-Author*) Nothing to Disclose
Ur Metser, MD, FRCPC (*Presenter*) Consultant, POINT Biopharma Inc

**PURPOSE**

To determine the impact of 18F-FDG PET/CT (PET) on the initial staging of patients with clinical stage II-IV squamous cell carcinoma of the anal canal and to assess association of clinical and PET-determined stage to patient outcomes.

**METHODS AND MATERIALS**

This single arm, prospective multicenter registry enrolled patients between September 2017 to March 2023 with clinical stage II-IV squamous cell carcinoma of the anal canal or with equivocal findings on conventional imaging (CI). Pre-PET clinical stage (based on clinical exam, CT ± MRI), PET stage and overall survival (OS) were recorded. For a subset of patients from one institution, progression free survival (PFS) was documented.

**RESULTS**

The registry cohort was comprised of 813 patients including 556/813 women (68.4%) and 257/813 men (31.6%), with a median age of 64 years (range:25-97). There were 232 patients referred for equivocal findings on CI and 577 patients with a clinical stage of II (326/577; 56.5%), III (229/577; 39.7%) or IV (22/577; 3.8%); clinical stage was missing for 4 patients. A specific stage was assigned to 200/232 patients (86.2%) with equivocal findings on CI after PET. There were 78/813 patients (9.6%) with equivocal findings for a specific stage following PET. Matched clinical and PET stage data was available for 531 patients. Following PET, 150/531 (28.2%) patients were upstaged and 84/531 (15.8%) were downstaged. PFS as shorter for patients with stage IV on PET compared to others (log rank; $p<0.001$), but there was no difference in PFS was observed for patients with pre-PET clinical stage IV vs stage I-III (log rank; $p= 0.556$). There was poorer overall survival for patients with PET stage IV vs stage I-III (log rank; $p=0.0013$), but no significant difference in survival between pre-PET clinical stage IV vs stage II-III (log rank; $p=0.06$).

**CONCLUSION**

PET upstages more than 28% of patients with squamous cell carcinoma of anal canal, compared to clinical stage and offers better prognostication of clinical outcomes. Following PET, a specific stage can be assigned for most patients with equivocal findings on CI.

**CLINICAL RELEVANCE/APPLICATION**

FDG PET/CT frequently impacts stage of patients with squamous cell carcinoma of the anal canal and allows for better prognostication at initial presentation.

## M3-SSGI05-5 PREDICTION OF LYMPH NODE METASTASIS IN RESECTABLE PANCREATIC DUCTAL ADENOCARCINOMA USING DUAL-LAYER SPECTRAL CT

Zheng-rong Zhou (*Abstract Co-Author*) Nothing to Disclose
Yu Wang (*Abstract Co-Author*) Nothing to Disclose
Yi Chen, BMedSc, MMedSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the predictive value of parameters from dual-layer spectral CT (DLCT) derived from the primary tumor for predicting lymph node metastasis (LNM) in patients with resectable pancreatic ductal adenocarcinoma (PDAC).

**METHODS AND MATERIALS**

In this retrospective study, patients with resectable PDAC who underwent three phase enhanced DLCT within two-week before surgery were enrolled. Patients were randomly divided into a training set (74 patients) and a validation set (33 patients). Clinical data, tumor morphological features, and DLCT parameters including tumor location, shape, presence of necrosis, long-axis diameter, iodine concentration (IC) at each enhancement phase and CT-derived extracellular volume (ECV) were collected. ECV was calculated as follows: ECV (%) = IC_tumor / IC_aorta × (100 - Hct%). These parameters were examined using univariate and multivariate logistic regression to identify predictors of LNM. A predictive model was constructed and its diagnostic efficacy was assessed using receiver operating characteristic (ROC) curves.

**RESULTS**

A total of 107 patients were enrolled (44 with LNM, and 63 without LNM). In the training set, there were no significant differences in clinical data between the LNM and non-LNM groups. Among all DLCT parameters and morphological features, ECV, IC in venous phase (VP), and long-axis diameter of tumor were identified as independent predictors of LNM. The AUCs of IC in VP, ECV and tumor long-axis diameter on the training and validation sets were 0.640, 0.665, 0.678 and 0.626, 0.673, 0.774. The combined model using these parameters achieved an AUC of 0.877 (95% CI: 0.803-0.952) and 0.842 (95% CI: 0.707-0.977) for predicting LNM in the training and validation set, respectively. The Hosmer-Lemeshow test suggested a good model calibration. Decision curves confirmed greater clinical applicability of the combined model.

**CONCLUSION**

The model integrating DLCT-derived ECV, IC in VP, and tumor long-axis diameter displays high diagnostic performance in predicting LNM in patients with resectable PDAC.

**CLINICAL RELEVANCE/APPLICATION**

Preoperative diagnosis of lymph node status suggests prognosis and facilitates therapeutic decision-making. However, morphological features of lymph nodes have limited value in diagnosing LNM. Considering the difficulty of image-pathology one-to-one correspondence of lymph nodes, our objective was to develop and validate a model using quantitative DLCT parameters derived from the primary tumor to accurately identify LNM in PDAC before initiating treatment.

## M3-SSGI05-6 EVALUATION OF THE EXPRESSION AND DISTRIBUTION OF VEGFA AND PD-L1 IN HEPATOCELLULAR CARCINOMA PATIENTS WITH MULTIPARAMETRIC MAGNETIC RESONANCE IMAGING

Shi-Ting Feng (*Abstract Co-Author*) Nothing to Disclose
Chenyu Song, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The combination of atezolizumab and bevacizumab therapy (CABT) showed a significant survival benefit compared with sorafenib in hepatocellular carcinoma. We aimed to explore the feasibility of multiparametric magnetic resonance imaging (MRI) in evaluating the expression and distribution of VEGFA and PD-L1 related to CABT.

## METHODS AND MATERIALS

MRI scan with liver-specific contrast was conducted on C57/BL6 mouse model. The corresponding planes of MRI with pathology (ntumor=15, nplane=115) were spatially matched with 3D printing technology. MRI parameters and the targeted indicators stained by immunohistochemistry were evaluated and analyzed in different spatial regions (margin, center, plane, whole tumor). We constructed the targeted indicators evaluation model with MRI parameters in different spatial regions, respectively. The combined targeted indicators related to CABT were grouped into VhighIhigh (high VEGFA, high PD-L1), VhighIlow, VlowIhigh, VlowIlow groups and the combined targeted indicators evaluation model was established.

## RESULTS

The expressions of VEGFA and PD-L1 were significantly different between the marginal and central regions. MRI parameters were significantly correlated to the targeted indicators in different spatial regions. MRI parameters, Ktrans, Kep, Ve, and a showed significant differences between VEGFA high- and low- groups in different spatial regions. The area under the curves (AUCs) of VEGFA evaluation model at the regions of margin combining center (ROCM+T) and margin (ROCM) were 0.732(95%CI 0.663-0.793), and 0.715(95%CI 0.621-0.797), respectively. MRI parameters, Kep, Ve, iAUC60, and T1pre, T1pos showed significant differences between PD-L1 high- and low- groups in different spatial regions. The AUCs of PD-L1 evaluation models of ROCM+T, ROCM, ROCplane were 0.707(95%CI 0.637-0.770), 0.647(95%CI 0.552-0.735), 0.648(95%CI 0.552-0.736), respectively. MRI parameters, Ktrans, Kep, Ve, and T1pre showed significant differences among VhighIhigh, VhighIlow, VlowIhigh, and VlowIlow groups. The combined targeted indicators evaluation model was statistically significant (P=0.001) with the goodness-of-fit test P> 0.8.

## CONCLUSION

Multiparametric MRI has the potential to evaluate the expression and distribution of VEGFA and PD-L1, and to group the combined targeted indicators related to CABT.

## CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI can noninvasively evaluate and group the targeted indicators related to CABT with the consideration of spatial heterogeneity, providing valuable information for clinical treatment decisions in HCC.

## M3-SSGI06-1 RADIOMICS FEATURES FOR RISK STRATIFICATION IN PRIMARY SCLEROSING CHOLANGITIS: A PROOF-OF-CONCEPT STUDY

Chiara Spasiano (*Abstract Co-Author*) Nothing to Disclose
Cesare Maino, MD (*Abstract Co-Author*) Nothing to Disclose
Davide G. Gandola, MD (*Abstract Co-Author*) Nothing to Disclose
Cammillo R. Talei Franzesi (*Abstract Co-Author*) Nothing to Disclose
Paolo N. Franco, MD (*Abstract Co-Author*) Nothing to Disclose
Davide Ippolito, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To identify the radiomics features, semi-automatically extracted from MRI-MRCP images, useful to identify patients at higher risk of clinical outcome development.

### METHODS AND MATERIALS

Fifty-eight PSC patients with an MRI-MRCP study acquired with a standardized protocol were prospectively enrolled from Jan-2020 to Dec-2021. Blood tests and liver stiffness measurement were collected close to the MRI-MRCP. Patients were classified into high-risk or low-risk for disease progression using the Mayo risk score (MRS) and liver stiffness measurement (LSM). Radiomics features have been extracted using PyRadiomics in each of the five MRI-MRCP sequences analyzed.

### RESULTS

Among the 58 patients, 15(25.0%) and 17(30.0%) were considered at high-risk using MRS and LSM, respectively. 107 radiomics features have been extracted from each MRI-MRCP sequence analyzed. The selection process individuated two features associated with high MRS: NGTDM-Busyness in the ADC and GLRLM-Run Entropy in T2spir showing both a mean cross-validated AUC of 80%. The multivariable model, including both features, showed an AUC of 87%(SD 11%). When considering LSM (>9.6Kpa) as a stratifier of disease severity, GLCM-Cluster Shade in T1W HBP phase, GLCM-Maximal Correlation Coefficient in T1W arterial phase, GLDM-Large Dependence Low Gray Level Emphasis in ADC, and GLRLM-Run Entropy in T2spir showed an AUC of 85%, 83%, 85%, and 92%, respectively. The most accurate multivariable model included three variables: GLDM-Large Dependence Low Gray Level Emphasis in ADC, GLRLM-Run Entropy in T2spir and GLCM-Cluster Shade in T1W HBP phase with a median AUC of 96%.

### CONCLUSION

This proof-of-concept study demonstrates the predictive value of the radiomics features in PSC and their potential role in risk stratification assessment

### CLINICAL RELEVANCE/APPLICATION

Radiomics can offer a quantitative approach in the risk stratification of PSC patients.

## M3-SSGI06-3 REDUCTION OF GHOST ARTIFACTS ON 3-D MRCP OF GASTRO-BILIARY TRACT WITH SIGNAL SUPPRESSING ORAL CONTRAST AGENTS: INSIGHTS FROM A PHANTOM STUDY

Zhen J. Wang, MD (*Abstract Co-Author*) Stockholder, Nextrast, Inc
Kasen Wong, BA, MS (*Abstract Co-Author*) Nothing to Disclose
Benjamin M. Yeh, MD (*Abstract Co-Author*) Grant, Koninklijke Philips NV;Grant, General Electric Company;Consultant, Canon Medical Systems Corporation;Speaker, Canon Medical Systems Corporation;Royalties, Oxford University Press;Shareholder, Nextrast, Inc;Board Member, Nextrast, Inc
Joy Liau, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuxin Sun, BS, MSc (*Abstract Co-Author*) Stockholder, Nextrast, Inc
Theresia Aschauer, MD (*Presenter*) Nothing to Disclose

### PURPOSE

T2-weighted (T2w) signal suppressing oral contrast agents, such as high manganese (Mn) content fruit juices, improves magnetic resonance cholangiopancreatography (MRCP) image quality. Oral dark borosilicate contrast materials (DBCM) also minimize natural bright T2 signals in the bowel. Our study aimed to evaluate the impact of these agents on MRCP ghost artifacts in a gastro-biliary phantom.

### METHODS AND MATERIALS

A saline-filled biliary phantom was constructed to simulate the gallbladder, biliary tract including, 1st and 2nd order bile duct branches, and pancreatic duct. An adjacent 7cm diameter gastric chamber was serially filled with saline, high and low [Mn] pineapple juice (PJ) with differing concentrations novel DBCM at different strengths. Imaging was performed using a 3-D T2W MRCP sequence (TE=894ms, TR=2152ms, Slice thickness=1mm, Matrix=320x200, Field of view=380mm, Number of averages=2, Echo train Length=160) on a 3T MR scanner (Premier Signa, GE HealthCare). On 12 contiguous 1mm coronal images per scan, regions of interest (ROI) were placed on the following to record signal intensities: stomach, gallbladder ghost, stomach ghost, and background free from ghost artifacts. Values were normalized to that of the gallbladder for each scan and averaged for each stomach lumen material.

### RESULTS

The mean stomach lumen signal significantly decreased when filled with the high or low [Mn] PJ (10.5, 18.2) or full or half-strength DBCM (8.7, 10.3) compared to saline (1862.8, p=0.004, 0.005, 0.004, 0.004). Saline stomach ghosts showed significantly higher mean signal (18.8) than for high and low [Mn] PJ (11.2, 11.1) and full and half-strength DBCM (12.3, 10.7) (p=0.031, 0.007, 0.045, 0.032). Gallbladder ghost signal with low [Mn] PJ (100.4) was significantly higher compared to saline (67.7, p=0.009), but not significantly higher for high [Mn] PJ, full and half-strength DBCM (64.4, 86.4, 77.1) compared to saline (p=0.723, 0.189, 0.411). Conversely, the artifact-free region signal intensity was not significantly different for saline (2.79) than low and high [Mn] PJ (3.65, 4.22) or full-and-half strength DBCM (3.82, 3.11) (p=0.255, 0.110, 0.210, 0.678, respectively).

### CONCLUSION

Signal-suppressing oral contrast materials effectively reduce stomach ghost and gallbladder ghost artifact signals in 3-D MRCP compared to bright T2w signal fluids such as saline, indicating their potential to reduce distracting overlapping signal at MRCP.

### CLINICAL RELEVANCE/APPLICATION

Reduction of bowel lumen T2 signal with oral signal suppressing agents minimize ghost artifacts in MRCP imaging, potentially improving image quality and clinical interpretation.

## M3-SSGI06-4 COMPUTED TOMOGRAPHY VERSUS ULTRASOUND FOR THE DIAGNOSIS OF ACUTE CHOLECYSTITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Stephan Altmayer, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Giovanni B. Torri, MD (*Abstract Co-Author*) Nothing to Disclose
Adriano Basso Dias, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Fernanda Engel Gandolfi (*Abstract Co-Author*) Nothing to Disclose
Guilherme De Oliveira (*Presenter*) Nothing to Disclose

### PURPOSE

Ultrasound (US) is considered the first-line diagnostic test for the diagnosis of acute cholecystitis (AC). Many patients with abdominal pain in the emergency department have both computed tomography (CT) and US as part of the same evaluation, which may lead to a prolonged length of stay, potentially discrepant interpretations, and increased costs. Our purpose was to perform a systematic review and meta-analysis comparing the diagnostic performance of US and CT in the diagnosis of AC.

### METHODS AND MATERIALS

Relevant databases were search through November 2023 for studies evaluating the diagnostic accuracy of US and CT for AC. The primary objective was to evaluate studies comparing the head-to-head performance of US and CT. For the secondary analysis, all individual US and CT studies were analyzed. The pooled sensitivities, specificities, and areas under the receiver operating characteristic curve (AUCs) for US and CT were determined along with 95% confidence intervals (CIs). The prevalence of specific imaging findings of US and CT in patients with and without AC was also evaluated.

### RESULTS

Sixty-four studies met the inclusion criteria. In the primary analysis of head-to-head studies (n = 5), CT had a pooled sensitivity of 83.9% (95% CI, 78.4-88.2%) versus 79.0% (95% CI, 68.8-86.6%) of US (P = .44). The pooled specificity of CT was 94% (95% CI, 82.0-98.0%) versus 93.6% (95% CI, 79.4-98.2%) of US (P = .85). The AUC of CT and US were 90.3% (95% CI, 82.0-95.7%) and 90.0% (95% CI, 81.1-95.2%) respectively (P = .92). The concordance of positive or negative test between both modalities was 82.3% (95% CI, 72.1-89.4%). US and CT led to a positive change in management in only 4 to 8% of cases, respectively, when ordered sequentially after the other test.

### CONCLUSION

The diagnostic performance of CT is comparable to US for the diagnosis of acute cholecystitis with a high rate of concordance between the two modalities.

### CLINICAL RELEVANCE/APPLICATION

A subsequent US after a positive or negative CT for suspected acute cholecystitis may be unnecessary in most cases.

## M3-SSGI06-5 COMPARATIVE EVALUATION OF THE PROGNOSTIC SIGNIFICANCE BETWEEN 68 GA - FAPI VERSUS F-18 FDG PET SCANS IN PATIENTS WITH CHOLANGIOCARCINOMA

Nadezhda N. Gloria JR, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare and evaluate the diagnostic efficiency of 68 Ga - FAPI versus F-18 FDG PET scans in patients with Cholangiocarcinoma on contrast-enhanced CT scans.

### METHODS AND MATERIALS

The study was conducted on 30 patients with Cholangiocarcinoma who had Ga 68 FAPI and 18 F FDG PET study and further underwent a histopathological analysis to determine the subtype. The SUV max,TLG and MTV was obtained on FAPI and FDG PET. Further, tumour size, lymph nodal and distant metastasis for each histological subtype and location of primary tumour was noted.

### RESULTS

Tumour SUVmax, MTV and TLG was more for FAPI PET scan in comparison to FDG PET scan ($p<0.005$). It was also shown higher SUV values on both scans denoted poorer prognosis of the tumour. Higher the SUV values, higher was the T stage of the primary tumour, lymph nodal and solid organ metastasis. Peritoneal metastatic disease associated with cholangiocarcinoma was better delineated on FAPI PET scan.

## CONCLUSION

From the present study, it could be concluded that the prognosis of patients with high SUVmax at baseline is significantly worse than that of patients with low SUVmax. Cholangiocarcinomas showed significant differences in SUVmax,MTV and TLG parameters on FAPI PET CT's than FDG PET CT's.

## CLINICAL RELEVANCE/APPLICATION

68Ga-FAPI scan demonstrates more efficient radiotracer uptake, especially in grade 3 tumours of cholangiocarcinoma and improved lesion detection especially peritoneal disease when compared with 18F-FDG PET/CT. Higher SUV max parameters gives accurate prognosis of the tumour along with superior tumour detection by 68Ga-FAPI PET led to tumour diagnosis in patients. Thus, FAPI proves to be a valuable option for imaging of cholangiocarcinoma.

### PURPOSE

To evaluate the efficacity of transarterial chemoembolization (TACE) for hepatocellular carcinoma (HCC) as a bridging therapy in liver transplantation (LT) recipients.

### METHODS AND MATERIALS

We analyzed 386 patients who underwent LT patients for HCC from 8 French transplant centers and =1 pre-LT session of TACE between 2012 and 2017. The radiological response was assessed on pre-LT imaging using mRECIST criteria. Survival regressions were Cox models with center-specific cluster robust variance. A nodule-by-nodule analysis (NBN), including patients with =2 HCCs was performed using a multilevel (center- and patient-specific random effects) linear regression with downsizing (%) as the continuous response variable.

### RESULTS

There were 328 (85%) males; median age 59 (interquartile range, IQR: 54, 63) years, the cause of cirrhosis was alcohol in 195 (50%). Median MELD score was 10 [IQR: 8, 15]. At baseline, the median number of HCCs was 2 [IQR: 1, 3] and the median sum of the target lesions size was 41mm [IQR: 30, 51]. Two hundred six patients (53%) were beyond Milan criteria. Patients received a median of 2 TACE sessions (IQR: 1-3). The response after TACE was complete, partial, stable, or progressive in 142 (36.8%), 127 (32.9%), 39 (10.1%), and 78 (20.2%) patients. Five years after LT 87% of patients was free of recurrence and estimated disease-free survival (DFS) was 76%.Using complete response as a reference, each type of response to TACE was independently associated with DFS [hazard ratio (HR) partial vs. complete: 2.04 (95% confidence interval, CI: 1.17, 3.55); stable vs. complete: 3.98 (95% CI: 2.39, 6.64); progressive vs. complete: 7.65 (95%CI: 4.27, 13.7); all p<0.01]. Similar results were obtained for the overall survival. NBN analysis included 281 HCCs nested in 239 patients; median tumor downsizing was -100% (IQR: -100, -36) and was correlated with pathological necrosis [correlation coefficient (r): -0.51 (95%CI: -0.59, -0.42)], p<0.001). A 10% downsizing was associated with DFS (conditional HR 0.94; 95%CI: 0.92, -0.95 p<0.001). Downsizing was independently associated with embolization (p=0.047), super-selective approach (tumoral feeding pedicle, p=0.036) as well as differentiation grade (p<0.001), microvascular invasion (p=0.036) and satellites nodules (p=0.006) on explants.

### CONCLUSION

The prognosis of patients with LT for HCC is associated with TACE response. A selective approach and embolization optimize the downsizing of targeted HCC, which histologically translates into increased necrosis and favorable pathological features.

### CLINICAL RELEVANCE/APPLICATION

The radiological response to TACE should be considered as an additional parameter in patient selection before liver transplantation.

## M3-SSGI07-2 Junhan Pan (*Presenter*) Nothing to Disclose

## PREOPERATIVE SCORING MODEL FOR IDENTIFYING PROLIFERATIVE HEPATOCELLULAR CARCINOMA ON MULTIPHASE LIVER MRI AND ITS IMPLICATION FOR SURGICAL RESECTION

### PURPOSE

To develop and validate a scoring model for preoperative identification of proliferative hepatocellular carcinoma (HCC) using multiphase liver MRI, and to compare the postoperative early recurrence rates between patients with model-predicted proliferative and nonproliferative HCCs.

### METHODS AND MATERIALS

Between September 2019 and August 2021, consecutive patients with surgically-proven HCC who underwent preoperative multiphase liver MRI were retrospectively included. The classification of HCCs into proliferative and nonproliferative classes was determined through histological analysis. Logistic regression analyses were conducted to identify predictors associated with the proliferative HCC. The significant predictors from the training cohort were used to establish a scoring model, which was then verified in a time-independent validation cohort using the area under the AUC. To assess the model's applicability in molecular classification, it was applied to a RNA sequencing dataset for discriminating proliferative HCCs (G1, G2, G3) from nonproliferative HCCs (G4, G5, G6). Early recurrence rates were evaluated by the Kaplan-Meier method with log-rank test.

### RESULTS

A total of 498 patients (391 men; median age, 59.1years; IQR, 18-83 years) were divided into the training cohort (n=332), time-independent validation cohort (n=144), and RNA sequencing dataset (n=22). Independent predictors for proliferative HCCs included irregular tumor margin (OR, 4.9; P < 0.001), rim arterial phase hyperenhancement (OR, 3.6; P = 0.002), marked diffusion restriction (OR, 3.3; P < 0.001), tumor-to-liver arterial phase ratio = 1.4 (OR, 3.1; P < 0.001), and serum alpha-fetoprotein > 100 ng/mL (OR, 3.1; P < 0.001). The scoring model was constructed using these predictors with cutoff values of >18 points. The AUC of the model was 0.83, 0.80, and 0.77 in the training cohort, validation cohort, and RNA sequencing dataset, respectively. Patients with model-predicted proliferative HCCs exhibited significantly higher postoperative early recurrence rates than those with model-predicted nonproliferative HCCs (P < 0.05). However, patients with BCLC stage B-C and predicted nonproliferative HCCs exhibited similar early recurrence rates to those with BCLC stage 0-A and predicted proliferative HCCs (P = 0.05).

### CONCLUSION

The developed scoring model, incorporating four MRI features and serum alpha-fetoprotein, showed promising potential for predicting proliferative HCCs and identifying suitable surgical candidates for patients with HCC.

### CLINICAL RELEVANCE/APPLICATION

The identification of potential imaging and clinical markers for proliferative hepatocellular carcinoma holds implications for tailoring therapies and predicting clinical outcomes.

## M3-SSGI07-3 SURGICAL RESECTION VERSUS MICROWAVE ABLATION FOLLOWING TACE FOR UNRESECTABLE HEPATOCELLULAR CARCINOMA: A NATIONWIDE MULTICENTER COHORT STUDY

Peihong Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Chao An (*Abstract Co-Author*) Nothing to Disclose
Hanyu Jiang (*Presenter*) Nothing to Disclose

### PURPOSE

The optimal curative-intent therapeutic option following successful conversion therapy for unresectable hepatocellular carcinoma (uHCC) is controversial. Therefore, we aimed to compare the efficacy and safety of surgical resection (SR) versus microwave ablation (MWA) after transarterial chemoembolization (TACE) for initially uHCC.

### METHODS AND MATERIALS

From June 2008 to October 2022, consecutive adult patients with treatment naive Barcelona Clinic Liver Cancer A/B stage uHCC who received upfront TACE and subsequent curative-intent SR or MWA were retrospectively identified from 15 tertiary-care hospitals. SR or MWA was recommended by multidisciplinary tumor boards if tumor burden reduced within BCLC A stage for =eight weeks and that R0 resection or complete ablation was anticipated achievable. Propensity score matching (PSM) was performed to balance baseline variables between the SR and MWA groups. Disease-free survival (DFS, time from TACE to recurrence or all-cause death after SR or MWA) and overall survival (OS) were estimated using the Kaplan-Meier method and compared with the log-rank test.

### RESULTS

1348 patients (age, 54.0 ± 7.5 years; 1,148 men) were included, 619 (45.9%) received SR and the remaining 729 (54.1%) received MWA. After 1:1 PSM, 542 patients were included in each group for analyses. Based on the matched cohort, SR demonstrated superior OS (median OS, 10.6 vs 5.8 years; hazard ratio [HR], 1.83; 95%CI, 1.48-2.25; p<0.001) and DFS (median DFS, 3.2 vs 2.5 years; HR, 1.27; 95%CI, 1.09-1.49; p=0.003) outcomes than MWA. However, for patients with tumors downstaged within the Milan criteria (n=578, 42.9%), the OS (HR, 1.13; 95% CI, 0.77-1.66; p = 0.543) and DFS (HR, 1.07; 95% CI, 0.83-1.37; p = 0.614) outcomes were comparable between the SR and MWA groups. After PSM, the major complication rates were similar between the two groups (p = 0.705), but the SR group had significantly longer operation time and hospitalization duration as well as higher cost than the MWA group (all p < 0.001).

### CONCLUSION

For initially uHCC patients eligible for curative-intent SR or MWA after TACE, SR was associated with superior OS and DFS than MWA. However, the survival outcomes of SR and MWA were comparable for patients with tumors downstaged within the Milan criteria.

### CLINICAL RELEVANCE/APPLICATION

MWA might be a safe and effective alternative to SR for initially uHCC patients eligible for curative-intent treatment after TACE in selected patients, especially for patients with tumors downstaged within the Milan criteria.

## M3-SSGI07-4 VISION TRANSFORMER-BASED BIOMARKER CAN OPTIMIZE CURATIVE TREATMENT FOR PATIENTS WITH RECURRENT HEPATOCELLULAR CARCINOMA

Ke Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

No definitive classification systems or clinical practice guidelines exist to advocate individual preferences for optimizing the treatment of recurrent hepatocellular carcinoma (rHCC). Our aim was to develop a Vision Transformer-based (ViT) strategy to optimize the treatment selection between thermal

ablation (TA) and repeat hepatic resection (RHR) for rHCC using multimodal imaging.

**METHODS AND MATERIALS**

This real-world, multicenter and retrospective cohort study included patients with HCC who underwent preoperative contrast-enhanced ultrasound and magnetic resonance imaging, and curative-intent TA or surgical resection (SR) from January 2012 to August 2023. Development of HEROVision-TA and -SR models, based on the 1stTA and 1stSR datasets using a ViT-based Cox proportional hazard regression algorithm to achieve individualized progression-free survival prediction. Concordance index (C-index) and time-independent area under the curve (AUC) were computed in the external testing cohort to compare the model with current staging systems. Both models were applied to each enrolled patient to investigate potential options for treatment optimization and to determine the potential to decrease risk after propensity score matching.

**RESULTS**

The study included 1434 patients with HCC: 885 from the TA dataset (median age, 59 years; interquartile range [IQR], 51-65 years) and 594 from the SR dataset (median age, 58 years; IQR, 51-66 years). The HEROVision model showed better prediction for early-stage recurrence than six staging systems in the external testing cohort (2-year C-index: 0.72 vs. 0.51-0.57 for the 2ndTA dataset and 0.74 vs 0.54-0.58 for the 2ndSR dataset, all P-values < 0.001; 2-year AUC: 0.78 vs. 0.51-0.59 and 0.82 vs. 0.51-0.61, respectively, all P-values < 0.001). The most substantial improvement was observed when HEROVision was incorporated into the analysis of the aforementioned systems for both the 2ndTA and 2ndSR datasets. We identified 26.0% 2ndTA and 5.6% 2ndSR patients in the high-risk group we would recommend switch treatment. The average risk of 2ndTA significantly decreased; switching to SR could be beneficial; however, 2ndSR patients switching to TA may not benefit.

**CONCLUSION**

The multimodal-based HEROVision model can optimize personalized curative treatment and holds promise as a tool to complement existing clinical guidelines for early-stage rHCC.

**CLINICAL RELEVANCE/APPLICATION**

The HEROVision model is an innovative AI model capable of simulating redecision-making between two treatment approaches and enhance patient care in the management of rHCC.

**PURPOSE**

Assess diagnostic performance of clinically implemented gadoxetate-enhanced hepatobiliary-phase (HBP) abbreviated MRI (HBP-AMRI) for surveillance of primary liver cancer (PLC: hepatocellular carcinoma [HCC], intrahepatic cholangiocarcinoma [iCCA], combined HCC and iCCA [cHCC-CCA]) in at-risk patients (cirrhosis or chronic hepatitis B viral infection).

**METHODS AND MATERIALS**

Our institution implemented HBP-AMRI for clinical care in 2014 as a surveillance method for detecting primary liver cancer in high-risk patients who had suboptimal ultrasound (US) surveillance due to poor liver visualization. HBP-AMRI exams were interpreted prospectively by abdominal radiologists using templated reports with a category code (positive, subthreshold, negative) analogous to LI-RADS US surveillance algorithm. For each patient and blinded to other data, one author reviewed all HBP-AMRI reports from June 2014-May 2019 until the first positive exam (if any) and recorded the highest category code (negative, subthreshold, positive). A second author reviewed each patient's electronic medical record through October 2023 to extract follow-up data. Blinded to HBP-AMRI results, the senior author applied a composite reference standard (imaging, pathology, or =4 years of clinical follow up) to classify each patient as PLC-positive, HCC-positive, PLC-negative, or lost to follow-up. Per-patient diagnostic performance parameters and their exact binomial 95% confidence intervals (CIs) were calculated. Subthreshold AMRI was considered negative in the analysis.

**RESULTS**

538 at-risk patients underwent 1160 AMRI exams. 119 were lost to follow-up (114 negative HBP-AMRI surveillance, 5 subthreshold) and excluded from final analysis. The remaining 419 patients (351 HBP-AMRI surveillance negative, 22 subthreshold, 46 positive) were classified by the reference standard as PLC-negative (n=385) or PLC-positive (n=34: 32 HCC, 2 iCCA). For detecting PLC, HBP-AMRI surveillance had 0.94 accuracy (393/419; 95% CIs: 0.91-0.96), 0.79 sensitivity (27/34, 0.62-0.91) and 0.95 specificity (366/385, 0.92-0.97). For detecting HCC in particular, HBP-AMRI had 0.93 accuracy (391/419, 0.91-0.96), 0.78 sensitivity (25/32, 0.60-0.91), specificity of 0.95 (366/387, 0.92-0.97).

**CONCLUSION**

Clinically implemented HBP-AMRI surveillance had good sensitivity and excellent specificity for detecting PLC in patients with suboptimal US surveillance. Future research is needed to compare HBP-AMRI surveillance directly with other surveillance methods.

## CLINICAL RELEVANCE/APPLICATION

HBP-AMRI can be implemented clinically for primary liver cancer surveillance with high diagnostic performance in at-risk patients with suboptimal US surveillance.

## M3-SSIN02-1 ADVANCED RETRIEVAL AUGMENTED GENERATION FOR AUTOMATED CLINICAL DATA EXTRACTION FROM UNSTRUCTURED RADIOLOGY REPORTS: ASSESSMENT OF APPROACHES AND PARAMETERS

Evan D. Calabrese, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kartikeye Gupta (*Abstract Co-Author*) Nothing to Disclose
Ayush Jain (*Abstract Co-Author*) Nothing to Disclose
Mohamed Sobhi Jabal, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The study purpose was to develop and evaluate a comprehensive automated system for extracting precise clinical information from unstructured radiology reports in returned structured formats using large language models (LLMs) and retrieval augmented generation (RAG). We aimed to build the end-to-end pipeline interface and assess its performance across different LLM architectures, embedding methods, parameters, and retrieval strategies.

### METHODS AND MATERIALS

A labeled dataset of 8315 radiology reports of patients with brain tumor was processed to extract brain follow-up score. Experiments included locally deployed open-source LLMs (Llama3, Biollama3, Llama2, Medllama2) at two quantization levels to reflect low and high resource settings. Open source local vector database was used for storing extracted embeddings. Different embedding models and retrieval strategies were compared, and the effect of LLM hyperparameter variance was examined. With the targeted output format being javascript object notation (JSON), extracted scores were analyzed against ground truth labels through binary and multiclass evaluation metrics.

### RESULTS

Preliminary results indicated the best-performing model was Llama3, achieving 80% accuracy, with 81% precision, 82% recall, 78% F1-score, and an AUROC of 82. Recent models notably outperformed their prior generation, while fine tuned medical LLMs and medical embedding did not yield significantly improved performance. LLM and RAG hyperparameters had varied influence over the extraction effectiveness. Comprehensive benchmarking of the overall combinations of experiments is underway.

### CONCLUSION

The proposed automated system showcases the potential of recent open-source LLMs and RAG methods in extracting clinical information from unstructured radiology reports and return structured formats. The choice of LLM architecture, embedding model, and retrieval strategy significantly impacts the method effectiveness. Such approaches could assist radiologists, clinicians, and researchers in efficiently mining valuable information from reports, enabling data-driven decision-making, real-time interactivity with diagnostic reports, as well as conducting efficient and labor-free clinical research.

### CLINICAL RELEVANCE/APPLICATION

The ability to extract specific clinical information automatically and accurately from unstructured radiological reports rendered in structured formats using locally deployed open-source RAG and LLMs can enhance and streamline medical workflows and drastically reduce research burden in data collection, both in low and high resource environments.

## M3-SSIN02-2 BUILDING AN AUTOMATED PROTOCOL COMPLIANCE MONITORING AND AUDITING SYSTEM USING A NOVEL FOUNDATION MODEL FOR MEDICAL IMAGING EXAMS

Deborah A. Langman, PhD (*Abstract Co-Author*) Employee, LANDAUER, Inc
Martin P. Smith, MD (*Abstract Co-Author*) Research Grant, Bracco GroupResearch Grant, Bayer AGConsultant, Bayer AGResearch Consultant, General Electric Company
Robert Macdougall (*Abstract Co-Author*) Nothing to Disclose
Christopher J. MacLellan, PhD (*Abstract Co-Author*) Stockholder, NNOX
Benoit Scherrer (*Abstract Co-Author*) Nothing to Disclose
Dimitri Falco (*Presenter*) Nothing to Disclose

**PURPOSE**

We introduce a system to automate the process of evaluating compliance of radiological exams subject to ACR MR Accreditation Program (MRAP) requirements. Our approach utilizes the embedding properties of a new foundational model of examinations to classify acquisition and exam-level features and evaluate compliance, with the goal of enabling continuous real-time monitoring and periodic auditing.

**METHODS AND MATERIALS**

MR Cholangiopancreatography (MRCP) exams were pre-selected to evaluate our system for automated compliance evaluation. For each exam, acquisitions were manually labeled (166 exams, 1965 labels) by sequence type {Localizer, Diffusion, Calibration, 2D MRCP, 3D MRCP, T1 Dynamic, T1 IPOP, T1 IPOP LOW FA, T1 Pre, T2, Timing Run, Other}, serving as the ground truth. A new foundational model of exams from acquisition metadata, based on graph representation learning, was used to generate embeddings and visualize MRCP exams with respect to other exam types. A neural network classifier was trained and tested to automatically classify the acquisition types solely based on their technical parameters (training test split: 79%/21%). We then assessed exam and acquisition-level compliance for both manual and NN-classified data sets using a deterministic, rule-based function embodying the ACR compliance criteria.

**RESULTS**

A qualitative analysis identified three distinct clusters where MRCP exams are situated, effectively highlighting the foundation model's ability to identify MRCP exams solely from their technical parameters. Our acquisition type classifier had an overall F1 score of 97%, demonstrating our ability to accurately detect acquisition type from technical parameters. Using the predicted series type and their associated technical parameters the compliance binary classification matched the ground truth for all 35 exams.

**CONCLUSION**

We built upon a new foundational model for imaging exams and showed the ability to isolate MRCP exams based solely on acquisition parameters. When combined with our sequence type classifier, we were able to accurately identify which acquisitions should be assessed against their respective MRAP criteria allowing us to optimize the QA workflow.

**CLINICAL RELEVANCE/APPLICATION**

Today, identifying studies for ACR MRAP submission is a manual process. Moreover, while imaging protocols are reviewed periodically, the instantiations of protocols (completed imaging studies) are not continuously evaluated for compliance and deviations in real-time. The current approach presents a path for streamlined study identification, compliance monitoring, and site self-monitoring against ACR accreditation, regulatory requirements, and local policies and procedures.

## M3-SSIN02-3 NOVEL LARGE LANGUAGE MODEL SYSTEM FOR CUSTOM-TAILORED RADIOLOGY RESEARCH USING RETRIEVAL-AUGMENTED GENERATION (RAG)

Dana Alkhulaifat, MD (*Abstract Co-Author*) Nothing to Disclose
Xinmeng Wang (*Abstract Co-Author*) Nothing to Disclose
Vahid Khalkhali, MSc (*Abstract Co-Author*) Nothing to Disclose
Julian Lopez Rippe, MD (*Abstract Co-Author*) Nothing to Disclose
Susan Sotardi, MD, MEng (*Abstract Co-Author*) Nothing to Disclose
Michael Welsh, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Large language models (LLMs) exhibit great potential in improving medical research, particularly in radiology, through assisted question-answering. Top publicly available LLMs such as OpenAI's GPT-4-Consensus use relevant articles as context to avoid hallucination/citing non-existent sources. Only privately deployed LLMs within an institution guarantee data privacy. Thus, our purpose was to build a secure LLM system at our institution, using web-scraped PubMed radiology-related abstracts and retrieval-augmented generation (RAG) techniques, and evaluate its performance relative to GPT-4-Consensus.

**METHODS AND MATERIALS**

In this retrospective IRB-approved study, 167,028 publicly available abstracts with keyword "radiology" published from 2000 to 2024 were programmatically web scraped off PubMed. Two pretrained 7-billion parameter open-source LLMs were used, one for embedding and one for response generation. Each abstract was converted to its embedded space representation and stored in a vector database to enable semantic search. Given a prompt, semantically similar abstracts were retrieved, the prompt was contextualized with the abstracts, then a response was generated with references appended at the end. A cross-comparison between our LLM system and GPT-4-Consensus was then performed on 20 different prompts by a cohort of radiologists and radiology researchers at our institution, using a consensual web-based survey. Participants were asked to submit radiology-related questions as prompts. Blinded to output origin, outputs from our LLM system and GPT-4-Consensus were then shown and evaluated using three 5-point Likert scale questions (1=very low, 5=very high) assessing the factual accuracy (FA), citation relevance (CR), and perceived performance (PP). Participants were then asked to choose their preferred output. The Likert scale ratings between outputs were compared using a Wilcoxon signed-rank test. A p-value less than 0.05 was considered statistically significant.

**RESULTS**

For our LLM system, the mean ± SD of FA, CR, and PP ratings were 4.15 ± 0.99, 3.70 ± 1.17, and 3.55 ± 1.39, respectively. For GPT-4-Consensus, they were 4.25 ± 0.72, 3.85 ± 1.23, and 3.90 ± 1.12, respectively. No statistically significant differences were found between these ratings (p-values of 0.97, 0.65, and 0.42, respectively). 50% of participants preferred our LLM system's output.

**CONCLUSION**

Using RAG, our LLM system achieved similar FA, CR, and PP, compared to GPT-4-Consensus, while ensuring data privacy by being securely deployed within our institution.

**CLINICAL RELEVANCE/APPLICATION**

Our LLM system demonstrates high potential in improving medical research in radiology while ensuring data privacy and can be adapted to other medical domains.

## M3-SSIN02-4 RECIST ASSESSMENT OF HEPATOCELLULAR CARCINOMA AFTER LOCOREGIONAL THERAPY WITH LARGE LANGUAGE MODELS: BARD, BING, CHATGPT-3.5, AND CHATGPT-4

Fatma Celiker, MD (*Abstract Co-Author*) Nothing to Disclose
Merve Solak (*Abstract Co-Author*) Nothing to Disclose
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
esat kaba, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to evaluate response evaluation criteria in solid tumors (RECIST) using tumor longest diameter measurements from computed tomography (CT) reports of hepatocellular carcinoma (HCC) patients before (baseline) and after (follow-up) transcatheter arterial chemoembolization (TACE) with four different large language models (LLM).

### METHODS AND MATERIALS

Ninety-three HCC patients were included in this study after exclusion criteria. RECIST assessment was performed using Bard, Bing, ChatGPT-3.5, and ChatGPT-4 LLMs based on baseline and follow-up measurements of the longest diameter of lesions obtained from contrast-enhanced CT of HCC patients. A zero-shot learning technique was used for the initial prompts entered into the LLMs. For each patient, the RECIST classification results provided by the LLMs were compared with the radiologist evaluations.

### RESULTS

Bard, Bing, ChatGPT-3.5, and ChatGPT-4 accuracy in a RECIST assessment were 0.581, 0.839, 0.871, and 1.000, respectively. The precisions were 0.429, 0.920, 0.919, and 1.000, respectively. Recalls were 0.544, 0.738, 0.773, and 1.000, respectively. ChatGPT-4 outperformed other LLMs and all ninety-three patients were correctly evaluated for RECIST. However, Bard showed the lowest performance in this study with an accuracy of 0.581.

### CONCLUSION

LLMs are highly successful in text analysis and studies on their potential applications of LLMs in medicine and radiology have been increasing rapidly in recent years. The results of this study demonstrate that LLMs, especially ChatGPT-4, can perform rapid and effective RECIST assessments using baseline and follow-up lesion diameters in CT reports.

### CLINICAL RELEVANCE/APPLICATION

Some LLMs can potentially help radiologists in the RECIST evaluation, which is very important in the field of interventional oncology. ChatGPT-4 in particular, with its remarkable performance, shows promise for future use for this purpose.

## M3-SSIN02-5 ASSESSING COMPLETENESS OF CLINICAL HISTORIES ACCOMPANYING IMAGING ORDERS USING OPEN- AND CLOSED-SOURCE LARGE LANGUAGE MODELS

### PURPOSE

Clinical histories accompanying imaging orders are often incomplete. Using completeness of the clinical history to measure quality, this study adapted open-source and proprietary large language models (LLMs) to extract five elements from provided clinical histories: past medical history, what, when, where, and clinical concern. Then, the completeness of 49,026 clinical histories from a large academic medical center was assessed to obtain a quality benchmark.

### METHODS AND MATERIALS

Prompt engineering with in-context learning (2-16 examples) was performed for open-source (LLaMA-2-7B, Mistral-7B) and proprietary (GPT-4-Turbo; GPT-4) LLMs. GPT-4, which cannot be fine-tuned, was included to assess maximum out-of-the-box performance. The best-performing open-source LLM was further fine-tuned using a training set and validation set (n=796 and 150, respectively). Following this, both GPT-4 and the fine-tuned open-source LLM were evaluated against a test set independently annotated by two radiologists (n=300). Model performance was compared using detection (accuracy, F1 score) and textual semantic similarity (BERTScore) metrics. Model-radiologist agreement was assessed using Cohen's kappa and BERTScore. Finally, the best-performing open-source LLM was used to extract the five elements and analyze the quality of 49,026 clinical histories from an academic center.

### RESULTS

Mistral-7B outperformed LLaMA-2-7B after prompt engineering. After further fine-tuning, Mistral-7B with 16 in-context examples rivaled GPT-4 (accuracy: 0.91, F1 score: 0.87, mean BERTScore: 0.97). Both Mistral-7B and GPT-4 achieved substantial agreement with the two radiologists, with model-radiologist agreement levels similar to that achieved between the two radiologists (Cohen's kappa: 0.73-0.77 vs. 0.76; mean BERTScore: 0.96-0.97 vs. 0.96). Using Mistral-7B on the 49,026 clinical histories, the weighted mean inclusion rate of all relevant elements was 73.8%.

### CONCLUSION

A fine-tuned open-source LLM, rivaling GPT-4 in performance, extracted clinical history elements with substantial agreement to radiologists and yielded a benchmark for clinical history quality. The model and code will be open-sourced to help enable similar quality assessments.

### CLINICAL RELEVANCE/APPLICATION

Quality improvement efforts for clinical histories have relied on manual analysis, which is tedious and costly. Smaller open-source LLMs can help automate such efforts, while maintaining data security. Providing clinical histories with the most relevant information can improve patient care by helping radiologists better understand the clinical context and may improve the accuracy of tasks like automated protocolling that rely on the history.

## PURPOSE

Previous work has demonstrated the impressive performance of GPT-4 (Open AI) on the image-rich American College of Radiology (ACR) Diagnostic Radiology In-Training Examination (DXIT). In our study, we compare the performance of GPT-4 to two other popular publicly available large multimodal models, Claude 3 Opus (Anthropic) and Gemini 1.5 Pro (Google) on the 2022 DXIT.

## METHODS AND MATERIALS

Multiple choice questions from the 2022 DXIT were sequentially input into GPT-4, Claude 3 Opus, and Gemini 1.5 Pro with a standardized prompt. Responses from each model for each question were recorded and accuracy was calculated, as was logic-adjusted accuracy, which counted a response as incorrect if there were significant flaws in reasoning or image interpretation, regardless of answer choice. Sub-analyses assessed accuracy on image-based versus text-only questions as well as accuracy by question subject. The confidence level for each answer was also noted. Confidence levels were compared between models and for correct versus incorrect answers. Means were compared using paired and 2-sample t-tests. Model accuracy was compared to nationwide resident performance.

## RESULTS

GPT-4 achieved an overall accuracy of 56.1%, lower than PGY-3 average (61.9%) but higher than PGY-2 average (52.8%). Gemini 1.5 Pro attained a non-statistically lower accuracy of 51.5%. Claude 3 Opus's accuracy was 25.7%, significantly worse than the other models and comparable to random guessing on this multiple choice question set. Adjusted accuracy, which accounts for flaws in logic and image analysis, was lower than overall accuracy for each model, at 51.5%, 45.5%, and 21.2% for GPT, Gemini, and Claude respectively. Performance on image-rich questions was also significantly poorer for each model, at 43.9%, 39.0%, and 19.5% for GPT, Gemini, and Claude respectively, than for text-based questions. GPT, which had the highest overall accuracy, had the lowest confidence at 84.3%. Claude, which had the lowest overall accuracy, had the highest confidence at 88.3%.

## CONCLUSION

GPT-4 outperformed Gemini and Claude with overall accuracy between PGY-2 and PGY-3 levels. Each model performed significantly poorer on image-based questions and at times struggled with logical decision making and interpretation.

## CLINICAL RELEVANCE/APPLICATION

This study highlights the numerous risks of using the current generation of general AI models in interpreting radiologic images as a diagnostic tool. Clinical implementers of general multimodal AI systems in radiology should exercise caution given the possibility of spurious yet confident responses, particularly given the risk of automation bias. Future work will assess whether domain specific models exhibit similar traits to the models evaluated in this study.

### PURPOSE

This study aims to test whether a deep learning-derived biomarker of aging from carotid ultrasound images is associated with incident stroke and cortical volume from brain MRI.

### METHODS AND MATERIALS

We developed a convolutional neural network model (called Carotid-Risk) using carotid ultrasound images of 59,137 participants in UK Biobank, a population study of volunteers in the UK. The model was trained on 80% of the dataset, to predict biological age, defined as an individual's chronologic age at the time of the ultrasound, adjusted for the presence of cardiovascular risk factors, comorbidities, and observed all-cause mortality and major cardiovascular events during follow-up. For testing (remaining 20% of the dataset), we assessed the association of the Carotid-Risk score with observed incident stroke over median 3.8 years of follow-up (based on International Classification of Disease codes) and brain volume of cortical grey matter (derived from T1-weighted brain MRI via FreeSurfer software; normalized for head size). Analyses were performed using regression models adjusted for age, sex, body mass index (BMI), history of smoking, type 2 diabetes, hypertension, and genetic ancestry principal components. Results are provided for the testing dataset only.

### RESULTS

59,137 participants in UK Biobank had carotid imaging. The full dataset had mean age of 65.5 (SD: 7.7), 48.2% male, 62.4% never smokers, mean BMI of 26.6 (SD: 4.5). In the testing dataset (N=11,832), after adjusting for the aforementioned covariates, each standard deviation increase in Carotid-Risk was significantly associated with incident stroke (aHR: 1.37, 95% CI [1.03 to 1.82], P=0.03). 38,135 of these participants also had brain MRI, with mean brain volume of 1,492.6 (SD: 73.8) cubic centimeters. In the subset of testing dataset participants with Brain MRI (N=7,559), after adjusting for all covariates, each standard deviation increase in Carotid-Risk was significantly associated with 0.05 SD decrease in cortical grey matter volume (Beta: -0.05, 95% CI [-0.02 to -0.07], P< 0.001). There was no significant association between Carotid-Risk and white matter volume (P=0.27).

### CONCLUSION

A deep learning-based measure of biological age from a carotid ultrasound image (Carotid-Risk) is associated with incident stroke and reduced brain grey matter, beyond chronological age and prevalent cardiovascular risk factors.

### CLINICAL RELEVANCE/APPLICATION

Deep learning derived Carotid-Risk may help direct preventive interventions to those at high-risk for neurovascular disease and improve understanding of the role of the carotid artery in neuronal degeneration.

## M3-SSNR03-3 EVALUATING THE CLINICAL RELEVANCE OF INTRAPLAQUE HEMORRHAGE VOLUME IN ISCHEMIC STROKE RISK ASSESSMENT

**PURPOSE**

The relationship between carotid intraplaque hemorrhage (IPH) volume and severity of the ischemic event is not well-established. We sought to determine whether IPH volume is related to the severity of ischemic events and what volume of IPH most likely contributes to ischemic symptoms.

**METHODS AND MATERIALS**

A retrospective review was conducted on consecutive patients who underwent magnetic resonance imaging of carotid plaque using specific sequences to detect IPH. The presence or absence of plaque and IPH was determined by a neuroradiologist, who also assessed the IPH volume. Patients were categorized into four groups: none, amaurosis fugax (AF), other transient ischemic attacks (TIA), and stroke. The categorization also considered the side of the event when possible. To focus on carotid plaque as the etiology of ischemic events, cases with bilateral ischemic events or without carotid plaque were excluded. The normality of the IPH volume in each ischemic category was checked and the mean IPH volume in each ischemic group was compared using either the Mann-Whitney or T-test, with p-values reported. The analyses were conducted separately for events on the left and right sides.

**RESULTS**

We included 358 patients in our study. Of these, 105 had right-sided symptoms, with 75 patients having plaque (23 IPH positive, 52 IPH negative). There were 121 patients with left-sided symptoms, with 101 patients having plaque (46 IPH positive, 55 IPH negative). Additionally, 32 patients had bilateral symptoms, and 100 presented with symptoms of unknown-sidedness. We observed 19 strokes, 1 AF, and 3 other TIAs for the right side. 28 strokes, 6 AF, and 12 other TIAs for the left side. Analyses revealed no significant differences in IPH volumes across different ischemic events. For left-sided comparisons, the p-values were 0.802 for stroke vs. other TIAs, 0.173 for AF vs. strokes, and 0.222 for AF vs. other TIAs, indicating no significant differences. For the right side, the p-values were 1.0 for stroke vs. other TIAs and 0.2 for stroke vs. AF. Comparisons between AF and other TIAs were inconclusive due to limited data. However, there is a certain threshold that corresponds to stroke (200 and 650 mm3 for the right and left side).

**CONCLUSION**

The study indicates that while carotid IPH is detectable in patients with various ischemic events, there is no linear correlation between IPH volume and symptomatic severity, there may be a threshold IPH volume that makes stroke more likely than other neurologic deficits.

**CLINICAL RELEVANCE/APPLICATION**

This study challenges the potential predictive value of IPH volume in clinical practice, emphasizing the need for further research to explore other factors that might influence the impact of carotid atherosclerosis on ischemic stroke risk.

## M3-SSNR03-4 INTEGRATING CLINICAL AND MRI DATA FOR STROKE PREDICTION IN AT-RISK SUBJECTS: A MULTIMODAL APPROACH ON UK BIOBANK DATA

Veena A. Nair, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Ischemic stroke, a global health burden accounting for significant mortality and morbidity, necessitates robust risk stratification strategies. Current risk prediction models have limitations in accurately identifying at-risk individuals who will develop a stroke. Leveraging a large dataset from the UK Biobank, this study integrates clinical information and MRI-derived metrics for robust prediction of ischemic stroke. We hypothesize that machine learning models that combine clinical, demographic, and imaging features can provide reliable prognostication of stroke for at-risk population.

**METHODS AND MATERIALS**

This study comprises n=1226 subjects from the UK biobank data (640 males, mean age = 55.5 years) who are at risk of ischemic stroke, all with at least one known vascular risk factor associated with stroke. Within this cohort, n=317 participants reported ischemic stroke during subsequent follow-up assessments within a span 10-years. Clinical features included demographics, traditional risk factors (e.g., age, hypertension), and cardiopulmonary features (e.g., Chronic Obstructive Pulmonary Disorder, Asthma). MRI-derived metrics included Fractional Anisotropy, Mean Diffusivity, and White Matter Hyperintensities volume, extracted from diffusion-weighted, susceptibility, T1w, and FLAIR sequences, totaling 114 features. Multivariate logistic regression was utilized to select relevant MRI features associated with stroke risk (p lt 0.05), which were then concatenated with the 18 clinical features. Individual as well as concatenated features sets were fed into the XGBoost (XGB) algorithm in a 5-fold cross-validation scheme for classifying individuals who develop stroke from those who remain at risk.

**RESULTS**

The regression models yielded a reduced MRI set of 32 features. When concatenated with the 18 clinical features, the combined clinical and MRI XGB model achieved an accuracy of 82.0%, precision of 0.93 and recall of 0.70, and AUC of 0.86 for stroke cases. The top 5 features were: history of high blood pressure, asthma, father's history of stroke, mean MD in the cerebral peduncle on the left FA skeleton, and mean MD in the superior corona radiata on the right FA skeleton. The clinical XGB model achieved an accuracy of 82.7% with precision and recall of 0.89 and 0.75, and an AUCROC of 0.85. The MRI XGB model achieved an accuracy of 56.0% with precision and recall of 0.60 and 0.35, and AUC of 0.57.

**CONCLUSION**

Our results demonstrate the potential of integrating clinical and MRI data, towards reliable prognostication of likelihood of developing ischemic stroke.

**CLINICAL RELEVANCE/APPLICATION**

Timely identification of at-risk individuals who develop ischemic stroke is essential for efficient treatment planning and improved outcomes.

## M3-SSNR03-5 HIGH BLOOD PRESSURE IN HOSPITALIZED PATIENTS WITH ACUTE SYMPTOMATIC INTRACRANIAL ATHEROSCLEROTIC DISEASE IS ASSOCIATED WITH POST-CONTRAST PLAQUE ENHANCEMENT: A WHOLE-BRAIN MR VESSEL WALL IMAGING STUDY

**PURPOSE**

To investigate the associations among a known history of hypertension, blood pressure (BP) during hospitalization, intraplaque hemorrhage (IPH), and plaque enhancement in patients who had acute symptomatic intracranial atherosclerotic disease (ICAD) using whole-brain MR vessel wall imaging (VWI).

**METHODS AND MATERIALS**

We retrospectively screened VWI data from consecutive hospitalized patients with acute symptomatic ICAD for atherosclerotic plaques. Intracranial internal carotid arteries, V4 segments of the vertebral arteries, and the basilar artery were considered proximal segments; A1, M1, and P1 segments of the anterior, middle, and posterior cerebral arteries were considered intermediate segments; A2, M2-3, and P2 segments were considered distal segments. Each plaque was reviewed for the presence of IPH (defined as a hyperintense region on pre-contrast VWI) and strong enhancement (defined as a greater enhancement degree than the pituitary on post-contrast VWI). During the hospitalization after stroke, the mean of 3 BP measurements from the first 3 days was used in the analyses.

**RESULTS**

Among 108 patients, 63 had a history of hypertension. Pre-stroke hypertension was associated with a higher plaque count ($p = 0.01$), specifically in the proximal segments (4.37 vs. 2.91, $p = 0.02$). No strong evidence was found in the association between a history of hypertension and the likelihood of having plaques with IPH or strong enhancement. Higher BP during hospitalization was associated with a higher count of plaques with strong enhancement, regardless of a history of hypertension. Specifically, for each 10 mmHg increase in diastolic BP (DBP), the count of plaques with strong enhancement would be as high as 1.23 times, 95% CI (1.11, 1.37), $p<0.01$. For systolic BP (SBP), the trend was similar but not as strong as that for DBP (1.07 times, 95% CI [1, 1.4], $p=0.05$). When examining the association between BP and the patient-level probability of having strong plaque enhancement, a consistent positive log-linear association was found in the proximal segments for both DBP and SBP with a slope of 1.19, 95% CI (1.04, 1.35), $p<0.01$ and 1.12, 95% CI (1.03, 1.21), $p<0.01$, respectively, but not in the intermediate or distal segments. Neither DBP nor SBP was significantly associated with the count of plaques with IPH.

**CONCLUSION**

Higher BP during hospitalization, especially DBP, was associated with a higher count of plaques with strong enhancement in patients with symptomatic ICAD.

**CLINICAL RELEVANCE/APPLICATION**

Elevated BP is common after acute stroke and is associated with poor prognosis. The unstable intracranial plaques in patients with post-stroke hypertension require close attention.

## M3-SSNR03-6 THE IMPACT OF WHITE MATTER HYPERINTENSITIES BURDEN AND CEREBRAL VESSELS MORPHOLOGICAL ALTERNATION ON THE ONE-YEAR RISK OF ISCHEMIC STROKE RECURRENCE

Hao Wang, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to evaluate the association of white matter hyperintensities (WMHs) burden and cerebral vessel morphological features with the one-year risk of ischemic stroke recurrence.

**METHODS AND MATERIALS**

We conducted a retrospective study on 677 patients diagnosed with ischemic stroke from January 2018 to April 2021. Automated segmentation was utilized to delineate WMH lesions and quantify their spatial distribution. In addition, cerebral vessel morphological features including volume, length, radius, density, tortuosity, branch, and degree of stenosis were extracted and calculated. Utilizing these measurements alongside clinical characteristics, a total of six predictive models were developed using Cox proportional hazards analysis to estimate one-year risk of stroke recurrence. The performance of these models was compared via concordance index (C-index).

**RESULTS**

The study found significant associations between the lack of antiplatelet therapy at discharge, increased burden of whole brain and periventricular WMHs, and reduced length and branching of cerebral vessels, with a higher one-year risk of recurrent ischemic stroke (all $P < 0.05$). The integrated model, incorporating WMHs, cerebral vessel morphology, and clinical characteristics, demonstrated superior prognostic capability (C-index: 0.750; 95% CI: 0.684-0.817), outperforming models based solely on clinical characteristics (C-index: 0.636; 95% CI: 0.555-0.717), cerebral vessel morphology (C-index: 0.601; 95% CI: 0.526-0.676), and WMH volume (C-index: 0.680; 95%CI: 0.603-0.757).

**CONCLUSION**

The quantitative assessment of WMHs and cerebral vessel morphological features provides a promising neuroimaging tool for estimating the likelihood of recurrence in patients who have experienced an ischemic stroke.

**CLINICAL RELEVANCE/APPLICATION**

The quantitative analysis of WMHs and cerebral vascular features may provide a new neuroimaging approach for predicting stroke recurrence.

### PURPOSE

Portable, ultra-low-field (LF) MRI has the potential to improve access to MRI and facilitate diagnosis of acute ischemic stroke (AIS). To evaluate the accuracy of LF-MRI for AIS detection, we scanned patients presenting to the emergency department across three US stroke centers within 24 hours of last known well (LKW) and determined the agreement and predictive values of accurately detecting stroke.

### METHODS AND MATERIALS

Sixty-six patients (50% female, 66±13 years) were enrolled at the Massachusetts General Brigham, Buffalo General Medical Center and Ohio State Hospitals and underwent diffusion weighted imaging (DWI; single direction b=900 s/mm2) on a 0.064T scanner (Hyperfine Inc.). Three independent assessors (each with >10 years of experience reading acute stroke MRI) underwent training on LF-MRI images. Assessors then evaluated LF-MRI scans from acute stroke patients and evaluated for the presence of a DWI lesion and its location. The agreement between assessors, positive (PPV; based on confirmed diagnosis of AIS on conventional neuroimaging obtained as part of clinical care) and negative (NPV; based on no acute intracranial findings on conventional imaging) predictive values, sensitivity and specificity were calculated [95% CI].

### RESULTS

There was strong agreement between assessors regarding lesion detection (?=0.80, [0.68-0.92]) and lesion location (?=0.95, [0.81-1.0]). Predictive values for detecting AIS on LF-MRI revealed a 96.4% PPV [81.7-99.9] and 65.8% NPV [48.6-80.4] which was associated with a 67.5% sensitivity [50.9-81.4] and 96.2% specificity [80.4-99.9].

### CONCLUSION

We observed agreement between assessors and favorable positive predictive values. Sources of disagreement were observed when lesions were smaller and less conspicuous. Our findings also reveal the importance of experience in both reading acute stroke exams and undergoing prior training to familiarize assessors with the nuances of LF-MRI images. NPV was higher than PPV, which may be a consequence of the single direction DWI. Multi-directional DWI could improve lesion detection and confidence between assessors, which is an avenue for future development.

### CLINICAL RELEVANCE/APPLICATION

LF-MRI has the potential to detect hyperacute stroke, which may increase access to MRI given its unique portable capabilities.

## M3-SSNR04-3 ASPECTS MISMATCH BETWEEN HEAD CT - HEAD CTA AND BRAIN COLLATERALS STATUS AS PROGNOSTIC FACTORS IN ACUTE ISCHEMIC STROKE

Manuel F. Granja, MD (*Abstract Co-Author*) Nothing to Disclose
Sonia Bermudez, MD (*Abstract Co-Author*) Nothing to Disclose
Silvia P. Marquez Zuchini, MD (*Abstract Co-Author*) Nothing to Disclose
Laura Andrea Campana Perilla, MD (*Abstract Co-Author*) Nothing to Disclose
Angela P. Guarnizo, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the association between the ASPECT score mismatch in head CT - head CTA and brain collaterals with the clinical outcome of patients with acute ischemic stroke.

### METHODS AND MATERIALS

We conducted a Retrospective cross-sectional observational study from patients who presented to the emergency department with acute ischemic stroke and underwent to head CT and head CTA between 2016 and 2022. Head CT and head CTA ASPECTS was calculated by two neuroradiologists as well as brain collaterals by using the Mass system. A univariate and bivariate analysis was performed as well as logistic regression model to assess the discrepancy between the two modalities and clinical outcomes

### RESULTS

A total of 121 patients were analyzed. A difference was found in the ASPECTS in head CT vs head CTA. Patients who presented a negative mismatch between head CT and head CTA (lower ASPECTS on head CTA than on head CT) had a higher proportion of atrial fibrillation as comorbidity (p 0.027), less collateral circulation in the infarcted cerebral hemispheres (p < 0.0001), higher blood pressure values ??(p 0.028) and blood glucose levels upon admission (p 0.05). Patients with negative mismatch also had a longer hospital stay (p 0.02), higher NIHSS score (p 0.002) and RANKIN score (p 0.05) at discharged. Most of the patients showed a mismatch ASPECTS between 0 to -2 points. Regarding the interobserver agreement it was moderate for head CTA ASPECTS and brain collaterals (k= 0.403 and 0.457 respectively). The interobserver agreement for head CT ASPECTS was low (k=0.374).

### CONCLUSION

The negative ASPECTS discrepancy between head CT and head CTA is associated with lower cerebral blood flow through collaterals and a higher probability of negative clinical outcomes. Thus, ASPECTS discrepancy constitutes a feasible marker when selecting optimal candidates for endovascular treatment.

### CLINICAL RELEVANCE/APPLICATION

ASPECTS head CT and head CTA mismatch constitutes a feasible marker when selecting optimal candidates for endovascular treatment.

## M3-SSNR04-4 DEEP LEARNING BASED AUTOMATIC DETECTION ALGORITHM FOR ACUTE ISCHEMIC STROKE ON BRAIN CT: A PIVOTAL RANDOMIZED CLINICAL TRIAL

### PURPOSE

Acute ischemic stroke (AIS) is a potentially life-threatening emergency that requires prompt and accurate assessment and management. This study aimed to develop and validate an artificial intelligence (AI) algorithm for the diagnosis of AIS using brain CT images.

### METHODS AND MATERIALS

A retrospective, multi-reader, pivotal, crossover, randomized study was performed to validate the performance of an AI algorithm using a novel approach that combines convolutional neural network and recurrent neural network using CT scans from 1,972 patients. Brain CT images from 917 patients were evaluated by nine reviewers belonging to one of three subgroups (non-radiologist physicians, n=3; board-certified radiologists, n=3; and neuroradiologists, n=3) with and without the aid of our AI algorithm. Sensitivity, specificity, and accuracy were compared between the AI-unassisted and AI-assisted interpretations using Chi-square tests.

### RESULTS

Brain CT interpretation with AI assistance resulted in significantly higher diagnostic accuracy compared to that without AI assistance (0.7563 vs. 0.7203 with a difference of 3.60%, p<0.0001). Among the three subgroups of reviewers, non-radiologist physicians demonstrated the greatest improvement in diagnostic accuracy for brain CT interpretation with AI assistance compared to that without AI assistance (0.7535 vs. 0.6997, with a difference of 5.38%, p<0.0001). For both board-certified radiologists and neuroradiologists, diagnostic accuracy for brain CT interpretation were also significantly higher with the use of AI assistance than without AI assistance (for board-certified radiologists, 0.7488 vs. 0.7230, with a difference of 2.58%, p=0.0299, for neuroradiologists, 0.7666 vs. 0.7383, with a difference of 2.84%, p=0.0148).

### CONCLUSION

We validated the improvement in diagnostic performance with the assistance of our AI algorithm for the detection of AIS on brain CT images in pivotal randomized clinical trial.

**CLINICAL RELEVANCE/APPLICATION**

1. Improvement in diagnostic performance with the assistance of our AI algorithm for the detection of AIS on brain CT images was validated in pivotal randomized clinical trial. 2. The AI algorithm described in this study may serve as a reliable assistant for the detection of acute ischemic stroke (for small acute ischemic stroke as well as acute ischemic stroke associated with large vessel occlusion) on brain CT scans in which prompt and accurate assessment are required.

## M3-SSNR04-5 COMPUTED TOMOGRAPHY PERFUSION ISCHEMIC CORE PREDICTS FAVORABLE OUTCOMES AFTER BASILAR ARTERY THROMBECTOMY

Xia Li (*Abstract Co-Author*) Nothing to Disclose
Pengjun Chen (*Presenter*) Nothing to Disclose

**PURPOSE**

Recent trials confirmed the predictive value of computed tomography perfusion (CTP) ischemic core in anterior circulation stroke patients caused by large vessel occlusion, however, the value of CTP for functional outcomes of successful endovascular thrombectomy (ET) remains to be investigated in patients with acute basilar artery occlusion (BAO). We tried to address this question by comparing the performance of Posterior Circulation Alberta Stroke Program Early CT Score (pc-ASPECTS) and Critical Area Perfusion Score (CAPS), based on the presumed ischemic core generated by syngo.via.

**METHODS AND MATERIALS**

A retrospective analysis was performed with a cohort of acute BAO uderwent successful ET in a comprehensive stroke center. The primary outcome was a good functional outcome 90-days (modified Rankin Scale 0-3). Pc-ASPECTS and CAPS were quantified by a 6-years experienced radiologist (observer-Li) and a 13-years experienced neuro-radiologist (observer-Chen) based on NCCT, CTP maps, severe hypoperfusion (Tmax > 10s generated by RAPID and syngo.via) and presumed ischemic core (CBF < 10 mL * min-1 * 100 g-1, 15 mL * min-1 * 100 g-1, and CBV < 1.2 mL * 100mL-1) generated by syngo.via. The intraclass correlation coefficient was used to assess the inter-observer reliability. Multivariate regression analyses and receiver operating characteristics (ROC) analyses were performed for the ability of predicting the primary outcome.

**RESULTS**

A total of 57 patients were matched the inclusion criteria. In binary logistic regression analyses, pc-ASPECTS and CAPS assessed by observer-Li and observer-Chen based on CBF < 10 ml * min-1 * 100 g-1 presented as independent predictors of 90-day favorable outcomes, and yielded the best performance in the ROC analyses with the areas under the curve (AUC) values were 0.790 ([95% CI, 0.669-0.911]), 0.824 ([95% CI, 0.714-0.934]), 0.818 ([95% CI, 0.707-0.928]), and 0.854 ([95% CI, 0.755-0.954]), respectively, with the intraclass correlation coefficients of 0.888 and 0.841. RAPID-Tmax > 10 s had moderate discriminatory power (AUC, 0.717, 0.718, 0.718, and 0.718, respectively), with the intraclass correlation coefficients of 0.970, 0.970.

**CONCLUSION**

CTP presumed ischemic core (CBF < 10 ml * min-1 * 100 g-1) generated by syngo.via contains prognostic information for functional outcome of successful ET in patients with basilar artery occlusion at an early stage of hospitalization.

**CLINICAL RELEVANCE/APPLICATION**

We tried to investigate the predictive value of computed tomography perfusion ischemic core in patients with acute basilar artery occlusion underwent successful endovascular thrombectomy, and to give more attention and active treatment to patients with potentially poor prognosis.

### PURPOSE

Deep learning reconstructions hold potential for dose reduction and image quality improvements, but interpretability and propensity for hallucinations limit translation. A new class of interpretable algorithms, diffusion posterior sampling (DPS), permits generation of multiple representative reconstructions from measurement data. Proper interpretation of these posterior samples is the key to combating hallucinations and understanding image outputs. In this work, we explore the effect of different communication strategies in an observer study.

### METHODS AND MATERIALS

Lung Image Database Consortium CT scans containing spiculated and non-spiculated lesions were assembled and treated as ground truth. Low dose projections were simulated and reconstructed using filtered-backprojection (FBP) and DPS. The dose level was intentionally set to a very low level where significant hallucinations were present. For DPS, 32 posterior samples were obtained. We performed a receiver operating characteristic study to evaluate the effect of communication strategies for specific imaging tasks. In preliminary investigations, an expert observer was asked to discriminate spiculated from non-spiculated lesions in 100 patients. Three strategies were evaluated: 1) low dose FBP, 2) a single DPS sample, and 3) an ensemble of 32 DPS samples presented as scrollable slices. High dose FBP was used to establish ground truth annotations. Additionally, we recorded the time taken to complete each task and confidence levels from 1-5.

### RESULTS

The percentage correct for low dose FBP, single sample DPS, and ensemble DPS is 66%, 68%, and 73%, respectively. The ensemble display has the highest true positives among all strategies, but slightly lower true negatives compared to low dose FBP, indicating that non-spiculated lesions tend to be misclassified as spiculated lesions due to spurious generation of lung parenchyma. The ensemble display outperforms the single sample display overall. For confidence, the single sample diffusion is highest due to the appearance of low image dose; the ensemble diffusion shows variability in outputs and therefore reduces confidence. The confidence for ensemble diffusion is overall higher than FBP.

### CONCLUSION

Diffusion model outputs improve performance relative to low dose FBP. Task performance improves by showing the variability in posterior samples, albeit at the cost of reduced confidence. This work provides initial evidence that novel communication strategies are important for this new class of deep learning algorithms.

### CLINICAL RELEVANCE/APPLICATION

Novel communication methods for a new class of interpretable deep learning reconstruction algorithms could mitigate the risk of hallucinations and facilitate clinical translation.

## M3-SSPH03-2 AI-BASED COMPUTER-AIDED VOLUMETRY FOR INVASIVENESS EVALUATION IN LUNG ADENOCARCINOMA: COMPARISON OF CAPABILITY FOR NODULE COMPONENT MEASUREMENT AND DIAGNOSTIC PERFORMANCE ON DIFFERENT DOSE LEVELS AND RECONSTRUCTION METHODS ON ULTRA-HIGH-RESOLUTION CT

Yoshiyuki Ozawa, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare capabilities of artificial intelligence (AI)-based computer-aided volumetry (CADv) for nodule component measurement and diagnostic performance to evaluate invasiveness in lung adenocarcinoma among standard-, reduced- and ultra-low-dose ultra-high-resolution CT (UHR-CT) reconstructed with hybrid-type iterative reconstruction (IR) and deep learning reconstruction (DLR) methods.

**METHODS AND MATERIALS**

112 consecutive patients with 181 lung adenocarcinomas underwent thin-section UHR-CTs at standard- (SDCT: 9.0±1.8 mGy), reduced- (RDCT: 1.7±0.2 mGy) and ultra-low-dose (ULDCT: 0.8±0.1 mGy) levels. All CT data were reconstructed with hybrid-type IR and DLR. Then, standard references for solid and GGO components and consolidation-to-tumor ratio (CTR) were computationally determined with the simultaneous truth and performance level estimation (STAPLE) method from annotated CT data by three board-certified chest radiologists. Then, each component volume and CTR on all UHR-CT data were measured by AI-based CADv software. Each component volume and consolidation-to-tumor ratio (CTR) were correlated between CADv measurement on each CT data and standard reference. Then, Measurement differences of each index between standard reference and each CADv measurement were compared among all CT data by Tukey's HSD test. Finally, diagnostic performance of invasiveness was compared among all CTR measurements by ROC analysis.

**RESULTS**

There were significant correlations for each component and volume and CTR on all UHR-CTs (hybrid-type IR: 0.71=r=0.88, p<0.0001DLR: 0.71=r=0.88, p<0.0001). Mean difference of each index between each CADv measurement and standard reference had no significant differences among all UHR-CT data (p>0.05). Area under the curve (AUC) of each CT protocol with DLR (SDCT: AUC=0.98, RDCT: AUC=0.98, ULD-CT: AUC=0.97) was significantly larger than that with hybrid-type IR (SDCT, RDCT and ULDCT: AUC=0.95, p<0.05).

**CONCLUSION**

DLR has better potential than hybrid-type IR for improving diagnostic performance of AI-based CADv for invasiveness evaluation in lung adenocarcinoma on UHR-CT with standard-reduced- and ultra-low-dose levels.

**CLINICAL RELEVANCE/APPLICATION**

DLR has better potential than hybrid-type IR for improving diagnostic performance of AI-based CADv for invasiveness evaluation in lung adenocarcinoma on UHR-CT with standard-reduced- and ultra-low-dose levels.

## M3-SSPH03-3 DEEP LEARNING-BASED METRIC FOR CT IMAGE QUALITY ASSESSMENT: CAPABILITIES AND POTENTIAL CLINICAL APPLICATIONS

Jie Zhang, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Evaluating CT image quality has become more challenging with the widespread use of iterative reconstruction (IR). Traditional metrics often fail to meet clinical requirements for assessing contrast resolution, noise levels, artifact presence, and visibility of critical details. This study examines the potential of a deep learning (DL)-based metric developed during the Low-dose CT Perceptual Image Quality Assessment Grand Challenge 2023 for clinical applications.

**METHODS AND MATERIALS**

Our DL model, which ranked in the top three of the Grand Challenge, is based on Efficient-Net V2-L and was enhanced by an ensemble of the best four outcomes from a 5-fold cross-validation. To evaluate its potential, we first conducted an animal study by scanning a 72 kg, four-year-old sheep using a Siemens CT scanner at exposure levels ranging from 360 mAs to 30 mAs. Images were reconstructed using both Advanced Modeled Iterative Reconstruction (ADMIRE) at strengths 1-5 and FBP. We then retrospectively analyzed abdominal CT images from 50 pediatric patients (ages 2-12) and 50 obese patients (BMI>35), investigating the impact of patient size and IR reconstruction parameters on image quality.

**RESULTS**

The animal study identified a radiation dose point at 210 mAs, beyond which increases in dose did not improve image quality for either FBP or IR. Above this point, FBP produced better images, while the use of IR degraded image quality. Below the point, the use of IR improved image quality, with the optimal IR strength varying based on the dose reduction. In pediatric patients, the average image quality score was 3.40 ± 0.15 for routine clinical images, demonstrating the effective use of AEC (CarekV CareDose4D) across various patient sizes. For obese patients, image quality scores decreased with increasing BMI, i.e., ranging from 2.64 (FBP) to 3.71 (IR strength 5) at a BMI of 34.46, and from 1.84 to 3.02 at a BMI of 66.22.

**CONCLUSION**

The DL-based metric shows promise in evaluating CT image quality, which can aid in optimizing CT imaging parameters and ensuring diagnostic adequacy while maintaining low radiation exposure to patient.

**CLINICAL RELEVANCE/APPLICATION**

A DL-based metric for assessing CT image quality can contribute to the improvement of imaging practices, patient care, and clinical outcomes by providing a reliable, efficient, and automated means of ensuring high-quality diagnostic images.

## M3-SSPH03-4 THE SEPARATION OF SIMULTANEOUSLY ADMINISTERED IODINE AND GADOLINIUM CONTRAST: PHOTON-COUNTING CT VERSUS DUAL-ENERGY CT

Paul Deak, PhD (*Abstract Co-Author*) Employee, General Electric Company
Gert van Gompel, PhD (*Abstract Co-Author*) Nothing to Disclose

**PURPOSE**

To compare a prototype silicon-based photon-counting CT (Si-PCCT) with dual-energy CT (DECT) for the differentiation of simultaneously administered Iodine (I) and Gadolinium (Gd).

**METHODS AND MATERIALS**

I-and Gd-based contrast agents, diluted with saline to achieve a similar 300 HU target in a conventional 120 kVp CT scan (13 mg/mL I, 31 mg/mL Gd), were mixed into five tubes containing different I/Gd fractions: 10/0, 7.5/2.5, 5/5, 2.5/7.5, 0/10 mL, and inserted into a 20 cm diameter water phantom along with a saline control tube. Helical scans were acquired using a prototype Si-PCCT system using 8 energy bins at 120 kVp and a conventional DECT system (80-140 Fast kVp switching). Three types of images were reconstructed: image data from 4 energy bins (44 - 52.2, 52.2 - 60, 60 - 80, 80+ keV), conventional mono-energetic kV reconstructions at 8 energies in a 40 - 120 keV interval (approximating the equivalent energies of the 4 Si-PCCT energy bins) and Iodine(water) maps. To evaluate the ability of the Si-PCCT system to separate I from Gd, their attenuation as function of energy, their differences in CT values, and the quantification accuracy of I throughout the different I/Gd fractions were compared between systems and evaluated using a paired sample t-test.

**RESULTS**

DECT-based attenuation curves for I and Gd allowed differentiation through distinct attenuation behavior across a 40 - 120 keV energy range. Binned Si-PCCT data and mono-energetic keV attenuation curves also revealed distinct attenuation patterns. Additionally, Gd K-edge absorption (50.2 keV) was observed on binned Si-PCCT data. The extent to which I attenuation differed from Gd attenuation, or the mean difference in CT-values between I and Gd across a 70 - 120 keV energy range was significantly increased for Si-PCCT (167 ± 60.5 HU), when compared to DECT (61.7 ± 30.4 HU), $p < 0.001$. I quantification throughout the different I/Gd fractions showed a significant reduced error towards the target concentration for Si-PCCT (1.2 ± 1.8 mg/mL), when compared to DECT (5.1 ± 3.3 mg/mL), $p < 0.001$.

**CONCLUSION**

Both DECT and Si-PCCT can differentiate I and Gd. However, only Si-PCCT energy binned images allowed to identify the K-edge of Gd. Furthermore, energy binning-based imaging enabled improved material separability, and made it possible to quantify iodine more correctly when diluted with Gd, when compared to DECT

**CLINICAL RELEVANCE/APPLICATION**

Using contrast agents with K-edges within the diagnostic CT energy range is challenging as basic assumptions of material decomposition are violated. While experimental K-edge imaging through energy binning with Si-PCCT may differentiate contrast materials regardless of their K-edge, potentially facilitating research on novel contrast agents and multi-contrast agent imaging.

## M3-SSPH03-5 COMPARISON OF WATER-CALCIUM AND WATER-HYDROXYAPATITE MATERIAL DECOMPOSITION IN BONE MARROW EDEMA ASSESSMENT USING DUAL-ENERGY CT: A MULTICENTER SMALL-COHORT STUDY

Xiaofeng Mao (*Abstract Co-Author*) Nothing to Disclose
Jie Wang (*Abstract Co-Author*) Nothing to Disclose
Guozhi Zhang (*Abstract Co-Author*) Nothing to Disclose
Zhiyan Chang (*Abstract Co-Author*) Nothing to Disclose
Kaibo He (*Abstract Co-Author*) Nothing to Disclose
Jintao Han (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the diagnostic performance of water-calcium and water-hydroxyapatite (HAP) material decomposition in dual-energy CT (DECT) for quantitatively assessing bone marrow edema (BME) in patients with fracture or arthritis.

**METHODS AND MATERIALS**

This retrospective study included 18 patients from three hospitals on whom DECT and magnetic resonance imaging (MRI) data were acquired at a similar time for the spine, knee, or ankle. The DECT images were post-processed with the water-calcium and the water-HAP material decomposition. Two readers independently measured the water mass density of the edema zone and of the normal bone marrow on the decomposed images from each of the two methods. The interreader agreement was evaluated using the interclass correlation coefficient (ICC). The MRI was used as the reference standard for the presence of BME. Diagnostic performance of DECT was assessed using the receiver operating characteristic (ROC) curve and the optimal cutoff value in detecting BME was determined.

**RESULTS**

A total of 49 vertebrae and 18 joint regions were included in the analysis, in which 23 vertebrae and 9 joint regions were found with BME on MRI. The interreader agreement of measurements on water-calcium and water-HAP images was good for the edema zone (ICC = 0.81 and 0.86, respectively) and excellent for the normal bone marrow (ICC = 0.92 and 0.94, respectively). The averaged water mass density of the BME area on water-calcium and water-HAP images was 1067.1 ± 16.8 and 1008.5 ± 19.0 mg/cm3, respectively, which was higher than that of the normal bone marrow (1014.0 ± 20.2 and 980.9 ± 18.2 mg/cm3, respectively, both $p < 0.001$). The area under the ROC curve of water-calcium and water-HAP images for identifying the BME was 0.98 and 0.86, respectively ($p = 0.006$). With a cutoff value of 1039.1 mg/cm3, the sensitivity, specificity, and accuracy of water-calcium images were 96.9%, 91.4%, and 94.0%. Similarly, with a cutoff value of 991.4 mg/cm3, the results of water-HAP images were 81.3%, 74.3%, and 77.6%.

**CONCLUSION**

Compared to water-HAP decomposition, water-calcium decomposition showed superior diagnostic performance in dual-energy CT for quantitatively assessing BME in patients with fracture or arthritis.

**CLINICAL RELEVANCE/APPLICATION**

Dual-energy CT with water-calcium material decomposition has the potential to be a reliable imaging tool in routine practice for detecting bone marrow edema.

## M3-SSPH03-6 DUAL-EXTRUDER PIXELPRINT PHANTOM FOR EVALUATION OF METAL ARTIFACT REDUCTION ALGORITHMS

## PURPOSE

Algorithms for Metal Artifact Reduction (MAR) enhance diagnostic image quality compromised by artifacts from implants. However, MAR algorithms are challenging to evaluate without ground truth information about the geometry of implants and adjacent structures. We adapted PixelPrint technology for dual-extrusion 3D printing to create lifelike metal-containing phantoms for the assessment of MAR algorithms.

## METHODS AND MATERIALS

To demonstrate the feasibility of fabricating multi-material lifelike CT phantoms, a dual-filament 3D printer (Epsilon W27, BCN3D Technologies) was modified to enable a novel dual-filament PixelPrint methodology to print metal components into a realistic background. Calcium-doped (StoneFil, Formfutura) and metal-doped PLA (Ultrafuse 17-4, BASF) was used to simulate bone and soft tissue and emulate orthopedic implants to generate realistic metal artifacts, respectively. These two materials were interleaved to seamlessly integrate orthopedic screw model and patient image data. Two types of phantoms were printed: homogeneous background featuring a screw and patient-specific knee with a superimposed orthopedic implant screw at low and high infills. Phantoms were scanned using a photon-counting CT (NAEOTOM Alpha, Siemens Healthineers). Conventional and virtual monoenergetic images (VMI) at 190 keV were reconstructed with and without MAR to qualitatively evaluate the phantoms' capabilities to generate realistic metal artifacts and replicate geometry and textures in both patient image data and metallic screws.

## RESULTS

Dual-filament phantoms produced realistic metal artifacts in conventional images, particularly the patient-specific knee phantom with a high infill orthopedic implant screw. The metal screw phantom produced significant metal artifacts, closely resembling those of an actual screw. VMI 190 keV images with MAR illuminated the geometry of the screw obscured by metal artifact on conventional images and matched that of the screw model. Similarly, the patient-specific knee phantom accurately reproduced lifelike geometry and textures of bone and soft tissue in addition to the screw.

## CONCLUSION

PixelPrint combined with dual-extruder 3D printing facilitated the fabrication of multi-material phantoms that closely mimic patient data and metal artifacts on images while also replicating the geometry of orthopedic screws. This innovative approach ensures a ground truth geometry of the metal artifact producing object critical for evaluating MAR algorithms.

## CLINICAL RELEVANCE/APPLICATION

Lifelike metal-containing phantoms offer a platform for designing and evaluating MAR algorithms that may improve diagnostic evaluation adjacent to metal implants and enable more precise assessment of implants.

### PURPOSE

Radiopaque microspheres provide a means for visualizing both on- and off-target deposition throughout hepatic transarterial embolization (TAE) procedures. In this study, we develop an interventional x-ray imaging sequence that can provide 2D dual-energy material-specific images both during and after each microsphere injection.

### METHODS AND MATERIALS

In the developed x-ray imaging sequence, initial images of the subject are acquired at high kV with a wedge filter (125 kV, 3.29 mGy/s). Several seconds prior to and throughout injection of radiopaque microspheres, the acquisition mode is switched to low kV imaging without a filter (64 kV, 7.70 mGy/s). Microsphere-specific dual-energy (DE) images are formed by a log subtraction approach with automatic weighting factor selection. For comparison, conventional DSA images can be formed from the low-kV portion of the acquisition. The sequence was tested in a 50 kg porcine model of hepatic TAE. With suspended ventilation, approximately 2-3mL of barium-loaded microspheres (70.3 mg iodine/mL equivalent) were injected into the left hepatic artery. Microspheres of progressively larger sizes (40um followed by 100um, then 250um) were injected. Microsphere visibility and vessel contrast were compared on DE and DSA images during and after each injection. Cone-beam CT (CBCT) scans were performed to establish ground truth microsphere positions.

### RESULTS

Microspheres were visible during injection on both 2D DE and DSA images. However, post-injection, the microspheres were only consistently visible in DE images. In post-injection DSA, pre-existing microspheres were subtracted and only visible in the form of misregistration artifacts. In a distal region containing previously embolized vessels, 2 vessel segments were identified using DSA, while 6 and 10 segments were identified on DE and CBCT, respectively. The measured contrast of the two vessels (full-width-at-half-maximum of 2.4 mm and 1.2 mm) on DSA were 5.2% and 1.6%, respectively; for DE images, contrast measurements were 12.9% and 4.1%. The DE imaging method automatically accounted for the presence of the wedge filter.

### CONCLUSION

A 2D imaging sequence was designed to form DE images throughout a progressive TAE procedure. Compared with DSA imaging, both imaging techniques could visualize barium-loaded microspheres during injection within an in-vivo porcine model. However, DE imaging was also able to provide direct visualization of previously injected microspheres.

### CLINICAL RELEVANCE/APPLICATION

Barium-loaded radiopaque microspheres visible on interventional imaging may provide direct intra- and post-procedural monitoring of both on- and off-target microsphere distribution and embolization.

**PURPOSE**

Radiation target volumes for gliomas are defined using MRI T1 post-gadolinium (T1-CE) and T2-FLAIR (T2) sequences. T1-CE is found where the blood-brain barrier (BBB) is broken. For low-grade astrocytomas (astros) and most oligodendrogliomas (oligos) of any grade, the BBB is mostly intact and radiation target volumes defined with T2 imaging. Due to lack of specificity of T2 hyperintensity, this practice may result in target volumes and radiation doses larger or smaller than optimal for a patient. Amino acid (AA) radiotracers are independent of BBB breakdown and have a low uptake in normal brain tissue. We hypothesize that the AA radiotracer, 3,4-dihydroxy-6-[18F]-fluoro-L-phenylalanine (18F-DOPA), will demonstrate volumetric uptake for non-enhancing tumors (T1-NCE) and extend beyond tumors with T1-CE.

**METHODS AND MATERIALS**

30 biopsy-proven newly diagnosed or recurrent glioma patients on two prospective clinical trials underwent an 18F-DOPA PET/CT with T1 post-gad and T2-FLAIR MR imaging between 2010-2015. The PET/CT was rigidly registered to the MRIs. Neuroradiologists created T1-CE, T2, and 18F-DOPA PET uptake volumes. Based on our previous studies, a tumor-to-background ratio (T/N) > 2.0 was used to define the aggressive tumor volume (HGG FDOPA) within the total PET uptake volume (FDOPA) for astro patients only. Concordant and discordant volumes between MRI and PET were evaluated.

**RESULTS**

Based on the 2016 WHO classifications, patient demographics: 20 male and 10 female patients; Age: 20-69 yrs; 22 new and 8 recur; 22 astros (n=5 grade II, 8 grade III, 9 grade IV) and 8 oligos (n=6 grade II and 2 grade III). For grade II, III, and IV astros, 40%, 52%, and 41% HGG FDOPA was outside the T1-CE, respectively. FDOPA uptake, but not T1-CE, was found in all grade III oligos. No significant vol of FDOPA was found outside T2.

**CONCLUSION**

Our initial hypothesis that 18F-DOPA imaging shows glioma outside of conventional T1-CE was confirmed. This was the case regardless of grade or tumor type. In addition, all astro patients, regardless of grade, contained both HGG FDOPA and total FDOPA uptake volume outside of the T1-CE volume. In patients with T1-NCE, 18F-DOPA uptake, including HGG FDOPA for some patients, was observed in all but 2 patients.

**CLINICAL RELEVANCE/APPLICATION**

Glioma patients have poor progression-free (PFS) and overall survival (OS). Tumor recurrences are predominantly central and in-field to the radiotherapy treatment plan. Given that additional FDOPA vol outside of T1-CE, more importantly HGG FDOPA, can be seen, we hypothesize that using both conventional MRI and 18F-DOPA imaging could improve PFS, recurrence patterns, and OS. The results justify an importance for clinical trials including both MRI and 18F-DOPA PET, dose escalation, and reduced margins.

## M3-SSPH04-5 A NOVEL ON-BOARD PHOTON COUNTING CONE-BEAM CT SYSTEM FOR PROTON THERAPY

Hao Gao (*Abstract Co-Author*) Nothing to Disclose
Yuting Lin, PhD (*Abstract Co-Author*) Nothing to Disclose
Christian De Caro (*Abstract Co-Author*) Nothing to Disclose
Ke Li, PhD (*Presenter*) Research Consultant, Pulmera Inc.

**PURPOSE**

While the steep dose gradient of protons enables highly conformal dose distributions, it also tightens the tolerance margins for positioning errors and anatomical changes. For optimal proton radiotherapy (RT) outcomes, it's imperative to adapt the dose delivery plan promptly upon detecting anatomy changes, ideally with the patient on the table, i.e., online adaptive proton therapy (APT). Implementing APT demands daily 3D imaging of the patient in the treatment position. Presently, proton RT machines typically feature a scintillator-based flat-panel detector (FPD) to generate cone-beam CT (CBCT) images for patient alignment. However, the existing CBCT system suffers from subpar image quality and fails to meet the clinical requirement for APT. This study aims to experimentally showcase the feasibility of producing high-quality CBCT images using photon counting detector (PCD) technology integrated into the existing proton RT gantry.

**METHODS AND MATERIALS**

A CdTe-based PCD, featuring a 50 cm field-of-view and 100 pixel pitch, was affixed onto the surface of the existing FPD in an IBA Proteus ONE proton RT system. The PCD's readout trigger was synchronized with the kV source using a high-sensitivity radiation sensor. The PCD-CBCT scan adopted the same acquisition protocol as the clinical FPD-CBCT scan for head imaging (100 kV, 204 mAs, total angular span = 204°, dose=9.0 mGy). Geometric distortion was estimated and rectified during image reconstruction. Low-contrast detectability and spatial resolution of both PCD-CBCT and FPD-CBCT were assessed using a Catphan and a water QA phantom. Additionally, the physics characteristics of the PCD and FPD were compared through measurements of MTF and DQE.

**RESULTS**

The PCD exhibits an MTF50 of 3.4 lp/mm, while the FPD's MTF50 is 1.1 lp/mm. For MTF10, the PCD achieves 6.7 lp/mm, compared to the FPD's 2.1 lp/mm. The DQE0 values are 0.81 for the PCD and 0.50 for the FPD. PCD-CBCT images demonstrate superior uniformity and reduced artifacts. The smallest resolvable low-contrast target in PCD-CBCT measures 6 mm in diameter with a 0.5% contrast disc, whereas FPD-CBCT images do not resolve any contrast discs in the Catphan. In terms of resolving line pair patterns, PCD-CBCT reaches 21 lp/cm, while FPD-CBCT achieves 3 lp/cm.

**CONCLUSION**

The feasibility of high-quality, on-board PCD-CBCT imaging has been demonstrated using the existing proton RT gantry. The PCD-CBCT prototype exhibits superior low-contrast detectability and spatial resolution compared to the existing FPD-CBCT.

## CLINICAL RELEVANCE/APPLICATION

High-quality on-board imaging via PCD-CBCT can potentially improve patient setup accuracy and enable daily APT with patients in the treatment position, to enhance delivery accuracy and treatment outcomes for proton RT.

## M3-SSPH04-6 ADVANCEMENTS IN DIGITAL IRRADIATION X-RAY SYSTEMS WITH CNT FOR RADIATION THERAPY

Jehwang Ryu, PhD (*Abstract Co-Author*) Nothing to Disclose
Jinho Choi (*Abstract Co-Author*) Nothing to Disclose
Hanna Lee (*Presenter*) Nothing to Disclose

## PURPOSE

The biological effects of high-dose radiation (HDR) have been studied for a long time and their effects are relatively well known. However, in the case of low-dose radiation (LDR), it is still unclear as previous studies have shown compatible in vivo effects depending on the dose range. Under these circumstances, we developed a pulsed cell irradiation system that can control the position of an electron gun (E-gun) based on carbon nanotube (CNT) field emission for the purpose of studying the effects of LDR on cells. In this study, the functions of the X-ray system were verified, and the amount of emitted dose was controlled. And the results of LDR irradiation on cells were described.

## METHODS AND MATERIALS

The component of the system is as follows; 1) a CNT-based E-gun that generates electrons by field emission 2) a vacuum chamber that delivers the emitted electrons, 3) an anode where radiation is generated, 4) a radiation emission part from which generated radiation is emitted, 5) a distance control part capable of adjusting the distance between the E-gun and the radiation emission part. The radiation generating part is a triode structure consists of an electron gun and an anode. The dose emitted in continuous and pulsed mode of the system was checked. And the cells were irradiated with a dose and their responses were analyzed.

## RESULTS

CNTs were randomly grown throughout the surface of the emitter, a component of the E-gun. The characteristics of the CNT-based E-gun were confirmed through the current emitted from the emitter according to the voltage applied to the emitter. In continuous mode, doses of about 1.2 cGy were obtained at 3 mA when the distance between the emitter and the window was 20 mm. Also in the pulse mode, it was confirmed that the emitted dose linearly increased according to the on-time ratio of the cathode, and that the dose was stably emitted with the time. Fibroblast cells irradiated with two modes in the LDR region showed that neither mode affected cell viability in the LDR region.

## CONCLUSION

In this study, we developed a cell irradiation digital X-ray system using CNT for field emission. We also demonstrated that high-speed digital drive-in pulse units with instantaneous on-off is possible, which is difficult to implement with conventional hot cathode X-ray system. The results of LDR irradiation on cells using the developed system are interpreted as statistically not affecting the viability of cells. However, the effect of LDR irradiated with the system on cells seems to require further study.

## CLINICAL RELEVANCE/APPLICATION

We exposed the cells to radiation using a cell irradiation digital X-ray system based on CNTs and examined their response. We anticipate that the developed system can be further utilized for application in orthovoltage radiation therapy.

## M3-SSRO02-1 SOFT TISSUE RESTORATION AFTER FEEDING TUBE INSERTION IN HEAD AND NECK CANCER PATIENTS UNDERGOING RADIOTHERAPY

X. Sharon Qi, PHD (*Abstract Co-Author*) Nothing to Disclose
Eulanca Y. Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Ricky R. Savjani, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Erika Jank, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Patients receiving radiation therapy to the head and neck undergo several adverse effects from treatment, most concerning of which are dysphagia and anorexia. Without adequate nutritional intake, several complications emerge including treatment interruption, dehydration, and hospitalization. Weight loss can be significant enough to require gastric tube (G-tube) insertion, which requires patients to learn how to use tube feeds and can lead to serious complications including infection. The current standard is to weigh patients weekly throughout treatment; however, weights can fluctuate drastically based on hydration, clothing, and bowel habits. Here, we repurpose routine daily cone beam computed tomography (CBCT) imaging to more frequently and accurately assess soft tissue decomposition in patients undergoing radiotherapy for head and neck cancers.

### METHODS AND MATERIALS

In this retrospective study, daily CBCT scans of 61 patients undergoing radiotherapy for head and neck cancers were used to obtain contours of the body, skeletal muscle, and subcutaneous fat automatically with TotalSegmentator. This patient cohort all received G-tubes during the treatment process. The percent change in skeletal muscle and subcutaneous fat relative to G-tube insertion was tracked daily during treatment. Additionally, weekly weights were obtained clinically and recorded for patients.

### RESULTS

Overall, feeding tube insertion slowed the progression of weight loss. Prior to G-tube insertion, patients were losing weight roughly linearly at 0.29% per day, which slowed to 0.05% per day after G-tube insertion. For soft tissue decomposition, prior to G-tube insertion, there was a 1.07% per day loss of subcutaneous fat and a 0.65% per day loss of skeletal muscle, both of which slowed to 0.02% per day (subcutaneous fat) and 0.19% per day (skeletal muscle). Of note, after G-tube insertion, subcutaneous fat loss followed a U-shaped trajectory with an initial continued loss followed by restoration at day 20 and later.

### CONCLUSION

By repurposing routine clinical CBCT images, we characterized soft tissue changes before and after G-tube insertion. Deep-learning autosegmentation provides a way to automate the detection of these changes. On average, patients tend to have significantly decreased rates of weight and soft tissue decomposition after G-tube insertion. Segmentation of CBCT images provides a more frequent and accurate assessment of nutritional compromise.

### CLINICAL RELEVANCE/APPLICATION

Our approach may help clinicians determine optimal and potentially earlier times for nutritional intervention including G-tube placement.

## M3-SSRO02-3 ACCURATE CLASSIFICATION OF HYPOPHARYNGEAL CANCER T4 STAGING BASED ON MRI RADIOMICS FEATURES

Cheyu Hsu, MD, MS (*Abstract Co-Author*) Nothing to Disclose

Hsin-Han Tsai (*Abstract Co-Author*) Nothing to Disclose
Rou-Yi Chen, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to use the radiomics features to predict TNM T4 stage versus others on hypopharyngeal cancer.

**METHODS AND MATERIALS**

In this retrospective study, clinical and MRI data for 560 patients, including 285 with clinical T4 stage according to AJCC 8th version and others with different stages, were collected. The dataset was divided into training (n = 444) and internal (n = 116) test sets. We extracted 1,781 radiomics features from original and derived images in total and performed skewness, reproducibility and high Pearson correlation screening to distinguish the most informative features. Employing XGBoost models within a nested5-fold cross-validation framework, we developed a classification system to distinguish T4 stage from other stages in hypopharyngeal cancer.

**RESULTS**

A total of 211 extracted features were selected to build the classification model for predicting T4 stage, and the ensembling model achieved an accuracy of 0.8671 and 0.8276, sensitivity of 0.8135 and 0.8902, and F1-score of 0.8418 and 0.8795 on the training cohort and internal testing cohort, respectively.

**CONCLUSION**

Radiomics features derived from MRI demonstrate a promising potential in identifying T4 stage, which leads the worst prognosis and survival rates, in hypopharyngeal cancer.

**CLINICAL RELEVANCE/APPLICATION**

The precise staging of T4 hypopharyngeal cancer lays the foundation for prognostic estimation and provides a rapid auxiliary method for clinicians to determine treatment decisions.The precise staging of T4 hypopharyngeal cancer lays the foundation for prognostic estimation and provides a rapid auxiliary method for clinicians to determine treatment decisions.

## M3-SSRO02-4 MODELING OF OUT-OF-POCKET COSTS ACROSS MEDICAID AND MEDICARE PLANS OF STANDARD-OF-CARE EXTERNAL BEAM RADIATION THERAPY VERSUS RADIOSURGERY FOR SYMPTOMATIC METASTATIC SPINE CANCER

Shearwood McClelland, MD (*Abstract Co-Author*) Consultant, Gilmartin Capital
Martha Khlopin (*Abstract Co-Author*) Nothing to Disclose
Victoria Wu (*Presenter*) Nothing to Disclose

**PURPOSE**

The choice between SBRT and EBRT for spine metastases depends on various factors: size, location, patient's health, prognosis, other treatments, and treatment goals. There remains limited evidence regarding the influence of insurance coverage on out-of-pocket (OOP) expenses for patients receiving different modalities of radiation and fractionation. This study seeks to assess costs across various insurance plans, thereby improving clarity and understanding of treatment expenses.

**METHODS AND MATERIALS**

NCCN guidelines and expert input determined standard treatment for symptomatic metastatic spine cancer. OOP costs were calculated based on deductibles, treatment costs, and copays from three public insurance plans: Original Medicare, Medigap Plan G, and Medicaid. All costs were calculated over a two-year time horizon (not adjusted for inflation), and all treatment and work-ups were assumed to have taken place at an Ohio hospital. EBRT was defined as 1 fraction (8 Gy x 1), 5 fractions (4 Gy x 5), or 10 fractions (3 Gy x 10).

**RESULTS**

RT-specific charges include on-treatment visits, planning, simulation, verification, delivery, and follow-ups. Medicare beneficiaries face OOP costs: $807.01, $871.51, $959.69 for EBRT 1 fraction, 5 fractions, and 10 fractions, respectively, after 2 years. Medicare beneficiaries face charges: $1,127.03, $1,444.92, $1,762.82, and $2,398.60 for SBRT 1, 2, 3, and 5 fractions, respectively. Under Medigap Part G, patients are only responsible for the annual deductible, facing a total charge of $480 after 2 years, regardless of radiation modality and fractionation. Medicaid beneficiaries face no OOP expenses as all expenses are covered with no cap, regardless of treatment option.

**CONCLUSION**

SBRT remains a more costly treatment modality compared to EBRT, regardless of the number of fractions. Under Medicare, single-fraction EBRT has OOP financial toxicity 19% less than 10-fraction EBRT, 40% than single-fraction SBRT, 79% less than two-fraction SBRT, and 197% less than five-fraction SBRT at two-years post-treatment.

**CLINICAL RELEVANCE/APPLICATION**

For spinal metastases patients unlikely to benefit from SBRT's durability, reduced OOP financial toxicity of EBRT may optimize quality of life. By understanding these cost differences, patients and their healthcare providers can work together to determine the best treatment option for each patient from a clinical and financial perspective.

## M3-SSRO02-5 DEEP LEARNING BASED PREDICTION MODEL FOR PATIENTS WITH PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

Sanjay Aneja, MD (*Abstract Co-Author*) Nothing to Disclose
Klara Osenberg (*Abstract Co-Author*) Nothing to Disclose
David Weiss (*Abstract Co-Author*) Nothing to Disclose
Sajid Hossain (*Abstract Co-Author*) Nothing to Disclose

Durga Sritharan (*Abstract Co-Author*) Nothing to Disclose
Saahil Chadha (*Abstract Co-Author*) Nothing to Disclose
Thomas Hager (*Abstract Co-Author*) Nothing to Disclose
Joshua Zhu, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Primary central nervous system lymphoma (PCNSL) is typically treated with chemotherapy, steroids, and/or whole brain radiotherapy (WBRT). Identifying which patients benefit from WBRT following chemotherapy, and which patients can be adequately treated with chemotherapy alone remains a persistent clinical challenge. Although WBRT is associated with improved outcomes, it also carries a risk of neuro-cognitive side effects. This study aims to refine patient phenotyping for PCNSL by leveraging deep learning (DL) extracted imaging biomarkers to enable personalized therapy.

**METHODS AND MATERIALS**

Our study included 71 patients treated at our institution between 2009-2021. The primary outcome of interest was overall survival (OS) assessed at one- and two-year cutoffs. The DL model leveraged an 8-layer 2D convolutional neural network which analyzed individual slices of post-contrast T1-weighted pre-treatment MRI scans. Survival predictions were made using a weighted voting system related to tumor size. Model performance was assessed with accuracy, sensitivity, specificity, and F1 scores. Time-dependent AUCs were calculated and C-statistics were computed to summarize the results. Kaplan-Meier (KM) survival analysis assessed differences between low and high-risk groups and statistically evaluated using the log-rank test.

**RESULTS**

The cohort's average age was 65.6 years with an average OS of 2.80 years. For one-year OS, the model achieved an AUC of 0.73 (0.60-0.85), accuracy of 0.73 (0.61-0.82), sensitivity of 0.72 (0.54-0.85), and specificity of 0.73 (0.58-0.84). For two-year OS, the model achieved an AUC of 0.70 (0.58-0.82), accuracy of 0.70 (0.58-0.79), sensitivity of 0.68 (0.55-0.81), and specificity of 0.71 (0.55-0.84). Model performance is presented with their respective 95% confidence intervals (CI).KM survival curves showed that the one and two-year models effectively discriminated between low- and high-risk groups across the entire cohort, reporting a c-statistic of 0.73 ($p<.001$) and 0.71 ($p<.001$) respectively. A sub-analysis confirmed consistent model performance across different tumor volumes and focality.

**CONCLUSION**

DL classifiers of PCNSL MRIs can stratify patient phenotypes beyond traditional risk paradigms. Given dissensus surrounding PCNSL treatment, DL can augment risk stratification and treatment personalization, especially with regards to WBRT decision making.

**CLINICAL RELEVANCE/APPLICATION**

PCNSL poses complex treatment decision-making challenges. To this end, we developed a novel DL model to aid in risk stratification of patients based on OS. Our approach shows that MRI-derived biomarkers are prognostic indicators for PCNSL, and can guide the personalization of chemoradiation treatment.

**PURPOSE**

The GLIAA trial was designed to evaluate the role of O-(2-[18F]fluoroethyl)-L-tyrosine (FET) positron emission tomography (PET) as compared to contrast-enhanced T1-weighted magnetic resonance imaging (GdT1-MRI) for the radiation treatment planning of recurrent glioblastoma.

**METHODS AND MATERIALS**

GLIAA was a prospective, multicenter, randomized clinical trial (NOA 10/ARO 2013-1, DKTK-a., NCT01252459), that included patients with rGBM of 1-6 cm. Patients were randomized 1:1 at 14 centers in Germany between FET-PET-based and T1Gd-MRI-based target volume delineation. High-precision stereotactic re-irradiation was performed with 39 Gy in 13 fractions. Primary endpoint was progression-free survival (PFS) from randomization. Secondary endpoints included overall survival (OS), locally controlled survival (LCS), volumetric analyses and safety.

## RESULTS

Between 26.11.2013 and 02.09.2021, 200 patients were randomized between FET-PET-based (n=100) and GdT1-MRI-based (n=100) target volume delineation. N=98 and n=97 patients, respectively, were treated per protocol. Median PFS was 4.0 months (95% confidence interval [CI] 3.7-5.2) in the FET-PET arm and 4.9 months (95% CI 3.7-6.0) in the GdT1-MRI arm (one-sided stratified log-rank test p=0.98; adjusted HR for the experimental versus the control arm 1.14 [95% CI 0.85-1.52], p=0.39;). Median OS was 9.4 months (95% CI 7.8-11.1) in the FET-PET arm and 9.0 months (95% CI 7.6-10.5) in the GdT1-MRI arm (HR 1.01 [95% CI 0.75-1.37], p=0.92). Median LCS was 6.3 months (95% CI 5.1-7.2) in the FET-PET arm and 6.8 months (95% CI 6.2-7.3) in the GdT1-MRI arm (HR 1.20 [95% CI 0.88-1.62], p=0.25). Tumor volumes on PET and MRI were of similar size (mean ± SD): 10.7 ± 9.9 ml and 10.0 ± 10.6 ml. The overlapping volume was 5.1 ± 5.9 in PET arm and 5.7 ± 6.3 in MRI arm. In 82% of patients in PET arm and 84% of patients in MRI arm there was a relevant difference of at least 2 ml between the MRI and PET volumes. For patients in PET arm, 93.2% ± 13.6% of the MRI volume received at least 30 Gy and 87.7% ± 17.7% received at least 37 Gy. For patients in MRI arm, 93.6% ± 14.5% of the PET volume received at least 30 Gy and 89.7% ± 15.9% received at least 37 Gy. There were no FET-PET-associated adverse events.

## CONCLUSION

The results of this trial could not demonstrate a significant difference in outcome following FET-PET- versus GdT1-MRI-based re-irradiation of rGBM. Both FET-PET and re-irradiation proved safe.

## CLINICAL RELEVANCE/APPLICATION

Both imaging methods - FET-PET and GdT1-MRI - led to similar outcomes and can therefore be used for the re-irradiation treatment planning of rGBM.

## M3-STCE1-1 EXPLORING ANATOMICAL RACE DIFFERENCES IN MAMMOGRAPHIC IMAGES USING AI: PRELIMINARY RESULTS

Robert M. Nishikawa, PhD (*Abstract Co-Author*) Research Grant, Hologic, Inc;Royalties, Hologic, Inc;Research Consultant, iCAD, Inc;Research Grant, Koios Medical, Inc;Research Consultant, maiData Corporation;Researcher, General Electric Company
Juhun Lee, PhD (*Abstract Co-Author*) Nothing to Disclose
Belayat Hossain, PhD (*Abstract Co-Author*) Nothing to Disclose
Tamerlan Mustafaev, MD (*Presenter*) Nothing to Disclose

### PURPOSE

AI models can predict patient race from medical images. Exploring race-wise differences is crucial for overcoming model bias and recognizing anatomical differences linked to disease risks. Identifying features used by AI for race prediction reveals important traits and distinctions among races.The purpose of this study was to conduct multiple ablation experiments to identify anatomical breast features that differentiate Black and Asian races. This approach differs from previous studies that focused on imaging features.

### METHODS AND MATERIALS

For our study, we used mammograms from Asian and Black women taken from the Emory EMBED dataset. We matched the Asian and Black cohorts by age and BI-RADS breast density for a total of 1039 Asian and 1016 Black women. These were divided 1485/263/307 into training/validation/ testing datasets. In addition, we had an independent test set consisting of 157/643 Asian/Black women from our institution. We stitched RCC, LCC, RMLO, and LMLO views and resized the composite to 224x224 as input to a ViT (transformer-based) model. To determine factors that allow AI to differentiate between Black and Asian, we used a segmentation model to segment breast area and fibro-glandular tissue. We produced three different ViT models trained and tested on the original images, binary breast area images (breast shape and size), and binary fibro-glandular tissue images (amount and distribution of fibroglandular tissue).

### RESULTS

Our ViT model trained on original images achieved an AUC of 0.90/0.82 (EMBED/Independent test set). With binary fibro-glandular tissue images, the AUC was 0.76/0.73 (EMBED/Independent test sets), highlighting density distribution differences between Asian and Black races. For the breast area, the AUC was 0.81/0.80 (EMBED/Independent test sets). Using the breast size (total number of pixels in the breast area) as a feature for ROC analysis, the resulting AUC was 0.72/0.73, indicating its importance for distinguishing races, but breast shape also had some discriminatory power. For Black women, the AI model focused on the pectoral muscle/axillary lymph node area, and for Asian women, it focused on the breast borders, suggesting shape and area differences. Breast area had higher discriminatory power than breast shape. There was also some discriminatory power in the amount and distribution of fibroglandular tissue.

### CONCLUSION

Our AI algorithm accurately predicted race from mammographic images. Attention map analysis revealed how the model views race images differently.

### CLINICAL RELEVANCE/APPLICATION

Identifying race-specific anatomical differences and variations in breast density distribution may help develop less racially biased AI algorithms and establish a link between different races and disease risk.

**PURPOSE**

The accurate detection of pulmonary embolism (PE) with CT pulmonary angiography (CTPA) and contrast-enhanced routine chest CT (CTCC) plays a pivotal role in prompt treatment. CTPA is the gold standard for the diagnosis of PE. We assessed the performance of an AI tool to triage and localize PE on CTPA and CTCC with a large, consecutive, and multicenter imaging data.

**METHODS AND MATERIALS**

Our IRB-approved study contained 2026 consecutive CTPA an CTCC exams in 913 adult males (45.1%) and 1113 adult females (54.9%) with mean age of 63±16 years. The data belonged to 7 imaging centers in urban (n=2), community (n=2), and rural settings (n=3). The presence/absence and the location of PE were recorded from radiology reports. The deidentified images were processed locally with the offline version of the AI model (UII, United Imaging Intelligence, 23-26F, No. 701, Yunjin Road, Xuhui District, Shanghai), and the AI output contained the presence/absence and the location of the PE. We calculated the NPV, PPV, F1-score, ROC Area Under the Curve (95% CI), sensitivity, and specificity to assess the performance of the AI model. Separately, we calculated the Chi-Square test to assess if there were significant differences in AI performance across different age groups, genders and hospitals.

**RESULTS**

Off the 2026 exams, there were 1894 without (93.5%) and 132 (6.5%) with PE. The AI algorithm was able to detect the lesion with NPV, PPV, F1-score, AUC (95% CI), sensitivity, and specificity of 0.987, 0.253, 0.390, 0.837 (0.801-0.874), 84.8%, and 82.6%, respectively. There were no significant differences in AI performance gender-wise (P=0.447) and age group-wise (< 66 years versus =/> 66 years; P=0.550), but there were significant differences in AI performance across different hospitals (P<0.001) with slightly lower performance (lowest AUC = 0.701) in complex, multi-comorbidities CT exams from urban settings.

**CONCLUSION**

Our consecutive, multicenter large cohort demonstrates the high performance of AI tools across different gender groups, age groups, CT scanners, CT protocols, and imaging practice types.

**CLINICAL RELEVANCE/APPLICATION**

Evaluation of the generalizability of AI models across different practices, protocols, and patient characteristics is crucial for trustworthy, equitable AI applications.

### PURPOSE

Papilledema, a sign of elevated intracranial pressure (eICP), often prompts ED referrals to rule out conditions requiring immediate neurosurgical attention. This study evaluates the effectiveness of low-field portable brain MRI (pMRI) in identifying space-occupying lesions (SOLs) and hydrocephalus in patients with papilledema / optic disc edema (ODE) and other ophthalmologic manifestations.

### METHODS AND MATERIALS

This retrospective study included patients with ODE and other ophthalmologic signs of possible eICP referred for same-day pMRI (Hyperfine Swoop) from our ophthalmology clinic and inpatients from March 2022 to July 2024. All underwent 64mT pMRI (Hyperfine Swoop) and conventional neuroimaging (CN), either MDCT, 1.5T or 3T MRI. Two raters, blinded to clinical and CN findings, evaluated pMRI images for mass lesions, mass effect (sulcal effacement, midline shift or herniation), hydrocephalus and empty sella. CN performed soonest after the pMRI scans was used as the reference. Interrater and intermodality agreement between pMRI and CN were evaluated using Cohen's ?.

### RESULTS

28 patients (median age 39.5 [IQR 27-50]; 64% females) were included: 15 (54%) had ODE, 7 (25%) less responsive, dilated or fixed pupils, 4 (14%) 6th cranial nerve palsy, and 2 (7%) visual field defects. pMRIs were done in 17 outpatients (61%) and 11 inpatients (39%). pMRI was 100% sensitive for findings requiring urgent neurosurgical evaluation compared to CN. On pMRI, 8 (29%) had mass lesions, 12 (43%) mass effect, and 8 (29%) hydrocephalus. Interrater agreement was very good for mass lesions (93%, ?=0.81), mass effect (93%, ?=0.85), and hydrocephalus (100%, ?=1.00). Comparison CN was CT in 10 (36%) and fixed MRI in 18 (64%) patients; median time interval between scans was 5.5 (IQR 0.5-22) days. Intracranial masses were seen in 9 (32%), while 8 (29%) had hydrocephalus on CN. Intermodality agreement was very good for intracranial masses (96%, ?=0.92), mass effect (100%, ?=1.00), and hydrocephalus (100%, ?=1.00). pMRI detected all except one intracranial mass (8/9, 89%); a posterior fossa mass was not included in the field of view due to positioning difficulties, but hydrocephalus was detected. Isolated empty sella was seen on pMRI in 8/16 (50%) patients without mass or hydrocephalus (interrater and intermodality agreement of 85%, ?=0.78 and 96%, ?=0.91, respectively), 7/8 (88.5%) of which had imaging features of idiopathic intracranial hypertension on CN.

### CONCLUSION

pMRI was an effective screening tool for identifying findings requiring urgent neurosurgical evaluation in patients presenting with ophthalmologic findings of possible eICP. Specifically, pMRI was highly sensitive for SOLs and hydrocephalus and had high concordance rates with CN.

### CLINICAL RELEVANCE/APPLICATION

Low-field pMRI is feasible for ruling out conditions requiring urgent neurosurgical assessment in patients presenting with ophthalmologic signs of possible eICP and may play a role in point of care assessment in clinics.

## M3-STCE2-2 DETERMINATION OF R1 RELAXIVITIES OF GADOBUTROL AND GADOQUATRANE AT LOW AND ULTRA-LOW MAGNETIC FIELD STRENGTHS

Felix Kreis (*Abstract Co-Author*) Nothing to Disclose
Stephan Gruendemann (*Abstract Co-Author*) Nothing to Disclose
Jessica Lohrke, PhD (*Abstract Co-Author*) Employee, Bayer AG

Gregor Jost, PhD (*Abstract Co-Author*) Employee, Bayer AG

**PURPOSE**

The efficacy and clinical utility of gadolinium-based contrast agents (GBCAs) in contrast-enhanced magnetic resonance imaging (CE-MRI) are well established at field strengths of 1.5 and 3.0 Tesla. Recently, significant advancements by OEMs, academic institutions, startups, and NGOs have aimed at increasing access to MR Imaging by substantially reducing the costs and infrastructural requirements of scanner hardware. Most cost reductions have been achieved by utilizing low-field and very low-field magnets. Consequently, it is essential to evaluate the potential of both new and established GBCAs at these lower field strengths.

**METHODS AND MATERIALS**

Human plasma was collected from six donors. Solutions of gadoquatrane and gadobutrol were prepared in aliquots of individual donor plasmas and in aliquots of water at concentrations of 1000 µmol/L, along with one blank plasma sample per donor. T1-relaxation rates were measured at 0.55, 1.5, and 3 Tesla using a Stelar High Field Relaxometer and at 0.06 Tesla using a Stelar Fast Field Cycling Relaxometer. Concentrations were corrected using ICP-OES measurements. Relaxivity was calculated as the change in relaxation rate per unit concentration.

**RESULTS**

R1 relaxivities (L/mmol/s) were as follows:
- Gadobutrol in plasma: 9.38 @0.06T, 5.84 @0.55T, 5.00 @1.5T, and 4.61 @3.0T
- Gadobutrol in water: 7.94 @0.06T, 3.83 @0.55T, 3.45 @1.5T, and 3.41 @3.0T
- Gadoquatrane in plasma: 13.17 @0.06T, 12.39 @0.55T, 11.36 @1.5T, and 10.03 @3.0T
- Gadoquatrane in water: 11.64 @0.06T, 10.09 @0.55T, 10.01 @1.5T, and 9.17 @3.0T These results are summarized and shown alongside measured relaxation rates of plasma and water, as well as literature values for gray and white matter (Fig. 1).

**CONCLUSION**

Since tissue and plasma relaxation rates increase at lower field strengths, an efficient low-field contrast agent must exhibit higher relaxivities at these lower field strengths. We demonstrate this increase in relaxivity at low field strengths for both gadoquatrane and gadobutrol. The next steps to establish CE-MRI at low magnetic field strengths should include phantom and in-vivo imaging studies.

**CLINICAL RELEVANCE/APPLICATION**

Using GBCAs in CE-MRI at low field strengths could significantly expand patient access to CE-MRI, enhancing diagnostic capabilities in a broader range of clinical settings.

## M3-STCE2-3 ACCELERATED MRI AT LOW MAGNETIC FIELDS. CAN FAST IMAGING APPROACHES FROM CLINICAL FIELD STRENGTHS BE TRANSLATED TO THE LOW-FIELD REGIME?

**PURPOSE**

The intrinsic low signal-to-noise ratio (SNR) of low-field MRI scanners often requires many signal averages, which can lead to impractically long acquisition times.Conventionally, MRI scans are accelerated via k-space undersampling and subsequent data restoration via compressed sensing (CS) and/or artificial intelligence (AI) reconstruction. However, complete k-space restoration requires high-fidelity data. Here, we test the performance of MRI acceleration methods across high and low field regimes, highlighting challenges unique to low-field MRI.

**METHODS AND MATERIALS**

Data sampling: Undersampling approaches (e.g. 2x, 4x acceleration) were tested experimentally and in silico. Low-field and high-field brain data from healthy subjects were acquired on a custom 6.5 mT MRI scanner and a 3 T Siemens Skyra, respectively, using a 3D balanced-steady state free precession (bSSFP) sequence. For in silico tests, data from the fastMRI 3 T database was synthetically degraded to simulate the transition from a high-field to low-field.Image Reconstruction: Undersampled data were reconstructed with an inverse fast Fourier transform (IFFT) after zero-filling as a baseline. Missing k-space data were restored with l1-wavelet regularized CS and two AI-based reconstruction methods (data-driven AUTOMAP and model-driven Unrolled Optimization).

**RESULTS**

Our in silico tests on fastMRI data showed that the highest quality sampling and reconstruction method depends on the SNR of the underlying image. At low-field, the best quality images were reconstructed from data undersampled by 2x with a Poisson Disc mask.Our undersampled 3 T data was reconstructed effectively with CS, AUTOMAP and Unrolled methods. However, at 6.5 mT, only the Unrolled AI method removed undersampling artifacts. The Unrolled AI network performs more robust denoising at low field.For the same bSSFP imaging sequence, significant differences in image contrast were observed between 3 T and 6.5 mT. E.g. ventricles appear much brighter than surrounding tissue at 3 T, as compared to low-field images.

**CONCLUSION**

MRI sampling and reconstruction approaches proven at clinical field strengths should not be assumed to translate directly to low-field MRI. The Unrolled reconstruction approach is likely superior to AUTOMAP at 6.5 mT due to its model-driven nature. Unrolled AI models have previously shown robustness to domain shifts between training and testing.Changes in contrast at low-field are consistent with the convergence of T1 and T2 times at 6.5 mT. New approaches to contrast in portable MRI will be needed.

**CLINICAL RELEVANCE/APPLICATION**

Our findings will enable the acquisition and reconstruction of higher quality images with portable MRI scanners, expanding their clinical diagnostic use.

## M5-STCE1-1 3D MR IMAGE SUPER RESOLUTION USING AUXILIARY 3D MR IMAGE WITH DISTINCT CONTRAST WEIGHTING

Yuehua Li (*Abstract Co-Author*) Nothing to Disclose
Zheng Zhang (*Abstract Co-Author*) Nothing to Disclose
Xin-Yu Song (*Abstract Co-Author*) Nothing to Disclose
Lei Xiang (*Abstract Co-Author*) Nothing to Disclose
Xiaoer Wei (*Abstract Co-Author*) Nothing to Disclose
Zechen Zhou (*Presenter*) Nothing to Disclose

### PURPOSE

3D Magnetic Resonance (MR) imaging can provide higher resolution and quality for diagnosis compared to multi-slice 2D MR scans. However, 3D MR scans require much longer acquisition time that hampers its clinical usage for all contrast weightings. To accelerate multi-contrast MR scans and allow 3D high resolution (HR) reconstruction, a novel deep learning approach is developed to enhance the resolution of 2D FLAIR and T2-weighted (T2) MR images by leveraging the distinct contrast weighting of auxiliary 3D HR T1-weighted (T1) image.

### METHODS AND MATERIALS

80 subjects with 2D thick-slice FLAIR/T2 MRI, 3D HR FLAIR/T2, and T1 MRI are acquired from a 3T MR scanner. The 3D T1 image serves as the reference image for cross-contrast registration, and then the 2D images are linearly interpolated to match the number of slices in 3D T1 volume. These 2D images are used as low resolution (LR) images, while 3D images are served as HR images. The dataset consisted of 65 pairs of LR and HR FLAIR/T2-T1 image volumes for training and 15 patient pairs for testing. Our approach proposes a 3D-based model, which utilizes a U-shaped network architecture enriched with residual convolutional neural network blocks. Overall image quality (IQ) was evaluated using Structural Similarity Index Measure (SSIM), Peak Signal Noise Ratio (PSNR), and Signal Noise Ratio (SNR). Paired t-test was used to compare across interpolated 2D, synthesized 3D and acquired 3D images.

### RESULTS

The proposed method can produce high quality multi-contrast volumetric images from corresponding 2D acquisitions with much less scan time (2D FLAIR/T2: 28/70s, 3D FLAIR/T2: 342/349s), particularly the through-plane resolution can be recovered to the same level as 3D scans enabling the depiction of lesions and small structures in sagittal or coronal view as shown in Fig. A and B. Quantitative IQ analysis in Fig. C also demonstrated that the synthesized 3D images are more close to the acquired 3D images.

### CONCLUSION

The novel approach significantly improves the quality of 2D MRI scans to a similar level as acquired 3D HR MRI, which enables a highly accelerated multi-contrast 3D MR acquisition strategy. This fast imaging strategy can reduce the brain protocol scan time by 5~12 times while providing similar IQ as 3D scans for diagnosis, which also allows MR scanners to service more patients.

### CLINICAL RELEVANCE/APPLICATION

A novel multi-contrast 3D MR imaging acceleration approach is developed and evaluated in a neurovascular application, allowing reduced scan time while providing high resolution 3D multiplanar reformation for clinical diagnosis.

## M6-SSCA04-1 PAEONIFLORIN'S CARDIOPROTECTIVE ROLE IN HIGH ALTITUDE MI: A CMR STUDY

Xin Fang (*Abstract Co-Author*) Nothing to Disclose
Lei Wang (*Abstract Co-Author*) Nothing to Disclose
Hongke Yin, MD (*Abstract Co-Author*) Nothing to Disclose
Fabao Gao (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to evaluate the potential protective role of paeoniflorin in a rat model of MI-induced ventricular remodeling under high-altitude hypobaric hypoxia using 7.0T cardiovascular magnetic resonance (CMR) strain analysis.

### METHODS AND MATERIALS

Sixty rats were randomly allocated to six groups (10 rats per group): plain sham operation control (PSO), high-altitude sham operation control (HSO), high-altitude myocardial infarction operation group (Model control), and low-dose, middle-dose, and high-dose paeoniflorin treatment groups. Rats in the high-altitude groups were transported to institution 1 (altitude: 4,250 m), while the plain group rats were transported to institution 2 (altitude: 500 m). The rats acclimatized to their respective environments under standard animal laboratory conditions for three months before undergoing experimental procedures. After four weeks of modeling, CMR was employed to assess cardiac function and left ventricular (LV) structural changes post-interventions. Strain analysis was performed to determine the protective effects of paeoniflorin on MI-induced ventricular remodeling in the high-altitude hypobaric hypoxia rat model.

### RESULTS

Paeoniflorin treatment groups (low-dose, middle-dose, and high-dose) demonstrated a dose-dependent enhancement in LV function compared to the Model control group. Regional strains, encompassing circumferential, longitudinal, and radial strains, showed significant differences between the paeoniflorin treatment groups and the Model control group. Additionally, histological analyses revealed reduced myocardial injury and fibrosis in the paeoniflorin treatment groups relative to the HMO group.

### CONCLUSION

This study's findings indicate that paeoniflorin exerts a protective effect on MI-induced ventricular remodeling in a high-altitude hypobaric hypoxia rat model. These results contribute to understanding the potential therapeutic advantages of paeoniflorin for patients at risk of MI in high-altitude environments, promoting further research into the underlying mechanisms and possible clinical applications.

### CLINICAL RELEVANCE/APPLICATION

The study's outcomes have implications for managing patients at risk of MI, especially those in high-altitude environments or exposed to hypobaric hypoxia. Recognizing the cardioprotective effects of paeoniflorin could lead to innovative therapeutic approaches, such as preconditioning interventions or pharmacological agents targeting hypoxia-related pathways. Utilizing advanced CMR techniques, including strain analysis, may offer valuable insights into myocardial function and injury, potentially enhancing diagnostic and prognostic precision in clinical settings.

## M6-SSCA04-3 CARDIOVASCULAR EFFECTS OF ANDROGEN DEPRIVATION THERAPY IN MEN WITH PROSTATE CANCER

Anant Mandawat (*Abstract Co-Author*) Nothing to Disclose
Carlotta Onnis, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Prostate cancer (PC) men receiving androgen-deprivation therapy (ADT) targeting the gonadotropin releasing hormone (GNRH) axis are at increased risk of major adverse cardiovascular events. However, the pathophysiologic basis of ADT and CVD is unclear. We hypothesize that ADT is associated with accelerated atherosclerosis due to GNRH-mediated inflammatory cascade. Herein, we prospectively examine coronary plaque progression using coronary computed tomography angiography (CCTA) in a cohort of PC men treated with versus without ADT.

**METHODS AND MATERIALS**

Sixty-three men with localized PC receiving radiation (XRT) alone (n=18) or XRT+ADT (n=45) were prospectively enrolled. Patients underwent CCTA, according to clinical protocols, at baseline and 12-month after completion of radiation. Plaque quantification was performed, blinded to therapy and time-point, using semi-automated software (Coronary analysis research prototype, Siemens Healthineers, Forchheim, Germany) and total plaque volume (TPV) and plaque volume by subtype were evaluated (calcified, CPV, non-calcified, NPV) on a per-patient basis. CAD-RADS was also evaluated.

**RESULTS**

At baseline, median (IQR) TPV, CPV, NPV (mm3) and CAD-RADS among patients who received XRT alone versus XRT+ADT were 358.2 (128.1-1034.1) vs 814.9 (204.6-1214.3), 22.6 (6.6-233.8) vs 74.3 (20.4-221.8), 343.1 (110.3-846.3) vs 626.3 (183.6-960.8), 2 (1-2) vs 2 (2-3), respectively. At 12-month follow-up, TPV, CPV, NPV, and CAD-RADS between XRT alone versus XRT+ADT were 422.7 (191.6-1207.6) vs 904.6 (312.9-1557.1), 23.8 (13.0-339.7) vs 111.9 (30.4-264.1), 393.7 (177.5-1030.9) vs 730.4 (271.3-1167.1), 2 (1-2) vs 3 (2-3), respectively. A statistically significant difference between baseline and follow-up was noted among patients treated with XRT+ADT for TPV ($p<0.001$), CPV ($p<0.001$), and NPV ($p=0.004$). A significant difference in CAD-RADS grade was noted in both cohorts ($p=0.025$ for XRT and $p<0.001$ for the XRT +ADT). There was no significant difference in any plaque volume between baseline and follow-up in the XRT alone cohort.

**CONCLUSION**

Addition of ADT to XRT in treatment of localized PC was associated with a significant increase in TPV, CPV, NPV and CAD-RADS grade over a 12-month period.

**CLINICAL RELEVANCE/APPLICATION**

Insights on treatment-associated cardiotoxicity may lead to enhanced cardioprotective strategies tailored to patients with PC treated with ADT, potentially improving overall outcomes.

## M6-SSCA04-4 IMPROVEMENT OF GLOBAL AND REGIONAL MYOCARDIAL FUNCTION MONITORED BY CARDIAC MAGNETIC RESONANCE IN STEMI PATIENTS WITH THROMBOLYTIC THERAPY BEFORE PRIMARY PCI

Yi Xu (*Abstract Co-Author*) Nothing to Disclose
Hao Gong, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine whether in patients presenting with ST-segment-elevation myocardial infarction (STEMI) a single bolus recombinant staphylokinase (r-SAK) within 120 minutes before their first medical contact with percutaneous coronary intervention (PCI) leads to improved global and regional myocardial function derived from cardiac magnetic resonance imaging (CMR).

**METHODS AND MATERIALS**

Sixty-seven STEMI patients [thrombolysis group(n=33), non-thrombolysis group (n=34)] from an open-label, prospective, multicenter randomized study(optimal-5) who underwent CMR one year later after PCI were included. According to the degree of late gadolinium enhancement (LGE) transmurality and circumferential involvement, myocardial segments were divided into the following four types: non-infarcted segments (LGE=0), locally infarcted segments (LGE circumferential involvement= 50%), non-transmural infarcted segments (LGE circumferential involvement>50% and transmurality = 50%), and transmural infarcted segments. Clinical features and CMR derived global and regional myocardial function were recorded and analyzed. The global function included conventional function parameters, global radial strain (GRS), global circumference strain (GCS), and global longitudinal strain (GLS). The regional function included segmental radial strain (SRS), segmental circumference strain (SCS), segmental longitudinal strain (SLS), segmental wall thickening and segmental wall motion.

**RESULTS**

At the patient level, the cardiac index, left ventricular (LV) wall thickening and LV wall motion in r-SAK thrombolysis group were higher than those in non-thrombolysis group (all $P<0.05$). There were no statistical differences in GRS, GCS and GLS between the two groups. At the segment level, SRS of non-transmural infarcted segments in thrombolysis group was superior than that in non-thrombolysis group (30.17% vs19.40%, $P=0.034$). The segmental wall motion of the locally infarcted segments in thrombolysis group was larger than that in the non-thrombolysis group (5.76mm vs 4.66mm, $P=0.025$). Compared with non-thrombolysis group, patients received r-SAK before primary PCI had better SCS, segmental wall thickening and segmental wall motion in the non-infarcted segments (all $P<0.05$).

**CONCLUSION**

The global and regional myocardial function of STEMI patients treated with r-SAK thrombolysis before primary PCI was better than that of non-thrombolysis group one year later.

**CLINICAL RELEVANCE/APPLICATION**

For STEMI patients without clear taboos, the optimal thrombolytic therapy before primary PCI maybe a beneficial choice to achieve a favorable restoration of myocardial function.

## M6-SSMK03-1 THE BENEFICIAL IMPACT OF IMPLEMENTING AN AI APPLICATION FOR FRACTURE DETECTION IN CLINICAL ROUTINE AT A NORWEGIAN HOSPITAL TRUST

Ramprabananth Sivanandan, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Line Tveiten, BMedSc (*Presenter*) Nothing to Disclose

### PURPOSE

Vestre Viken Hospital Trust (VV) in Norway is pioneered in implementing a CE-approved artificial intelligence (AI) application in a real-world clinical setting in four hospitals. This study evaluates the impact and benefits of adopting a fracture detection algorithm on clinical workflow, patient waiting times, and doctor consultations across four hospitals within the trust.

### METHODS AND MATERIALS

This AI application analyzed the x-ray images of patients presenting with trauma. An external validation was performed before being integrated into the daily workflow of radiology departments across four hospitals. Pre-implementation, each hospital had various workflows (fig.1) for handling these patients until treatment. Steps were taken to simplify and streamline the process on implementation. Radiographers used this AI application's result as preliminary reports to navigate patients accordingly. Triaging was incorporated within the Radiology Information System (RIS) with flagging system for the AI results. The study analyzed 20,083 patient examinations by this AI algorithm, collecting data on workflow types, patient waiting times, the necessity for doctor consultations, and the triaging process.

### RESULTS

Post-implementation the various (six) workflow pathways were consolidated to a single standardized pattern which significantly improved the function in radiology department (fig.2). The application enabled radiographers to directly discharge 4,697 patients with negative findings unless there is request by the clinician, thereby reducing total patient waiting time by 201.3 days in total (fig. 3). Since then, there was a decrease in the need for 2,348.5 doctor consultations at emergency departments (ED, ER) and utilizing the doctor’s time for sick patients, and potentially increasing the patient safety. The AI-enhanced triaging capability in RIS allowed radiologists to prioritize reporting of urgent cases facilitating the flow (fig. 4).

### CONCLUSION

Workflow changes brought standardization across the four hospitals. Examinations with AI negative results drastically reduced the waiting time for those patients and are sent home (fig.5). Patients with positive AI results are prioritized for treatment. Flagging in RIS enhanced efficiency of radiologists.

### CLINICAL RELEVANCE/APPLICATION

The integration of an AI-based fracture detection application in the radiology departments significantly optimized clinical workflows, reduced patient waiting times, decreased crowding in waiting rooms, and saved time by reducing unnecessary doctor consultations. This enhanced hospital efficiency and effectiveness, especially in high-volume clinical settings.

## M6-SSMK03-2 LEVERAGING DEEP LEARNING FOR QUANTITATIVE ASSESSMENT OF LOWER LIMB MUSCLES THROUGH WHOLE LIMB AND 3D SECTIONAL ANALYSIS ON A COHORT OF 21,464 HEALTHY PATIENTS

### PURPOSE

Establishing normative aging curves is imperative to understand the aging process and allows for interventions when deviations occur, to that end the purpose of this study is to establish the normative curves for the musculoskeletal system of the lower limbs.

### METHODS AND MATERIALS

T1-weighted whole-body MRI sequences were utilized in two datasets: 72 scans for training segmentation model and another 21,464 patients for establishing the normative. The deep learning (DL) pipeline quantifies the thigh and calf muscles volumes relative to femur and tibial bones using 3D nnU-Net segmentation model. To ensure consistency in 3D sectional measurements, the leg bones and their corresponding muscles were rotated to align with the axial axis. This enabled the division of the lower limb into nine overlapped sections (P1 to P9), with subsequent computation and normalization of muscle volumes based on bone length, as illustrated in Figure A. Regression analysis was performed on the normalized muscle volumes to generate normative curves, which were further stratified by gender and plotted against ages ranging from 18 to 85 years old.

### RESULTS

As depicted in Figure B, normative analysis shows a decline in thigh muscle volume for both genders from their 30s, with females experiencing earlier reduction in calf muscle volume by their late 40s, and males in their mid-50s. Detailed 3D section analysis reveals more age-related variations than total muscle volumes. Thigh and calf muscle sections farther from the belly continue to decline with age, while the muscle belly increases during the 30s before declining faster afterwards. Similarly, 3D sections covering the gastrocnemius muscle belly increase until age 60 for males and 50 for females, followed by a faster decline.

### CONCLUSION

DL-based analysis of lower limb muscles provides a powerful means to quantify volume differences across genders and ages. By scrutinizing 3D muscle sections, we gain insights into how muscle volumes change at different parts of the muscle.

### CLINICAL RELEVANCE/APPLICATION

3D segmental and whole lower limb musculoskeletal analysis aids radiologists in quantifying volume variations in muscle belly, origin and insertion, facilitating muscle degeneration risk assessment. This capability enables longitudinal tracking of volume changes, aiding in the diagnosis of conditions like Muscular Dystrophy and Amyotrophic Lateral Sclerosis (ALS).

## M6-SSMK03-3 ESTABLISHMENT OF A NOVEL CASCADE RADIOMICS PIPELINE FOR PREDICTING THE ONSET AND PROGRESSION OF OSTEOARTHRITIS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

Lin Mu, MD,MS (*Abstract Co-Author*) Nothing to Disclose
Jiahui Fu (*Abstract Co-Author*) Nothing to Disclose
Huimao Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Chunjie Guo, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop novel cascading radiomics model based on cartilage and subchondral bone to predict the onset and progression of knee osteoarthritis (KOA) within 4 years.

### METHODS AND MATERIALS

The prospective nested case-control study conducted on 456 participants with Kellgren-Lawrence (KL) grade 0 or 1 at baseline from the Osteoarthritis Initiative (OAI). Utilizing 3.0T Magnetic Resonance Imaging (MRI) of the right knee, participants were stratified into KOA and non-KOA groups based on 4-year radiographic follow-up and 1:2 propensity score matching (PSM). Early and late progressors were further classified based on the timing of KOA progression. All patients were randomly divided into train set and test set according to 7:3 ratio. Clinical information at baseline and all 3D DESS MRI images of the right knee during 4-year follow-up were collected. ITK-SNAP was used to segment the cartilage and subchondral bone of femur, tibia and patella in 3D DESS MRI. Radiomic features were extracted from cartilage and subchondral bone to establish logistic regression (LR) models for predicting KOA onset and progression, respectively. These models were then cascaded to achieve a one-stop multi-classification system. Model performance was primarily evaluated using the receiver operating characteristic (ROC) curve. Other model evaluation indicators include sensitivity, specificity, F1 score.

### RESULTS

After PSM, there was no statistical difference between KOA group and non-KOA group($P<0.05$). The combined cartilage and subchondral bone radiomics models demonstrated superior performance in predicting KOA onset and progression. The area under the ROC curve (AUC) for predicting KOA occurrence was 0.985 (95%CI,0.969-1.000), and for progression, it was 0.738 (95%CI,0.565-0.911). In the model predicting onset of KOA, cartilage-based performance was slightly better than that based on subchondral bone, with AUC of 0.974 (95%CI,0.944-1.000) and 0.941 (95%CI,0.941-0.979), respectively. However, the model predicting progression of KOA based on subchondral bone (AUC,0.721) was slightly higher than that of cartilage (AUC,0.676). After cascading the LR models above, the AUC values of each category are predicted to be above 0.800 with accuracy of 0.791.

### CONCLUSION

The MRI-based radiomics model of combined cartilage and subchondral bone information, effectively predicts the onset and progression of KOA within 4-year, facilitating earlier identification of high-risk individuals in clinical.

### CLINICAL RELEVANCE/APPLICATION

The novel cascade radiomic pipeline we constructed to predict the occurrence and progression of KOA can provide one-stop technical support for early diagnosis of KOA, screening of high-risk populations, and prediction of disease progression.

## M6-SSMK03-4 IMPLEMENTATION OF FULLY AUTOMATIC DEEP LEARNING SYSTEM FOR BODY COMPOSITION ASSESSMENT ON CT FOR OPPORTUNISTIC SARCOPENIA SCREENING

Yousun Ko, PhD (*Abstract Co-Author*) Nothing to Disclose
Seongwon Na (*Abstract Co-Author*) Nothing to Disclose

Jimi Huh, MD (*Abstract Co-Author*) Nothing to Disclose
Kyung Won Kim, MD (*Presenter*) CEO, Trial Informatics Company

### PURPOSE

Opportunistic screening for the evaluation of sarcopenia and obesity has been gaining emphasis. A fully automatic deep learning system for body composition assessment on abdominal CT scans is a prerequisite for opportunistic screening. We aimed to evaluate the efficiency and effectiveness of the

implemented fully automatic deep learning system for body composition assessment for routine health check-ups.

**METHODS AND MATERIALS**

Our fully automatic deep learning system is composed of selecting L3 slices and segmenting muscle and fat areas in an end-to-end manner, which has been used in 30 published scientific sarcopenia research. Our AI system was integrated into the Picture Archiving and Communication System (PACS) of three health check-up institutions. Our AI system's performance was assessed for technical success rate, overall processing time, and segmentation accuracy across three different institutions to confirm its robustness and scalability. The AI system was applied to 532 CT scans consecutively.

**RESULTS**

The AI system was implemented on on-premise servers which were successfully integrated into the PACS in three institutions. The technical success rate of the AI system was 100% without any failed cases requiring manual adjustment. The mean processing time from the completion of CT acquisition to the generation of AI results was 4.12 seconds. The segmentation accuracy comparing AI results and human expert results was 97.4%. In addition, our AI system also provided a diagnosis of sarcopenia and myosteatosis.

**CONCLUSION**

Implementing the AI-based system for sarcopenia screening from opportunistic CT scans significantly enhances diagnostic processes, drastically reducing the time and effort required compared to conventional methods. This improvement in diagnostic capability allows for quicker and more accurate assessments, facilitating earlier and potentially more effective interventions.

**CLINICAL RELEVANCE/APPLICATION**

The integration of AI in detecting sarcopenia offers significant clinical benefits, enabling earlier and more accurate diagnoses that can lead to improved patient management and outcomes. This technological advancement is poised to transform clinical practices, ensuring that patients receive timely and appropriate care informed by precise and reliable diagnostic data.

## M6-SSMK03-5 CHARACTERIZING PREOPERATIVE MRI VIA MACHINELEARNING FOR PREDICTING PROGRESSION-FREE SURVIVALOF OSTEOSARCOMA: A MULTICENTER STUDY

Qiuping Ren (*Abstract Co-Author*) Nothing to Disclose
Xiao Zhang (*Abstract Co-Author*) Nothing to Disclose
Shui Xing Zhang Sr, MD (*Abstract Co-Author*) Nothing to Disclose
Xiaoyun Liang (*Abstract Co-Author*) Nothing to Disclose
Bin Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Yuchi Tian (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of preoperative MRI combined with machine learning in predicting progression-free survival (PFS) of osteosarcoma.

**METHODS AND MATERIALS**

A total of 270 patients with histologically confirmed osteosarcoma from 14 hospitals were retrospectively enrolled, which were strictly divided into the training (n=166), test cohort 1 (n=56), and test cohort 2 (n=48). Univariate and multivariate logistic regressions were used to analyze the correlation between PFS and clinical features. Contrast-enhanced fat-suppressed T1-weighted images (CE-FS-T1WI)-based radiomics analysis was based on 1130 radiomics features, which were filtered by Pearson correlation coefficient analysis and Relief algorithm successively, and finally modeled by comparing multiple classifiers. In addition, the effectiveness of features from three advanced deep learning framework (ResNet-50, DenseNet-121, and EfficientNet-B7) for PFS prediction was investigated. Unsupervised segmentation was adopted to extract the nucleus from the pathological images, based on which 150 features were further extracted and finally aggregated into individual-level pathological features. The correlations between score of the optimal predictive model and pathological features were evaluated by Spearman correlation analysis.

**RESULTS**

The performance of the radiomics model constructed by 12 features exceeded that of clinical features and deep learning features ($P < 0.001$), with AUCs of 0.916 (0.900-0.932), 0.802 (0.777-0.828), and 0.895 (0.879-0.911) in the training cohort, validation cohort 1, and validation cohort 2, respectively (FIGURE 1). The high- and low-risk groups showed significant differences in PFS (FIGURE 2, $P < 0.05$). As independent prognostic factors of PFS, six pathological features showed strong correlations with the radiomics scores (FIGURE 3, $P < 0.05$).

**CONCLUSION**

Our study verified the effectiveness of the CE-FS-T1WI-based radiomics model for predicting PFS in osteosarcoma, which can be used as a non-invasive prognostic tool before treatment.

**CLINICAL RELEVANCE/APPLICATION**

The proposed radiomics model can help clinicians identify patients with poor prognosis and adjust treatment accordingly, thus leading to a better prognosis for osteosarcoma patients.

## M6-SSMK03-6 AN ARTIFICIAL INTELLIGENCE ASSESSMENT SYSTEM FOR RISK GRADING OF SARCOPENIA BASED ON ULTRASONOGRAPHIC MULTIDIMENSIONAL DATA: A CROSS-REGIONAL, MULTI-ETHNIC, CROSS-SECTIONAL STUDY

Li Qiu (*Abstract Co-Author*) Nothing to Disclose
Xinyi Tang (*Presenter*) Nothing to Disclose

**PURPOSE**

To establish an ultrasound-centered intelligent risk grading system for sarcopenia in the older adults.

**METHODS AND MATERIALS**

Participants in were recruited from one medical centre, one urban community, and three plateau communities. According to AWGS2019, the diagnosis of sarcopenia was made through the sarcopenia-related symptoms (low muscle mass, low gait speed, low handgrip strength). Three trained sonographers scanned the upper arms, forearms, thighs, and legs of each subject and obtained corresponding ultrasound images. We concatenated four ultrasound images of each sample and input them into the RESNET50 network and concatenated the corresponding muscle thickness measurements, BMI, and age values and input them into the MLP. After re-concatenating the two sections and adding a linear layer, we initially established the model.

**RESULTS**

A total of 990 volunteers were recruited, and after amplification, 1145 samples were included in this study. In the first step, the determination of whether there is muscle mass loss or muscle function decline, our model achieved AUC of 0.879 and 0.813 in men and women, respectively. For men, there is a sensitivity of 87.1% and a specificity of 75.8% in detecting the presence of sarcopenia related symptoms, while for women, there is a sensitivity of 85.8% and a specificity of 65.5%. In further assessment of the presence of two or more symptoms, AUC of 0.770 and 0.662 were achieved in men and women, respectively.Based on the classification results of these two steps, we classified all image samples into different risk groups. Overall, out of 380 samples identified as low-risk, only 1.3% were ultimately diagnosed with sarcopenia. Among the 466 samples classified as middle-risk, 80.7% had at least one sarcopenia related symptom and 17.6% were ultimately diagnosed with sarcopenia. Among the 299 samples classified as high-risk, more than half were ultimately diagnosed with sarcopenia, and about one-third were diagnosed with severe sarcopenia.

**CONCLUSION**

We established an ultrasound-centered intelligent risk grading system for sarcopenia in the older adults, which can classify the risk of sarcopenia in a cross-regional, multi-ethnic population.

**CLINICAL RELEVANCE/APPLICATION**

In middle- to low-income areas, the identification of sarcopenia in older adults is very low, due in part to the lack of good accessibility of equipment, including DXA and high-end BIA equipment, as well as a cumbersome assessment process. A four-image ultrasound-centered risk grading system for sarcopenia is not only cost-effective, but also helps community primary care providers to quickly assess the risk of sarcopenia in older adults and provide further medical advice.

### PURPOSE

To assess the longitudinal effects of glucagon-like peptide-1 (GLP-1) receptor agonists on the AI-derived abdominal body composition biomarkers on abdomen-pelvis CT examinations.

### METHODS AND MATERIALS

The study included 102 adult patients (mean age: 60±14 years; F:M 64:38) from seven quaternary and community hospitals. Using a radiology report search database (mPower, Nuance) and electronic medical records (Epic), we identified consecutive patients who underwent abdominal CT examinations before (CT1) and after (CT2) their first GLP-1 prescription. We also included a third CT examination (CT3) of 79/102 patients performed after 14 months (mean) of their second CT. The time between the radiological examination and the medication prescriptions was recorded. We de-identified, exported, and processed thin-section CT images of each examination with an AI tool (ClariMETABO, ClariPI) to segment and quantify the area of abdominal wall muscles, psoas muscles, visceral adipose tissues, and subcutaneous adipose tissues at T12, L1, L2, L3, and L4 vertebral levels. We performed paired two-tailed t-tests to compare AI output at each vertebral level and time point.

### RESULTS

There were significant statistical differences between the visceral and subcutaneous adipose tissues on follow-up CT2 and CT3 exams when compared to the baseline CT1 (p 0.44-<0.001). However, between the two follow-ups, CT2 and CT3, only subcutaneous adipose tissue decreased significantly at all vertebral levels (p<0.001). There was a larger decrease in adipose tissues and waist circumference at lower lumbar levels than at T12/L1 levels. Interestingly, there was also a decrease in the overall abdominal wall and psoas muscles between baseline CT1 and follow-up CT2, but not between the two follow-up CT1 and CT2 exams.

### CONCLUSION

We demonstrate that AI-inferred abdominal body composition biomarkers from abdomen-pelvis CT examinations can help in the longitudinal assessment of visceral and subcutaneous adiposity changes in patients on glucagon-like peptide-1 (GLP-1) receptor agonists.

### CLINICAL RELEVANCE/APPLICATION

The metabolic biomarker evaluation AI tool can provide useful information for monitoring intra- and post-treatment changes in adipose tissues and waist circumference in patients on GLP-1 treatment.

## M6-SSMS01-2 ASSOCIATION BETWEEN BRAF$^{V600E}$ MUTATION, DISEASE SEVERITY, AND GERM LINE LAYER INVOLVEMENT IN ERDHEIM-CHESTER DISEASE BY USING RADIOLOGICAL FINDINGS FROM A UNIQUE ECD POPULATION

**PURPOSE**

This study evaluates the relationship between BRAFV600E mutation, disease severity, and germ line layer involvement in Erdheim-Chester Disease (ECD) using radiological findings.

**METHODS AND MATERIALS**

A prospective analysis of radiological findings from a cohort of 40 biopsy-confirmed ECD patients were conducted. These patients had available imaging data along with BRAFV600E mutation status. Our evaluation of radiological findings comprised 10 organ involvements (including bone, pulmonary, CNS, uropathy, nephropathy, cardiac, vascular, orbit, hepatobiliary, and spleen)(table 1) and germ line layer involvement (Mesoderm, Endoderm, Ectoderm), based on radiological findings. A team of expert radiologists, comprising 5 body, 2 neuro, 1 thoracic, 2 clinical fellows, and 2 nuclear medicine specialists, reviewed MRI/CT/PET-CT/Bone Scan studies. Discrepancies were resolved either by a third reader or by achieving consensus between two radiologists.

**RESULTS**

A significant association was found between BRAFV600E mutation and disease severity based on organ involvement. Bone and pulmonary regions exhibited the highest frequency of involvement, regardless of the presence of BRAFV600E mutation (95% and 92% respectively). Positive associations were found between BRAFV600E mutation and cardiac (OR=4.55, p=0.027) and vascular (OR=5.60, p=0.013) involvement. ECD patients showed full involvement in Mesoderm (100%), 93% in Endoderm, and 75% in Ectoderm using radiological findings. However, no significant correlation existed between germ line layer involvement and BRAFV600E mutation.

**CONCLUSION**

BRAF mutation is associated with disease severity in ECD, particularly in cases with more organ involvement. Bone and pulmonary regions are consistently affected, while cardiac and vascular involvement are associated with BRAFV600E mutation. ECD patients showed full involvement in Mesoderm while no direct correlation was found with BRAFV600E mutation with any specific germ line layer.

**CLINICAL RELEVANCE/APPLICATION**

This study represents the largest single-center investigation of ECD patients, encompassing a comprehensive assessment of radiological findings to elucidate the impact of the BRAFV600E mutation on disease severity, thereby facilitating risk stratification and treatment decision-making in ECD. Furthermore, the identification of BRAFV600E mutation status as a potential prognostic indicator highlights the multifaceted nature of ECD, underscoring the imperative for targeted therapeutic approaches and additional molecular research.

## M6-SSMS01-3 CAN OPPORTUNISTIC AI-BASED AUTOMATED MEASURES OF ABDOMINAL FAT, MUSCLES, AND WAIST CIRCUMFERENCE ON EMERGENCY ABDOMEN CT IN 30-39-YEAR-OLD PREDICT FUTURE DIABETES AND HYPERTENSION? A MULTICENTER MULTI-YEAR FOLLOW-UP STUDY

Seyedehelaheh Hosseini, MD (*Abstract Co-Author*) Nothing to Disclose
Emiliano Garza Frias, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We assessed if AI-enabled measures of abdominal fat, muscles, and waist circumference on abdomen CT in 30-39-year-old predict future diabetes (DM) and hypertension (HT) over a multi-year follow-up.

**METHODS AND MATERIALS**

Our IRB-approved, retrospective study included 1277 patients (between 30-39 years; 776 females, 501 men) with an abdomen-pelvis CT performed as part of their emergency department workup for clinical reasons unrelated to diabetes and hypertension. We excluded patients with known diagnosis of DM and HT either at or before their CT examinations. From the review of their electronic medical records, we assessed if patients developed DM or HT over an eight-year follow-up since their CT. We processed all CT exams with an AI algorithm (ClariMetabo, Claripi.ai) and obtained following measures: HU and volume of subcutaneous fat (SAT) and visceral fat (VAT), waist circumference (WC), psoas muscle, and abdominal wall muscles, at five levels including

T12-L4 vertebrae. We used each level measurements and divided the patients according to their respective quartiles. Cox Regression tests were performed across different categories using the lowest quartile of measures as the references for comparing the hazard ratios (HR) for predicting DM and HT. The highest quartile was used as a reference for mean skeletal and psoas muscle density analysis.

**RESULTS**

Our study demonstrates that VAT (HR:1.4-2.5; p<0.001), SAT volumes (HR:1.9 to 2.2; p<0.001), and WC (HR:1.9 to 2.6; p<0.001) in the highest quartiles were the best and most significant to assess the risk of developing DM. The HR for DM in VAT and WC increased progressively from T12 to L4 (HR @ T12 1.4 and 2.1, respectively, vs HR @ L4 2.5 and 2.6). Patients in the lowest quartile of mean skeletal muscle density had higher HT and DM risks (HT HR: 1 to 1.4; DM HR 1.1 to 1.7) at multiple levels than the psoas muscle (HT HR: 0.6 to 1.3; DM HR: 0.8 to 1.2). We also found that the DM HR in the lowest quartile group for mean skeletal muscle density was higher as the spine level increased (T12 HR:1.7 vs L4 HR:1.1).

**CONCLUSION**

Our study demonstrates that the use of opportunistic AI-based body composition analysis of emergency abdominal CT examinations in tricenarians can be used for predicting hypertension and diabetes mellitus.

**CLINICAL RELEVANCE/APPLICATION**

Larger, prospective studies can help assess if opportunistic screening in young patients with an autonomous, efficient, single-click AI tool can increase the lead time for preventive steps to detect patients at risk of diabetes mellitus and hypertension.

## M6-SSMS01-5 EXPLORING ASSOCIATIONS BETWEEN OBESITY AND SARCOPENIA WITH DEMENTIA USING BODY AND BRAIN MRI QUANTITATIVE MEASUREMENTS

Fan Huang, PhD (*Abstract Co-Author*) Nothing to Disclose
Varut V. Vardhanabhuti, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Man Kwun Andrew Li, BSc, MBBS (*Presenter*) Nothing to Disclose

**PURPOSE**

Previous studies have shown a strong association between obesity and sarcopenia with risk of dementia. However, only physical/biometric measurements, such as body mass index, grip strength and gait speed, and DEXA scan quantitative measurements, such as appendicular lean mass index, have been used to demonstrate this association. Recent advances in MRI segmentation have led to the development of more specific quantitative measures of fat content and muscle quantity, allowing for a more standardized means of characterizing obesity and sarcopenia in patients. Furthermore, the relationship between these MRI quantitative measurements with MRI brain volumetric measurements of dementia has not been explored. This study aims to identify associations between body MRI quantitative measurements of central obesity and quantitative muscle assessment with MRI brain volumetric measurements of dementia.

**METHODS AND MATERIALS**

We randomly identified 9,938 patients from the UK Biobank cohort who underwent both body MRI and MRI brain studies. For body MRI, we derived quantitative measurements of central obesity and quantitative muscle assessment. More specifically, fat percentages and normalized fat free indices of large muscle groups, including abdominal wall and thigh muscles, were derived using in-house deep learning segmentation algorithm. For MRI brain, we utilized volumetric measurements known to be associated with dementia. Linear regression was performed, with incorporation of important confounders, such as age, gender, body mass index, smoking and alcohol status, to determine the significance of associations between the two groups of MRI quantitative parameters.

**RESULTS**

In our analysis, bilateral anterior thigh fat percentage was demonstrated to be the most consistent quantitative parameter that was predictive of MRI volumetric measurements related to dementia, with significant associations with total brain volume, total grey matter volume, and bilateral hippocampal volume. In addition, fat free index whole abdominal wall muscle from T1 to L5 levels was found to be a significant predictor of multiple MRI volumetric measurements related to dementia, including total grey matter volume, mean peripheral cortical grey matter volume, and bilateral hippocampal volume.

**CONCLUSION**

This study demonstrated the predictive ability of MRI-derived quantitative measurements of central obesity and quantitative muscle assessment with MRI brain volumetric parameters of dementia, consistent with previous studies showing the strong association between these conditions.

**CLINICAL RELEVANCE/APPLICATION**

This study lends support for the use of body MRI to characterize the degree of sarcopenia and obesity in patients to predict the risk of dementia.

## M6-SSMS01-6 SCREENING OF PATIENTS DIAGNOSED WITH HHT (HEREDITARY HEMORRHAGIC TELANGIECTASIA) OR THEIR FIRST-DEGREE RELATIVES FOR DISEASE EXPRESSION IN BRAIN, LIVER AND LUNG BY MAGNETIC RESONANCE IMAGING

Peter Fries, MD (*Abstract Co-Author*) Research Grant, Guerbet SA

Diane Wagner-Jochem (*Abstract Co-Author*) Nothing to Disclose
Guenther K. Schneider, MD, PhD (*Presenter*) Research Grant, Siemens AG;Speakers Bureau, Siemens AG;Speakers Bureau, Bracco Group;Research Grant, Bracco Group

**PURPOSE**

To evaluate MRI for screening of pediatric and adult patients with clinical and/or genetic proven diagnosis of HHT or first-degree relatives of HHT patients for AVMs (arterio-venous malformations) in the brain, liver or lung.

## METHODS AND MATERIALS

419 patients (3-86 years; mean 42 +/-19 years; male/female 157/262) underwent MRI of the brain, liver and pulmonary vasculature for the detection of AVMs in a single examination. The imaging protocol included unenhanced MRI of the brain (T2w, FLAIR, SWI, DWI and T1w imaging) followed by T1w and T2w liver imaging and flow-sensitive GRE-sequences of the liver to detect increased vessel density. This was followed by a time-resolved and a high-resolution contrast-enhanced MR-angiography of the thorax. Finally a contrast-enhanced T1w scan of the liver and of the brain was performed, so with one CM dose a complete work-up could be performed. The total magnet time was 40-45 minutes.

## RESULTS

In 278 of 419 Pts. (66%) at least one disease expression in either brain, liver or lung was found with a mean age at diagnosis of 44 +/-18 years. The total number of Pts. with cerebral AVMs was 34 (8 %), pulmonary AVMs 236 (56%) and liver AVMs 64 (15%). Of these 5 Pts. only showed AVMs in the brain, 188 only in the lung and 34 only in the liver respectively. 21 Pts. had simultaneous AVMs in both brain and lung, 3 in both brain and liver and 22 in both lung and liver. Only 5 Pts. demonstrated AVMs in all evaluated organs. With regard to male female ratio 179 out of 262 female Pts. (68%) and 98 out of 157 male Pts. (62%) at least showed one disease expression in either brain, liver or lung. All AVMs detected in the screening MRI were confirmed either by catheter angiography during treatment, dedicated MRI or CT studies or in follow-up imaging. No clinically relevant AVMs were missed in screening, only some small additional PAVMs (feeding vessel </= 1mm) were detected on CT imaging of the lung.

## CONCLUSION

MRI is a feasible, radiation-free one stop screening method for evaluation of disease expression in brain, liver and lung in Pts. diagnosed with HHT. The average age at first imaging of 44 +/-18 years shows that in many Pts. clinically relevant AVMs are diagnosed relatively late and in fact several Pts. were already suffering from brain abscess or stroke, cerebral hemorrhage, heart failure (due to left-to-right shunt in liver AVMs), impaired liver function or respiratory failure at the time of diagnosis.

## CLINICAL RELEVANCE/APPLICATION

Early diagnosis of disease expression in the brain, liver and lungs in patients with HHT is essential to avoid irreversible complications of the disease. Therefore, a single MRI study that provides an overview of disease expression is an important tool for the treatment of patients with HHT with the goal of normal quality of life and life expectancy.

## M6-SSNPM01-1 ENERGY-EFFICIENT USAGE OF CT SCANNERS THROUGH OPTIMIZED EXAMINATION SCHEDULING - EVALUATION OF TWO MATHEMATICAL MODELS

Armin Nurkanovic (*Abstract Co-Author*) Nothing to Disclose
Tobias Heye, MD (*Abstract Co-Author*) Nothing to Disclose
Jan Vosshenrich, MD (*Abstract Co-Author*) Nothing to Disclose
Martin Segeroth, MD, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

Medical imaging devices are large consumers of electricity. This study aimed to estimate potential energy savings through optimized CT examination scheduling using an ideal (hypothetical) and a realistic mathematical model.

### METHODS AND MATERIALS

Examination timestamps and power consumption data of all CT examinations performed on three CT scanners in our tertiary care radiology department in 2015 were retrospectively included. Both scheduling models were formulated mathematically using linear constraints, a linear objective function and only binary decision variables as a binary linear programming (BLP) model. This formulation allows for rigorous modelling of a non-convex and non-differentiable objective function and offers the possibility to compute the optimal solution in a significantly reduced solution time. The BLPs were formulated and solved using the commercial integer programming solver Gurobi. The lower bound model (LB-model) allowed to power down all CT scanners, except the one in the emergency department. For the realistic model (R-model), the emergency department CT scanner and one CT scanner in the radiology department remained online to allow for continuous scanning of non-emergent exams as well.

### RESULTS

Measurements included 261 workdays with 15,072 CT examinations. The median duration to solve the BLP for each workday was 9.9 s (9.2-10.6 s) for the LB-model and 6.0s (5.5-6.6 s; p<.001) for the R-model. The LB-model yielded a 34.8% (34.2-35.5%) reduction in combined daily energy consumption through optimal examination scheduling, the R-model yielded an 11.0% (10.7-11.3%) reduction. In absolute numbers, daily energy consumption could hypothetically be decreased by 41.9 kWh from (121.0 kWh to 79.1 kWh; p<.001) for the LB-model and by 13.3 kWh (121.0 kWh to 107.9 kWh; p<.001) for the R-model.Hypothetical energy savings for the LB-model were primarily realized through examination shifting to the emergency CT scanner, thus increased system off times for the other CT scanners. The R-model compensated for this mechanism, rendering the estimated savings realistically achievable.Estimated annual savings were 10,933 kWh in energy consumption, $2,865 in costs, and 1,399 kgCO2eq in carbon emissions for the LB-model, and 3,460 kWh, $907 and 443 kgCO2eq for the R-model.

### CONCLUSION

Optimized CT examination scheduling through mathematic modelling could have substantial sustainability and cost benefits for radiology departments. Feasibility of model implementation in clinical routine however needs further investigation.

### CLINICAL RELEVANCE/APPLICATION

Mathematic modelling could allow for automated CT examination scheduling to realize an optimized and more energy efficient usage of CT scanners within radiology departments.

## M6-SSNPM01-2 MRI SUSTAINABILITY: UNLOCKING THE POWER OF HEAT RECOVERY IN RADIOLOGY

Daniel Audette (*Abstract Co-Author*) Nothing to Disclose
Filipp Alaverdyan (*Abstract Co-Author*) Nothing to Disclose
Daniel J. Margolis, MD (*Abstract Co-Author*) In-kind support, Siemens AG;Consultant, Promaxo, Inc
Akhil Soman (*Abstract Co-Author*) Nothing to Disclose
Lara Pes (*Abstract Co-Author*) Nothing to Disclose
Akua Amoah, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

Magnetic Resonance Imaging (MRI) scanners are indispensable tools in modern healthcare, providing detailed diagnostic images for various medical conditions. However, the operation of MRI scanners consumes significantly energy and generates an enormous amount of waste heat, presenting an

opportunity for sustainable energy utilization. By harnessing heat pumps, heat generated by MRI machines can be repurposed for warming buildings rather than wasted. We hypothesized that a heat pump system can be designed for incorporation into a heat recovery system to exploit heat generated by MRI.

**METHODS AND MATERIALS**

An Office of Energy Sustainability and Department of Radiology at one institution in the United States coordinated with a commercial entity to design a proposed schematics for heat capture. The existing heat capture and waste exhaust for the MRI and the heating system for the hospital system were evaluated. These were used to design a heat pump schematic and cost analysis.

**RESULTS**

A potential schematic for integration of a heat pump into MRI siting with a breakdown of implementation and costs was generated. Incorporating a heat recovery system using heat pump will cost $813,433. Preliminary calculations estimate a total savings of 6,209 million British thermal units (mmBTU) annually, resulting in a substantial reduction (30%) in fossil fuel usage for the building's entire heating system.

**CONCLUSION**

By embracing innovative energy conservation and emission reduction approaches, radiology departments can serve as catalysts for transformative change within healthcare facilities. Energy currently being rejected by the MRI chiller cooling towers will be recovered and reused. While this may be straightforward to apply for future MRI site designs, integration into existing MRI installation may be challenging and require additional investigation and costs, and potentially taking the MRI offline for implementation.

**CLINICAL RELEVANCE/APPLICATION**

This provides a comprehensive framework for leveraging radiology's energy-intensive operations to drive decarbonization within healthcare facilities. Specifically, we highlight the potential of repurposing MRI heat as a sustainable heating source and offer a leading edge for medical facilities to reduce their reliance on fossil fuels and mitigate their environmental impact.

## M6-SSNPM01-3 REDUCING THE AMOUNT OF EXCRETED CONTRAST MEDIA IN SEWAGE WATER: A PILOT STUDY USING A SPECIALIZED TOILET FILTER SYSTEM

Mathias Prokop, MD, PhD (*Abstract Co-Author*) Speakers Bureau, Canon Medical Systems Corporation;Research Grant, Siemens AG;Speakers Bureau, Siemens AG
Alex Hol (*Abstract Co-Author*) Nothing to Disclose
Anne Talsma, MS (*Abstract Co-Author*) Nothing to Disclose
Helena M. Dekker, MD, MBA (*Presenter*) Nothing to Disclose

**PURPOSE**

Contrast media has been shown to be increasingly present in surface water and entering drinking water supply. We tested and optimized a toilet filtration system (TFS) to reduce the amount of contrast media entering sewage water.

**METHODS AND MATERIALS**

The TFS (manufactured by Zereau, Nijmegen, The Netherlands) consists of a specialized toilet system with two cartridges, the first of which retains faecal matter and toilet paper, the second contains adsorbents that bind contrast media. Cartridge configurations were adapted in a stepwise fashion to optimize the amount of retained contrast material. These configurations were tested in two settings in which patients were asked to use the TFS (a) during their stay in a cardiology holding unit after interventional cardiac procedures (ICP) with Iomeron 300 (Bracco, Italy) and (b) after an outpatient contrast-enhanced MRI (ceMRI) with Dotaram (Guerbet, France). Contrast media concentrations were measured in both influent and effluent streams and contrast removal efficiency was determined from the ratios between excreted and injected contrast.

**RESULTS**

The TFS was optimized in 170 ICP patients and 140 ceMRI patients to find the optimal cartridge configurations. The contrast removal efficiency with the optimized cartridge configurations was tested on 34 ICP patients and 37 ceMRI patients who had, on average, received 115 ml Iomeron and 20 ml Dotarem, respectively. Patients after ICP stayed on average 200 minutes in the cardiology holding unit and used the TFS there. Patients after ceMRI could leave the hospital immediately after having used the TFS. While contrast removal efficiency was 99% for Iomeron and 99% for Dotarem, 42% of the injected iodine and 14% of the injected Gd could be retrieved with the TFS.

**CONCLUSION**

The toilet filtration system was highly effective in removing iodinated and Gd-based contrast agents from the excreted urine. However, the total amount of contrast that was excreted when the patients used the toilet, needs to be further optimized and this retrieval is higher for longer hospital stays.

**CLINICAL RELEVANCE/APPLICATION**

This is the first study to show that nearly all contrast media can be removed from excreted urine when using a toilet filtration system, reducing the amount of contrast media in waste water. However, further measures need to be taken to optimize the amount of excreted contrast in the urine during a hospital stay.

## M6-SSNPM01-4 WHERE DO WE GO FROM HERE? STRUCTURED SCOPING REVIEW AND ROADMAP FOR SUSTAINABILITY RESEARCH IN RADIOLOGY

Marisa Martin, MD (*Abstract Co-Author*) Nothing to Disclose
Katherine E. Maturen, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Mark P. MacEachern (*Abstract Co-Author*) Nothing to Disclose
Sean A. Woolen, MD, MS (*Abstract Co-Author*) Research Grant, Siemens AG;Investigator, Siemens AG
Colby Foster, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This scoping review of environmental sustainability in radiology summarizes current literature and identifies research gaps with the ultimate intention to reduce the carbon footprint of medical imaging.

**METHODS AND MATERIALS**

A scoping review using PRISMA-ScR guidelines searched multiple databases from inception to 2/12/2024. Citations were screened in a multi-reader structured process, including all original research on diagnostic imaging and/or image-guided procedures with environmental impact as an outcome.

Conference abstracts, narrative reviews, commentaries and editorials were excluded. Data extraction was performed by two investigators. The outcomes and research gaps were summarized using descriptive statistics and narrative reviews. Outcomes were converted to CO2e for purposes of comparison.

**RESULTS**

2280 citations were reviewed and 75 studies containing original data from 28 countries were included, spanning 1975 to 2024, most using an observational cross-sectional design. Five thematic domains emerged: nuclear medicine waste (27 publications), energy and waste from image acquisition (26), energy from radiology operations (11), energy in radiation oncology (7), and sustainability perceptions (4). Annual CO2 emissions from radiology equipment varied by modality, with MRI emitting 34.3-72.1 MT, CT 6.0-17.1 MT, IR suites 8.6-10.6 MT, fluoroscopy 4.8 MT, X-Ray 4.0 MT, workstations 0.2-1.0 MT, and US 0.3 MT. An IR suite on a single weekday generated 1.6 MT CO2, with the highest contributors being HVAC and single use devices (solid waste weight was converted to CO2e). A few studies analyzed contrast media and radiotracers in water systems. Research gaps include: validating existing estimates of modality specific emissions; initial emissions estimates for nuclear medicine and breast imaging; solid waste from single-use devices; hospital vs. ambulatory center imaging; MR imaging at lower field strengths; cooling systems; and data center impacts; and efficacy of proposed mitigation strategies.

**CONCLUSION**

Among thousands of publications addressing environmental sustainability and medical imaging, only a small percentage provide primary data. This structured scoping review consolidates the literature on radiology's environmental impact and summarizes existing estimates and potential interventions, highlighting areas for future research to improve sustainability in radiology.

**CLINICAL RELEVANCE/APPLICATION**

A scoping review of a large but diffuse body of literature establishes a roadmap for future original research on environmental sustainability in radiology practice, ultimately contributing to climate change mitigation and public health improvement.

## M6-SSNPM01-5 COMMUNITY SUPPORT FOR LUNG CANCER SCREENING

Farouk Dako, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Farouk Dako, MD, MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

Lung cancer screening (LCS) using low-dose CT (LDCT) for high-risk individuals is a critical public health tool for reducing lung cancer mortality. Despite the recent expansion of the inclusion criteria to be more equitable, uptake and adherence remains low and is lowest among low-income and racial/ethnic minority populations and in individuals with a negative baseline screening study. Community-based programs promoting cancer screening uptake have demonstrated increased screening engagement compared to clinic-based programs in reaching disadvantaged individuals but suffer from lack of robust funding and limited data demonstrating impact on a population level.

**METHODS AND MATERIALS**

We performed a pragmatic clinical trial to measure the effect of our community support program (free rideshare, education and navigation) on adherence to annual LCS in patients with a scheduled exam following a previous negative study. We designed an educational program for LCS a grade 6 readability to train a community health worker who was tasked with reaching out to patients with upcoming appointments and offering free ride, education and health system navigation. We defined our intervention group (West Philadelphia) and control group (SW Philadelphia) using geospatial analysis of census track data. After a 6-month period, we compared adherence rates between participants in the intervention group and participants in the control group, who received routine care. We also compared outcomes between individuals in the intervention group who opted into our program vs those who did not. We utilized parts of the RE-AIM framework for planning and evaluation. Descriptive statistics was performed, and chi-square test was performed.

**RESULTS**

Within the intervention group (191 individuals),14% of individuals opted to participate in our program. 88% of the participants in our program attended their LCS appointment versus 68% of the individuals who chose not to. In the control group (52 individuals), 62% of individuals attended their appointment. The was a statistically significant difference in the rate of adherence to appointments between individuals in our program and those who received routine care, $p < 0.05$. 69% of individuals in the program opted to take a rideshare. Average age and smoking history were similar among all groups. Individuals in our program were more likely to be African American and Female.

**CONCLUSION**

Our study demonstrates that providing social support could improve adherence to LCS appointment. However more work needs to be done to improve the reach of such programs

**CLINICAL RELEVANCE/APPLICATION**

Provides data supporting community based approaches for health promotion

## M6-SSNPM01-6 PREDICTIVE MODELING FOR GUIDELINE-CONCORDANT FOLLOW UP OF INCIDENTAL LUNG NODULES: A TOOL FOR CARE DELIVERY

Saul Blecker, MD,MS (*Abstract Co-Author*) Nothing to Disclose
Mutita Siriruchatanon (*Abstract Co-Author*) Nothing to Disclose
Samrachana Adhikari (*Abstract Co-Author*) Nothing to Disclose
Stella Kang, MD, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Evidence-based follow up for incidental lung nodules (ILN) represents an important opportunity to improve early detection of lung cancer and racial-ethnic disparities in outcomes. We assessed the feasibility of developing an accurate and fair predictive model for guideline-concordant follow up of ILN.

**METHODS AND MATERIALS**

We compared various machine learning approaches for prediction of inappropriate follow-up care for ILN. The data consisted of 8,910 patients with ILN with structured follow-up recommendations and 12 predictors for patients (sex, age, race, ethnicity, smoking history, type/size of nodules), care setting (inpatient, Emergency Department, ambulatory), and census-tract level social determinants of health (Index of Concentration of Extremes and Social Vulnerability Index). Five-fold cross validation was performed for hyperparameter tuning and assessing out of sample prediction performance. Algorithm fairness using an "equal opportunity" approach was assessed using true positive rates (TPR) and positive predictive value (PPV) in Black patients as compared with Non-Hispanic white patients, given that this minority group experiences the worst disparity in lung cancer outcomes nationally.

## RESULTS

Lack of appropriate follow up occurred similarly in Black and other minority groups compared with Non-Hispanic White patients (45-48%). Higher risk ILN with recommended follow up within 3 or 3-6 months underwent inappropriate care more often in minorities than in non-Hispanic white patients (68% vs. 61%, respectively, p=0.01). Several machine learning methods performed well; a decision tree algorithm achieved high accuracy (85%) and AUC (0.89) for predicting inappropriate care, with TPR 99% and FPR 28%. The predictive model also had high positive predictive value (76%). In terms of algorithm fairness, TPR and PPV were similar for Black patients vs. non-Hispanic white patients with TPR 99% and PPV 78% in Black patients vs 99% and 75% in Non-Hispanic white patients, respectively, suggesting feasibility to develop a fair prediction model with high accuracy.

## CONCLUSION

The developed predictive model can aid identification of patients at greatest risk of receiving inadequate follow-up care for ILN and facilitate care delivery strategies for follow up. The model performed with adequate fairness with high TPR and PPV for a minority group experiencing the worst early-stage detection and survival rates in lung cancer.

## CLINICAL RELEVANCE/APPLICATION

This predictive model for inadequate ILN follow up is a tool that may ultimately facilitate health systems leaders in multilevel interventions when implementing ILN follow-up guidelines. Algorithm fairness better establishes the model's validity for addressing health disparities.

## M6-SSVA02-1 IMAGING-INFORMED MORPHOELASTIC GROWTH MODEL OF AORTIC SHAPE EVOLUTION

Nhung Nguyen (*Abstract Co-Author*) Nothing to Disclose
Junsung Kim (*Abstract Co-Author*) Nothing to Disclose
Luka Pocivavsek (*Abstract Co-Author*) Nothing to Disclose
Kameel Khabaz, BA (*Presenter*) Nothing to Disclose

### PURPOSE

Minimally invasive approaches for type B aortic dissection (TBAD) have raised the specter of long-term risks, including device failure. Proper identification of patients for endovascular repair and accurate timing of surgical intervention are critical in preventing disease-related complications. We develop an imaging-informed finite element (FE) morphoelastic model of aortic shape evolution. Based on the hypothesis that pathologic growth drives morphologic heterogeneity, we incorporate past geometric information into FE simulations to predict future aortic shape change.

### METHODS AND MATERIALS

Four TBAD patients, each with two 3D segmentations at different time points, are modeled. Per-element growth rates are defined by mapping localized area changes between the two geometries. Specifically, each patient's two scans are anatomically mapped with rigid and non-rigid registration algorithms. The meshes are subdivided into corresponding partitions, and the growth rate of each region in the initial scan is calculated as the time-normalized area change from the corresponding region in the second scan. Per-element growth rates are smoothed into a globally contiguous growth field, which serves as input to FE simulation. Resulting geometries are quantitatively analyzed for size, measured as surface area (A), and shape, defined using a previously published shape signal of aortic pathology (dS).

### RESULTS

The spatially mapped growth fields model the heterogenous aneurysmal evolution of aortic dissections, such that the geometries modeled in the FE simulations demonstrate a high degree of similarity to real aortic geometric trajectories, both in visual 3D space and the shape-size feature space (dS vs. A). A standard FE simulation modeling uniform growth failed to reproduce the trend of increasing shape deformity coupled to increased surface area.

### CONCLUSION

Imaging-informed FE growth simulations show promising trends in modeling aortic shape evolution in TBAD patients. We show that the source of the morphologic shape signal (dS), which has been shown to be the hallmark of aortic pathology, is embedded in the spatial gradients of local aortic growth.

### CLINICAL RELEVANCE/APPLICATION

Individualized prediction of a patient's future aortic geometry carries the potential to improve TBAD management by better informing timing of surveillance imaging and surgical interventions.

## M6-SSVA02-2 UTILIZING SIZE-SHAPE METRICS TO ADJUDICATE DISEASE SEVERITY IN ASCENDING THORACIC AORTIC ANEURYSM DISEASE

Nicholas S. Burris, MD (*Abstract Co-Author*) Royalties, ImBio, LLC
Timothy Baker, PhD (*Abstract Co-Author*) Nothing to Disclose
Prabhvir S. Marway, BA, MBBChir (*Abstract Co-Author*) Nothing to Disclose
Nic Tjahjadi (*Abstract Co-Author*) Nothing to Disclose
Gregory Spahlinger (*Abstract Co-Author*) Nothing to Disclose
Carlos Alberto Campello Jorge, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Borderline ascending aortic dilation diagnosis is increasing due to incidental detection on CT/MRI, with potential increase in patient and healthcare burden due to often-indolent disease and low complication rate. Diagnosis is based on maximal diameter measurements, which vary with age and body size and neglect 3D morphologic features. New methods are needed to adjudicate normal vs. pathologic anatomy in marginal degrees of dilation. We aimed to harness ascending aortic shape, taken from clinical CT angiography (CTA), and statistical shape modeling (SSM), a method to quantify deviation of 3D shapes, to investigate new combined size-shape metrics to adjudicate disease severity.

### METHODS AND MATERIALS

We retrospectively analyzed CTA scans of 334 adults without prior aortic repair, categorized into 3 groups: ascending thoracic aortic aneurysm (aTAA; mid-ascending "MA" diameter >45 mm), Normal aorta controls (MA diameter: males <34 mm; females <33 mm), and a "Borderline" group meeting neither criterion. We excluded patients with bicuspid or significant aortic valve dysfunction, genetic aortopathy or first degree relative with aTAA. We computed aortic size index (ASI) to account for body size differences (ASI=max diameter/body surface area). We generated a new metric (M/S ratio) to reflect relative size of the MA aorta relative to sinuses (M/S=MA/sinus diameters). An SSM score for each patient was calculated to quantify 3D similarity between an individual patient's aortic shape and mean Normal ascending aortic shape.

### RESULTS

Included were 334 patients (54% male; average age 55 ± 15 years). Within the aTAA group (n=42), 91% had hypertension, average age of 65 ± 10 years, mid-ascending diameter of 47 ± 2 mm, and predominant mid-ascending dilation (M/S ratio = 1.13 ± 0.13). The normal aorta group (n=165) demonstrated a lower hypertension rate (14%; p<0.001), smaller mid-ascending diameter (29 ± 3 mm), lower M/S ratio (0.87 ± 0.08; p<0.001), and younger age (48 ± 14 years; p<0.001). The remaining 127 patients were in the Borderline group. Combined SSM scores and ASI showed that 54% of borderline cases were closer to aTAA, while 34% were closer to normal aortas. Adding M/S ratio to a 3D plot revealed a discernible upward and rightward trend with increasing SSM score, ASI, and M/S ratio across disease severity strata.

### CONCLUSION

Differences in 3D shapes and size ratios between normal ascending aortas and aTAA from CTAs can be exploited to quantify anatomic abnormalities in patients with borderline degrees of dilation.

### CLINICAL RELEVANCE/APPLICATION

Combined shape-size assessment shows promise in adjudicating ascending aortic disease severity, especially in borderline cases, which could alleviate overdiagnosis and tailor patient-specific management strategies.

## M6-SSVA02-3 TRACKING AORTIC GROWTH WITH MANUAL DIAMETER MEASUREMENTS OVER TIME IS UNABLE TO RELIABLY DIFFERENTIATE STABLE VERSUS GROWING CASES, IMPAIRING DISEASE DETECTION

Gregory Spahlinger (*Abstract Co-Author*) Nothing to Disclose
Juliana Robayo (*Abstract Co-Author*) Nothing to Disclose
Nicholas S. Burris, MD (*Abstract Co-Author*) Royalties, ImBio, LLC

Prabhvir S. Marway, BA, MBBChir (*Presenter*) Nothing to Disclose

### PURPOSE

Determining the trajectory of growth in ascending thoracic aortic aneurysm (aTAA) is central to management. Recent work implicates increased growth rates (>1mm/year) with a 2-3X risk of aortic dissection, with guidelines incorporating rapid growth (>3-5mm) as an indication for prophylactic surgical repair, regardless of size. However, a reliable assessment of aortic growth is limited in clinical practice by significant variability in manual diameter measurements (±3-5 mm). Our group has developed vascular deformation mapping (VDM), a validated registration-based image analysis technique that allow for 3D growth measurement with sub-millimeter accuracy using clinical CT angiograms (CTAs). The purpose of this study was to compare the consistency of aTAA growth trajectories measured by manual diameters measurements versus by VDM.

### METHODS AND MATERIALS

We included patients with a chart diagnosis of aTAA without repair, selecting a random sample of 50 patients. Manual diameters were collected by trained 3D lab technicians in all available CTAs including the maximal diameter of the ascending aorta. VDM analysis was conducted between the baseline and every subsequent CTA. Each patient's growth trajectory by both methods was assessed for inconsistency, defined as growth less than -1mm between serial CTAs (biologically implausible). Agreement was assessed by intraclass correlation coefficients (ICC).

### RESULTS

We included 196 non-overlapping intervals from 240 CTAs across 44 aTAA patients (6 excluded for <3 CTAs). Median (IQR) growth across all intervals was 0.0 mm (-0.8, 0.9) for manual measurements vs. 0.2mm (0.0, 0.5) for VDM (p = 0.041), with a median time between CTAs of 1.5 years (1.0, 2.2). 41% (18) of patients had at least one negative growth interval (i.e., <-1mm) by manual measurements, whereas 0 patients showed negative growth by VDM (p <0.01). By manual measurements, 11 patients had >2mm growth intervals, however, these were preceded or followed by negative growth in 8 (73%) cases. By contrast, VDM had 3 patients with >2mm growth intervals, with no preceding or following negative growth. Median growth over the whole follow-up period (median 6.3 years) was 0.3mm (-1.0, 1.4) for manual measurements vs. 0.7mm (0.4, 1.4) for VDM (p =0.03), with an ICC of 0.49 (95% CI: 0.30, 0.63).

### CONCLUSION

Tracking aTAA growth by manual measurements exhibits high variability compared to VDM, with most negative and positive growth intervals (73%) likely due measurement error with manual approaches.

### CLINICAL RELEVANCE/APPLICATION

The current clinical practice of manual diameter measurements in monitoring ascending aortic aneurysm is unable to reliably differentiate stability from growth, a significant limitation to characterizing disease progression over time.

## M6-SSVA02-4 AORTIC TORTUOSITY AS A GENOTYPE-ASSOCIATED MARKER OF MORTALITY IN LOEYS-DIETZ SYNDROME

Joao A. Lima, MD (*Abstract Co-Author*) Nothing to Disclose
Harry Dietz (*Abstract Co-Author*) Nothing to Disclose
Bharath Ambale-Venkatesh, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation;Co-founder, Third Eye Health Inc;Research Grant, Myocardial Solutions, Inc
Stefan L. Zimmerman, MD (*Abstract Co-Author*) Consultant, Siemens AGSupport, Siemens AG
Shadi Afyouni, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Patients with Loeys-Dietz (LDS) syndromes are susceptible to dilation of the proximal aorta and other vascular segments leading to a higher prevalence of aneurysms and dissections. LDS is secondary to mutations in genes involved in the transforming growth factor beta pathway, with aggressive genotypes associated with severe morbidity and mortality. Our goal was to assess the utility of different markers of aortic shape in predicting mortality as compared to aortic diameter.

### METHODS AND MATERIALS

This retrospective study used the PMCOE database (Precision Medicine Center of Excellence - Aortopathies) at Johns Hopkins. All patients with LDS since 2005 with a CT angiography were included in this study. Clinical and follow-up data was obtained from electronic medical records, and all patients included had genotypic classification. Images were loaded into Slicer 3D, and TotalSegmentator was used to segment the aorta and adjacent vessels. Users corrected the segmentation as needed. The vascular modeling toolkit (VMTK) was used for generating centerlines and geometric parameters such as aortic volume, tortuosity, mean curvature, maximum cross-sectional diameter (CSd), and the diameter of the maximum inscribed sphere (MISd). Patients were followed up every 1-2 years to assess their status. Hazard ratios (HR) from Cox regression adjusted for age and gender assessed the association of imaging markers with mortality. Ideal cut-offs were chosen using a classification and regression tree. $P<0.05$ was considered significant.

### RESULTS

In all, 102 patients were included in the study - and were distributed across the 6 LDS subtypes 1 to 6 - 23, 43, 10, 14, 10, and 2 respectively. Patients with LDS type 2 had the highest tortuosity and CSd, followed by those with LDS type 1. LDS types 3 and 6 had the smallest diameters and lowest aortic tortuosity. Over the follow-up period, there were 22 deaths. LDS types 1, 2, and 4 had 5, 16 and 1 deaths respectively with no deaths recorded in the other groups. Tortuosity was the only parameter that was independently associated with mortality both univariately (HR: 1.93, $p=0.024$) and after adjustments for age and gender (HR:1.98, $p=0.032$). There was an observed interaction between gender and tortuosity. Females with high tortuosity (more than 1.55) were at a higher risk of mortality as compared to males ($p<0.05$).

### CONCLUSION

Aortic tortuosity was associated with aggressive genotypes and mortality in LDS patients. Females with high tortuosity were at a particularly high risk of mortality as compared to males, and females with low tortuosity.

### CLINICAL RELEVANCE/APPLICATION

Imaging markers play a critical role in the surveillance of LDS patients and tortuosity may potentially be a more useful marker than currently used measures of aortic dimension.

## M6-SSVA02-6 ASSESSMENT OF THE THORACIC AORTA AFTER ASCENDING AORTIC SURGERY USING 3D MODIFIED RELAXATION-ENHANCED ANGIOGRAPHY WITHOUT CONTRAST AND TRIGGERING

Kenan Kaya, MD (*Abstract Co-Author*) Nothing to Disclose
Carsten H. Gietzen, MD (*Abstract Co-Author*) Nothing to Disclose

Lenhard Pennig, MD (*Presenter*) Speakers Bureau, Koninklijke Philips NV;Institutional Grant, Koninklijke Philips NV

### PURPOSE

Relaxation-Enhanced Angiography without Contrast and Triggering (REACT) is a novel 3D isotropic flow-independent non-contrast-enhanced MRA (non-CE-MRA) sequence and has already shown promising results in imaging of the thoracic aorta, primarily in patients without prior aortic surgery. Hence, its performance after ascending aortic surgery is unknown. The purpose of this study was to evaluate the performance of REACT in patients after surgery of the ascending aorta by performing an intraindividual comparison to CE-MRA.

### METHODS AND MATERIALS

This retrospective single center study included 38 consecutive MRI studies of 17 patients (mean age at first examination 50.20±13.80 years, 11 (64.71%) female) after ascending aortic surgery. MRI was performed at 1.5T using a standardized protocol comprising modified REACT (ECG- and respiratory-triggering, Compressed SENSE factor 9, nominal scan time: 2:11 min, reconstructed resolution 0.8 × 0.8 × 0.9 mm3) and 3D CE-MRA. Independently, two radiologists measured vessel diameters and evaluated image quality (5-point scale, 5=excellent) for the following levels (inner-edge): mid-graft, distal landing zone, ascending aorta, aortic arch, and descending aorta. Additionally, readers evaluated MRAs for the presence of aortic dissection (AD) and graded the quality of depiction as well as their diagnostic confidence using 5-point scales (5=excellent).

### RESULTS

David procedure was performed in 6 (35.29%), Bentall procedure in 7 (41.18%), and supracoronary ascending aorta replacement in 4 (23.53%) patients. Overall, vessel diameters were larger in CE-MRA compared to REACT (total acquisition time: 05:42±00:38 minutes), albeit without statistical significance (CE-MRA: 28.79±4.02 vs. REACT: 28.65±4.05, $p=.36$). Image quality for all levels combined was higher in REACT (median [IQR] 3 [3-4] vs. 4 [3-4], $p=.052$), with statistically significant difference at mid-graft (3 [3-4] vs. 4 [4-4], $p<.001$) and ascending aorta (3 [3-4] vs. 4 [3-4], $p=.02$). Using CE-MRA as the standard of reference, readers detected all cases of AD (Stanford A: 15 (82.35%); Stanford B: 3 (17.65%)) in REACT with equal quality of depiction (4 [3-5] vs. 4 [3-4], $p=.45$) and diagnostic confidence (4 [4-4] vs. 4 [3-4]), $p=.15$) in both sequences.

### CONCLUSION

REACT enables fast and reliable imaging of the thoracic aorta after ascending aortic surgery with superior image quality compared to CE-MRA at the aortic graft without diagnostic compromise regarding the detection of AD.

### CLINICAL RELEVANCE/APPLICATION

This study indicates the feasibility of REACT for assessment of the thoracic aorta after ascending aortic surgery and expands its clinical use for gadolinium-free MRA to these patients.

## M6-STCE1-2 DEVELOPMENT OF A THERAGNOSTIC RADIOPHARMACEUTICAL FOR PANCREATIC CANCER

Anuja Konda (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this research is to develop a radiotheragnostic strategy targeting claudin-4 (CLDN4), a tight junction protein highly upregulated in pancreatic cancer, with a radiolabeled peptide for the diagnostic imaging and treatment of pancreatic cancer. We identified a CLDN4 binding peptide (C4BP) fragment with high affinity and conjugated a chelator at the N-terminus of the peptide to incorporate 64Cu (half-life: 12.7h) for diagnostic imaging and 177Lu (half-life: 6.7 days) for therapy. In vivo studies have been conducted to evaluate the 64Cu-labeled CLDN4 peptides in mouse models of pancreatic cancer. We aimed to assess the accumulation, clearance and intratumoral distribution of 64Cu-labeled C4BP (64Cu-C4BP), along with co-injected non-labeled C4BP (blocking), in xenograft mouse model of pancreatic cancer from PET/CT images.

### METHODS AND MATERIALS

PET/CT scans of mice bearing pancreatic cancers were analyzed using Siemens Inveon Research Workplace. The tumor region of interest (ROI) was drawn based on anatomical information from CT and functional information from PET. The following ROIs were assessed for accumulation and clearance of radiolabeled peptides: left tumor, right tumor, muscle (identified in quadriceps), blood (identified in ventricles), left and right kidney. ROI data is exported as percent injected does per gram (%ID/g) or standardized uptake value (SUV).

### RESULTS

Using the ROIs that were drawn on blood, tumors, muscle, kidneys, and bladder, time activity curve (TAC) was generated as a plot of %ID/g over multiple time frames. While the 64Cu-C4BP clearance from blood pool was similar between two groups, PET image thresholding at 5%ID/g of maximum radioactivity showed significantly greater tumor uptake in mice injected with 64Cu-C4BP ($p<0.01$) compared to 64Cu-C4BP in blocking group co-injected with excess C4BP. 64Cu-C4BP was cleared through the kidneys and bladder as shown by the steady increase and accumulation over time (min), but there was no significant difference in accumulation between the blocking and non-blocking studies. Blood demonstrated the fastest clearance of the peptide at all the timepoints.

### CONCLUSION

64Cu-C4BP was retained well in tumor expressing CLDN-4 receptors representing pancreatic cancer tumors. Co-injection of excess non-labeled C4BP blocked tumor accumulation demonstrates that 64Cu-C4BP binding is specific to CLDN4. Therefore, in pancreatic cancer xenograft model, we were able to confirm the specificity of C4BP to CLDN4.

### CLINICAL RELEVANCE/APPLICATION

We can translate these findings to develop the therapeutic approach. Future research endeavors will explore developing this C4BP for therapeutic use by switching the isotope to 177Lu as treatment for pancreatic cancer.

## M6-STCE1-3 EQUIPPING BACTERIA WITH A VISUALLY THERAPEUTIC NANOCOATING FOR THE INTEGRATION OF DIAGNOSIS AND TREATMENT

Shi-Xiong Chen (*Presenter*) Nothing to Disclose

### PURPOSE

Oral probiotic therapy has been considered as an effective strategy for treating intestinal dysbiosis-associated diseases. Monitoring the treatment process to understand the relationships between microbiome regulation and disease progression is valuable but remains a formidable challenge. Current bacterial modification strategies fail to address issues of low bioavailability, limited therapeutic responses, and difficulty in visualization simultaneously.

### METHODS AND MATERIALS

Here, the use of a visually therapeutic nanocoating is reported to enable the integrated diagnosis and treatment of oral probiotics. Specifically, inspired by the biomineralization in nature, the probiotics were wrapped in a calcium carbonate/manganese dioxide/ferric oxide hybrid nanocoating by sequential triple biointerface mineralization.

### RESULTS

Following administration, the outermost calcium carbonate layer of the coating can rapidly neutralize gastric acid via a spontaneous double-decomposition reaction, facilitating the adaptive release of manganese dioxide/ferric oxide dual-mineralized bacteria. This process enhances the stability of the newly

exposed layer and protects the encapsulated probiotics from harsh gastric conditions. Upon reaching the lesion site, the manganese dioxide/ferric oxide layer can act as nanozymes with superoxide dismutase and catalase activities, achieving increased synergistic therapeutic effects with probiotics. Meanwhile, the layer can also serve as a contrast agent of T1 and T2 dual-mode magnetic resonance imaging, allowing visualization of the probiotics and disease treatment progression in vivo. The integrated diagnostic and therapeutic potential of the triple mineralized probiotics has been demonstrated in both a Salmonella-induced mouse model of colitis and an apolipoprotein E-deficient mouse model of atherosclerosis.

## CONCLUSION

In summary, we have reported the utilization of a visually therapeutic nanocoating to integrate diagnosis and treatment for oral probiotics. The probiotics wrapped in a hybrid nanocoating of $CaCO_3$, $MnO_2$, and $Fe_2O_3$ are fabricated through sequential triple biointerface mineralization. Upon oral ingestion, the triple mineral coating acts as a physical barrier, with the outermost $CaCO_3$ layer reacting spontaneously with gastric acid to neutralize it rapidly and adaptively release the $MnO_2/Fe_2O_3$ dual-mineralized bacteria. This process enhances the stability of the newly exposed coating and protects the encapsulated probiotics from harsh gastric conditions. At the lesion site, $MnO_2/Fe_2O_3$ dual-mineralized coating functions as a nanozyme with SOD and CAT activities, reducing inflammation, eliminating ROS, and synergizing with probiotics for enhanced therapeutic effects. Additionally, $MnO_2/Fe_2O_3$ coating acts as an MRI contrast agent, enabling T1 and T2 dual-mode imaging, thereby allowing visualization of the in vivo distribution of probiotics and monitoring the progression of related disease treatments. Both a Salmonella-induced mouse model of colitis and an ApoE-/- mouse model of AS have demonstrated the concurrent diagnostic and therapeutic potential of triple mineralized probiotics.

## CLINICAL RELEVANCE/APPLICATION

This work will provide new insights and potential solutions for developing innovative microbial theranostic agents for treating flora disturbance-associated intestinal and extraintestinal diseases.

## M6-STCE2-1 ADDED VALUE OF THE MDIXON-QUANT MRI SEQUENCE AS ONE-STEP EXAM IN RESEARCH WITH RESPECT TO TIME, ENERGY CONSUMPTION AND CLINICAL BENEFITS

Thuy Mai Luu (*Abstract Co-Author*) Nothing to Disclose
Lena Ahmarani (*Abstract Co-Author*) Nothing to Disclose
Anne Monique Nuyt (*Abstract Co-Author*) Nothing to Disclose
Anik Cloutier (*Abstract Co-Author*) Nothing to Disclose
Ramy El-Jalbout (*Abstract Co-Author*) Nothing to Disclose
Alexander Mavromatis (*Presenter*) Nothing to Disclose

### PURPOSE

The mDIXON-Quant MRI sequence is valued for delivering several different quantitative measurements efficiently. Its rapid acquisition and low energy footprint make it more valuable in research settings. In this perspective, in preterm birth, the mDIXON-Quant as a one time sequence measures transverse relaxation rate (R2*), reflecting deoxyhemoglobin levels and fat fraction (FF) in both the liver and kidneys. Typical abdominal MRIs sequences give less clinical information and consume significant energy contributing notably to greenhouse gas emissions. This study aims to 1) highlight the energy benefits of the mDIXON-Quant sequence, and to 2) demonstrate its benefits and efficiency for both liver and kidney evaluation in young adults born preterm as a one-step exam in research settings.

### METHODS AND MATERIALS

A prospective observational study was conducted on a subgroup of the Health of Adults born Preterm Investigation (HAPI) cohort. Energy consumption during the acquisition of the mDIXON-Quant sequence was recorded using energy consumption meter (kWh) and compared to that of a VIBE T1 sequence using Philips Ingenia 1.5T MRI system. R2* and FF measurements were made in the renal cortex and medulla of all kidney poles. FF was also measured in the liver.

### RESULTS

An analysis demonstrated that a single mDIXON-Quant sequence takes 82 seconds, with a total energy expenditure of 0.670 kWh, compared to a VIBE T1 sequence, consuming 1.204 kWh in 153 seconds. Seventy-four adults born preterm (mean age 29.91 years) and 69 born at term (mean age 29.08 years) were recruited. mDIXON-Quant feasibility was 97.2% with excellent intra- and inter-operator reproducibility for all the quantitative measures. Mean R2* values of the right kidney cortex and medulla were lower in preterm adults compared to term adults (18.7 ± 2.67 /s vs 19.9 ± 2.88 /s, p=0.01 and 20.5 ± 2.68 /s vs 21.4 ± 2.53 /s, p=0.045 respectively). Preterm adults had higher though not significant liver FF than term controls.

### CONCLUSION

mDIXON-Quant sequence is a rapid and energy efficient method for assessing liver and renal structural changes using 2 reproducible parameters R2* and FF in a one-step MRI exam in young adults born preterm in the research setting. The decreased renal R2* values in preterm group indicate glomerular hyperfiltration, an early sign of renal damage.

### CLINICAL RELEVANCE/APPLICATION

Rapid and efficient, this technique delivers more information in a single sequence with improved time and less energy consumption. It supports sustainable healthcare at all levels including early diagnosis of kidney and liver disease contributing to research advancements with reproducible measurements.

## M6-STCE2-2 PUTTING CARBON EMISSION RISK IN PERSPECTIVE OF RADIATION AND CLINICAL RISK IN COMPUTED TOMOGRAPHY

Ehsan Samei, PHD (*Abstract Co-Author*) Research Grant, General Electric Company;Advisory Board, General Electric Company;Research Grant, Siemens AG;Advisory Board, Siemens AG;Advisory Board, medInt Holdings, LLC;Advisory Board, Metis Health Analytics;Research Consultant, Nanox Imaging Ltd;Royalties, General Electric Company;Royalties, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Mirion Technologies, Inc;Royalties, Cambridge University Press;Royalties, John Wiley & Sons, Inc
Liesbeth Vancoillie, PhD (*Abstract Co-Author*) Nothing to Disclose
Mina Mohammadi (*Abstract Co-Author*) Nothing to Disclose
Francesco Ria, DMP (*Presenter*) Metis Health Analytics

**PURPOSE**

Energy production impacts climate change, causing a significant number of excess deaths, and Computed Tomography (CT) represents one of the largest energy intensive consumer procedure in medicine. However, next to the risk induced by energy consumption and production, there are other risks related to CT practice, namely the radiation risk and the risk associated with a misdiagnosis. To guide policymakers and healthcare professionals in the effort of reducing the patient detriment, it is essential to gauge all the risks associated with a radiological procedure. In this study we calculated and compared the risks induced to the patient by energy consumption, radiation exposure, and misdiagnosis in clinical CT.

**METHODS AND MATERIALS**

Using a previously reported method and informed by census data, we simulated a dataset of 1 million CT studies for the investigation of localized stage liver cancer. Per each patient, we calculated organ-specific radiation doses and the Risk Index according to BEIR-VII report. Then, the related radiation exposure-induced mortality was calculated, giving the so-called radiation risk. The clinical risk was calculated as the expected life-expectancy loss for an incorrect diagnosis for different age, sex, and race, with a typical false positive rate of 5%, and average radiologist interpretative performance of 0.75 AUC. Lastly, the carbon emission risk was calculated by combining known energy consumption data per CT scan and the related mortality cost. The average radiation, clinical, and carbon emission risks were compared in terms of mortality per 100 studies.

**RESULTS**

The average radiation risk for the simulated population was 9.3×10-3 deaths per 100 patients and the average clinical risk was 5.4×10-2 deaths per 100 patients. The average energy consumption for abdominal CT studies was reported in 10.3 kWh, including 1.2 kWh for CT active usage, 0.8 kWh for the cooling system, and 8.2 kWh for idle time. The associated carbon emission (CO2) was 4.3 kg, corresponding to 9.1×10-5 excess induced deaths per 100 patients.

**CONCLUSION**

The risk induced by carbon emission associated with CT energy consumption is small when compared with radiation and clinical risks. Energy sustainable practice should be implemented in radiology without compromising the CT procedure performance in terms of radiation dose and effective diagnosis.

**CLINICAL RELEVANCE/APPLICATION**

Putting carbon emission risk in perspective of radiation and clinical risk in radiology can inform the implementation of sustainable practices without compromising patient safety.

## M6-STCE2-3 SPARKLE: A MULTICENTER, OPEN-LABEL STUDY TO EVALUATE THE SAFETY AND DIAGNOSTIC EFFICACY OF ACE-MBCA IN PATIENTS WITH KNOWN OR SUSPECTED FOCAL LIVER LESIONS AND SEVERE RENAL IMPAIRMENT

Alvin C. Silva, MD (*Presenter*) Scientific Advisory Committee, HealthMyne, Inc;Consultant, Exact Sciences Corporation;Research Grant, Ascelia Pharma AB

**PURPOSE**

ACE-MBCA (Ascelia Pharma Manganese Based Contrast Agent, proposed trade name Orviglance), is an oral contrast agent developed for liver MRI. Given the known risks of Gd-based contrast agents, including Gd retention and NSF, developing non-Gd agents is a new frontier in MR imaging. More than 35 million Americans live with renal disease, and those with severe renal disease are particularly exposed to risks associated with Gd. This phase 3 study evaluates the safety and efficacy of ACE-MBCA in patients with known or suspected focal liver lesions and severe renal impairment, potentially enhancing health equity in an underserved population that will benefit from a targeted imaging solution.

**METHODS AND MATERIALS**

This global study was approved by relevant institutions and conformed to current GCP guidelines. Informed patient consent was obtained. Patients (N=85) with known or suspected focal liver lesions and severe renal impairment received a liver MRI before and 4±1 h after the administration of ACE-MBCA (800 mg). The primary analysis, improvement in visualization of focal lesions was evaluated by 3 independent readers by qualitative scoring of the change in two co-primary variables, lesion contrast (LC) and border delineation (BD) (scores from 1= poor to 4= excellent). Safety was assessed at 24 (± 4) h, 48 (± 4) h, and 5 (± 2) days post-dose.

**RESULTS**

The primary analysis showed highly significant ($p<0.001$) improvement of the mean LC and BD scores in combined MRI (CMRI: combined contrast-enhanced + unenhanced MRI) compared to unenhanced MRI: Across the 3 readers, the mean (SD) LC increased by 0.65 (0.622) to 0.95 (0.824) score points and mean (SD) BD was increased by 0.81 (0.678) to 1.02 (0.909) score points.No patients were withdrawn from the study. The most reported post dose AEs were mild to moderate nausea (16.1%), diarrhea (13.8%), vomiting (9.2%), and blood urea increased (3.4%). No drug-related serious AE or deaths were reported.

**CONCLUSION**

ACE-MBCA 800 mg provides significant improvement in focal lesion visualization over unenhanced MR and was safe for patients with suspected or known liver lesion and severe kidney impairment.

**CLINICAL RELEVANCE/APPLICATION**

Using manganese as an MR contrast agent may benefit patients lacking alternatives to Gd-based agents or unenhanced MR. This targeted approach supports equitable healthcare for underserved populations, ensuring all patients receive necessary care. Following further development, ACE-MBCA has the potential to be used in a broader population and thereby reduce Gd release into the environment and water supply.

## M7-SSCH04-5 ADVANCED LUNG IMAGING WITH PHOTON-COUNTING DETECTORS: INSIGHTS FROM THERMOLUMINESCENCE DOSIMETRY

Jan P. Grunz, MD (*Abstract Co-Author*) Research Consultant, Siemens AG
Carsten Hackenbroch, MD (*Abstract Co-Author*) Nothing to Disclose
Simone Schuele, MD (*Abstract Co-Author*) Nothing to Disclose
Tobias Wech (*Abstract Co-Author*) Nothing to Disclose
Meinrad J. Beer, MD (*Abstract Co-Author*) Nothing to Disclose
Henner Huflage, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Thermoluminescence dosimetry allows for precise assessment of effective radiation dose. The objective of this study was to investigate the absolute dose burden of photon-counting detector (PCD) lung CT with ultra-high-resolution (UHR) and standard mode with and without organ-based tube current modulation (OBTCM).

### METHODS AND MATERIALS

An anthropomorphic Alderson-Rando phantom was scanned in UHR and standard mode with and without OBTCM on three dose levels each (IQ 5 [Sn 100 kVp], IQ 20 and IQ 50 [both Sn 140 kVp]). The effective radiation dose was determined by thermoluminescent dosimetry in 13 measurement sites and compared with the calculated effective dose derived from the dose-length product. Criteria of image quality (image noise and sharpness) were evaluated independently by six radiologists using an equidistant 7-point scale. Additionally, the modulation transfer function was compared among protocols using a dedicated line-pair phantom.

### RESULTS

Measured effective radiation exposure as the sum of weighted organ doses did not differ substantially between UHR and standard mode with and without OBTCM (IQ 5: 0.31-0.33 mSv, IQ 20: 1.42-1.54 mSv, IQ 50: 3.41-3.62 mSv). Compared with the “effective dose” calculated from the dose-length product, the measured effective doses were 108-144% higher. Image noise in lung tissue of UHR images was rated lower compared to standard (all P=0.42) and OBTCM protocols (all P=0.28) on all dose levels. Similarly, image sharpness was also considered higher in UHR than in standard-resolution images with and without OBTCM (all P=0.42). In standard mode, the use of OBTCM had no significant effect on either dimension of subjective image quality (all P=0.99). Modulation transfer function analysis confirmed the highest spatial frequency in UHR datasets on each dose level.

### CONCLUSION

In PCD-CT, UHR image acquisition entails no effective dose disadvantage over standard mode despite resulting in superior image quality. Meanwhile, the dose saving potential of OBTCM over standard protocols is minimal.

### CLINICAL RELEVANCE/APPLICATION

Thermoluminescence dosimetry revealed substantially higher effective doses than calculation from the dose-length products included in the automatically scanner-generated report.

## M7-SSCH04-6 CT TAKES THE LEAD WITH LOWER DOSES THAN CONVENTIONAL X-RAY: CHEST CT AT 0.098 MSV

Patrik Rogalla, MD, MBA (*Presenter*) Institutional Research Grant, Canon Medical Systems Corporation;Institutional Research Grant, KA Imaging

### PURPOSE

To explore the combination of a primary silver beam filter (Ag+) with deep-learning reconstruction to achieve an effective radiation dose below 0.1 mSv for non-contrast chest CT in adults.

## METHODS AND MATERIALS

81 patients who underwent a CT-guided chest biopsy (Canon Aquilion Prism) were included in this study with research ethics board approval. Prior to the patients' departure from the CT table, an ultra-low dose (ULD) chest CT was obtained to rule out complications using the following parameters based on body weight (BW) groups: 120 kV, 20 mAs for BW < 90 kg (group I), 30 mAs for BW 90-120 kg (group II), and 40 mAs for BW >120 kg (group III). An additional 0.5 mm silver filter was employed to harden the X-ray energy spectrum. Images were reconstructed using deep-learning reconstruction (AiCE, Canon Medical Systems). All patients received a chest X-ray 1h after the procedure end (standard-of-care). Reporting radiologists evaluated the clinical suitability of the CT images using a dedicated reporting template, considering both post-biopsy diagnostic criteria and subjective adequacy for clinical interpretation, as well as the potential need for higher dose CT. The dose-length products (DLP, scout and helical) and the dose-area product (DAP, chest X-ray) were recorded.

## RESULTS

The mean/standard deviation (SD) of the DLP in mGy*cm for the scout views and helical in all patients, in group I (n=49), II (n=28), and III (n=4) were 1.2/0.02 and 8.6/2.39, 1.2/0.01 and 7.0/0.68, 1.2/0.04 and 10.4/1.34, and 1.2/0.0 and 14.9/1.65, respectively. Utilizing conversion factors of 0.014 mSv/(mGycm) for DLP and 0.16 mSv/(Gy*cm2) for DAP, the effective radiation doses in CT/X-ray (p-value) for all patients, group I, II, and III were 0.12/0.15 ($p<0.001$), 0.098/0.13 ($p<0.001$), 0.15/0.19 ($p<0.001$), and 0.21/0.21 ($p=0.93$) mSv, respectively. On average, the scout view in CT increased the dose in all patients, group I, II, and III by 13.9%, 17.1%, 11.5%, and 8.0%, respectively. All CT scans were deemed suitable for clinical interpretation, with reporting radiologists not recommending a higher dose for any patient.

## CONCLUSION

By combining an additional silver beam filter with DLR, the effective radiation dose in non-contrast chest CT can be reduced to dose parity with a single chest X-ray while providing subjectively sufficient image quality for assessing the lung parenchyma post biopsy. Further research is needed to validate these findings across diverse clinical indications and patient populations.

## CLINICAL RELEVANCE/APPLICATION

For a typical adult weighing up to 90kg body weight, the CT radiation dose can be reduced to less than 0.1 mSv while maintaining diagnostic image quality for excluding post chest biopsy complications, equivalent to a single chest X-ray.

## M7-SSNMMI03-1 STRUCTURED REPORTING FOR THE DIAGNOSIS OF NEUROENDOCRINE TUMOR (NET) IN $^{18}$F-SIFALIN-TATE PET/CT - IMPACT ON QUALITY AND INTERDISCIPLINARY COMMUNICATION

Freba Grawe, MD (*Abstract Co-Author*) Nothing to Disclose
Johannes Ruebenthaler, MD (*Abstract Co-Author*) Nothing to Disclose
Anna Hinterberger (*Presenter*) Nothing to Disclose

### PURPOSE

Our retrospective single-center study aims to evaluate the impact of structured reporting (SR) using a self-developed template on report quality compared to conventional free-text reporting (FR) in 18F-SiFAlin-TATE Positron Emission Tomography/Computer Tomography (PET/CT) for the primary staging and therapy monitoring of patients diagnosed with neuroendocrine tumors (NET).

### METHODS AND MATERIALS

We included 50 patients who underwent 18F-SiFAlin-TATE-PET/CTs for NET staging. FR reports were generated post-examination and compared to SR reports, which were composed retrospectively using a self-developed template within an established software tool (Smart Reporting). All findings were evaluated by a radiologist and a surgeon through a questionnaire to determine their contribution to facilitating clinical decision-making and to assess their completeness, linguistic quality, and overall quality.

### RESULTS

In SR the rate of missing at least one key feature was significantly lower than in FR with missing information in 51% of FR vs. 11% of SR ($p < 0.001$). SR significantly increased the capacity of facilitating therapy decision-making from 32% in FR to 55% in SR ($p<0.001$). Trust in the report was significantly higher in SR with a mean of 5.0 (SD= 0.5) vs. 4.7 (SD= 0.5) for FR ($p < 0.001$). SR received significantly higher mean ratings regarding linguistic quality with 4.7 for SR vs. 4.4 for FR ($p =0.004$) and overall report quality with a mean of 4.9 for SR vs. 4.6 for FR ($p < 0.001$).

### CONCLUSION

Using SR over traditional FR enhances the overall quality of reports in 18F-SiFAlin-TATE-PET/CTs for NET staging, serving as a tool to streamline clinical decision-making and enhance interdisciplinary communication in the future.

### CLINICAL RELEVANCE/APPLICATION

The enhancement in report quality not only reduces the likelihood of missing key information but also facilitates more informed and confident clinical decision-making, thereby fostering greater trust in the reported findings and improving interdisciplinary communication to simplify the process of making treatment decisions.

## M7-SSNMMI03-2 AN AUTOMATED PHEOCHROMOCYTOMA AND PARAGANGLIOMA LESION SEGMENTATION AI-MODEL FOR WHOLE-BODY $^{68}$GA-DOTATATE PET/CT IMAGE

Fahmida Haque, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Pheochromocytoma and paraganglioma (PHEOs/PGLs) are rare neuroendocrine tumors (NET), which can lead to extensive metastases in the whole body and can be surgically inoperable. Positron emission tomography (PET) with computed tomography (CT) imaging-targeting somatostatin receptor 68Ga-DOTATATE is frequently used to assess patients with PHEOs/PGLs. Currently, imaging physicians rely on qualitative assessments of tumor burden

parameters after manual segmentation of tumor lesions, which is a tedious and time-consuming process. The goal of this study is to develop a deep learning-based automated lesion segmentation artificial intelligence (AI) model for whole-body 3D DOTATATE-PET/CT and automate the tumor burden calculation.

**METHODS AND MATERIALS**

In this study, 129 68Ga-DOTATATE PET/CT scans from 38 patients with inoperable PHEOs/PGLs were split into 55, 14, and 60 scans, from 15, 5, and 18 patients for training, validation, and test sets, respectively. 3D full resolution nnUNet configuration (3D_FullRes) was trained with 5-fold cross-validation. The model's performance was evaluated on the test set for lesion segmentation using dice similarity coefficient (DSC). Both lesion-level and patient-level statistical analysis including total lesion glycolysis (TLG), and metabolic tumor volume (MTV), was conducted to validate the diagnostic performance of the model.

**RESULTS**

The developed 3D_FullRes model achieved an average 5-fold validation DSC of 0.84. The model achieved a DSC of 0.87, a sensitivity of 0.87, and a positive predictive value of 0.88, with 4 median false positive lesions per scan on the test set. The average mean difference with 95% confidence interval and Spearman correlation coefficient between AI-predicted and ground truth (GT) lesions' MTV and TLG were -32.27 (-281.06, 216.53), -395.44 (6072.86, -6863.73), and 0.95 and 0.96 respectively, which was slightly less than GT annotations, because of false negative (FN). Anatomical position-based failure analysis showed that most of the FN lesions (70 out of 504 lesions) were observed in the liver. Due to the high hepatic background and image noise in 68Ga- DOTATATE scans, detection of metastatic lesions in the liver, was difficult for the model.

**CONCLUSION**

The developed deep learning-based lesion segmentation AI model showed promising and reliable performance for the whole-body DOTATATE-PET/CT images, which has the potential to be used by imaging physicians to make the annotation process more efficient.

**CLINICAL RELEVANCE/APPLICATION**

The proposed lesion-segmentation model for DOTATATE PET/CT scan can help imaging physicians in lesion segmentation, tracking progression, and determining better treatment decisions for patients with PHEOs/PGLs.

## M7-SSNMMI03-3 THERAPY GUIDANCE OF177LU DOTA-TATEPRRT IN GEP-NET PATIENTS BY MULTIMODALITY IMAGING

**PURPOSE**

To evaluate the incremental diagnostic value Gd-EOB-DTPA MRI of the liver to somtatostatin-receptor (SSR)-PET/CT for response assessment and management of gastroenteropancreatic neuroendocrine tumors (GEP-NET) in patients undergoing 177Lu DOTA-TATE Peptide Receptor Radionuclide Therapy (PRRT).

**METHODS AND MATERIALS**

In this single center retrospective study, we reviewed patients undergoing PRRT for GEP-NET between 2012-2023. 178 patients (78 female, mean 63.4 years) who were treated with at least two consecutive cycles of PRRT were included. Therapy response was assessed by SSR-PET/CT after 2 (~6 months) and 4 PRRT-cycles (~12 months) using RECIST 1.1 criteria as well as multidisciplinary team (MDT) review. All metastases were grouped by region, size and SSR-conversion ("flip-flop" phenomenon). Also, findings were compared to available Gd-EOB-DTPA liver MRI after 2 (n=52) and after 4 PRRT cycles (n = 118).

**RESULTS**

At baseline, whole body SSR PET/CT revealed NET metastases in the liver in 80.1% of cases, in the head and neck area in 28.1%, the thoracic region in 55.1%, the lower extremities in 7.3% and in the upper extremities in 7.9% of cases. SSR-PET/CT detected progressive disease (PD) in 9 and 10 patients, compared to 10 and 14 patients at MDT after 2 cycles and 4 cycles of PRRT, respectively. Isolated extra-abdominal PD was detected in 1 patient (0.5%) after two cycles of PRRT and 1 patient (0.7%) after 4 cycles of PRRT. PD was associated with hepatic PD in 90.0% / 92.6% cases after 2 cycles and 4 cycles of PRRT respectively. Gd-EOB-DTPA liver MRI detected all patients with progressive hepatic disease, revealing SSR-PET/CT occult hepatic PD in n=4 patients after 4 cycles of PRRT. Among patients with PD, SSR-PET/CT demonstrated a "flip-flop" phenomenon in 2 patients (0.9%) after 2 cycles and 1 patient (0.7%) after 4 cycles of PRRT.

**CONCLUSION**

Our results demonstrate that PD is observed in less than 10% of patients with GEP-NET undergoing PRRT after both 2 and 4 cycles of PRRT and is associated with hepatic PD in more than 90% of cases. Gd-EOB-DTPA liver MRI had improved sensitivity for liver evaluation, resulting in MDT upstaging of four patients after 4 cycles of PRRT compared to SSR-PET/CT alone. Tumor dedifferentiation and isolated extrahepatic disease progression detected in SSR-PET/CT were rare.

**CLINICAL RELEVANCE/APPLICATION**

Gd-EOB-DTPA MRI of the liver presents as overall promising response assessment strategy in patients with GEP-NET undergoing PRRT. Considering cumulative life-time radiation dose and associated costs SSR-PET/CT may be reserved to selected cases and troubleshooting. Further studies to evaluate the imaging strategy are warranted.

## PURPOSE

177Lu DOTATATE is a radionuclide therapy for metastatic enteropancreatic neuroendocrine tumors, administered in a course of four cycles eight weeks apart. Many patients treated with 177Lu DOTATATE have a complex medical history including cytopenia, renal function impairment, and multiple previous treatment modalities. We aim to characterize prognostic features associated with overall survival following 177Lu DOTATATE treatment.

## METHODS AND MATERIALS

Consecutive patients (n=98) treated with 177Lu DOTATATE for metastatic enteropancreatic neuroendocrine tumors were retrospectively reviewed. Clinical and imaging data prior to treatment, number of cycles administered, and overall survival from the start of radionuclide therapy were recorded. Cox proportional hazards regression estimated a hazard ratio (HR) for baseline predictors of survival, adjusted for therapy completion status. Groups of participants who underwent complete (=4 cycles) and incomplete therapy (< 4 cycles) were compared. Linear model ANOVA or Pearson's Chi-squared test were used to compare categorical and continuous variables, respectively (alpha = 0.05).

## RESULTS

Prior to the start of 177Lu DOTATATE, statistically significant predictors of overall survival include lymph node metastasis, baseline hemoglobin, previous external beam radiation, largest lesion diameter, body mass index, and functional status (Figure). Expected prognostic variables of age and time from initial diagnosis to the start of therapy were also statistically significant predictors of overall survival. Kaplan Meier survival curves demonstrate significantly different overall survival comparing those who do (n=78) and do not (n=20) complete all four cycles of therapy (HR 4.6, 95% CI 2.7-8.1) (Figure). Statistically significant factors associated with early discontinuation of 177Lu DOTATATE included age, baseline hemoglobin, functional status, body mass index, and estimated glomerular filtration rate.

## CONCLUSION

Patients with nodal metastasis, previous radiation treatment, lower hemoglobin, lower body mass index, poor functional status, or inability to complete the four cycles of therapy had worse survival outcomes following 177Lu DOTATATE. The group of patients who did not complete therapy had worse survival outcomes than those who did. Although it may still be appropriate to treat patients with risk factors for poor survival prognosis, this may inform patient counseling discussions.

## CLINICAL RELEVANCE/APPLICATION

Patient characteristics at the start of treatment may predict overall survival following 177Lu DOTATATE therapy. Those who did not complete therapy had significantly worse survival outcomes and may represent a distinct population with poor prognosis.

## M7-SSNR05-1 HIGHER BRAIN IRON LEVELS IN THE OLDER ADULT ARE ASSOCIATED WITH ELEVATED TRANSVERSE RELAXATION RATE ($R_2$) IN GRAY MATTER AND MORE WHITE MATTER HYPERINTENSITIES: AN EX-VIVO MRI, NEUROPATHOLOGY AND MASS SPECTROMETRY STUDY

Julie A. Schneider, MD (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Arfanakis, PhD (*Abstract Co-Author*) Nothing to Disclose
David A. Bennett, MD (*Abstract Co-Author*) Nothing to Disclose
Md Tahmid Yasar, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

Higher iron in brain is a source of free radicals that causes oxidative stress which has been linked to cognitive impairment, dementia and age-related pathologies including Alzheimer's disease among older adults. The aim of this study was to investigate the association of iron levels with relaxation rate, R2, and white matter hyperintensities (WMH), independent of the effects of other trace metals and neuropathologies.

### METHODS AND MATERIALS

Cerebral hemispheres from 437 older adults participating in the Rush Memory and Aging Project were imaged ex vivo using 3T MRI scanners. R2 maps were generated from multi-echo spin-echo data and then registered to an ex vivo brain template. WMH were segmented based on T2-weighted images. WMH volume was normalized by the total hemisphere volume and then log-transformed. Following ex vivo MRI, all hemispheres underwent pathologic assessment including Aß plaques, neurofibrillary tangles, hippocampal sclerosis, Lewy bodies, cerebral amyloid angiopathy, gross infarcts, microinfarcts, atherosclerosis, arteriolosclerosis and TDP-43 pathology.Inductively coupled plasma mass spectrometry (ICP-MS) was used to measure brain trace metal levels. The assessed metals included iron, boron, titanium, manganese, copper, zinc, selenium, rubidium, molybdenum and mercury.Linear regression was used to test the association of R2 and WMH burden with iron levels. All models were controlled for all other trace metals and pathologies listed above, demographics (age at death, sex, years of education), the presence of the APOE-e4 allele, postmortem interval to fixation and imaging and scanners. Statistical analysis was performed using PALM, with tail-accelerated 5000 permutations. Statistical significance was set at $p<0.05$ after family wise error rate correction.

### RESULTS

The voxel-wise analysis revealed a spatial pattern of higher R2 for higher brain iron levels, particularly in gray matter. The pattern included basal ganglia structures such as the globus pallidus, caudate and putamen, and cortical regions including the precentral, postcentral and occipital cortex. Higher lobar and total WMH burden also showed statistically significant positive association with brain iron levels. No negative associations were observed.

### CONCLUSION

This investigation combined ex vivo MRI, neuropathology and ICP-MS in a community-based older adults and showed that higher brain iron levels were independently associated with elevated R2 in gray matter and higher WMH burden.

### CLINICAL RELEVANCE/APPLICATION

Our work demonstrates the association of brain iron level with gray matter R2 and white matter hyperintensities in older adults. The findings will help to understand the mechanism of brain iron accumulation and its impact in older adults.

## M7-SSNR05-2 THE TRAJECTORY OF OLFACTORY CORTEX DEGENERATION FROM COGNITIVE NORMAL CONTROLS TO ALZHEIMER'S DISEASE

Chunjie Guo, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Olfactory dysfunction serves as a potential biomarker for early detection and progression of Alzheimer's Disease (AD). We aim to validate olfactory impairments and further explore the trajectory of olfactory cortex degeneration, from cognitive normal controls (NCs) to mild cognitive impairment (MCI) and AD.

### METHODS AND MATERIALS

In this study, 42 individuals with AD, 35 with MCI, and 28 with NC were recruited. Based on the clinical and multimodal MRI dataset, including individual structural MRI (grey matter volume, GMV and white matter volume, WMV), resting-stated functional MRI (amplitude of low-frequency fluctuation, ALFF and regional homogeneity, ReHo), and olfactory-task functional MRI (olfactory activation values), as well as neuropsychological assessment and University of Pennsylvania Smell Identification Test (UPSIT), comparisons measured in olfactory-related regions were made among the three groups . Logistic regression was employed to differentiate between the AD, MCI, and NC groups and to further delineate the trajectory of olfactory cortex degeneration from NCs to AD.

### RESULTS

From the NC to individuals with MCI and then to those with AD groups, a consistent pattern emerged, showing declining GMV, WMV, and olfactory activation values, coupled with increased ALFF and ReHo in olfactory subregions. Additionally, corresponding decreases in olfactory and cognitive function assessment scores were evident. Logistic regression analyses revealed an early and pronounced decline in olfactory function, particularly in terms of olfactory activation, as individuals progressed from NC to MCI. Moreover, our finding discovered a quadratic accelerated atrophic trajectory in the olfactory cortex from MCI to AD.

### CONCLUSION

Olfactory deficits are evident throughout the AD trajectory. Functional MRI (fMRI), especially olfactory fMRI, stands out as a pivotal tool for early detection, particularly during the MCI stage, which could help a comprehensive understanding of AD development and offer a potential biomarker for the progressive trajectory of AD.

### CLINICAL RELEVANCE/APPLICATION

Olfactory deficits play a significant role in the progression of AD and are evident even in its early stages. This study indicates that functional MRI, especially olfactory-task fMRI, is crucial for early AD detection, particularly during the transition from normal cognition to MCI. These findings point to the potential of olfactory measures as biomarkers for tracking AD, underscoring the importance of early and precise detection methods for the disease.

## M7-SSNR05-3 BRAIN ARTERIOLOSCLEROSIS IS ASSOCIATED WITH LOWER GRAY MATTER VOLUME

Konstantinos Arfanakis, PhD (*Abstract Co-Author*) Nothing to Disclose
Julie A. Schneider, MD (*Abstract Co-Author*) Nothing to Disclose
David A. Bennett, MD (*Abstract Co-Author*) Nothing to Disclose
Mahir Tazwar, BS (*Abstract Co-Author*) Nothing to Disclose
Md Tahmid Yasar, BSc (*Abstract Co-Author*) Nothing to Disclose
Ana Tomash (*Presenter*) Nothing to Disclose

### PURPOSE

Brain arteriolosclerosis, characterized by vessel wall thickening and arteriolar stenosis, is a common pathology of cerebral small vessel disease. It shows a higher prevalence among older adults and increased severity in women and black individuals. It is linked to decreased cognitive and motor function and increased dementia risk. This study investigates the relationship between brain arteriolosclerosis and regional gray matter volumes in a large cohort of community-based older adults.

### METHODS AND MATERIALS

The ex-vivo MRI and neuropathological data from 882 older adults were collected from four aging studies: the Rush Memory and Aging Project, Religious Orders Study, Minority Aging Research Study, and Clinical Core of the Rush Alzheimer's Disease Research Center. Cerebral hemispheres obtained at autopsy were imaged ex-vivo with a multi-echo spin-echo sequence (ME-SE) (0.6 × 0.6 × 1.5mm3) on 3T clinical MRI scanners about one month postmortem. Gray and white matter were segmented, and gray matter was divided into 42 regions using multi-atlas segmentation. Each volume was normalized by cerebral hemisphere volume. Following ex-vivo MRI, a detailed neuropathologic assessment was performed on pathologies including arteriolosclerosis, atherosclerosis, cerebral amyloid angiopathy, gross and microscopic infarcts, Alzheimer's pathology, Lewy bodies, limbic-predominant age-related TDP-43 encephalopathy neuropathological change (LATE-NC), and hippocampal sclerosis.The association between brain arteriolosclerosis and regional gray matter volumes (normalized by cerebral hemisphere volume), while controlling for all other neuropathologies, demographic variables (age at death, sex, years of education), postmortem intervals, and the scanner was investigated by utilizing linear regression. Statistical analysis was performed using FSL's PALM tool with 10,000 permutations. The significance level was established at $p<0.05$ after correcting for multiple tests using the false discovery rate (FDR).

### RESULTS

More severe brain arteriolosclerosis was associated with lower volume in several gray matter regions, including medial orbitofrontal, superior frontal, pericalcarine, cuneus, and lateral occipital areas, independently of the effects of other neuropathologies.

### CONCLUSION

The given study illustrated that brain arteriolosclerosis is associated with lower volume in multiple gray matter regions independently of the effects of other vascular or neurodegenerative pathologies.

### CLINICAL RELEVANCE/APPLICATION

The finding enriches our comprehension of the brain anomalies associated with this common small vessel disease pathology and may improve prediction performance of ARTS, a novel in-vivo marker of arteriolosclerosis.

**PURPOSE**

Obesity in midlife is a risk factor for developing Alzheimer disease later in life. However, the metabolic and inflammatory effects of body fat vary based on its anatomical localization. In this study, we aimed to investigate the association of MRI-derived abdominal visceral and subcutaneous adipose tissue (VAT and SAT), liver proton-density fat fraction (PDFF), thigh fat-to-muscle ratio (FMR), and insulin resistance with whole-brain amyloid burden in cognitively normal midlife individuals.

**METHODS AND MATERIALS**

A total of 62 cognitively normal midlife individuals (Age: 50.35 years, 61.3% female, BMI: 32.30 kg/m2, 53.2% obese) underwent brain PET scan, body MRI, and metabolic assessment. Homeostatic Model Assessment for Insulin Resistance (HOMAIR) was used for measuring insulin resistance. Dynamic amyloid imaging was performed with a bolus injection of ~15mCi [11C]PiB, and a 60-min scan. Data from the 30-60 minute post-injection window was used for calculating whole-brain amyloid Centiloid. VAT and SAT were semi-automatically segmented using an in-house MATLAB-based software. The PDFF maps were generated from liver chemical shift encoded MR images and segmented using a 3D CNN model and manual correction. After preprocessing and N4ITK bias correction on mid-thigh slices between the ischial ramus and the medial knee condyle, an in-house MATLAB program was used for segmenting thigh total fat (subcutaneous, inter-, and intra-muscular fat) and muscle volumes. Total thigh fat-to-muscle ratio (FMR) was calculated. Using linear regression, the association between Centiloid and BMI, HOMAIR, VAT, SAT, PDFF, and FMR was assessed, with age and sex as covariates.

**RESULTS**

Obese individuals had higher Centiloids compared to the non-obese ($p=0.008$). Centiloids were significantly associated with VAT (Adj-$R^2=0.25$, $p<0.0001$), HOMAIR (Adj-$R^2=0.08$, $p=0.02$), SAT (Adj-$R^2=0.08$, $p=0.02$), and BMI (Adj-$R^2=0.09$, $p=0.01$), but not other fat metrics. A mediation analysis showed that the effects of BMI on Centiloid is fully mediated by VAT (ACME= 0.282, $p <2e-16$, and ADE= 0.061, $p=0.56$) and there is a significant direct effect of VAT (ADE=0.0104, $p<2e-16$) on amyloid burden, not explained by HOMAIR (ACME=-0.003, $p=0.86$).

**CONCLUSION**

Obesity, higher visceral fat, and to a lesser extent insulin resistance, BMI, subcutaneous fat, but not liver or thigh fat, are associated with higher whole-brain amyloid in midlife. This highlights the importance of anatomical characterization of body fat for Alzheimer risk, where obesity-related amyloid pathology is fully explained by visceral fat.

**CLINICAL RELEVANCE/APPLICATION**

Modifying visceral adipose tissue can be considered to reduce obesity-related risk of Alzheimer pathology in midlife years before its development.

## M7-SSNR05-5 NORMAL AGEING-RELATED BRAIN MORPHOLOGICAL SUBNETWORKS WERE DIFFERENTLY INTERACT WITH MULTIPLE NEUROLOGICAL DISEASES

Li Yuna, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Zhizheng Zhuo (*Presenter*) Nothing to Disclose

**PURPOSE**

How ageing interacts with various neurological diseases at the brain network level remains unclear.

**METHODS AND MATERIALS**

We collected 2770 healthy controls aged 20-90 years and 1121 patients with neurological diseases, including MCI, AD, PD, SVD and MS. First, to define the ageing-related subnetworks, we constructed individual MCN in the HC group and decomposed the MCN into distinct subnetworks using ICA. Ageing-related subnetworks were defined as subnetworks that had significant associations with age. Second, to characterize the relationships between the ageing-related subnetworks and multiple neurological diseases, we spatially correlated ageing-related subnetworks with disease-related MCN disruption via age- and sex-matched case-control analyses. Third, to determine the clinical significance of the ageing-related subnetworks, we calculated the regression coefficients of the ageing-related subnetworks for each individual MCN of patient group using linear regression. The regression coefficients of the ageing-related subnetworks were further correlated with specific clinical variables. Finally, annotated biological maps were utilized to advance the biological interpretation of ageing-related subnetworks .

**RESULTS**

(1) Three ageing-related subnetworks, including default mode network-predominant (DMNpre), dorsal attention network-predominant (DANpre) and somatomotor network-predominant (SMNpre), exhibited heterogeneous trajectories, in which the loading of the DMNpre subnetwork increased with ageing, while the loading of the DANpre and SMNpre subnetworks decreased with ageing. (2) Distinct relationships between the ageing-related subnetworks and MCN disruption in various neurological diseases were observed;(3) Ageing-related subnetworks were associated with cognitive scores of MCI and AD , MRI disease burden of SVD , and physical disability and language ability of MS. (4) Glucose metabolism and several neurotransmitters were possibly biological factors driving the identified age-related subnetworks.

**CONCLUSION**

Ageing-related subnetworks were identified, correlated with brain network disruptions and clinical variables of multiple neurological diseases, and used to identify potential therapeutic targets for diseases.

**CLINICAL RELEVANCE/APPLICATION**

(1)The present study offers a new dimension to understand the complex ageing process. (2)The ageing-related subnetworks may serve as network markers capable of discriminating normal ageing effects from disease-specific mechanisms, and for disease monitoring and evaluation. (3)Biological explanation for the ageing-related subnetworks provide a clue for alleviating the adverse effects of ageing on neurological diseases

### PURPOSE

The malfunction of the glymphatic system, marked by increased MRI-visible Perivascular Spaces (PVS), is suggested to contribute to the accelerating of amyloid accumulation in Alzheimer's Disease (AD). However, while PVS is also commonly observed in Vascular Dementia (VD), the specific pathological variances in regional PVS between AD and VD remain largely unexplored. In this study, we examined these pathology-driven localization patterns using automated PVS segmentations from T2-weighted MRI within a mixed dementia cohort.

### METHODS AND MATERIALS

Total 99 cognitively unimpaired (CU) and 190 cognitively impaired (CI) patients were included from the Seoul National University Dementia cohort. Expert radiologists visually assessed 18F-Florbetaben PET, FLAIR, and SWI images to categorize CI patients into four groups based on both amyloid and vascular-damage burden (26 A-VB-, 63 A-VB+, 26 A+VB-, and 75 A+VB+). PVS segmentation entailed masking and thresholding hyperintense vessel structures using slice-wise Frangi filters on T2-weighted MRIs, targeting the basal ganglia (BG) and cerebral white matter (WM), segmented into four major lobes (frontal, parietal, temporal, and occipital). PVS volume fractions (PVS-VF) were computed as voxel counts normalized by intracranial volumes. Groupwise disparities were assessed using two-sample t-tests, with adjustments made for multiple comparisons.

### RESULTS

The accuracy of automated segmentations was verified against manually segmented PVS volumes at BG and WM (rank correlation coefficients: 0.634, 0.539). In the A+ groups, significant increases in PVS-VF were observed within the temporal and occipital lobes compared to CU, consistent with previous visual rating studies. Conversely, the VB+ showed significant PVS-VF increases across all lobes compared to CU. Specifically, the BG demonstrated the most distinct PVS expansion associated with VD, with notably higher PVS-VF in the VB+ compared to their VB- counterparts. Intriguingly, there were no significant increases in PVS volume ratios for lobar regions and BG in the A-VB+, while all A+ groups demonstrated significant increases in the temporal and occipital regions compared to CU.

### CONCLUSION

To leverage PVS as a biomarker for distinguishing glymphatic dysfunctions in AD, a comprehensive understanding of their characteristics within these contexts is essential. The cross-sectional differentiation of regional PVS localization in AD could serve as a foundational step toward elucidating these associations within the AD continuum.

### CLINICAL RELEVANCE/APPLICATION

This study reveals distinct regional PVS patterns in AD and VD, enhancing our understanding of the correlation between glymphatic dysfunctions marked as PVS patterns and the AD continuum.

## M7-SSNR06-1 GADOQUATRANE: PHARMACOKINETICS IN HEALTHY VOLUNTEERS AND PATIENTS WITH CNS LESIONS IN COMBINATION WITH MR IMAGING IN COMPARISON TO GADOBUTROL SUPPORT DOSE SELECTION FOR THE NOVEL TETRAMERIC GBCA (Kuo York Chynn Neuroradiology Research Award)

Gabriele Sutter, PhD (*Abstract Co-Author*) Employee, Bayer AG
Birte M. Hofmann, DVM, PhD (*Abstract Co-Author*) Employee, Bayer AG
Mark Klemens, MD (*Abstract Co-Author*) Employee, Bayer AG
Petra Palkowitsch (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of the Phase 1 and 2 studies was to select the gadoquatrane dose for further development by using signal enhancement data in relation to dose in healthy volunteers (HV) together with clinical efficacy in patients with CNS lesions, supported by gadolinium (Gd) plasma concentration-time data (PK) from both studies.

### METHODS AND MATERIALS

Two single-blind, cross-over studies were conducted, one Phase (Ph) 1 in healthy volunteers receiving 3 different doses of gadoquatrane (0.01, 0.03, 0.06 mmol Gd/kg) and one Ph 2 in patients with known or highly suspected CNS lesions receiving gadoquatrane at a dose of 0.04 mmol Gd/kg. Gadobutrol was used as comparator at a dose of 0.1 mmol Gd/kg and Gd plasma concentrations were determined by Inductively Coupled Plasma Mass Spectrometry after each GBCA injection at 3 time points post injection (p.i.; 20-60 min, 2-4 h and 6-8 h). In the Ph 2 study an additional sample was collected at 24h p.i.. The dose-response relationship of gadoquatrane in HVs was assessed as relative signal enhancement (RSE) and compared with the RSE after gadobutrol injection. RSEs were determined in 5 regions of the head and neck area (carotid artery, parotid gland, sagittal sinus, sigmoidal sinus, submandibular gland) representing different degrees of vascularization. Dose-response curves were established individually per region by linear regression at 5-, 10- and 15-minutes p.i. using a Bayesian method of inverse regression. In the Phase 2 study, overall diagnostic preference and non-inferiority of lesion visualization parameters at 5 min p.i. were used to confirm the dose.

### RESULTS

For all 5 regions gadoquatrane demonstrated a linear increase in RSE with dose. For each region the equivalent dose was less than half the Gd dose of gadobutrol, in line with the more than 2-fold higher relaxivity (r1) of gadoquatrane. Dose-normalized plasma Gd concentrations for both GBCAs were almost equivalent demonstrating very similar PK. Based on this, the starting dose of 0.04 mmol Gd/kg was selected for Ph2, which was confirmed by the overall image preference and non-inferiority of the lesion visualization parameters. Dose-normalized plasma concentration-time curves were essentially the same in HVs and patients with CNS lesion vs gadobutrol.

### CONCLUSION

The aggregated results of both studies confirmed that the common mode of action, relaxivity and pharmacokinetic behavior allow to select a Gd dose that will yield adequate clinical efficacy as confirmed by the Ph 2 study to lead the way into Ph 3 of clinical development and beyond.

### CLINICAL RELEVANCE/APPLICATION

The novel, tetrameric macrocyclic gadoquatrane is a promising GBCA in development for MRI and MRA at a substantially reduced Gd (by 60%) and molecule dose (by 90%) compared to established macrocyclic GBCAs.

**PURPOSE**

The anterior portion of the medial temporal lobe (MTL) is one of the first regions targeted by pathology in sporadic Alzheimer's disease (AD)indicating a potential for this region to be used as a valuable imaging biomarker. However, most existing automated approaches for MTL segmentation do not incorporate anterior MTL subregions, and the few that do fail to account for complex anatomical variability of this region. Leveraging a unique postmortem dataset consisting of histology and MRI scans we aimed to develop an anatomically valid segmentation protocol for anterior entorhinal cortex (ERC), Brodmann Area (BA) 35, and BA36 and apply it for automated MTL segmentation of in vivo 3 tesla (T) MRI.

**METHODS AND MATERIALS**

We enrolled 20 cases between 61 to 97 years of age (50% females) including individuals both with and without neurodegenerative diseases (11 vs. 9 cases) to ensure broad generalizability of the developed protocol. Serial coronal Nissl-stained histology sections of the MTL from these cases were digitized, registered to same-subject 0.2x0.2x0.2-mm3 9.4T postmortem MRI and annotated by an expert neuroanatomist. To develop the segmentation protocol, we determined the location of cytoarchitectonic borders of interest in relation to anatomical landmarks observable on in vivo MRI. The protocol was first applied manually to 29 3T in vivo MRI scans and then used to train an automatic segmentation method, Automatic Segmentation of Hippocampal Subfields (ASHS)-T1. Intra-rater reliability of a manual rater and five-fold cross-validation accuracy of ASHS-T1 were assessed with the Dice Similarity Index (DSI).

**RESULTS**

We developed segmentation rules for the borders of ERC, BA35 and BA36 based on systematic analysis of inter-landmark distances on histological sections. The intra-rater reliability for the manual rater applying these rules to 15 in vivo 3T MRI scans was high, with the DSI ranging from 0.85 to 0.88. However, cross-validation of automated segmentations with ASHS-T1 against the manual segmentation showed moderate reliability (DSI ranging from 0.67 to 0.78), reflecting the challenging anatomy of this region. Notably, segmentation accuracy for the entire MTL, including the newly added region, remained comparable to the previously reported accuracy for the MTL (DSI: 0.79).

**CONCLUSION**

We developed a reliable, and anatomically valid segmentation protocol for the anterior MTL cortices and incorporated it in an automated approach.

**CLINICAL RELEVANCE/APPLICATION**

Our protocol makes automated segmentation of anterior MTL regions on 3T MRI feasible. Given the vulnerability of these regions to tau deposition in AD, we expect this updated automated pipeline will help generate improved imaging biomarkersfor early AD.

## M7-SSNR06-3 REGIONAL MAPPING OF HUMAN BRAIN SODIUM USING ANATOMICALLY-GUIDED RECONSTRUCTION OF DUAL ECHO SODIUM-23 MR IMAGES

Ying-Chia Lin (*Abstract Co-Author*) Nothing to Disclose
Georg Schramm (*Abstract Co-Author*) Nothing to Disclose
Fernando E. Boada, PhD (*Abstract Co-Author*) Nothing to Disclose
Yvonne W. Lui, MD (*Abstract Co-Author*) Nothing to Disclose
Johan Nuyts, PhD (*Abstract Co-Author*) Nothing to Disclose
Yongxian Qian (*Abstract Co-Author*) Founder, General Labs Cloud, LLC
Alaleh Alivar, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

23Na-MRI provides unique in-vivo ionic information relevant to a host of neurological diseases. However, challenges with low signal-to-noise have made it difficult to provide accurate quantitative measures of tissue sodium. Here, we attempt to map regional total sodium concentration in the human brain using our novel anatomically-guided reconstruction (AGR) method that employs a proton (1H) T1w image as anatomical information to address both spatial resolution and partial volume effect (PVE). The mapping was compared against standard reconstruction (SR).

**METHODS AND MATERIALS**

20 healthy subjects were scanned on a 3T MRI scanner (Prisma, Siemens) using a dual-tuned (1H-23Na) birdcage coil, TPI sequence (TR=100ms, TE1/TE2=0.5/5ms), and 1H T1w MPRAGE. AGR was performed with previously optimized regularization parameter =2.0. SR was performed on k-space data from the TPI trajectory using re-gridding algorithm with compensation for non-uniform sampling. Coregistration was done with rigid simpleITK. Sodium images were calibrated using vitreous humor (145 mmol/L) and air (0 mmol/L) as internal references. Total Sodium Concentration (TSC) was calculated in lobar cortical gray matter (GM), subcortical GM, callosal and whole brain white matter (WM). Paired Sampled T-test was used to compare regional TSC between AGR and SR.

**RESULTS**

We observed a significant increase in SNR with visible WM and GM boundaries on AGR images ($p<0.001$). Differences between GM and WM TSC were more evident using AGR compared to SR with significantly higher values in GM (48.1±2.8 mmol/L) compared to WM (30.6±2.5 mmol/L) ($p<0.001$) in line with previous studies, possibly due to improved ability of AGR to resolve PVE. TSC in subcortical GM regions was more variable and fell between measures for cortical GM and WM depending on the region, likely relating to variable mix of GM and WM in subcortical nuclei. Cortical measures were more

consistent across brain lobes. Unlike for WM and subcortical GM regions, there were no significant differences in cortical GM TSC between two methods; possibly relating to opposing PVE from CSF and WM occurring in the SR for measures of cortical sodium.

**CONCLUSION**

In this study, we are able to address PVE in low resolution 23Na-MRI followed by improved TSC quantifications in different brain regions including WM, cortical and subcortical GM using the novel AGR method. This work provides a foundation for future investigation of ionic changes in the setting of neurological disease.

**CLINICAL RELEVANCE/APPLICATION**

Brain sodium content is vital for neuronal function and understanding of neurological disease; This novel approach improves in vivo 23Na-MRI quantification, previously unattainable.

## M7-SSNR06-5 MQSM: MULTITASK LEARNING-BASED QUANTITATIVE SUSCEPTIBILITY MAPPING FOR IRON ANALYSIS IN BRAIN

Junjie He (*Abstract Co-Author*) Nothing to Disclose
Rongpin Wang, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Quantitative analysis of brain iron is widely utilized in neurodegenerative diseases, typically accomplished through the utilization of quantitative susceptibility mapping (QSM) and medical image registration. However, this approach heavily relies on registration accuracy, and image registration can alter QSM values, leading to distorted quantitative analysis results. This study employs a deep learning-based multimodal whole-brain segmentation instead of registration, thereby achieving accurate analysis of whole-brain iron quantification without altering QSM values.

**METHODS AND MATERIALS**

The article employs 65 MRI subjects matched between T1 and QSM for deep learning modeling. This paper proposes a multi-modal multitask QSM reconstruction algorithm (mQSM) and introduces a mutual Transformer mechanism (mTrans) to efficiently fuse multi-modal information for QSM reconstruction and brain region segmentation tasks. The proposed mTrans leverages Transformer computations on Query and Value feature matrices for mutual attention calculation, eliminating the need for additional computational modules and ensuring high efficiency in multi-modal data fusion.

**RESULTS**

Experimental results demonstrate an average dice coefficient of 0.92 for segmentation, and QSM reconstruction achieves an SSIM evaluation of 0.9854 compared to the gold standard. Moreover, segmentation-based (mQSM) brain iron quantitative analysis shows no significant difference from the ground truth in all 115 brain regions, whereas the registration-based approach exhibits notable differences in brain cortical regions compared to the ground truth.

**CONCLUSION**

Results from segmentation-based brain iron quantification are more effective than the registration-based. This research provides an all-in-one method for QSM reconstruction and brain iron quantification analysis.

**CLINICAL RELEVANCE/APPLICATION**

The proposed mQSM enables precise quantification of iron deposition in 115 brain regions, providing an opportunity for assisting the diagnosis of neurodegenerative diseases.

## M7-SSNR06-6 ALTERATIONS IN BRAIN CONNECTIVITY PATTERNS AMONG PREMENSTRUAL SYNDROME PATIENTS FOLLOWING IMMEDIATE TRANSCUTANEOUS VAGUS NERVE STIMULATION AT VARIED FREQUENCIES

Yinqi Lai, BS, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Premenstrual Syndrome (PMS) periodically causes significant distress in women and may lead to depression. Characterized by physical pain and emotional disturbances. Transcutaneous vagus nerve stimulation (tVNS) is a non-invasive neuromodulation technique that has shown promising results in pilot studies for treating pain and depression. However, its precise neurophysiological mechanisms remain unclear. This study evaluates the intrinsic connectivity networks in PMS patients, examining changes in brain connectivity patterns and their clinical correlations following immediate frequency-varied tVNS applications.

**METHODS AND MATERIALS**

A total of 71 PMS patients and 81 healthy controls were recruited. Baseline evaluations measured sex hormone and inflammatory cytokine levels. Participants received immediate 2Hz, 25Hz, and sham tVNS treatments during the late luteal phase, accompanied by pre- and post-treatment resting-state functional MRI scans. Brain connectivity changes were analyzed using degree centrality (DC) and seed-based functional connectivity (FC).

**RESULTS**

At baseline, PMS patients exhibited higher scores in somatic symptoms, emotional disturbances, and sleep issues. Although no significant hormonal differences were noted compared to controls. PMS patients showed higher inflammatory markers and altered connectivity in pain and emotion-related brain areas, such as increased right putamen DC and altered FC in the right orbital inferior frontal gyrus, right orbital middle frontal gyrus, and right superior temporal gyrus. Post-treatment, 25Hz tVNS notably enhanced connectivity in the Striato-Cortical Circuit, particularly between the right caudate and right anterior cingulate, demonstrating more effective modulation compared to 2Hz. No significant changes were observed with sham tVNS.

**CONCLUSION**

PMS is associated with enhanced nodal properties in the right putamen and altered functional connectivity in emotion and pain-related brain areas. This study highlights the potential of tVNS, especially at 25Hz, to effectively modulate brain circuits involved in PMS, providing insights into its mechanisms and clinical benefits.

**CLINICAL RELEVANCE/APPLICATION**

tVNS represents a promising neuromodulation strategy for treating PMS, with 25Hz applications showing greater efficacy in alleviating symptoms.

### PURPOSE

Accurate quantitative measurement of low concentration iodine in spectral computed tomography (CT) remains challenging using current technologies. This accuracy is required for the development of clinical biomarkers and to leverage spectrally derived imaging capabilities. This study highlights the performance of a hybrid spectral CT system equipped with a clinical-grade rapid kVp-switching x-ray tube and a dual-layer detector.

### METHODS AND MATERIALS

A spectral CT bench system built with clinical-grade rapid kVp-switching x-ray tube and dual-layer detector (Philips Healthcare) was operated at tube voltages 140/80 kVp, tube current of 570 mA, and three duty cycle ratios from 15/85 to 75/25. This produced three dose levels. A 270 mm diameter polyamide phantom containing eight tissue mimicking inserts (iodine 0.5-20 mg/mL, solid water) was rotated at 1 Hz. Four unique spectral projection channels were available per kVp pair. Three weighting schemes were created to reduce the four spectral channels into two projection inputs for 2D material decomposition. These schemes represented a kVp-switching scheme that included all four channels, an "All 80/HighE 140" weighting scheme which included three channels, and a "maximum separation" scheme which used only two channels: 80 kVp low photon energy and 140 kVp high photon energy spectral information. Photoelectric effect, scatter, iodine density, and virtual non-contrast images were generated. Regions of interest placed on each insert measured the mean and standard deviation value of estimated iodine concentration for each slice. Bias was calculated by taking the difference between measured iodine concentration and expected insert concentration.

### RESULTS

The 15/85 duty cycle scans produced iodine density images with lower average bias across inserts compared to 33/67 and 75/25 duty cycles. Comparing weighting schemes, using the 15/85 duty cycle ratio, maximum separation contained the lowest average bias across all inserts of 0.12 ± 0.11 mg/mL whereas All 80/HighE 140 and kVp-switching schemes contained biases of 0.34 ± 0.22 and 0.30 ± 0.25 mg/mL respectively. The 75/25 duty cycle ratio produced the worst average biases with -1.26 ± 0.97 mg/mL and -1.06 ± 0.84 mg/mL for kVp-switching and maximum separation respectively.

### CONCLUSION

We demonstrate enhanced quantification accuracy, achieving a bias below 0.25 mg/mL, through maximum spectral separation with combined dual-layer and rapid kVp-switching technologies.

### CLINICAL RELEVANCE/APPLICATION

The combination of rapid kVp-switching x-ray tube and dual-layer CT increases spectral separation and enables high sensitivity quantitative iodine imaging strengthening the diagnostic benefit of spectral CT.

## M7-SSPH05-2 HIGH-FIDELITY PREFILTRATION USING A DOUBLE BOWTIE DESIGN FOR QUANTITATIVE LOW-DOSE PEDIATRIC SPECTRAL CT IMAGING

Olivia Sandvold, BS (*Abstract Co-Author*) Nothing to Disclose
Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips

NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation
Roland Proksa (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Yinglin Ge, BEng (*Presenter*) Nothing to Disclose

**PURPOSE**

Spectral computed tomography (CT) yields more information, benefiting pediatric diagnostic imaging. But existing spectral CT systems are optimized primarily for adults. We hypothesize that an innovative prefiltration concept, termed "double bowtie", combining traditional Teflon with K-edge filtration, will enhance the quantification accuracy of iodinated contrast and reduce radiation dose in pediatric CT imaging.

**METHODS AND MATERIALS**

A spectral CT system with rapid kVp-switching X-ray source in fan-beam geometry was simulated. The incident x-ray was generated at tube voltages of 120/70 kVp, tube current of 100 mA, and duty cycle ratio of 10/90. A circular pediatric-sized phantom of 150 mm diameter was comprised of water [1 g/mL] and 1 mm of iodine [4.93 g/mL]. The reference dose was established using a conventional Teflon bowtie filter. The Cramer Rao lower bound of variance (CRLB) was used to estimate the signal to noise ratio (SNR) in monoenergetic maps after decomposition. The area under mono-energy curve (AUMC) represented the integral of the SNR estimated for each photon energy. Filter thicknesses (0.0-0.4 mm) for three K-edge materials, holmium (Ho), erbium (Er), ytterbium (Yb) were optimized at 0ŗ fan angle without Teflon filtration. The ideal thickness for each K-edge material was determined by maximizing the AUMC. To achieve the reference dose, imaging parameters were adjusted within the system's limitations. After determining ideal system parameters and K-edge filter thickness at the center of the fan angle, our optimization procedure determined a new thickness for the Teflon filter along the fan-beam geometry. This adjustment ensured an equivalent dose compared to the reference system, while maximizing AUMC for the double bowtie design.

**RESULTS**

The optimized combination of characterized K-edge material filters and Teflon bowtie filter with corresponding system settings of the kVp-switching CT system improves AUMC relative to unoptimized system at the same dose. The maximum improvement is 39.8% for 0.242 mm of Ho compared to 34.3% and 10.9% maximum improvement using optimal thickness Er and Yb. To match patient dose compared to reference system, tube currents for the optimal systems were adjusted to 665 mA (Ho), 662 mA (Er), 584 mA (Yb).

**CONCLUSION**

In this study, we demonstrate initial simulation results of a novel double bowtie design enhancing spectral imaging in pediatric diagnostics. Our results illustrate that noise can be significantly reduced using our concept. This improvement in SNR can be leveraged to reduce dose while maintaining current image quality.

**CLINICAL RELEVANCE/APPLICATION**

Given the rise in CT imaging and the vulnerability of pediatric populations, it is crucial to provide high-quality, low-dose spectral CT imaging.

## M7-SSPH05-3 SPECTRAL DEPENDENCE OF LIVER FAT VOLUME FRACTION RELATIONSHIP TO CT NUMBER IN UNENHANCED FAT LESIONS

Yifang Zhou, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Correct assessment of fat volume fraction (FVF) is vitally important for non-alcoholic fatty liver disease. Compared with MRI, CT may be more desirable for FVF quantification due to its lower cost, faster speed, and wider use. Although it is expected that the FVF linearly depends on the CT number (Hounsfield Units- HU) for true monochromatic beams, the linearity can be compromised in reality due to the polychromatic x-ray property. Our objectives were to find the relationship from various single and dual energy settings and to suggest the optimal selections for least FVF errors.

**METHODS AND MATERIALS**

: Six un-enhanced focal fat lesions (0.79- 6.28 cc) with known and clinically relevant FVF (5- 40%) were built in a medium size anthropomorphic liver phantom. Siemens Force and GE Revolution scanners were used for single energy (120 kV) and dual energy acquisitions at CT volume dose index 14 mGy (80 kV/140 kV for GE, 80 kV/150 kV(Sn) and 100 kV/150 kV(Sn) for Siemens). Virtual monochromatic images (40- 140 keV) were obtained from all dual-energy scans. The HU of each lesion was measured using a volume of interest for each monochromatic image set. The final HU values were obtained from the average of the three repeated scans. Similar analysis was performed on single-energy images.

**RESULTS**

The measured HU was found to increase as FVF decreases, but the relationship is not always well characterized with linearity, depending on the choices of dual energy technology and keV values. The deviation from linearity was the worst at 40- 50 keV for both scanners. With the 80 kV/150 kV(Sn) dual energy option, the linear fit showed FVF estimate errors of 3.1% or less at 110 - 140 keV. However, the 100 kV/150 kV(Sn) selection resulted in 10.3% FVF errors at the best at 80 keV. With 80 kV/140 kV fast switch dual energy option, the best linear fits showed 4.8% and 5.1% FVF errors at 90 and 100 keV, respectively. With single energy 120 kV, both scanners showed comparable FVF errors (9.1- 9.5%).

**CONCLUSION**

Optimal virtual monochromatic energy settings were identified to estimate FVF from the CT number using linear relations with RMS errors < 5.1%. The results were more accurate than from the single energy (120 kVp) where the errors were about 9%.

**CLINICAL RELEVANCE/APPLICATION**

Liver fat content quantification for non-alcoholic fatty liver disease

## M7-SSPH05-4 K-EDGE IMAGING IN A FIRST-GENERATION CLINICAL PHOTON-COUNTING CT SYSTEM

Harold I. Litt, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV

Michael Grasruck, PhD (*Abstract Co-Author*) Employee, Siemens AG
Jonas Neumann (*Abstract Co-Author*) Nothing to Disclose

Pooyan Sahbaee, PhD (*Abstract Co-Author*) Employee, Siemens AG
Leening Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon-counting computed tomography (PCCT) can uniquely detect and quantify K-edge materials, thereby facilitating clinical applications of dual-contrast imaging to evaluate multiple perfusion states simultaneously. We assess the accuracy of multi-material decomposition with k-edge materials, tungsten (W) and bismuth (Bi) in a first-generation clinical PCCT.

**METHODS AND MATERIALS**

Solutions with different concentrations of iodine (I), W, and Bi were inserted into an anthropomorphic phantom (QRM Abdomen, QRM). These included each material at 10 mg/mL and I and W mixes at 2, 5, and 10 mg/mL. The phantom was then scanned on a PCCT (Naeotom Alpha, Siemens Healthineers) without (20 x 30 cm, small) and with its extension ring (25 x 35 cm, large) at a tube voltage of 140 kVp with energy thresholds of 20, 55, 72, and 90 keV. Three exposure levels (50, 200, 501 mAs) were utilized. From the reconstructed threshold images, three and four material decomposition were implemented to generate material maps of water/I/W and water/I/W/Bi, respectively. Regions of interest were then placed on 10 central slices for each material map to measure mean and standard deviation for each material solution. Additionally, relative error was calculated to examine the accuracy of three and four material decomposition at different phantom sizes and radiation doses.

**RESULTS**

Material maps derived from three and four material decomposition showed accurate results, minimally affected by phantom size and radiation dose. With three material decomposition, water, I, and W maps illustrated comparable average errors between large and small phantoms with errors of -21 ± 26, 0.06 ± 0.24, and 0.9 ± 1.1 and -20 ± 23, -0.2 ± 0.3, and -1.0 ± 0.9 mg/mL, respectively. The addition of Bi improved the accuracy of I and W maps, resulting in errors of -0.06 ± 0.26 mg/mL and 0.09 ± 0.22 mg/mL, respectively. Meanwhile, the relative errors for water and Bi were 26 ± 48 and -1 ± 2 mg/mL, respectively. However, it traded off with significant errors in Bi maps of -5 and -2 mg/mL for W 10 mg/mL and W+I 10 mg/mL, respectively, suggesting challenges in separating W and Bi. Radiation dose exhibited a small effect on quantification with average errors ranging from 0.9 to 1.0 and 0.09 to 0.57 mg/mL for W in three and four material decomposition, respectively.

**CONCLUSION**

PCCT effectively differentiated and quantified water, iodine, tungsten, and bismuth in both three and four material decompositions, with minimal influence from phantom size and radiation dose.

**CLINICAL RELEVANCE/APPLICATION**

Recent PCCT adoption enables diverse applications; precise K-edge material discrimination marks innovative progress, paving the way for advanced simultaneous arterial and portal phase imaging to assess multiple perfusion stages in one scan.

## M7-SSPH05-5 METAL ARTIFACT REDUCTION IN PHOTON COUNTING DETECTOR CT USING FOUR-ENERGY THRESHOLDS

Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Kishore Rajendran, PhD (*Abstract Co-Author*) Nothing to Disclose
Elisabeth Shanblatt, PhD (*Abstract Co-Author*) Employee, Siemens AG
Michael R. Bruesewitz, RT (*Abstract Co-Author*) Nothing to Disclose
Joseph R. Swicklik, RT, BS (*Abstract Co-Author*) Nothing to Disclose
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Shaojie Chang, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to investigate the reduction of metal artifacts through the use of high-energy threshold images from a photon-counting detector (PCD) computed tomography (CT), utilizing a four-energy threshold mode.

**METHODS AND MATERIALS**

A 3D-printed spine model with pedicle screws, placed within a 30-cm-wide water phantom, was scanned using a clinical PCD-CT system (NAEOTOM Alpha, Siemens Healthineers), utilizing a four-energy threshold mode (140 kV) with thresholds set at 20, 55, 72, and 90 keV. This setup categorized x-ray photons into four datasets, each representing photons above a specified energy threshold, resulting in four threshold images: T1 (20-140 keV), T2 (55-140 keV), T3 (72-140 keV), and T4 (90-140 keV). T1 images, equivalent to single-energy equivalent (T3D) images on the scanner, utilized all x-ray photons above 20 keV incident on the detectors. Images were reconstructed using the Filtered Back-Projection (FBP) algorithm with a 3 mm slice thickness and a quantitative (Qr40) kernel. The severity of artifacts and image noise were assessed across the four images. An Artifact Index (AI) was employed to measure the severity of metal artifacts, defined as v(SD_m-SD_b ), where SD_m and SD_b is the standard deviation within regions affected by metal artifacts and background (reference) regions without artifacts, respectively. Noise was quantified by measuring the standard deviation of CT numbers in uniform water regions unaffected by artifacts.

**RESULTS**

Metal artifacts progressively decreased from T1 to T4 images, with the T4 images (90-140 keV) demonstrating the most significant reduction. The AI value confirmed a clear trend of decreasing values with higher thresholds, dropping by 60% (from 4.4 to 1.8) from T1 to T4. This indicates substantial artifact reduction at higher energy levels. Conversely, noise levels rose with increased thresholds due to the reduced number of photons utilized. Specifically, noise levels escalated from 16.4 HU in T1 to 37.6 HU in T4.

**CONCLUSION**

The highest energy threshold images (90-140 keV), acquired with a four-energy threshold mode on PCD-CT, significantly reduced metal artifacts but also exhibited increased noise levels compared to lower energy threshold images. With effective noise control, this could provide improved diagnostic performance adjacent to metal implants.

**CLINICAL RELEVANCE/APPLICATION**

Using PCD-CT with a four-energy threshold mode to reconstruct high-energy photons offers a substantial improvement for patients with metal implants. This technique significantly reduces metal artifacts, thereby improving image quality and aiding more accurate clinical diagnoses.

## M7-SSPH05-6 IMPROVING THE SPECTRAL SEPARABILITY OF K-EDGE CONTRAST AGENTS WITH DEEP-SI PHOTON-COUNTING CT

Yuxin Sun, BS, MSc (*Abstract Co-Author*) Stockholder, Nextrast, Inc
Changlyong Kim (*Abstract Co-Author*) Employee, General Electric Company

Nariman Nezami, MD (*Abstract Co-Author*) Consultant, CAPS Medical Ltd
Zhye Yin (*Abstract Co-Author*) Employee, General Electric Company
Arnaud Choux (*Abstract Co-Author*) Nothing to Disclose
Amir Pourmorteza, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon-counting detector (PCD) CT offers multi-material separation beyond what is available with dual-energy CT which is commonly used to separate iodine and soft tissue. this is achieved by tuning the energy thresholds of the detector to the characteristic K-edge energy of specific contrast agents such as those based on Gd, Bi, and Ta. While narrower energy bins will lead to better detection of the K-edge, it will lead to fewer detected photons per energy bins and therefore more noise. The tradeoff between noise and energy bin width remains an open area of research. Here we investigate different threshold settings to maximize spectral separability (SS) of K-edge contrast agents with iodine.

**METHODS AND MATERIALS**

A series of inserts with calibrated contrast agents (iodine, Gd, Ta, Bi) and tissue mimicking materials (hydroxyapatite (HA): calcifications, ferrous sulfate: blood), were placed inside a 20-cm diameter circular phantom filled with ballistic gel. The phantom was scanned on a prototype clinical deep-Si PCD-CT scanner at two different settings of tube voltage with top 5 energy thresholds: 1- 120kVp, thresholds [33, 44, 52, 60, 80] keV, optimized for equal noise in all energy bins, 2- 120kVp optimized for Gd(50keV), Ta(67 keV), and Bi (90 keV) K-edge imaging [33, 50, 67,78, 90] keV. The top 5 energy bins were used for material decomposition and spectral analyses. We measured the angles between basis materials in the 5D spectral space as a measure of spectral separability. Signal difference to noise ratio (SDNR) of iodine and gadolinium were calculated.

**RESULTS**

The revised K-edge energies of gadolinium and Tantalum improved their SS. Iodine-Gd separation improved from 15.3° to 19.5°, iodine-Ta from 14.2° to 29.3°, and iodine-Bi from 6.5° to 14.2°. In addition, Iodine-blood separation improved from 7.9° to 19.5°. Maximum SNDR for Gd and iodine improved from 5.1 to 7.6 and 10.3 to 16.9, respectively.

**CONCLUSION**

Bracketing K-edge energies of contrast agents improved their spectral separability from iodine-based contrast agents and increased their maximum SDNR. The bins above the K-edge of materials which do not improve SS may be combined to improve SDNR. These results translate to improved performance of multi-contrast material decomposition algorithms.

**CLINICAL RELEVANCE/APPLICATION**

The ability to distinguish multiple contrast agents will lead to visualization of multiple perfusion phases of an organ and will significantly reduce the radiation dose required by combining multiple CT scans into one.

### PURPOSE

The use of portable ultra-low field MRI systems offers greater accessibility to neuroimaging, though it poses challenges in the quantitative measurement of brain microstructure due to the limited hardware capabilities of portable scanners and the relatively unexplored physics at such low fields. Myelin, vital in the brain's function and impacted in various neurodegenerative diseases like multiple sclerosis (MS), can be assessed using myelin water imaging (MWI), although typically at higher magnetic fields. MWI acquires multi-echo T2 decay data to derive the myelin water fraction (MWF), a histologically validated biomarker for evaluating myelin integrity. This work aims to integrate novel MWI data acquisition and analysis techniques tailored for ultra-low field MRI, effectively assessing myelin damage in MS, as demonstrated by a case study.

### METHODS AND MATERIALS

A 0.064T portable MRI scanner (Swoop, Hyperfine Inc., Guilford, CT) was employed to scan a participant diagnosed with MS. The imaging protocol included: (1) FLAIR for MS lesion identification: 1.7x1.7x5 mm3 resolution, 8 minutes; (2) MWI for myelin quantification: multi-echo spin echo sequence with CALIPR acceleration, 80 echoes, ?TE/TR = 4.31/800 ms, 3x3x5 mm3 resolution, 7.5 minutes. MWI Data were postprocessed using a recently proposed machine learning method SLED to derive the MWF map.

### RESULTS

The FLAIR images successfully identified MS lesions. The novel MWI technique revealed substantial MWF reduction in these regions, indicating myelin loss. The spatial alignment of decreased MWF with the FLAIR-detected lesions supports the capability of our method for myelin assessment at ultra-low field.

### CONCLUSION

The correspondence between MWF maps and FLAIR images in detecting myelin loss demonstrates the feasibility of applying MWI at ultra-low field strengths, showcasing the potential for quantitative measurements for brain microstructures using a portable MRI platform.

### CLINICAL RELEVANCE/APPLICATION

Implementing MWI on portable ultra-low field MRI systems provides a promising avenue for frequent and cost-effective monitoring of myelin-related diseases. This approach is especially beneficial in regions lacking high-field MRI facilities, enabling improved management and understanding of disease progression associated with myelin.

## M7-STCE1-2 LOW FIELD STRENGTH PELVIC MRI: IMAGE QUALITY CONSIDERATIONS AND COMPARISON WITH HIGH FIELD STRENGTH MRI

**PURPOSE**

The purpose of this study was to perform a quantitative and qualitative evaluation of image quality of low-field strength open magnetic resonance (MR) scanners compared to traditional high-field strength closed MR scanners in imaging of the female pelvis.

**METHODS AND MATERIALS**

This retrospective study included patients undergoing pelvic MRI exam on a low field strength open MRI scanner (between Jan 2017 to June 2022). Prior MRI on high-field strength closed MR scanners were used for comparison. Three subspecialty board-certified radiologists, blinded to examination details performed qualitative evaluation of the pelvic MR scans on pre- and post-contrast T1-weighted, T2-weighted and Diffusion-weighted (DWI) images using a 5-point Likert scale (1 = unacceptable, and 5 = excellent). Qualitative evaluation included assessment of edge/contour sharpness (UO1), ability to resolve adjacent structures (UO2), visual analysis of signal homogeneity (UO3), and visual analysis of image contrast with respect to organs such as the uterus and ovaries (UO4), other organs, and any pathologies identified. Uterus was evaluated for clarity of myometrium, endometrial stripe, and cervix, and ovaries were assessed for clarity of small and large ovarian follicles. Separate proportional odds logistical models were constructed, producing odds ratios for objectively comparing closed and open MR images. Gwet's AC2 statistic was performed to compute inter-reader agreement. Wilcoxon signed rank test was performed to compare image quality considerations on low and high field strength MRI.

**RESULTS**

Out of 152 patients scanned on low field strength MRI, 15.8% (n=24/152) had comparison MRI on high field strength MRI. Image quality scores were higher for high field strength MRI for pre and post contrast T1 and T2-weighted images but were not statistically significant. Image quality of DWI was scored higher compared to low field strength MRI with an odds ratio of 5.66 (1.68-19.0; $p<0.05$) in favor of closed MRI. The odds ratio for non-gynecological organ assessment on DWI was 5.77 in favor of high field strength MRI. Good inter-reader agreement (AC2 statistic of 0.70 or higher) was observed for all pre-contrast T1 image quality parameters except visual analysis of signal homogeneity of uterus and ovaries, T2 evaluation of other organs and artifacts, all post-contrast T1 image quality parameters and all DWI image quality parameters for closed MRI.

**CONCLUSION**

Pelvic MRI scans performed on low field strength MRI have adequate image quality but scored lower compared to pelvic MRI scans performed on high field strength MRI.

**CLINICAL RELEVANCE/APPLICATION**

Low field strength open MRI scanners provide adequate image quality in patients unable to undergo clinically indicated scans due to claustrophobia despite their lower score compared to high field strength MRI.

## M7-STCE1-3 CARDIAC IMAGING AT 0.55T - A COMPARISON TO 1.5T

Stefan Zicha (*Abstract Co-Author*) Nothing to Disclose
Matthias S. May, MD (*Abstract Co-Author*) Speakers Bureau, Siemens AG
Simon Mayr (*Presenter*) Nothing to Disclose

**PURPOSE**

Low-field magnetic resonance imaging (MRI) might improve accessibility of MRI. Leveraging compressed sensing-based image acquisition techniques, cardiovascular magnetic resonance (CMR) at low-field MRI has become more feasible than ever. This study aimed to compare functional and structural measurements of the left ventricle from 0.55T to 1.5T in patients with a clinical indication for cardiac MRI under routine clinical conditions.

**METHODS AND MATERIALS**

We recruited 13 consecutive patients who were scheduled for cardiac MRI on conventional 1.5T scanners for preceding examinations on the same day using a clinical 0.55T system. An external ECG device was used for triggering. The average delay between the examinations was one hour. Research bSSFP sequences with segmented cine, T1 and T2 mapping sequences were used. All data were automatically segmented and manually corrected by a radiologist using a dedicated software. Ten healthy volunteers were additionally examined with the mapping protocol at 0.55T to calculate a reference for this study. Two-sided t-tests or Wilcoxon-tests were used for comparison of the two field strengths, Pearson's coefficient for correlation.

**RESULTS**

The ejection fraction from 0.55T measurements was comparable to 1.5T ($p=0.12$, $r=0.98$). The measurements of end-diastolic, and systolic volumes, stroke volume, and end-diastolic mass were slightly smaller than the reference (all $p<0.05$) but correlated all very well ($r=0.95$; 0.98; 0.94; 0.99). Comparison of T1 mapping resulted in significantly lower mean relaxation times at 0.55T (690.38 ± 31.1 ms, $p<0.01$) compared to 1.5T (1026.6 ± 42.4 ms). T2 mapping relaxation times (0.55T: 68.5 ± 3.9; 1.5T: 49 ± 2.2 ms) were increased at 0.55T ($p<0.01$). Both exhibited a strong correlation to the reference ($r=0.79$; $p<0.01$ and $r=0.63$; $p=0.02$). Reference values at 0.55T were at 678.6 ms ± 13.5 ms for T1, and at 66.5 ms ± 4.1 ms for T2 mapping. 0.55T measurements had a 97% accuracy in differentiating patients between physiological and pathological.

**CONCLUSION**

Cardiac functional analysis and mapping of the left ventricle at low-field MRI has a good correlation with conventional 1.5T measurements. T1 mapping values at low field strength are decreased, while T2 times are increased. Clinical stratification in normal and abnormal functional and structural characteristics is reliable.

**CLINICAL RELEVANCE/APPLICATION**

Low-field MRI at 0.55T has the potential to increase the world wide availability to standardized functional and structural assessment of the left ventricle, once it becomes clinically available.

### PURPOSE

To assess the value of radiomics model based on contrast-enhanced CT (ceCT) in predicting platinum-based chemotherapy response of epithelial ovarian carcinoma (EOC).

### METHODS AND MATERIALS

Consecutive patients with histologically confirmed EOC with pre-treatment ceCT were retrospectively recruited from 5 centers. All patients underwent standard platinum-based chemotherapy before or after optimal cytoreduction. Platinum sensitivity was based on treatment response assessment with refractory disease or resistant disease defined as disease progression while on platinum-based chemotherapy or disease recurrence within 6 months after completion of platinum-based chemotherapy, respectively; otherwise, they were considered as platinum sensitive. The whole volume of primary tumor was manually delineated on each slice of the baseline ceCT images. Radiomics features were extracted using the open-source package PyRadiomics (version 3.0.1). Patients from the center A-C were randomly divided into training set and internal validation set with a ratio of 4:1. Patients from the center D and E were assigned as independent external testing sets. First, Spearsman rank correlation was used to exclude those highly correlated features (r>0.9), followed by 5-fold stratified cross validation (SCV) elastic net repeated for 100 times for feature selection, only features that were there for > 400 times were selected. Next, Mann-Whitney U test was performed for feature reduction. Then, adaptive synthetic sampling (ADASYN) was applied to minimize class biases. Finally, extra trees (ET) classifier across 10-fold grid-search SCV was used for model building.

### RESULTS

Seven hundred and three EOC patients (51.6 ± 9.3 years) were recruited. The training data from center A-C (n=608) yielded classification metrics: area under the curve (AUC) (0.917), sensitivity (83.9%), specificity (94.4%), and accuracy (91.7%) in the internal validation set; AUC (0.877), sensitivity (76.5%), specificity (92.6%), and accuracy (86.4%) in the external testing set using center D (n=44); AUC (0.845), sensitivity (73.3%), specificity (86.1%), and accuracy (82.4%) in external testing set using center E (n=51) in predicting platinum sensitivity.

### CONCLUSION

CT radiomics model proposed could be useful in predicting platinum sensitivity in EOC with potential in guiding personalized treatment in EOC.

### CLINICAL RELEVANCE/APPLICATION

As a non-invasive imaging biomarker, the proposed CT-based radiomics model may allow predicting the treatment response to platinum-based chemotherapy and guiding personalized treatment in EOC patients. It may enable treatment stratification and selection for clinical trials to improve disease prognostication. It also helps platinum-resistant patients avoid chemotherapy toxicity and save time and financial costs.

## M7-STCE2-3 INVESTIGATING THE IMPACT OF METABOLIC DYSFUNCTION ON FOLLICLE COUNT AND ENDOMETRIAL THICKNESS IN WOMEN OF REPRODUCTIVE AGE USING DEEP LEARNING ON MR PELVIS SCANS

Saqib Basar (*Abstract Co-Author*) Nothing to Disclose
Yosef G. Chodakiewitz, MD (*Abstract Co-Author*) Nothing to Disclose
Sam Hashemi, MSc (*Abstract Co-Author*) Nothing to Disclose
Siavash Khallaghi (*Abstract Co-Author*) Nothing to Disclose
Javad Khaghani, MSc (*Abstract Co-Author*) Nothing to Disclose
Soojin Lee (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to leverage deep learning insights applied to MR pelvis scans to investigate the impact of metabolic dysfunction on the number of follicles and endometrial thickness in women of reproductive age.

## METHODS AND MATERIALS

A semantic segmentation network extracted the endometrium and ovaries from sagittal T2 pelvis scans obtained as part of a 1.5T whole body MRI protocol across various sites in US and Canada. Endometrial thickness was measured by applying a distance transform on the sagittal slice with the largest endometrial area. An instance detection solution identified the bounding boxes of individual follicles within each ovary to count the total number of follicles per patient. Metabolic dysfunction was assessed from the patient's medical history through a medical intake form. One-way Analysis of Variance (ANOVA) and Kruskal-Wallis (KW) tests analyzed the effects of each metabolic dysfunction on follicle count and endometrial thickness in reproductive age women (n=1536). Patients with missing information for any metabolic dysfunction were excluded.

## RESULTS

Significant differences in total follicle count were observed across different blood pressure grades (ANOVA: $F=4.95$, $p=0.01$; KW: $H=8.31$, $p=0.02$), blood sugar grades (ANOVA: $F=3.35$, $p=0.04$; KW: $H=7.87$, $p=0.02$), and diabetes status (ANOVA: $F=3.21$, $p=0.04$; KW: $H=8.62$, $p=0.01$). Specifically, the mean follicle counts were 29.09 (normotensive), 24.49 (elevated), and 25.2 (Stage 1 hypertension) for blood pressure grades, and 29.26 (Normal), 24.25 (Prediabetes), and 28.43 (Diabetic) for blood sugar grades. Further, mean follicle counts were 29.48 (No Diabetes), 39.3 (Type 1 Diabetes), and 22.27 (Type 2 Diabetes) for diabetes classification. No significant differences in total follicle count were found for thyroid hormone grades (ANOVA: $F=0.05$, $p=0.82$; KW: $H=0.25$, $p=0.62$) or thyroid conditions (ANOVA: $F=0.59$, $p=0.62$; KW: $H=1.33$, $p=0.72$). The mean follicle counts were 29.1 (Normal) and 29.44 (Abnormal) for thyroid hormone grades, and 29.61 (No thyroid condition), 28.0 (Hyperthyroidism), 29.1 (Hypothyroidism), and 23.0 (Parathyroidism) for thyroid condition groups. No significant differences in endometrial thickness were observed across any metabolic dysfunction groups.

## CONCLUSION

While metabolic factors and conditions such as blood pressure, blood sugar, and diabetes influence follicle count, they do not significantly impact endometrial measurements.

## CLINICAL RELEVANCE/APPLICATION

Metabolics dysfunction is a complex entity that affects multiple organs and systems across the body. The effect of metabolic dysfunction on women's reproductive health provides valuable insights in fertility assessment and improving patient outcomes.

## R1-SSBR10-1 USING ARTIFICIAL INTELLIGENCE (AI) SCORES FOR MAMMOGRAPHY INTERPRETATION IN PREDICTING RECURRENCE AFTER DCIS TREATMENT

Hye Jung Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Jung Min Chang, MD (*Abstract Co-Author*) Research Consultant, Genoray Co, Ltd
Jin Chung, MD (*Abstract Co-Author*) Nothing to Disclose
Na Lae Eun, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jung Hyun Yoon, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate whether artificial intelligence (AI) scores on preoperative mammography along with clinical and radiologic factors is associated to recurrence after DCIS treatment.

### METHODS AND MATERIALS

This multicenter, retrospective study has been approved by the institutional review board (IRB) of five institutions, all academic referral centers. From January 2012 to December 2017, 1,741 women (mean age, 51.5±10.3 years, range, 20-83 years) with final diagnosis of pure DCIS were included. Preoperative routine 4-view mammograms were analyzed by a commercially-available AI algorithm (Lunit INSIGHT for Mammography, Lunit Inc.) for assisting mammography interpretation which provides marks and corresponding abnormality scores (range, 0-100%) per view. Recurrence-free survival rates were estimated using the Kaplan-Meier method and the log-rank test. Uni- and multivariable Cox regression analysis was used to evaluate the factors associated to recurrence after DCIS treatment. Subgroup analysis was performed in women with mastectomy vs. breast-conserving surgery (BCS).

### RESULTS

Of the 1,740 women treated for DCIS, 35 (2.0%) had ipsilateral recurrences and 25 (1.5%) contralateral breast cancer, and 1,680 (96.5%) were recurrence-free. Mean AI scores (66.9±39.3 vs. 46.4±40.4, P=0.003) were significantly higher in ipsilateral recurrences, but not for contralateral second cancers (P=0.197). Recurrence-free survival rate was significantly lower in ipsilateral recurrences for DCIS with AI scores =75% (P<0.001), but not for contralateral breast cancers (P=0.399). Multivariable analysis showed that younger age (OR: 0.920, 95% CI: 0.866, 0.959, P<0.001), DCIS on surgical margins (OR: 4.640, 95% CI: 1.645, 13.091, P=0.004), hormone receptor negativity (OR: 0.284, 95% CI: 0.138, 0.584, P<0.001), and AI score=75% (OR: 3.493, 95% CI: 1.695, 7.196, P=0.007) were significant factors associated to ipsilateral recurrence. Among the subgroup of women with BCS (n=1118), similar trend was seen. AI scores did not show significant association to contralateral second cancers, regardless of surgery type.

### CONCLUSION

AI scores in the upper quartile (=75%) can be used in predicting ipsilateral recurrences after DCIS treatment, especially for women who had breast-conserving surgery, but not for contralateral second breast cancers.

### CLINICAL RELEVANCE/APPLICATION

Quantitative AI scores for assisting mammography interpretation can be used as a imaging biomarker for predicting ipsilateral recurrences in women treated for DCIS. Based on our results, more aggressive treatment may be considered in women diagnosed with DCIS showing AI scores in the upper quartile (=75%) on preoperative mammography.

## R1-SSBR10-2 PERSONALIZED NEOADJUVANT THERAPY RECOMMENDATIONS IN BREAST CANCER FROM A MULTI-OMICS CAUSAL ARTIFICIAL INTELLIGENCE RESPONSE MODEL

Yuan Gao, MS (*Abstract Co-Author*) Nothing to Disclose
Luyi Han (*Abstract Co-Author*) Nothing to Disclose

ScreenPoint Medical BV
Tianyu Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the use of multi-omics causal artificial intelligence (AI) response models in providing breast cancer patients with personalized neoadjuvant therapy (NAT) recommendations based on individual clinical information and pre-treatment DCE-MRI.

**METHODS AND MATERIALS**

The model learned the causal relationship between individual patient data, factual regimen, and corresponding treatment outcomes. This enables selection of the optimal regimen by estimating the effects of all potential regimens. 1310 breast cancer patients treated with one of the NAT regimens (anthracycline backbone, anthracycline plus taxane backbone, single HER2 antibody, multiple HER2 antibodies, and hormone therapy) between 2000 and 2020 at a Cancer Institute from Europe were retrospectively collected. 655 cases were randomly selected for 5-fold cross-validation, and the remaining 655 cases were used for independent validation. Each factual regimen population was divided into two risk groups using the optimal regimen recommended by the model, or participation in a clinical trial when predicted survival with standard regimens was poor. Survival outcomes between the created groups were compared.

**RESULTS**

The model input with DCE-MRI accurately predicted survival for potential regimens with overall survival C indexes of 0.583 (95% CI 0.407-0.743) for HER2-enriched, 0.662 (95% CI 0.557-0.765) for triple-negative, and 0.629 (95% CI 0.536-0.716) for HR-positive populations, which brings increase of C indexes of 0.061, 0.025, and 0.068 for each population compared with using clinical information only. For patients treated with an anthracycline backbone regimen, the group for whom supplemental taxane was recommended by the model had a worse prognosis than for cases where taxane was not recommended by the model, as reflected by a hazard ratio (HR) of 1.62 (95% CI 0.81-3.26). Likewise, for patients treated with anthracycline plus taxane backbone regimen, the risk group for whom a clinical trial was recommended by the model, because current therapy was judged to be likely insufficient, had a worse prognosis than other recommended regimens, as reflected by an HR of 2.31 (95% CI 1.07-4.98).

**CONCLUSION**

The regimen recommended by the model can select high-risk groups with poorer treatment effects among a factual regimen population, which may enable personal NAT regimen recommendations for breast cancer patients.

**CLINICAL RELEVANCE/APPLICATION**

This research helps to provide personalized NAT regimen recommendations for breast cancer patients, which can avoid inefficiency or overtreatment caused by regimens generally determined according to cancer stage and molecular subtypes without fully considering the individual variants of patients.

## R1-SSBR10-3 PREOPERATIVE PREDICTION OF DUCTAL CARCINOMA IN SITU UPGRADE RISK USING MAMMOGRAPHIC IMAGING, DEEP LEARNING, AND RADIOMICS

Manisha Bahl, MD, MPH (*Abstract Co-Author*) Consultant, Lunit Inc;Expert Advisory Committee, 2nd.MD
Synho Do, PhD, MS (*Abstract Co-Author*) Nothing to Disclose
Adham Alkhadrawi (*Abstract Co-Author*) Nothing to Disclose
Kyungsu Kim, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Active surveillance has emerged as a strategy to manage ductal carcinoma in situ (DCIS). The Comparison of Operative versus Monitoring and Endocrine Therapy (COMET) active surveillance trial is a United States-based randomized controlled clinical trial in which women with DCIS undergo standard-of-care treatment with surgery and radiation or active surveillance with imaging and clinical monitoring. Critical to the implementation of active surveillance programs is precise selection of eligible patients. The purpose of this study is to pre-operatively predict the upgrade risk of DCIS at biopsy to invasive carcinoma at surgery, using mammographic imaging, deep learning, and radiomics techniques, in order to inform eligibility for the COMET active surveillance trial.

**METHODS AND MATERIALS**

This Institutional Review Board-approved and Health Insurance Portability and Accountability Act-compliant study includes 2D mammograms from 484 women with DCIS who presented with calcifications and subsequently underwent surgery from 2007 to 2016. Utilizing the Rank-Driven Learning Data Exclusion (RLDE) technique, nonupgraded cases for which the artificial intelligence algorithm had low classification confidence were excluded from the training dataset, thereby reducing the impact of low-confidence cases on algorithm performance. Deep learning and radiomics models were developed, with and without RLDE, to predict DCIS upgrade risk, and their performance was compared to current COMET active surveillance trial eligibility criteria using standard statistical techniques.

**RESULTS**

The imaging-based models attained areas under the receiver operating characteristic curves (AUCs) of 0.66 to 0.67. All models significantly improved with use of RLDE (all $p<0.001$). If the hybrid model incorporating both deep learning and radiomics features was used to determine active surveillance eligibility rather than current COMET trial eligibility criteria, then the number of eligible women would be reduced by approximately one-half (44.9% to 21.4%, $p<0.001$), but the number of missed invasive cancers would be reduced by a greater degree, approximately one-third (30.5% to 9.5%, $p<0.001$).

**CONCLUSION**

Compared to current COMET active surveillance trial eligibility criteria, use of a mammographic imaging-based model to determine eligibility would lead to one-third fewer misses of upgraded DCIS cases.

**CLINICAL RELEVANCE/APPLICATION**

Mammographic imaging-based deep learning and radiomics models show promise for the preoperative prediction of DCIS upgrade risk and could thus help determine which patients are appropriate candidates for active surveillance.

## R1-SSBR10-4 STABLE AND INTERPRETABLE RADIOMIC FEATURES REVEAL TUMOR HETEROGENEITY ASSOCIATED WITH THE RESPONSE TO NEOADJUVANT CHEMOTHERAPY IN LUMINAL BREAST CANCER: A MULTICENTER STUDY

Jinhui Li (*Abstract Co-Author*) Nothing to Disclose
Chao You, MD (*Abstract Co-Author*) Nothing to Disclose

Yajia Gu (*Abstract Co-Author*) Nothing to Disclose
Shiyun Sun (*Presenter*) Nothing to Disclose

**PURPOSE**

To identify stable and interpretable MRI radiomic features to develop a predictive model for NAC response in luminal breast cancer, ultimately promoting personalized precision medicine.

**METHODS AND MATERIALS**

This study retrospectively included luminal breast cancer patients from four cohorts: a development cohort (n=253), an external validation cohort (n=176), the I-SPY 1 cohort with both imaging and genetic information (n=49), and a GEO gene validation cohort (n=227). Patients were divided into NAC response (M-P 4-5) and non-response (M-P 1-3) group. Multiregional MRI radiomic features analyzed included intratumoral subregional, peritumoral, whole tumor, and kinetic features. We introduced a novel two-step feature selection approach using four common methods (LR, SVM, Lasso, XGBoost), performing 50 random rounds of feature selection within each and retaining features chosen over 25 times. We then identified features consistently selected by at least two methods to create a set of 'stable features'. These were cross-combined with four classifiers (LR, Lasso, SVM, XGBoost) to develop and validate the predictive model. In the I-SPY1 cohort, we correlated mRNA data to explore the biological significance of the optimal MRI prediction model.

**RESULTS**

Stable features showed significantly better predictive performance than other features (AUC=0.70-0.90 vs 0.59-0.87), while XGBoost outperformed other classifiers (AUC=0.83-0.90 vs 0.59-0.78). Among 20 cross-combined models, the stable features and XGBoost model had the best performance (AUC=0.78-0.90) and prognostic value (log-rank, P<0.001). Adding clinical and pathological features improved performance further (AUC=0.87-0.92). We identified seven key genes through mRNA correlation with the MRI model, and the predictive model based on these genes performed well in the genetic validation cohort (AUC=0.70). Patients resistant to NAC were primarily associated with activation of the PI3K-Akt, RTK/Ras, Raf/MAPK, and cell cycle signaling pathways, potentially benefiting from CDK4/6i and PARPi inhibitors. Patients sensitive to NAC showed minimal T cell infiltration, possibly indicating some degree of immune activity.

**CONCLUSION**

Our study proposes a method for identifying stable and interpretable MRI features, offering alternative treatment options for luminal breast cancer patients unresponsive to NAC, and recommending additional beneficial treatments for responders.

**CLINICAL RELEVANCE/APPLICATION**

This study targets the largest breast cancer patients by developing an interpretable model for predicting NAC responses, using innovative feature selection and radiogenomic analysis. This allows for tailored management of luminal breast cancer.

## R1-SSBR10-5 A FULLY AUTOMATED DEEP LEARNING SYSTEM BASED ON DYNAMIC CONTRAST-ENHANCED MRI FOR PREDICTION OF PATHOLOGICAL COMPLETE RESPONSE TO NEOADJUVANT CHEMOTHERAPY IN BREAST CANCER: A MULTICENTER STUDY

Ning Mao (*Abstract Co-Author*) Nothing to Disclose
Jing Gao (*Abstract Co-Author*) Nothing to Disclose
Haizhu Xie (*Abstract Co-Author*) Nothing to Disclose
Qi Wang (*Abstract Co-Author*) Nothing to Disclose
Yi Dai, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to develop and validate a fully automated deep learning system (FADLS) utilizing the pre-enhanced and peak enhanced phases images of dynamic contrast-enhanced MRI (DCE-MRI) for the prediction of pathological complete response (pCR) to neoadjuvant chemotherapy (NAC) in breast cancer, and further explored the biological basis underlying FADLS prediction.

**METHODS AND MATERIALS**

The study included 4041 patients underwent DCE-MRI before NAC from ten medical centers and TCGA dataset. They were divided into training, internal testing, external testing, and prospective testing sets. A FADLS were developed with an U-shaped segmentation network and a Siamese-Vision Transformer to perform tumor segmentation and pCR prediction sequentially. The performance of FADLS was compared to Desnet121 and Swin Transformer network. The area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, specificity and heatmap were used to assess the predictive performance of FADLS. RNA sequencing and genetic analysis were conducted on 100 patients to explore the biological basis of FADLS.

**RESULTS**

The results demonstrated that FADLS achieved optimum predictive performance in the training set (AUC=0.853), the internal testing set (AUC=0.850), the external testing set (AUC range from 0.807 to 0.834), and the prospective testing set (AUC=0.833). Furthermore, genetic analysis revealed that high FADLS scores were associated with the up-regulation of immune-mediated genes and pathways.

**CONCLUSION**

The FADLS has the potential to provide an automatic, non-invasive and reliable tool for the early prediction of pCR to NAC in breast cancer patients, which can guide the formulation and adjustment of clinical treatment strategies. patients. Moreover, the underlying biological basis of deep learning for pCR prediction to NAC might be related to the up-regulation f immune-mediated genes and pathways.

**CLINICAL RELEVANCE/APPLICATION**

The FADLS may provide an automatic, non-invasive and reliable tool for the early prediction of pCR to NAC in breast cancer patients, which can guide the formulation and adjustment of clinical treatment strategies.

## R1-SSBR10-6 END-TO-END PROGNOSTICATION AND SURVIVAL ANALYSIS OF BREAST CANCER BY COMBINED VISUAL-LANGUAGE DEEP LEARNING

## PURPOSE

To assess the stand-alone and combined performance of AI prognostication and survival analysis models in women with breast cancer using dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) and electronic health record (EHR) data.

## METHODS AND MATERIALS

We retrospectively collected 10,336 of women with breast cancer presenting at our Cancer Institute between January 2010 and November 2020. Cases with poor MRI imaging quality, and cases with missing or incomplete electronic health records and/or follow-up data were excluded. Finally, 2079 patients were included, and divided into training (n=1455), validation (n=416) and test (n=208) sets. A visual-language (V-L) -based Cox proportional hazards model was developed to predict breast cancer survival. Patients were grouped in low and high-risk cohorts using the median predicted risk. Kaplan-Meier analysis and log-rank test were used to compare survival differences between groups. C-index and hazard ratio (HR) were calculated based on the model-predicted risk scores to compare survival outcomes between these groups. The area under the receiver operating characteristic curve (AUC) was used as an indicator to evaluate the performance of the model in predicting 5-year survival. 95% confidence intervals (CI) were generated using bootstrapping with 1000 replications.

## RESULTS

Breast cancer patients can be divided into high-risk and low-risk using a deep learning-based risk score. In the independent test set, the V-L survival analysis model we developed performed the best, with a C-index of 0.710 (95% CI 0.631, 0.780), significantly better than the model based on only DCE-MRI (C-index=0.601; 95% CI 0.503, 0.706; $p<0.001$), and only EHRs (C-index=0.683; 95% CI 0.601, 0.759; $p<0.001$). The HR for death in the high-risk group using the V-L model was 5.62 (95% CI 1.91, 16.52) (log-rank $p=0.002$), higher than that obtained with the model based on images only (HR=1.79; 95% CI 1.42, 4.14; log-rank $p=0.172$), and on EHRs only (HR=3.67; 95% CI 1.36, 9.89; log-rank $p=0.010$). 5-year survival prediction using the visual-language model showed an AUC of 0.81 (95% CI 0.73, 0.88).

## CONCLUSION

The developed V-L survival analysis model shows potential in risk grouping and survival prediction of breast cancer. V-L deep learning outperforms models in a single mode - only images or only text - setting.

## CLINICAL RELEVANCE/APPLICATION

This study contributes to risk grouping and survival analysis of breast cancer patients and shows that incorporating images in risk models may improve their predictive power. The visual-language survival analysis model we developed can efficiently utilize medical imaging data and EHRs, and may be valuable to select breast cancer patients for more or less intensive adjuvant treatment.

### PURPOSE

Mitral annular disjunction (MAD) refers to the separation of the mitral valve annulus from the left ventricular (LV) myocardium. MAD has recently gained interest in research and clinical practice; however, its prevalence in Marfan syndrome (MFS) based on cardiovascular magnetic resonance (CMR) imaging data is unknown. The purpose of this study was to evaluate the prevalence of MAD in MFS patients using CMR and to examine its association with other CMR findings.

### METHODS AND MATERIALS

This retrospective multicenter study included baseline CMR studies of patients treated for MFS at four tertiary care medical centers with diagnosis based on the revised Ghent criteria and a confirmed (likely) pathogenic FBN1 gene variant. The authors evaluated the datasets for MAD (at the attachment of the mitral valve to the anterior, anterolateral, inferolateral, and inferior segments; =1 mm), mitral valve prolapse (MVP; =2 mm), aortic root z-score, LV ejection fraction (LVEF), LV end-diastolic diameter (LVEDD), and left atrial (LA) size.

### RESULTS

Among 91 patients (28.9±14.0 years, 43 (47.3%) female, body surface area (BSA) 1.9±0.4), 74 (81.3%) had MAD (6.1±2.6 mm), most commonly at the inferior ventricular wall (66 (72.5%), 6.9±3.2 mm). The remaining sites showed a similar prevalence (anterior: 56 (61.5%), 6.0±2.5 mm; anterolateral: 55 (60.4%), 6.1±3.1 mm; inferolateral: 54 (59.3%), 7.0±3.6 mm). There were no significant differences (all p>0.05) between MAD and no MAD groups in aortic root z-score (5.3±3.1 vs. 5.5±3.1), LVEF (62.3±8.0 vs. 57.7±14.7 %), LVEDD/BSA (29.7±7.7 vs. 30.0±8.6 mm/m2), and LA size (11.2±3.1 vs. 11.4±2.7 cm/m2). Decreased LVEF was associated with anterolateral (r=-0.46) and inferolateral (r=-0.39) MAD, whereas increased LVEDD/BSA was mainly observed in anterior (r=0.63) and anterolateral (r=0.46) MAD. Thirty-five patients (38.5%) had MVP, predominantly in patients with MAD (33 (36.3%) vs. 2 (2.2%), p=0.017), especially in anterior MAD (r=0.69).

### CONCLUSION

MAD is highly prevalent in MFS and mostly located at the inferior site. While aortic dimensions, LV parameters, and LA size in patients with MAD were not different in patients without MAD, certain locations showed an association with decreased LV function and increased diameter. MVP was almost exclusively found in MAD and was mostly associated with anterior MAD.

### CLINICAL RELEVANCE/APPLICATION

This study provides insight into the prevalence of MAD in MFS and underscores the need to analyze the different insertion sites of the atrioventricular junction using CMR.

## R1-SSCA09-2 ASSESSMENT OF MYOCARDIAL INJURY IN PATIENTS WITH CHRONIC HIGH ALTITUDE DISEASE BY USING CARDIAC MAGNETIC RESONANCE NATIVE T1 AND T2 MAPPING

Zhenlin Li, MD (*Abstract Co-Author*) Nothing to Disclose
Chunchao Xia (*Abstract Co-Author*) Nothing to Disclose
Ke Shi (*Abstract Co-Author*) Nothing to Disclose
Wanlin Peng, MS (*Abstract Co-Author*) Nothing to Disclose
Xinyang Lv (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate left ventricular myocardial injury in patients with chronic high altitude disease (CHAD) using native T1 and T2 mapping, and further explore the relationship between left ventricular myocardial impairment and ventricular function and strain.

**METHODS AND MATERIALS**

This study prospectively recruited patients with CHAD in our hospital from November 2019 to January 2024. Meanwhile, age- and gender-matched high altitude (HA) healthy controls and sea level (SL) healthy controls were prospectively recruited. All participants underwent cardiac magnetic resonance (CMR) examinations. Native T1 values, T2 values and myocardial strain parameters (the longitudinal peak strain (LPS), circumferential peak strain (CPS) and radial peak strain (RPS) of left and right ventricles) from CMR were measured and compared. Bivariate correlation was used to analyze the relationship between the native T1 and T2 values and ventricular function and myocardial strain.

**RESULTS**

A total of 30 CHAD patients, 14 HA and 12 SL healthy controls were recruited. 47% (14/30) of patients with CHAD were identified as having right heart dysfunction according to the right ventricular ejection fractions (RVEF) < 40% as the threshold. The global native T1 value of patients with CHAD was increased and was the highest among the three groups ($P<0.05$). There was no significant difference in native T1 of the apical segment among the three groups ($P=0.055$). The T2 value of the myocardial basal segment in patients with CHAD was higher than that in the two control groups ($P<0.05$), but there were no significant differences between HA and SL groups. In addition, there was a slightly negative correlation between left ventricular ejection fractions and the myocardial native T1 value of the third segment ($r = -.498$, $P=0.019$). Moreover, there was a negative correlation between RVEF and the native T1 value of the basal segment ($r =-0.431$, $P=0.045$).

**CONCLUSION**

The multiple CMR sequences demonstrated diffuse myocardial fibrosis existed in patients with CHAD, accompanied by segmental myocardial edema. Hypoxia and hypoxia induced right ventricular injury together contributed to myocardial fibrosis, which is related to the left ventricular strain and function impairment.

**CLINICAL RELEVANCE/APPLICATION**

Myocardial edema and myocardial fibrosis are the common pathological manifestation of different cardiovascular disease, and further lead to cardiac remodeling. The T1 and T2 mapping has emerged as potential technology to quantitate the degree of myocardial injury in the early stage, and it is important to make an accurate diagnosis on account of difference in progression and treatment.

## R1-SSCA09-3 INCREMENTAL VALUE OF MULTIPARAMETRIC CARDIAC MRI FOR THE IDENTIFICATION OF SIGNIFICANT ACUTE CARDIAC ALLOGRAFT REJECTION: A PROSPECTIVE AND BIOPSY-PROVEN STUDY

Shihua Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Zhixiang Dong (*Abstract Co-Author*) Nothing to Disclose
Pengyu Zhou, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Using endomyocardial biopsy (EMB) as the reference standard, this study aimed to evaluate the association between multiparametric cardiac magnetic resonance (CMR) parameters and acute cardiac allograft rejection (SR), and assess the incremental value of CMR parameters over conventional cardiac examinations for identifying SR.

**METHODS AND MATERIALS**

Heart transplantation (HTx) recipients with EMBs and healthy controls were prospectively recruited for CMR assessment including cine, late gadolinium enhancement, T1 mapping, and T2 mapping. CMR feature tracking (CMR-FT) was performed to evaluate the left ventricular (LV) global strain in all three directions. The serum examinations including N-terminal pro brain natriuretic peptide (NT-proBNP) before anti-immunotherapy were recorded. Participants were divided into 3 groups based on EMB grade: control, SR (acute cellular rejection grade=2R and/or antibody-mediated rejection [AMR] grade=pAMR1), and NSR (non-SR).

**RESULTS**

Thirty controls (43.3±13.6 years, 26 male) and 51 HTx recipients comprising 23 SRs (48.6±12.6 years, 24 male) and 28 NSRs (42.7±14.9 years, 16 male) were enrolled for analysis. Compared with NSRs, SRs showed elevated NT-proBNP (7797.0±7527.6pg/ml vs 3334.6±5935.3pg/ml, $p<.001$), worse LV global longitudinal strain (GLS) (-9.7±3.1% vs -13.1±2.9%, $p<.001$), and increased native T1 (1384±80.1ms vs 1321±69.9ms, $p<.001$) and T2 values (50.9±2.7ms vs 45.7±4.3ms, $p<.001$). In multivariable analysis, LV GLS (OR=0.76, 95%CI, 0.59 to 0.98, $p=.03$) and T2 value (OR=1.35, 95%CI, 1.10 to 1.65, $p=.01$) were independently associated with SR after NT-proBNP adjustment. The likelihood ratio test showed LV GLS (-2 log likelihood=55.8, X2=14.4, $p=.002$) and T2 value (-2 log likelihood=50.3, X2= 20.0, $p<.001$) had incremental value over NT-proBNP for identifying SR. Furthermore, when added the combination of LV GLS and T2, there was a further improvement for the identification of SR (-2 log likelihood=44.9, X2=25.3, P= .02).

**CONCLUSION**

LV GLS and T2 value were independently associated with SR, providing incremental value for the non-invasive rejection surveillance in HTx recipients.

**CLINICAL RELEVANCE/APPLICATION**

Given the increasing need for non-invasive rejection surveillance in HTx recipients, our research found that LV GLS and T2 value were independently associated with SR in HTx recipients, providing incremental value for the non-invasive rejection surveillance after heart transplantation, which may help define the clinical benefit and appropriate application of multiparametric CMR in HTx recipients for clinical use and future randomized trials.

## R1-SSCA09-6 REALTIME CINE CARDIAC MRI BASED ON DISENTANGLED REPRESENTATION LEARNING ENABLES FEATURE TRACKING STRAIN ANALYSIS IN PATIENTS WITH ARRHYTHMIA

Thorsten A. Bley, MD (*Abstract Co-Author*) Speakers Bureau, F. Hoffmann-La Roche Ltd;Research Consultant, F. Hoffmann-La Roche Ltd;Speakers Bureau, Novartis AG;Research Consultant, Novartis AG;Research Consultant, Baltimore RH Typing Laboratory

Tobias Wech (*Abstract Co-Author*) Nothing to Disclose
Nils Petri (*Abstract Co-Author*) Nothing to Disclose
Oliver Schad (*Abstract Co-Author*) Nothing to Disclose
Julius F. Heidenreich, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Myocardial strain is proposed as more sensitive imaging biomarker of myocardial disease compared to ejection fraction. If conventional segmented cine MRI is used, the analysis is based on a synthetic (temporally averaged) cardiac cycle. We demonstrate realtime cardiac MRI based on undersampled spiral acquisitions and a reconstruction using disentangled representation learning, and evaluate preliminary data of feature tracking (FT) strain analysis in a small cohort of arrhythmic patients with atrial fibrillation.

**METHODS AND MATERIALS**

A neural network with extended spatial decomposition architecture (xSDNet) was trained for joint reconstruction and semantic segmentation of undersampled realtime cardiac data acquired with a spiral bSSFP pulse sequence. Two healthy participants and four patients with atrial fibrillation were examined on a 1.5 T MRI in breath-hold. Realtime MRI was acquired across four sequential R-R cycles; ECG-gated segmented cine MRI covering one synthetic heartbeat served as reference. Strain analysis was performed on a single mid-ventricular short axis slice for each individual. Global radial (GRS) and circumferential strain (GCS; each in %) were calculated using cvi42®. Peak strain from segmented cine MRT was compared with maximum, minimum and calculated mean peak strain across the four acquired heartbeats from realtime MRI.

**RESULTS**

Overall, mean peak GRS and GCS were well comparable in realtime and segmented CMR (GRS: realtime = 31.9 ± 7.6 % vs. segmented = 31.4 ± 6.9 %, mean difference = 0.53 %; GCS: realtime = -18.5 ± 3.0 % vs segmented = -18.4 ± 2.7 %, mean difference = 0.53 %). One patient exhibited relevant arrhythmia during examination with a variance of 11.9 % for GRS (max: 26.6 %, min: 17.5 %) and 2.4 % (max: -12.4 %, max: -16.4%) for GCS across the four examined heartbeats. For the same patient, mean values from realtime were largely comparable to GRS (23.2 % vs. 20.9 %) and GCS (-15.2 % vs. -14.3 %) from segmented CMR. Both healthy participants had stable heartbeats and a low variance of GRS (0.88 %) and GCS (0.3 %).

**CONCLUSION**

Realtime imaging has the potential to accelerate the cine building block of CMR and may omit the need of ECG gating. In healthy participants peak radial and circumferential strain were highly comparable between both imaging techniques, accompanied by a very low variance across the measured R-R cycles in real-time imaging. In patients with arrhythmia, traditional ECG-gated segmented cine imaging can be severely affected by image artifacts which may lead to incorrect strain analysis.

**CLINICAL RELEVANCE/APPLICATION**

Strain analysis is proposed as a sensitive biomarker for myocardial disease, but analysis may be incorrect in patients with arrhythmia. Strain analysis from realtime cine MRI may overcome this drawback.

## R1-SSCH09-1 A PHANTOM VALIDATION STUDY OF ARTIFICIAL INTELLIGENCE GENERATED 1024-AND 2048-MATRIX CT IMAGES

Qingyao LI, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the image quality of AI-generated 2048-matrix CT images versus standard 512-matrix CT images, standard 1024-matrix and AI-generated 1024-matrix CT images at different dose levels.

### METHODS AND MATERIALS

Standard 512-matrix and 1024-matrix CT images were acquired by scanning the Catphan® phantom 600 using a chest protocol under four different radiation doses. These images were subsequently processed with super-resolution techniques to generate AI-generated 2048-matrix and AI-generated 1024-matrix CT images. An observer utilized the commercial software ImQuest (Reference) to measure the Noise Power Spectrum (NPS), Task Transfer Function (TTF), noise, and signal-to-noise ratio (SNR) for the CT images; this software has been validated in multiple peer-reviewed studies. Statistical analyses for NPS, TTF, noise levels, and SNR were conducted using the non-parametric rank sum test. Additionally, the uniformity of CT values across peripheral and intermediate regions of interest was examined using the Bland-Altman method at a consistent image level of the Catphan® phantom.

### RESULTS

Overall, Super-resolution processing of original CT images improved the TTF50%Teflon, Noise, NPSpeak, and NPSave, while maintaining CT value uniformity and accuracy. In visual analysis, AI-2048 matrix CT images had the largest identifiable line pairs,which also confirms this. Additionally, there is a trend of decreasing NPS_peak and increasing NPS_ave with increasing dose, suggesting an improvement in noise texture.However, using super-resolution swin2SR technology in lung kernel may reduce the image's signal-to-noise ratio (SNR).

### CONCLUSION

The utilization of the Swin2SR model for generating super-resolution CT images has demonstrated promising results, contributing to advancements in spatial resolution and a decrease in image noise without compromising the accuracy and uniformity of CT values.

### CLINICAL RELEVANCE/APPLICATION

The Swin2SR model can be applied to medical CT image processing to improve the resolution of medical images and help doctors make more accurate diagnoses.

## R1-SSCH09-2 DYNAMIC CONTRAST-ENHANCED AREA-DETECTOR CT FOR DETECTION OF TISSUE BLOOD SUPPLY CHANGES IN STAGE I NSCLC PATIENTS WITH PF-ILD

Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Yoshiharu Ohno, MD, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

### PURPOSE

Although thin-section CT is widely used for management of progressive fibrosing ILD (PF-ILD), PF-ILD warrants additional quantitative radiological imaging for evaluation of lung structure change and pharmacologic treatment or prediction of therapeutic effect. The purpose of this study was to determine the capability of dynamic first-pass contrast-enhanced (CE-) perfusion area-detector CT (ADCT) for detecting pathological structure changes in stage I non-small cell lung cancer (NSCLC) patients with PF-ILD.

### METHODS AND MATERIALS

63 consecutive stage I NSCLC patients with PF-ILD underwent dynamic CE-perfusion ADCT, surgical treatment and pathological examination, followed by computational generation of total perfusion (TPDMS), pulmonary arterial perfusion (PAPDMS) and systemic arterial perfusion (SAPDMS) maps by dual-input maximum slope model. ROIs were then placed over sites pathologically diagnosed as normal lung, pulmonary emphysema, usual interstitial pneumonia (UIP) pattern, probable UIP pattern and indeterminate for UIP pattern the resected lung. Next, Tukey's honesty significant difference (HSD) test was performed for a comparison of each of the perfusion parameters for normal lung, pulmonary emphysema, UIP pattern, probable UIP pattern, and indeterminate for UIP pattern. Finally, discrimination accuracy for evaluation of lung structure change was compared for all indexes as well as combined methods.

### RESULTS

PAPDMSs of abnormal lungs other than emphysematous were significantly lower than those of normal lungs ($p<0.0001$). SAPDMSs of normal or emphysematous lungs were significantly lower than those of others ($p<0.0001$). SAPDMS of indeterminate for UIP was significantly lower than that for probable UIP and UIP ($p<0.0001$). Discrimination accuracies of PAPDMS (52.6%) and SAPDMS (54.9%) were significantly higher than that of TPDMs (TPDMS: 41.8%, $p<0.0001$). Discrimination accuracy of the combined method (71.6%) was significantly higher than that of each of the perfusion indexes (TPDMS: $p<0.0001$, PAPDMS: $p<0.0001$, SAPDMS: $p<0.0001$).

### CONCLUSION

Dynamic first-pass CE-perfusion ADCT is useful for detecting pathological structural changes in stage I NSCLC patients with PF-ILD.

### CLINICAL RELEVANCE/APPLICATION

Dynamic first-pass CE-perfusion ADCT is useful for detecting pathological structure changes in stage I NSCLC patients with PF-ILD.

## R1-SSCH09-3 THE IMPACT OF DEEP LEARNING RECONSTRUCTION COMBINED WITH CONTRAST-ENHANCED BOOST TECHNOLOGY ON CT PULMONARY ARTERY IMAGING WITH LOW CONTRAST VOLUME AND LOW FLOW RATE

Rulin Xu (*Abstract Co-Author*) Nothing to Disclose
Zhiman Lai (*Abstract Co-Author*) Nothing to Disclose
Hui Ma (*Abstract Co-Author*) Nothing to Disclose
Jingyi Lin (*Abstract Co-Author*) Nothing to Disclose
Mulan Huang (*Abstract Co-Author*) Nothing to Disclose
Dingxiang Xie (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to assess the impact of deep learning reconstruction (DLR) algorithm combined with contrast enhanced boost (CE-boost) technology on CT pulmonary artery (CTPA) imaging under conditions of low contrast volume and low flow rate.

### METHODS AND MATERIALS

This study enrolled 106 prospective suspected pulmonary embolism patients, who were randomly assigned to two groups (each n=53) for CTPA examination. For Group A, 30 ml contrast agent was administered at a flow rate of 3 ml/s; while volume 50 ml and flow rate 4ml/s were used with Group B. And images in Group A were reconstructed and underwent post-processing with four different methods, namely 4 subgroups: using only hybrid iterative reconstruction (HIR, Group A1) or DLR (Group A2), and using CE-boost combined with HIR (Group A3) or DLR (Group A4). Images in Group B were reconstructed using HIR exclusively. We quantified CT values and image noise of the main pulmonary artery, left and right pulmonary arteries, and upper and lower pulmonary arteries in all groups, and calculated the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). Subjective evaluations of vascular enhancement degree, sub-segmental pulmonary artery visualization, noise, and overall image quality in five groups of images were conducted.

### RESULTS

In Groups A1-A4 and Group B, 46, 46, 53, 53, and 48 cases met the objective diagnostic criteria, namely pulmonary artery CT values >250 HU, respectively. Following CE-boost, the diagnostic rates increased by 13.21% in Groups A1 and A2. Group A4 exhibited the lowest noise values, and the highest SNRs and CNRs, in all measurement areas among all groups; additionally, Group A4 had the highest CT values in all measurement areas, significantly higher than those of Groups A1, A2, and B (all $P < 0.01$), but the difference with Group A3 did not reach statistical significance ($P > 0.05$). Group A4 scored higher in subjective assessments of sub-segmental pulmonary artery visualization and noise compared to the other four groups (all $P < 0.05$). The overall subjective image score of Group A4 was higher than that of Groups A1 and B, respectively (all $P < 0.05$).

### CONCLUSION

The application of DLR combined with CE-boost technology for CTPA can enhance pulmonary artery visualization and achieve better image quality, in condition of substantially reduced contrast flow rate and total volume.

### CLINICAL RELEVANCE/APPLICATION

This technological approach holds particular promise for patients susceptible to contrast-induced nephropathy or elderly individuals with compromised vascular conditions, potentially aiding in the detection of sub-segmental pulmonary artery embolism. Considering the current research findings, there remains potential for further reduction in radiation dose and contrast volume.

## R1-SSCH09-4 OPPORTUNISTIC SCREENING FOR OSTEOPOROSIS USING ARTIFICIAL INTELLIGENCE IN CHEST CT SCANS: VALIDATION AGAINST DEXA SCANS

Orhan K. Oz, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Christopher Fan (*Abstract Co-Author*) Nothing to Disclose
Ronald M. Peshock, MD (*Abstract Co-Author*) Stockholder, General Electric Company;Researcher, Siemens AG;Researcher, Aidoc Medical
Fernando U. Kay, MD, PhD (*Abstract Co-Author*) Research Grant, Edwards Lifesciences Corporation
Michael Long, MS (*Abstract Co-Author*) Nothing to Disclose
Roderick McColl, PhD (*Abstract Co-Author*) Nothing to Disclose
Angelo Scanio (*Presenter*) Nothing to Disclose

### PURPOSE

Osteoporosis, characterized by low bone mineral density (BMD), is a prevalent yet often undiagnosed condition, leading to significant morbidity and mortality. Dual-energy X-ray absorptiometry (DXA) is the current gold standard for measurement of BMD. Leveraging existing chest CT scans, this study

proposes an opportunistic approach using an Artificial Intelligence tool, (AI Rad Companion, Siemens), along with a machine learning algorithm to predict low BMD as defined by DXA scans.

**METHODS AND MATERIALS**

A total of 781 patients underwent a non-contrast chest CT and a DXA scan within a one-year period between Sept. 9, 2022, and Dec. 29, 2023. Utilizing Hounsfield units of the trabecular bone from chest CT scans and vertebral body height collected from AI-Rad companion, we trained a Light Gradient Boosting Machine Learning model (LightGBM) to predict low BMD from multiple covariates. A Logistic Regression (LR) model was derived using only Hounsfield units at the most caudal thoracic spine vertebra for comparison, which is the standard approach for opportunistic screening of low BMD on chest CT.

**RESULTS**

In the unseen test cohort (30% of the sample), the LightGBM model achieved an area under the receiver operating characteristics curve of 0.84, in comparison to the LR model of 0.76 ($p<0.001$). The LightGBM model demonstrated higher accuracy and sensitivity in predicting low BMD, 79% and 87% respectively, compared to the chest CT radiological reports, 36% and 12%, respectively. However, the AI model reported a lower specificity of 59% compared to 94%.

**CONCLUSION**

Quantitative metrics extracted from chest CT scans using AI can be integrated with machine learning algorithms to predict low BMD. The LightGBM machine learning model demonstrated robust performance in detecting low BMD, outperforming the sensitivity of radiological reports.

**CLINICAL RELEVANCE/APPLICATION**

These findings advocate for a broader adoption of AI models in opportunistic screening for low BMD among patients undergoing chest CTs. Integration of these models in screening for low BMD can possibly reduce the morbidity and mortality of patients with osteoporosis or osteopenia.

## R1-SSCH09-5 WHOLE-BODY STATIC CT SYSTEM WITH DUAL-RING STRUCTURE AND TWENTY-FOUR SOURCES: INITIAL EXPERIENCE IN LUNG

Weisen Yang (*Abstract Co-Author*) Nothing to Disclose
Mu Lin, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Recently, the clinical trial of a prototype stationary CT with dual-ring structure has started. The stationary architecture doesn't have gantry rotation related blurring and provides ultra-high spatial resolution. This study aims to evaluate the clinical image quality and potential clinical benefits of the stationary CT system in chest imaging by comparing it with a traditional helical CT system using visual grading analysis (VGA) scores.

**METHODS AND MATERIALS**

The prototype static CT system (CompoundEye™ 24, Nanovision Medical Technology Co., Ltd., Shanghai, China) has an 83-cm bore size and 50-cm FOV. It has a unique dual-ring structure comprising an X-ray source ring and a detector ring. The X-ray source ring incorporates 24 X-ray tubes and the detector ring consists of 10240 channels across 288 rows with each element having a size of 0.265mm × 0.265mm. Cone beam projections are collected by electronically triggering all X-ray sources sequentially. An FDK-based iterative scheme with total variation was adapted for reconstruction. The study included fifty patients who underwent scans with the stationary CT system (3072-matrix, 0.33-mm slice thickness, 120 kVp, 100 mAs) and had previously received a helical CT scan (512-matrix, 0.625-mm slice thickness, 100 mAs) within the last 12 months. Two radiologists evaluated the visibility of various lung structures using a 5-point scale (-2 = worse visibility on stationary CT impacting diagnosis, -1 = worse visibility without impact, 0 = equivalent visibility, 1 = better visibility without impact, 2 = better visibility on stationary CT impacting diagnosis). The median VGA scores were compared and statistically analyzed using one-sample Wilcoxon signed-rank tests with hypothesized median values of 0 and 2, considering p-values < 0.05 as statistically significant.

**RESULTS**

All lung structures had significantly better visibility on stationary CT compared to helical CT (mean VGA > 0), with notable improvements noted in peripheral airways, micronodules, inter- and intralobular lines, emphysema, and calcifications (mean VGA > 1). Although better visibility, a perceived difference in diagnostic interpretation could not be demonstrated, since the median VGA was significantly different from 2.

**CONCLUSION**

The stationary CT system provides markedly superior visibility of multiple lung structures compared to traditional helical CT. Despite these imaging improvements, the impact on clinical diagnostic interpretation remains inconclusive, suggesting a need for further studies to assess how these visibility enhancements influence clinical outcomes.

**CLINICAL RELEVANCE/APPLICATION**

The ultra-high-resolution images of the stationary CT has potential to improved diagnostic performance in chest imaging.

**PURPOSE**

Radiology reports contain medical jargon limiting patients' understanding of their health and negatively impacting treatment compliance. We developed an automated patient-sensitive radiology report summarization model, i.e., model generates different summaries of the same report for patients with different levels of education/knowledge.

## METHODS AND MATERIALS

We finetuned 3 LLMs; T5 (0.77B), GPT2 (1.5B) and BioGPT (1.5B) for generating layman and expert-level summaries of findings in chest CT exam reports, conditioned on prompt describing patient's knowledge level (expert vs. layman). 6970 reports (2013-2022) were collected for development; impression sections were used as technical/expert summary surrogates while layman summaries were curated using LLaMA-13B as zero-shot framework and manual filtering of inaccurate summaries (~15% data filtered). Three board-certified radiologists (experts) and three readers with non-clinical backgrounds (laymen) evaluated summaries generated by our model. Comparative analysis with ChatGPT (zero-shot) was performed on 50 randomly sampled reports.

## RESULTS

Quantitative analysis established superiority of T5 (encoder-decoder model) over GPT2 and BioGPT (decoder-only). Among decoder-only models, BioGPT (pretrained on PubMed abstracts) outperformed GPT2. In manual evaluation of 23 reports, i) experts indicated one case of missed information in expert-level and one in laymen summaries; ii) 5 cases of hallucination were found in laymen summaries which mostly concerned with fracture locations. This may be due to insufficient training data for a finding like fracture (<10% of training reports mentioned fractures). Layman users reported 63% improvement in their understanding of information by reading model-generated layman summaries. ChatGPT (zero-shot) i) hallucinated twice as often and ii) missed information five-times more frequently than our model, and always generated unnecessarily long summaries which can negatively impact comprehension.

## CONCLUSION

Task-specific training of smaller LLM on limited training data achieved reliable performance for radiology report summarization, compared to zero-shot performance of ChatGPT. Integration of our summarizer framework in clinical workflow can improve patients’ understanding of their radiology reports.

## CLINICAL RELEVANCE/APPLICATION

Patients' lack of understanding of their clinical status, often reported in radiology reports, may lead to missed follow-up and potentially poor clinical outcomes. We present a solution to this challenge, i.e., development of automated report summarizers that can customize their response to each patients, thus improving their comprehension of clinical information.

## R1-SSGU06-1 COMPARING BIPARAMETRIC AND MULTIPARAMETRIC MAGNETIC RESONANCE IMAGING FOR THE DETECTION OF PROSTATE CANCER: AN INTERNATIONAL, MULTICENTRE, NON-INFERIORITY CLINICAL TRIAL (NCT04571840)

PRIME Trial Group (*Abstract Co-Author*) Nothing to Disclose
Aqua Asif, MBChB, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Multiparametric MRI (mpMRI) with or without prostate biopsy has become the new standard of care for diagnosing clinically significant prostate cancer. However, resource limitations limit widespread adoption. The PRIME (Prostate Imaging using MRI ± Contrast Enhancement) trial aimed to evaluate whether biparametric MRI (bpMRI), a shorter, more streamlined MRI, without contrast enhancement, was non-inferior to mpMRI in detecting clinically significant PCa (csPCa).

### METHODS AND MATERIALS

Multiparametric MRI (mpMRI) with or without prostate biopsy has become the new standard of care for diagnosing clinically significant prostate cancer. However, resource limitations limit widespread adoption. The PRIME (Prostate Imaging using MRI ± Contrast Enhancement) trial aimed to evaluate whether biparametric MRI (bpMRI), a shorter, more streamlined MRI, without contrast enhancement, was non-inferior to mpMRI in detecting clinically significant PCa (csPCa).

### RESULTS

A total of 555 men were recruited in 22 centres across 12 countries, of which 490 men were included in the primary outcome analysis. In the bpMRI group (T2W and DWI), clinically significant cancer was detected in 141 of 490 men (28.8%), as compared to 143 of 490 men (29.2%) with the addition of the DCE sequences in the mpMRI group (adjusted difference, 0.4 percentage points; 95 confidence intervals [CI], -0.4 to 1.2; P=0.5). bpMRI, with or without targeted biopsy, was non-inferior to mpMRI, with or without targeted biopsy. bpMRI detected clinically insignificant cancer in 47 of 490 men (9.6%), as compared to 49 of 490 men (10.0%) on mpMRI (adjusted difference, 0.4 percentage points; 95% CI, -0.4, 1.2; P=0.5). Central quality control demonstrated that 95% of scans were of adequate diagnostic quality.

### CONCLUSION

In men with suspected prostate cancer, bpMRI with or without targeted biopsy should become the new standard of care for prostate cancer diagnosis in scans of adequate diagnostic quality.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrates that biparametric MRI (bpMRI) can reliably diagnose prostate cancer without the use of dynamic contrast-enhanced sequences, potentially reducing healthcare costs and increasing the accessibility of prostate MRI.By establishing bpMRI as a sufficient diagnostic approach in cases where MRI quality meets diagnostic standards, it supports the adaptation of prostate cancer screening protocols to be more efficient while maintaining high diagnostic accuracy. This change could lead to wider implementation in various healthcare settings, improving patient outcomes by providing timely and effective prostate cancer diagnosis.

## R1-SSGU06-2 MRI WITHOUT CONTRAST MEDIA INJECTION FOR PROSTATE CANCER SCREENING: RESULTS FROM PROSTATE CANCER SECONDARY SCREENING IN SAPIENZA (PROSA)

Martina Pecoraro, MD (*Abstract Co-Author*) Nothing to Disclose
Ludovica Laschena, MD (*Abstract Co-Author*) Nothing to Disclose

Emanuele Messina, MD (*Presenter*) Nothing to Disclose

### PURPOSE

PROSA (Prostate Cancer Secondary Screening in Sapienza) is a randomized MRI-based screening protocol, investigating the role of MRI without the injection of contrast media (bi-parametric MRI, bpMRI) as a secondary prevention test for prostate cancer (PCa) early diagnosis, comparing MRI with the

prostate specific antigen (PSA) test. PROSA has the aim to investigate the efficiency of this screening protocol, both in terms of diagnostic accuracy, and cost-effectiveness.

**METHODS AND MATERIALS**

590 men aged 49 to 69 years have been enrolled and blindly randomized into two different arms: (A) Men underwent bpMRI regardless of their PSA values;(B) Men with increased PSA were referred to bpMRI, while those with normal PSA were not.Men who screened positive on MRI were directed to MR-directed targeted biopsy.To evaluate the efficiency of the protocol we calculated the experimental event rate (EER), control event rate (CER), absolute risk reduction (ARR), number needed to treat (NNT).Health Technology Assessment analysis was implemented to evaluate the cost-effectiveness.

**RESULTS**

285 men were randomized on Arm A and among them 12 clinically significant PCa (csPCa) were detected; 305 men were randomized on Arm B, with 5 csPCa detected (p = 0.070). The two arms did not show any statistically significant difference in terms of demographic and clinical variables, resulting comparable. Considering the efficiency of the screening protocol, EER was 4.21%, CER 1.64%, ARR 2.57%, NNT 39.0%. Considering long term costs, and more specifically the management of csPCa, the present screening programs shows promising results in terms of economic impact, and could be associated with cost-savings over no screening, when treatment costs for the screened diseases are considered.

**CONCLUSION**

Prostate MRI without contrast medium injection showed promising results compared to the use of PSA analysis alone as a screening tool, both in terms of accuracy and cost-effectiveness.

**CLINICAL RELEVANCE/APPLICATION**

This new approach to PCa screening could facilitate the early diagnosis of csPCa, allowing cost-savings of csPCa management and it could reduce the number of unnecessary prostate biopsies and the detection of ciPCa.

## R1-SSGU06-3 INTEGRATING PREOPERATIVE MRI AND CLINICOPATHOLOGICAL FEATURES TO PREDICT POSITIVE SURGICAL MARGINS IN PROSTATE CANCER PATIENTS UNDERGOING RADICAL PROSTATECTOMY

Haiyi Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Mengqiu Cui (*Abstract Co-Author*) Nothing to Disclose
Bai Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Xueyi Ning (*Abstract Co-Author*) Nothing to Disclose
Baichuan Liu (*Abstract Co-Author*) Nothing to Disclose
Yuanhao Ma (*Abstract Co-Author*) Nothing to Disclose
Honghao Xu (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a lesion-based grading system for predicting the risk of positive surgical margin (PSM) following robotic-assisted laparoscopic prostatectomy (RALP) among prostate cancer (PCa) patients, utilizing the MRI features and clinicopathological examination.

**METHODS AND MATERIALS**

Consecutive MRI exams of patients undergoing RALP for PCa were retrospectively collected from two institutions (center 1: 297 patients; center 2: 119 patients). Patients who underwent RALP between January 2020 and December 2021 were included in the derivation cohort (n = 227) and those who underwent RALP between January 2022 and December 2022 were assigned to the internal validation cohort (n = 70). Patients from center 2 were assigned to the external test cohort. MRI-based predictors associated with PSM were assessed: tumor size, curvilinear contact length of lesions (CCL), capsular irregularity and bulge, the Prostate Imaging Reporting and Data System category (PI-RADS), tumor location (apex abutting or lateral portion near the neurovascular bundle), apical depth (APD), asymmetry of neurovascular bundles, obliteration of rectoprostatic angle and frank extraprostatic extension (EPE) at MRI. Clinicopathological parameters include prostate-specific antigen (PSA), clinical T stage and Gleason score, which transformed into a three-tiered risk stratification system (RISK) according to the European Society for Medical Oncology (ESMO) guidelines. A prediction model was developed by using fixed effect logistic regression and classification and regression tree (CART) analysis, and then it was transformed into a scoring system. The prediction performance of lesion-based scoring system was evaluated using the area under the curve (AUC).

**RESULTS**

A total of 396 patients (derivation cohort: 227, validation cohort: 69 and test cohort: 107) were included and 489 lesions (derivation cohort: 282, validation cohort: 90 and test cohort: 117) were identified. Of these, 82 (29.1%), 32(35.6%) and 42 (35.9%) of lesions in the derivation, validation and test cohorts, respectively, had PSMs after RALP. The scoring system consisted of the following variables: CCL, RISK, tumor location (apex abutting), APD and frank EPE at MRI. This scoring system provided good prediction performance for PSM in the derivation (AUC 0.82 [95% CI: 0.77, 0.87]), validation (AUC 0.78 [95% CI: 0.68, 0.87]) and test (AUC 0.79 [95% CI: 0.70, 0.87]) cohorts.

**CONCLUSION**

A lesion-based scoring system integrating MRI and clinicopathological features can help efficiently estimate the risk of PSM after RALP.

**CLINICAL RELEVANCE/APPLICATION**

This scoring system evaluating per-lesion risk of PSM based on MRI and clinicopathological features can assist surgeons in making surgical strategies.

## R1-SSGU06-4 PROSPECTIVE VALIDATION OF AN AUTOMATED HYBRID MULTI-DIMENSIONAL MR IMAGING TOOL FOR PROSTATE CANCER DETECTION USING TARGETED BIOPSY: COMPARISON WITH PIRADS- BASED ASSESSMENT

**PURPOSE**

The purpose of this study was to evaluate the use of an automated Hybrid Multidimensional MRI (HM-MRI) based tool to prospectively identify targets before MR-US fusion biopsy in comparison with PIRADS based evaluation by expert radiologists for prostate cancer (PCa) diagnosis.

**METHODS AND MATERIALS**

In this prospective clinical trial, 91 patients with known or suspected PCa underwent 3T MRI with a conventional mpMRI protocol and HM-MRI and subsequent biopsy. Using the HM-MRI tool, tissue composition was calculated using a three-compartment model and suspected PCa regions with elevated epithelium (>40%) and reduced lumen (<20%) meeting the minimum size requirement of 25 mm2 were identified. Up to two additional biopsy targets per patient were automatically selected by the HM-MRI tool, in addition to the biopsy targets selected based on an expert radiologist's mpMRI interpretation (=PI-RADS 3) using Uronav MR-US fusion biopsy device. Additional 12-core TRUS-guided sextant random biopsy cores were also obtained.

**RESULTS**

The diagnostic performance of HM-MRI for diagnosing clinically significant cancers (=Gleason 3+4), was either higher than, or on par with that of mpMRI. On a per-patient basis, HM-MRI had significantly higher accuracy (55% vs 44%, p=0.022) and specificity (36% vs 14%, p=0.002) than mpMRI. On a per-lesion basis, HM-MRI has significantly higher accuracy compared to mpMRI (58% vs 39%, p<0.001) and PPV (31% vs 22%, p=0.003). On a per-sextant basis, HM-MRI showed significantly better performance than mpMRI for all metrics, including primary endpoints, AUC (0.760 vs 0.647, p<0.001) and accuracy (83.9% vs 79.0%, p<0.001).

**CONCLUSION**

This study demonstrates that HM-MRI has the potential to improve MR-US fusion biopsy results by providing more accurate results compared to PIRADS based evaluation by expert radiologists.

**CLINICAL RELEVANCE/APPLICATION**

HM-MRI has the potential to improve MR-US fusion biopsy and prostate cancer (PCa) diagnosis.

## R1-SSGU06-5 MAGNETIC RESONANCE ELASTOGRAPHY COMBINED WITH PI-RADS V2.1 IMPROVES THE IDENTIFICATION OF CLINICALLY SIGNIFICANT PROSTATE CANCER

Jun Chen, PhD (*Abstract Co-Author*) Nothing to Disclose
Meng Yin, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuntian Chen (*Abstract Co-Author*) Nothing to Disclose
Bin Song, MD (*Abstract Co-Author*) Nothing to Disclose
Jin Yao (*Abstract Co-Author*) Nothing to Disclose
JIE CHEN (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the diagnostic value of tissue stiffness for clinically significant prostate cancer (CSPCa) and to determine the added value of incorporating stiffness into the PI-RADS v2.1 for CSPCa detection.

**METHODS AND MATERIALS**

Patients screened for CSPCa were prospectively included for magnetic resonance elastography and contrast-enhanced MR examination (Clinical trial registration: ChiCTR2300076464). PI-RADS V2.1 score was assessed. Shear stiffness at 60Hz (SS@60Hz) and 90Hz (SS@90Hz) were measured and compared between groups. Area under the receiver operating characteristic curve (AUC) analysis was used to assess diagnostic performance of each variable in detecting CSPCa. AUCs were compared by using the DeLong test.

**RESULTS**

Final cohort included 147 participants (mean age, 67 years±9), including 71 with CSPCa (68 years±9) and 76 without CSPCa (65 years±10). In the peripheral zone, CSPCa had higher stiffness than indolent PCa and chronic prostatitis. No significant difference in stiffness was found between CSPCa and prostate hyperplasia in the transitional zone. For detecting CSPCa in the peripheral zone, sensitivity, specificity, and AUC were 100% (35/35), 58% (30/52), and 0.79 with PI-RADS v2.1, 97% (34/35), 52% (27/52), and 0.80 with SS@60Hz, and 63% (22/35), 87% (45/52), and 0.78 with SS@90Hz. While maintaining high sensitivity, the modified PI-RADS score by incorporating SS@60Hz into PI-RADS v2.1 produced an increased ACU of 0.86, surpassing PI-RADS v2.1 (p=0.02), with a sensitivity of 97% (34/35) and specificity of 75% (39/52).

**CONCLUSION**

The MRE-derived stiffness showed diagnostic performance comparable to the Prostate Imaging Reporting and Data System version 2.1 (PI-RADS v2.1) for clinically significant prostate cancer (CSPCa) in the peripheral zone. Integrating stiffness into the PI-RADS v2.1 improved the diagnostic accuracy and specificity for CSPCa in the peripheral zone.

**CLINICAL RELEVANCE/APPLICATION**

Including lesion stiffness in the Prostate Imaging Reporting and Data System version 2.1 improved the diagnostic accuracy and specificity for clinically significant prostate cancer in the peripheral zone, thus reducing the use of unnecessary biopsy.

## R1-SSGU06-6 THE EFFICACY OF SYNTHETIC DWI IN MULTIPARAMETRIC MRI FOR PROSTATE CANCER DETECTION

Takuma Maruhisa (*Abstract Co-Author*) Nothing to Disclose
Atsushi Higaki, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

For prostate evaluation in multiparametric MRI (mpMRI), image contrast between benign and malignant tissues using conventional high-b-value single-shot echo-planar diffusion-weighted imaging (DWI) is often insufficient. Inadequate diagnostic accuracy in mpMRI leads to unnecessary biopsies. This study evaluated whether synthetic DWI (syDWI), designed to improve diffusion contrast by adjusting TR and TE in response to the shorter T1 and T2 values of prostate cancer compared to benign prostatic tissue, can enhance the diagnostic performance for clinically significant prostate cancer (csPC) over native acquired conventional DWI (nDWI).

## METHODS AND MATERIALS

This study analyzed 52 patients with csPC who underwent mpMRI using a 3.0T scanner followed by radical prostatectomy. nDWI with a b-value of 2000 s/mm2 (b2000) was obtained with a TR of 6000 ms and TE of 70 ms, followed by the b2000 syDWI was created using dedicated software with a TR of 1000 ms to enhance T1 shine-through and a TE of 0 ms to eliminate T2 shine-through (Figures 1 and 2). syDWI acquisition includes b0 images acquired with two different TR and TE to calculate T1 and T2 values, and b2000 acquired with single TR and TE (Figures 2 and 3). Three radiologists independently assessed each prostate in 12 regions, six peripheral zone (PZ) and six transition zone (TZ) using PI-RADS v2.1 assessment category, where a category =3 indicated positive csPC detection. After evaluating nDWI, syDWI was evaluated 3 weeks later. The index lesion in each patient was also evaluated quantitatively for the tumor contrast ratio.

## RESULTS

In a PI-RADS v2.1-based assessment using radical prostatectomy specimens as a pathological reference standard, syDWI showed a significantly higher diagnostic performance than nDWI for csPC across various prostate zones (Figure 4, 5). For combined the PZ and the TZ evaluations, AUC in syDWI was significantly higher than that in nDWI for all three readers ($P<0.001$ to $P=0.019$). In the PZ assessments, syDWI also provided significantly higher AUC for two readers ($P=0.001$ and $P=0.002$). TZ evaluation confirmed significantly higher AUC on syDWI for all three readers ($P<0.001$ to $P=0.015$). In addition, syDWI tended to have higher sensitivity and specificity in PZ and higher sensitivity in TZ compared to nDWI. The tumor contrast ratio for syDWI was significantly higher than that for nDWI ($0.67\pm0.12$ vs $0.37\pm0.12$, $P < 0.001$).

## CONCLUSION

Compared with nDWI, syDWI demonstrated a higher diagnostic performance for csPC. Utilizing syDWI could be advantageous in avoiding unnecessary biopsies because of its higher diagnostic accuracy for csPC.

## CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of syDWI to improve the accuracy of prostate cancer diagnosis and reduce unnecessary biopsies.

## R1-SSNMMI07-1 FIRST CLINICAL RESULTS WITH Z-SCANNER, A NOVEL ROBOTIC, HIGH-RESOLUTION SPECT SCANNER

Roxanna Juarez, MD, BA (*Abstract Co-Author*) Nothing to Disclose
Leena Awni (*Abstract Co-Author*) Nothing to Disclose
Andrei Claudiu Cosma (*Abstract Co-Author*) Nothing to Disclose
Kyle Champley (*Abstract Co-Author*) Nothing to Disclose
Paul Barton, PhD (*Abstract Co-Author*) Nothing to Disclose
Lucian Mihailescu (*Abstract Co-Author*) Nothing to Disclose
Youngho Seo, PhD (*Presenter*) Consultant, Biolaurus, Inc;Consultant, BioClinica, Inc;Stockholder, Fortis Therapeutics

### PURPOSE

Leveraging CZT detectors and coded aperture imaging, Z-Scanner is a novel, portable, and robotic SPECT system designed to provide both higher resolution and higher sensitivity per detector area compared to existing gantry-based SPECT systems. A SPECT system able to provide higher imaging performance can have a significant clinical impact for multiple indications. Our main purpose for the study was to demonstrate the clinical feasibility and the technical capability of Z-Scanner in several clinical indications.

### METHODS AND MATERIALS

Twelve patients scheduled to receive a standard-of-care SPECT scan as part of their clinical workups have been recruited in this observational study. Following their regular clinical SPECT scan, the patients were scanned using the Z-Scanner SPECT system in a similar amount of scanning time. Image qualities of images from the clinical standard system and the Z-Scanner system were compared. The scans were focused on constrained anatomical areas because the sensor panel of the current Z-Scanner prototype has a relatively small field-of-view, approximately 22 cm x 12 cm.

### RESULTS

Whereas earlier patient scans were performed to mainly support Z-Scanner development efforts, imaging results were obtained from several different scan types, including lymphoscintigraphy with 99mTc-tilmanocept, thyroid/parathyroid scans with 99mTc-sestamibi, DaTScan with 123I-ioflupane, and regional bone scan with 99mTc-MDP. Compared to the standard of care SPECT, Z-Scanner images indicated superior definition of radiotracer uptake distribution, with increased contrast, higher resolution, and lower noise. Laboratory measurements also indicate that Z-Scanner provides 1-2 mm FWHM resolution, depending on the optics used, and approximately 10 times better contrast to noise ratio for lesions as small as 7.9 mm in diameter in a phantom with spherical lesions with warm background (8:1 lesion-to-background ratio) when compared to standard-of-care SPECT.

### CONCLUSION

Clinical feasibility was demonstrated for the portable, robotic Z-Scanner SPECT system. Clinical images indicate superior representation of radiotracer uptake distribution for regional scans of patients of several indications.

### CLINICAL RELEVANCE/APPLICATION

Whereas the current Z-Scanner prototype has a small single panel with a relatively small field-of-view, the next version of Z-Scanner will have four times the field-of-view and six times the sensitivity. That version is expected to provide fast, high image quality scans of expanded scan coverage. Combined with its portable and open configuration, Z-Scanner may bring a significant change in how molecular imaging will be used throughout the clinical practice.

## R1-SSNMMI07-3 CLINICAL UTILITY OF AI DENOISING FOR COUNT-POOR AMYLOID BRAIN PET/CT STUDIES

Karin Knesaurek, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of our study is to enhance the clinical utility of count-poor amyloid brain PET/CT studies using AI denoising.

### METHODS AND MATERIALS

A time-of-flight (TOF) PET/CT system, specifically the Biograph128_Vision 600 Edge (Siemens Medical Systems, Erlangen, Germany), was utilized for the acquisition of amyloid brain PET/CT studies in list mode. This mode permitted the creation of shorter reconstructed studies in addition to the standard 10-minute study. Images were reconstructed using the iterative 3D Poisson-OSEM algorithm with 8 iterations, 5 subsets (8i5s), an all-pass filter, and corrections for point spread function and TOF. Low-dose CT at 80 kV and exposure 120 mAs was utilized for PET attenuation correction. The

reconstruction matrix size was 440 x 440 mm, resulting in a pixel size of 1.65 x 1.65 mm and a slice thickness of 3.0 mm. The gold standard 10-minute study was visually and quantitatively compared with a 2-minute study processed with FDA-cleared AI denoising software, SubtlePET (Subtle Medical, Menlo Park, CA). Cortical-to-cerebellum SUVr was calculated using six target cortical regions (anterior cingulate gyrus, inferior medial frontal gyrus, lateral temporal lobe, posterior cingulate gyrus, precuneus areas, and superior parietal lobule) along with the cerebellum, employing the MIM Neuro application (MIM Software Inc., Cleveland, OH, Version 7.1).

**RESULTS**

In Figure 1, the visual similarity between the 10-minute and 2-minute corrected scans is notable. The figure displays 2-minute, 10-minute, and 2-minute corrected amyloid PET scans. SUVr values for the anterior cingulate gyrus, inferior medial frontal gyrus, lateral temporal lobe, posterior cingulate gyrus, precuneus areas, and superior parietal lobule were 1.17, 1.20, 1.37, 0.93, 1.26, and 0.95, respectively, for both the 10-minute scan and the 2-minute corrected scan. The average SUVr from all six cortical ROIs in both cases was 1.15, indicating a pathological, amyloid-positive case. Figure 2 presents the Z-score analysis for the 2-minute corrected and 10-minute scans, showing almost identical results.

**CONCLUSION**

The results suggest that 2-minute corrected PET amyloid scans are virtually indistinguishable, both visually and quantitatively, from standard 10-minute PET amyloid scans.

**CLINICAL RELEVANCE/APPLICATION**

Our findings demonstrate that count-poor and noisy amyloid brain PET/CT studies can be rendered clinically useful through AI denoising.

## R1-SSNMMI07-4 COLLAGEN-TARGETED PET/CT IMAGING OF TUBERCULOSIS PATIENTS

Alvaro Ordonez, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

After completing treatment for tuberculosis (TB), millions of TB survivors each year suffer from chronic lung damage. Post-TB lung disease (PTLD) is a multifactorial process that leads to tissue remodeling of the extracellular matrix components, which include fibrillar collagen. 68Ga-CBP8 is a peptide-based type I collagen-targeted probe developed for imaging of tissue fibrosis (Desogere et al. 2017). We hypothesized that PET imaging of pulmonary fibrosis in TB patients would provide valuable data on pathogenesis and serve as an early-disease biomarker for PTLD. Newly identified patients with pulmonary TB were enrolled for the first evaluation of collagen-specific PET imaging in TB patients.

**METHODS AND MATERIALS**

We prospectively enrolled patients with recently confirmed active pulmonary TB with a moderate to severe lung burden as determined by X-ray. Patients were injected IV with 68Ga-CBP8 followed by a PET/CT. Images were analyzed using MIM, and volumes of interest (VOIs) were drawn using the CT as reference. The % affected lung volume was determined by histogram analysis of segmented PET VOIs and included values with an SUVmean >1. Pulmonary function tests and evaluation of blood and sputum inflammatory markers were also performed.

**RESULTS**

Nineteen patients (age 19-58, 6 females) were imaged. The mean administered activity of 68Ga-CBP8 was 120.5 ± 33.2 MBq. There were no adverse effects in any of the subjects. 68Ga-CBP8 demonstrated predominantly renal clearance. CT demonstrated heterogeneity of pulmonary TB, including multiple different lesions (e.g., nodular opacities and cavities). Whole lung and lesion VOIs [122 pulmonary lesions (28 cavitary) and 19 control regions] were analyzed. 68Ga-CBP8 localized in the areas of tissue remodeling (based on tissue density and CT characteristics). The mean % affected lung (based on PET values with SUVmean > 1) was 4.9 ± 3.4 % (range, 0.3 - 13.8 %). The % affected lung volume based on 68Ga-CBP8 PET correlated with decreased lung capacity measured by spirometry (P=0.02). Increased tracer signal was also observed in regions where fibrosis was not apparent by CT, suggesting that 68Ga-CBP8 PET may detect active collagen deposition that is not yet visible by anatomical imaging.

**CONCLUSION**

We present data from a prospective study evaluating collagen-specific PET to characterize fibrotic changes in TB patients. 68Ga-CBP8 PET signal localized to areas of cavitation and consolidation observed in CT. Quantification of 68Ga-CBP8 PET correlated with decreased lung capacity as measured by spirometry.

**CLINICAL RELEVANCE/APPLICATION**

PET imaging of fibrosis represents a clinically translatable tool to noninvasively evaluate early fibrotic changes that could lead to optimization of the diagnosis and management of PTLD.

**PURPOSE**

Uncertainty exists as to whether the subcellular location of targeted alpha therapy (TAT) affects its cytotoxicity. Using a model system that provides a subcellular “zip code” for TAT, we examined the hypothesis that alpha emitters localized closer to the DNA cause higher cytotoxicity.

**METHODS AND MATERIALS**

Human pleural mesothelioma (I45) and ovarian adenocarcinoma (SKOV3) cell lines were engineered to express a fusion Escherichia coli dihydrofolate reductase-yellow fluorescent protein (eDHFR-YFP) localized to the DNA, nucleus, cytoplasm, and plasma membrane. Subcellular TAT was achieved by targeting eDHFR with [211At]At-TMP, the small molecule trimethoprim (TMP) radiolabeled with alpha-emitting astatine-211. This model system was characterized using confocal microscopy, flow cytometry, and radioligand binding assays. In vitro cytotoxicity of subcellular [211At]At-TMP therapy was measured, followed by Monte Carlo microdosimetry. In vivo biodistribution of [211At]At-TMP was measured.

## RESULTS

Live-cell confocal microscopy confirmed the proper subcellular localization of eDHFR-YFP in the nucleus (+/- DNA binding), cytoplasm, and plasma membrane. eDHFR and DNA fluorescence showed co-localization for DNA-bound eDHFR ($p<0.001$) and inverse localization for nuclear eDHFR ($p=0.005$). eDHFR-YFP fluorescence was strongly correlated with the binding assay Bmax ($R2=0.97$). The Kd of [211At]At-TMP was 4.8 ± 0.1 nM. eDHFR-expressing cells showed significantly higher cytotoxicity from [211At]At-TMP compared to the wild-type cells ($p<0.0001$), but not from free 211At treatment. The highest cytotoxicity was seen when [211At]At-TMP was targeted to the DNA, followed by the nucleus. Targeting the plasma membrane caused similar to higher cytotoxicity compared to cytoplasmic targeting. Based on microdosimetry, the relative biological effectiveness (RBE) of 3 was obtained for the recoil nuclei compared to alpha particles and the RBE of 0.1 was obtained for dose deposition in the plasma membrane vs. nucleus. The cytotoxic advantage of DNA-bound and nuclear [211At]At-TMP was maximized in individual tumor cells and tumor cell clusters below 100 µm. Biodistribution showed 84% higher radiation dose in eDHFR-positive vs. wild-type tumors ($p<0.001$). The effect of subcellular TAT is being examined in vivo. *Only I45 results are reported here; SKOV3 yielded similar results.

## CONCLUSION

An alpha emitter's subcellular localization to the DNA or nucleus leads to higher cytotoxicity, and the plasma membrane may also represent a sensitive radiobiological target.

## CLINICAL RELEVANCE/APPLICATION

Our results help understand TAT radiobiology to guide future drug development, and our model system has potential for application in broader TAT research.

## R1-SSNMMI07-6 EXPLORING 3D SPECT FOR LUNG SHUNT FRACTION ESTIMATION IN Y-90 RADIOEMBOLIZATION COMPARED TO 2D PLANAR IMAGING

James R. Halama, PhD (*Abstract Co-Author*) Nothing to Disclose
Jian-Feng Chen, PhD (*Abstract Co-Author*) Nothing to Disclose
Robert H. Wagner, MD (*Abstract Co-Author*) Nothing to Disclose

Christopher A. Molvar, MD (*Abstract Co-Author*) Nothing to Disclose
Paula Patricia Gamero Kubota, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Transarterial radioembolization with Yttrium-90 (Y-90) microspheres is an effective treatment for HCC. It is essential to calculate the lung shunt fraction (LSF) to ensure its safety and efficacy. Current LSF calculations employ 2D planar imaging, which may lead to overestimations. Literature suggests that 3D SPECT offers a more accurate LSF. The aim is to compare the LSF calculated using 2D and 3D SPECT images to determine whether using 3D images would yield a more accurate LSF.

## METHODS AND MATERIALS

A retrospective analysis was conducted on LSF and cumulative doses for 56 patients and 86 tumors with HCC, who underwent 99mTc-MAA mapping before the Y-90 treatment. 2D planar and 3D SPECT images of these patients were reviewed. Tomo-SPECT with CT pre-Y90 images was reconstructed using the OESM technique within Q-Volumetrix software to obtain 3D images, allowing visualization of 99mTc-MAA activity in the organs. The software was utilized for the segmentation of the liver and the lungs, providing an automated LSF calculation from 3D SPECT. Calculated Y-90 liver dose and lung dose to be delivered using 2D Planar LSF were compared using the newly obtained 3D SPECT LSF values. The mean LSF between the different calculation methods was compared with paired t-tests and Pearson's correlations. Y-90 doses using 2D Planar LSF and the newly obtained 3D SPECT LSF values were also compared using the same statistical tools.

## RESULTS

The mean LSF in the 2D images was 5.13%, contrasting with 2.12% in 3D SPECT ($p < 0.05$). In 43 out of 56 patients, there was more than 40% increase in the LSF obtained on 2D vs. 3D. Of those, $n=36$, the increase was more than 50%. This could be due to planar imaging may overestimate LSF by providing a global assessment, whereas SPECT offers 3D visualization and calculation of the tracer distribution. The average Y-90 liver dose was found to be 201.42Gy with 2D, while 3D SPECT was 207.70Gy, with a strong Pearson correlation of 0.99. The lung dose showed lower mean values with the 3D, 1.47Gy, compared to the 2D, 3.7Gy ($p < 0.05$), with a Pearson correlation that showed a strong correlation of 0.87. The LSF results with the 3D approach show that a higher liver dose could be administered while delivering lower doses to the lungs.

## CONCLUSION

The abstract highlights the discrepancy in LSF calculation between using a 2D planar or 3D SPECT assessment, and the resulting variance in the dosage delivered. Acknowledging these differences and their significance for patients is essential.

## CLINICAL RELEVANCE/APPLICATION

The significant differences in LSF results between planar and SPECT imaging have potential implications for Y-90 therapy. 3D SPECT could help avoid unnecessary dose reductions, leading to more precise dosage determination and potentially improved treatment outcomes.

## R1-SSRO04-1 SINGLE-STEP AUTOMATED SEGMENTATION AND SYNTHETIC CT GENERATION FOR ADAPTIVE PROTON THERAPY

Susu Yan, PHD (*Abstract Co-Author*) Nothing to Disclose
Derek Tang, BS, BA (*Presenter*) Nothing to Disclose

### PURPOSE

To develop and evaluate a single-step deep learning method for simultaneous segmentation and synthetic CT (sCT) generation for adaptive proton radiotherapy using cone-beam CT (CBCT) acquisitions.

### METHODS AND MATERIALS

In this study, a cycle-consistent generative adversarial network (CycleGAN) is used for simultaneous segmentation and sCT generation. CT and CBCT acquisitions from 150 patients with prostate cancer were used to train and validate the model. Transverse CT slices are paired with physician contours of the prostate, bladder, and rectum to form the input images for the CT-to-CBCT generator. Hounsfield unit data and segmentations are stored in individual image channels. A modified cycle-consistent loss is introduced to account for the cross-entropy loss between a physician contour and the segmentation result from a full generative cycle of the model. The mean absolute error (MAE), root-mean-squared error (RMSE), and Dice scores are used to determine sCT and segmentation quality of the model output relative to a deformably registered ground truth. Results of this single-step method are compared to a sequential approach using a traditional CycleGAN model for sCT generation and TotalSegmentor for segmentation of resulting sCT images.

### RESULTS

The proposed single-shot CycleGAN method demonstrated the best performance for automated segmentation and sCT generation. The MAE, RMSE, and Dice scores of generated outputs from this model, relative to the ground truth, are 50.67± 6.82 HU, 92.20 ± 0.45 HU, and 0.85 ± 0.03 respectively. The MAE, RMSE, and Dice of the sequential CycleGAN and TotalSegmentor method are 52.26 ± 7.42 HU, 100.78 ± 0.48 HU, and 0.62 ± 0.11.

### CONCLUSION

The CycleGAN network successfully implemented simultaneous segmentation and unsupervised image translation, outperforming a sequential workflow. This single-shot method drops the runtime of sCT generation and segmentation, providing improved patient care by reducing the duration a patient is on the treatment table. Furthermore, slight decreases in the MAE minimize uncertainties in range during adaptive proton treatments. The DIRs used to establish the ground truth are limited in accurately conforming a CT scan and contours to its corresponding CBCT geometry, especially with the bladder and rectum. This suggests that the Dice scores reported are deflated and highlights the benefits of an adaptive workflow for improved organ-at-risk monitoring. Ongoing work focuses on improving proton treatment planning outcomes using this model.

### CLINICAL RELEVANCE/APPLICATION

This work accelerates the adaptive proton therapy workflow to improve the patient treatment experience while minimizing setup errors and range uncertainties due to changes in patient position and internal anatomies.

**PURPOSE**

Multiparametric MRI (mpMRI) has significantly improved detection of clinically significant Prostate cancer (csPCa), but a lack of expert sub-specialist radiologists leads to widespread variation in the performance of Prostate Imaging Reporting Data System [PI-RADS] v2.1. A reliable, reproducible quantitative imaging biomarker with objective interpretation could mitigate variation in subjective mpMRI interpretation, leading to more equitable patient care. Restriction Spectrum Imaging restriction score (RSIrs) is an MRI biomarker previously shown to improve quantitative interpretation of prostate MRI. Patient-level factors (age, race, ethnicity, and 5-alpha-reductase inhibitors [5-ARIs]) might affect interpretation of MRI. Their impact on quantitative RSIrs is unknown.

**METHODS AND MATERIALS**

RSI data was gathered at 4 institutions. Inclusion criteria for this retrospective analysis were: prostate MRI performed for suspicion of csPCa, no hip implant, and no csPCa detected (i.e., PI-RADS v2.1 score of 1 or 2 with prostate specific antigen density < 0.15 or any PI-RADS score followed by biopsy negative for csPCa within 6 months of mpMRI). RSI data was corrected to account for noise, B0-inhomogeneities, gradient nonlinearities, and eddy currents. Maximum RSIrs (RSIrsmax) was calculated using the maximum restricted signal intensity divided by the median b=0 diffusion signal within the prostate. Linear mixed effects modeling was used to estimate effects of patient-level factors on RSIrsmax.

**RESULTS**

427 patients met the inclusion criteria. Median (IQR) age was 69 (63,74). Self-reported race was 313 White, 36 Asian, 13 Black, 65 Other; 50 also self-reported Hispanic ethnicity. 66 patients were on 5-ARIs at the time of mpMRI. Median (IQR) RSIrsmax was 169 (136, 205), consistent with a low probability of csPCa. None of the patient-level factors was associated with a significant difference in RSIrsmax.

**CONCLUSION**

RSIrs is a promising biomarker and is not noticeably affected by age or 5-ARIs in patients without csPCa, suggesting reliability across a broad population. There was no indication of effects by race or ethnicity, either, but more data are needed to confirm.

**CLINICAL RELEVANCE/APPLICATION**

An imaging score, RSIrsmax, that has been previously shown to make prostate cancer more consistently detectable on prostate MRI, appears unaffected by patient age, race, ethnicity, or use of common medications for urinary symptoms (5-ARIs) and therefore may be useful for a wide range of patients.

## R1-SSRO04-4 MULTIMODAL ARTIFICIAL INTELLIGENCE FOR PROSTATE CANCER TREATMENT OUTCOME PREDICTION: A PILOT STUDY

Benjamin Simon, BS, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

Prostate cancer (PCa) is the second most common cause of mortality among biological males in the US. Risk stratification techniques such as the D'Amico risk categories and NCCN risk groups have suboptimal performance. Presently, there are no high-quality, artificial intelligence (AI)-based computer vision (CV) models to risk stratify patients with PCa based on T2W MRI. Here, we report the development of a multimodal, deep-learning pipeline using CV enhanced with clinical covariates to predict the probability of biochemical recurrence (BCR) for patients with PCa undergoing definitive radiotherapy (RT) ± androgen deprivation therapy (ADT).

**METHODS AND MATERIALS**

A single-center cohort (n=176 [RT:17% / RT+ADT:83%]) was used to develop a pilot model prior to an ongoing multicenter study (n□1000). Three models were developed: a unimodal CV model (M1), a unimodal random forest (RF) model (M2), and a multimodal RF model (M3). Using an open-source, pre-trained segmentation algorithm, we used transfer learning to create a T2W MRI-based risk prediction score by augmenting a pre-trained, 34-layer ResNet with additional layers. For M1, a train (n=100)/validation (n=28)/test (n=48) split was used. Subsequently, RF models (M2-3) were developed using equivalent data partitioning, utilizing 128 cases for training/cross-validation and the same test set (n=48) as in M1 development. Clinical variables included pre-RT PSA, Gleason score, primary Gleason pattern, and seminal vesicle invasion (SVI) confirmed with biopsy. Evaluated performance metrics included accuracy, sensitivity, specificity, and area under the receiver operating curve (AUROC), reported with corresponding bootstrapped intervals (n=5000); M2 and M3 were compared via a paired z-test on each bootstrapped sample for each metric.

**RESULTS**

At a median follow-up of 6.3 years, 22 BCR events were observed. M3 had the highest test set performance (90% accuracy, 86% sensitivity, 90% specificity, and AUROC of .92) with no significant difference over M2 (all p>0.05).

**CONCLUSION**

We present the first multimodal computer vision-based model for predicting BCR after RT±ADT and demonstrate its potential for superior performance over unimodal models. Planned expansion in a future multi-center study will augment the training set and provide external validation. With this novel approach, we demonstrate that this model combining computer vision and clinical co-variates may improve model performance over purely clinical or radiologic models alone.

**CLINICAL RELEVANCE/APPLICATION**

Leveraging AI to predict BCR from MRI has the potential to improve PCa risk stratification over clinical variables alone. After further external validation, future models based on this pilot work may inform treatment selection.

## R1-SSRO04-5 RELATIONSHIP BETWEEN RADIATION-RELATED BONE SIDE EFFECTS IN FEMALES TREATED FOR GYNECOLOGICAL CANCERS AND THEIR PRETREATMENT BONE DENSITIES OF L1 VERTEBRAL BODY AND THE TOTAL RECEIVED RADIATION DOSE

Hana Malikova, PhD, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of our study was to evaluate the rate of radiation-related bone side effects in females treated for gynecological cancer as cervical and endometrial cancer and to study the relationship between radiation-related bone side effects and patient´s age, pretreatment bone densities of the L1 vertebral body and the total received radiation dose.

**METHODS AND MATERIALS**

We retrospectively studied all imaging scans (CT and MRI) in patients that were treated by radical radiotherapy (RT) for cervical cancer and patients with endometrial carcer who were treated by radical surgery followed by RT. On available imaging scans we searched for radiation-related bone side effects as insufficiency fractures or osteonecrosis. Bone density was measured on pretreatment CT in the center of the L1 vertebral body with a region of interest of 4 cm2. The total received radiation dose was calculated as the sum of external beam RT, brachy-RT and lymph nodes RT doses. Data were compared by pair t-test.

**RESULTS**

We included 127 females, 63 treated for cervical and 64 treated for endometrial cancer. The rate of radiation-related bone side effects mostly fractures was similar in both groups; 28.6 % versus 26.6% of subjects. Both groups significantly differed in age, in the values of pretreatment densities at L1 and in the total received RT dose. Females with cervical cancer were significantly younger than females with endometrial cancer; 52.8 ± 13.1 versus 66.0 ± 9.9 years ($p < 0.001$); their mean bone densities were higher 150.5 ± 54.5 versus 125.8 ± 41.2 HU $p = 0.005$); they received higher total RT dose 80.1 ± 14.1 versus 62.1 ± 13.9 Gy ($p < 0.001$). When we compared only subjects with radiation-related fractures, we found that subjects treated for cervical cancer with fractures were still significantly younger than subjects treated for endometrial cancer that suffered from bone side effects, mean 62.4 ± 10.1 versus 70.0 ± 7.3 years ($p = 0.018$), and they received higher total RT dose, 77.9 ± 5.8 versus 62.2 ± 11.4 Gy ($p < 0.001$). However, bone densities were comparably low in both subgroups, 106.3 ± 40.0 versus 103.8 ± 29.0 HU ($p = 0.829$).

**CONCLUSION**

Despite of age and total received RT dose differences between groups of females treated for cervical and endometrial cancers, we found similarly high rate of radiation-related fractures in both groups, 28.6 % versus 26.6%, respectively. Radiation-related bone side effects were strongly associated with low pretreatment bone densities at L1 that reflected osteoporosis.

**CLINICAL RELEVANCE/APPLICATION**

L1 bone densities measurement is easy without additional cost and could help to search for patients in risk; in those patients preventive treatment could be considered.

## R1-SSRO04-6 DOES SEQUENCING MATTER? GENITOURINARY (GU) TOXICITY RISK FOR COMBINATION HIGH DOSE-RATE (HDR) BRACHYTHERAPY PLUS INTENSITY MODULATED RADIOTHERAPY (IMRT) FOR PROSTATE CANCER (PC)

Thandiwe Gray, MD (*Abstract Co-Author*) Nothing to Disclose
Patricia Watkins (*Abstract Co-Author*) Nothing to Disclose
Keaton A. Rummel, BS (*Abstract Co-Author*) Nothing to Disclose
John M. Watkins, MD (*Abstract Co-Author*) Nothing to Disclose

Jackson S. Wilson, BS (*Abstract Co-Author*) Nothing to Disclose
Annika O. Price, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Determine whether clinically significant acute and late GU toxicity risks differ for IMRT followed by HDR (IMRT->HDR) versus HDR followed by IMRT (HDR->IMRT) for PC.

**METHODS AND MATERIALS**

Intradepartmental quality assurance database was utilized to identify patients with non-metastatic PC treated with combination single-fraction HDR brachytherapy (15 Gy) plus IMRT (37.5-45 Gy in 15-25 fractions) with minimum 90 day post-HDR follow-up, and charts were reviewed for GU toxicities. Acute toxicities occurred within 90 days of treatment completion, while late were those persisting/developing >90 days. Clinically significant toxicities (G3+) were defined as refractory to initial medication therapy or emergency/inpatient management or procedure. Regression analyses were performed on clinical (e.g., age, GU symptom score, pre-/post-HDR medication) and treatment (HDR/IMRT sequence/interval, dosimetry) factors for association with G3+ GU toxicities.

**RESULTS**

From 2019 to 2023, 76 HDR/IMRT patients were identified for inclusion. Nineteen (25%) underwent IMRT->HDR and 57 (75%) HDR->IMRT. Median age was 69 years (range, 50-84), median PSA 8.0 ng/mL (4.3-144.1), and 62 (82%) received hormone therapy (HT; median 6 months). Median prostate volume was 35cc (17-82). Median intervals between HDR and IMRT was 13 days (1-50). Treatment groups were balanced by clinical and treatment factors. Sixteen patients experienced G3+ acute GU toxicity (n=3 (16%) IMRT->HDR, 13 (23%) HDR->IMRT), including 7 requiring catheter. At a median follow-up of 32mo (4-58), 13 patients experienced G3+ late GU toxicity; 4 patients (21%) IMRT->HDR and 9 (16%) HDR->IMRT. Toxicities were medication-refractory dysuria or urgency/frequency (8), catheter (2), stricture (1), or other (2). No statistically significant difference was detected for treatment sequence and either G3+ acute (p=0.516) or late (p=0.587) GU toxicity risks. Only pre-HDR NSAID (p=0.034) and post-HDR urinary modifier medication (p=0.027) were significantly correlated with reduced risk of acute GU toxicity, while higher volume receiving 200% of prescribed HDR dose (V200) was associated with increased risk of late toxicity (p=0.028).

**CONCLUSION**

HDR/IMRT sequence does not appear to impact G3+ acute or late GU toxicity risks. Further investigation of medication intervention and dosimetric factor associations with GU toxicity risks are warranted.

**CLINICAL RELEVANCE/APPLICATION**

HDR brachytherapy and IMRT is a safe and effective option for localized PC. The present study demonstrates that clinicians can select either sequence of HDR or IMRT first without detectable differences in G3+ GU toxicity risk.

## R1-SSVA04-1 HIGH-RESOLUTION SPINAL CORD MR ANGIOGRAPHY (HRSPC-MRA)FOR DETECTING ARTERIAL SUPPLY AND FISTULAE IN SPINAL DURAL ARTERIOVENOUS FISTULAE(SDAVF)

Kai Ai (*Abstract Co-Author*) Nothing to Disclose
Jing Zhang (*Abstract Co-Author*) Nothing to Disclose
Wanjun Hu (*Presenter*) Nothing to Disclose

### PURPOSE

Non-invasive arterial supply and fistula location detection in SDAVF is a tremendous clinical challenge. This study aimed to improve the diagnostic efficacy of SDAVF disease by detecting the arterial supply location and fistula in SDAVF with HRSPC-MRA and comparing it with digital silhouette angiography (DSA).

### METHODS AND MATERIALS

A total of 21 patients with clinically suspected and confirmed dural arteriovenous fistulae were enrolled in this prospective study. All patients underwent HRSPC-MRA preoperatively, with the following imaging parameters: FOV: 380×380, matrix: 480×480, and voxel: 0.8 mm×0.8 mm×0.8 mm, and then double-dose Magnevist and saline were injected using a high-pressure syringe at a flow rate of 4 ml/s. Finally, maximum-density projection images were used to identify and confirm the dural arteriovenous fistulae. A double dose of Magnevist and saline was injected using a high-pressure syringe at a flow rate of 4 ml/s while spinal cord dynamic angiography and HRSPC-MRA were acquired. Finally, maximum density projection images were used to identify and confirm the arteries supplying blood to the dural arteriovenous fistula and the fistula location and number, and the results were compared with the intraoperative DSA imaging results. The agreement between the two imaging techniques was also assessed using Bland-Altman analysis with t-test and Mann-Whitney test for measurement data and Chi2 for dichotomous/categorical variables.

### RESULTS

Demographic data (age, gender, tumor location) of all patients were not statistically significant, the number of fistulas was obtained based on HRSPC-MRA detection (n=25) and DSA imaging (n=28), the two imaging methods were not statistically significant in detecting the number of fistulas (p=0.256), whereas the location of the supplying arteries was obtained by HRSPC-MRA detection and the number of fistulas were comparable to DSA imaging, with high agreement in Bland-Altman analysis.

### CONCLUSION

HRSPC-MRA is comparable to DSA in detecting the location of blood-supplying arteries and the number of fistulas in SDAVF and can detect and confirm the location of blood-supplying arteries and fistulas in SDAVF noninvasively before surgery, which provides an essential value for the clinical treatment of SDAVF.

### CLINICAL RELEVANCE/APPLICATION

HRSPC-MRA can not only detect SDAVF blood-supplying arteries and the number and location of fistulas non-invasively before surgery, but also improve the ability to treat SDAVF, reduce the cost of patients, shorten the treatment time of clinical patients, and reduce the radiation dose to patients and clinicians.

## R1-SSVA04-2 DOES CT ANGIOGRAPHY FOR THE ARTERY OF ADAMKIEWICZ TRULY PROVIDE VALUE-ADDED INFORMATION OVER STANDARD CT ANGIOGRAPHY?

**PURPOSE**

Finding the critical segmental artery supplying the artery of Adamkiewicz (AKA) is crucial to assess the risk of spinal cord ischemia (SCI) before treating the descending aorta. AKA-CTA has high success rates in AKA identification, but its effectiveness in TEVAR scenarios needs to be confirmed. This study aims to determine whether additional information from AKA-CTA, beyond standard CTA, influences TEVAR strategy and which cases would benefit from this additional procedure.

**METHODS AND MATERIALS**

A retrospective analysis was conducted on 176 consecutive cases from January 2021 to February 2024, where both standard CTA and specialized AKA-CTA were performed to evaluate the AKA before treatment. Cases with more than 90 days interval between two CTAs or those using reduced contrast protocols due to renal impairment were excluded. A single specialist assessed the level and laterality of the AKA. The consistency of the results between CTA and AKA-CTA was measured by the accuracy and positive predictive value (PPV) and negative predictive value (NPV) using AKA-CTA as the reference standard. Planning for TEVAR was also evaluated based on CTA, with changes in TEVAR strategy and SCI risk score upon incorporating additional information from AKA-CTA. Predictors of these value-added AKA-CTA cases were assessed in a multivariate analysis.

**RESULTS**

Out of 160 cases (median age 70 [IQR 58-77], 50 females, 101 dissections, 47 aneurysms, and 12 others), CTA identified the AKA in 94 cases (58.8%). In comparison, AKA-CTA did so in 155 cases (96.9%). AKA-CTA resulted in significantly higher radiation exposure (CTDIvol 16.3 [13.9-23.0] vs. 7.3 [5.8-8.9] mGy) and contrast agent dosage (498±61.6 vs. 385±54.0 mgI/kg). CTA had an accuracy of 50% (80/160), PPV of 83% (77/94), and NPV of 5% (3/66) compared to AKA-CTA. AKA at the thoracic level was more consistent than at the lumbar level (P = 0.04). TEVAR planning was conducted in 55 cases out of 80 with inconsistent results for CTA and AKA-CTA. Using CTA, a proximal landing zone =3 was observed in 39 cases (71%), a distal landing zone =5 in 23 cases (47%), and a cover length of 150mm [IQR 131-150]. An SCI risk score of =1 was observed in 35 cases (64%). Based on additional AKA-CTA information, 17 cases (31%) had TEVAR planning or SCI risk score changes. Multivariate analysis showed that only the distal landing zone =5 (OR=18.4, 95%CI 4.3-130) were a significant independent predictor of these changes.

**CONCLUSION**

AKA-CTA provided value-added insights over CTA in TEVAR cases with the distal landing zones=5, influencing treatment decisions.

**CLINICAL RELEVANCE/APPLICATION**

In the current TEVAR era, AKA CTA is only sometimes part of the routine before treating the descending aorta. However, it is a worthwhile addition in cases with the distal landing zone =5.

## R1-SSVA04-3 DEEP LEARNING ENHANCED MR TIME-OF-FLIGHT REDUCES ACQUISITION TIME AND IMPROVES DELINEATION OF SMALL ARTERIES

Suzie C. Bash, MD (*Abstract Co-Author*) Consultant, CorTechs Labs, Inc;Consultant, icoMetrix NV;Consultant, Subtle Medical, Inc;Consultant, Darmiyan, Inc

Lawrence N. Tanenbaum, MD (*Presenter*) Speaker, General Electric Company;Speaker, Siemens AG;Speaker, Guerbet SA;Speaker, Koninklijke Philips NV;Consultant, icoMetrix NV;Consultant, Subtle Medical, Inc;Consultant, Columbo;Consultant, iMedis;Consultant, Agamon;Consultant, FUJIFILM Holdings Corporation

**PURPOSE**

3D Time-of-Flight (TOF) Magnetic Resonance (MR) angiography has demonstrated its diagnostic value in detecting cerebrovascular diseases. Compressed Sensing (CS) and Parallel Imaging (PI) have been used to accelerate 3D TOF scans, but the amplified noise may hinder image quality and limit scan acceleration. In this work, we propose a Deep Learning (DL) enhancement method to improve the quality of accelerated TOF and evaluate its performance for artery delineation in comparison to the standard-of-care (SOC) TOF.

**METHODS AND MATERIALS**

A novel DL network was developed based on ConvNext with local and global skip connections, and trained on a larger training dataset with 2051 low and high quality MR image pairs, covering a wide range of different MR field strengths, contrast weightings and anatomies. For this study, 30 3D TOF brain image sets were acquired for qualitative and quantitative evaluation: 25 TOF sets (Hitachi/Fuji 1.16T) with PI accelerated protocols (scan time from 3:55 to 9:14, acceleration factor from 1.9 to 2.4, TR from 20ms to 34ms), 1 TOF set (Siemens 1.5T) acquired with SOC (with PI x2, 8:26), and 2-fold/5-fold CS accelerated SOC (8:45/4:22), and 4 TOF sets (United Imaging 3T) acquired with paired SOC (with PI, 1:43) and further CS accelerated SOC (1:08). We applied the trained DL model on the accelerated TOF and qualitatively compared quality against the input. On the 5 test sets with a SOC series, we measured the Signal-to-Noise Ratio (SNR) on the TOF slices (within a local uniform white matter region) and Contrast-to-Noise Ratio (CNR) on the axial Maximum Intensity Projection (MIP) images (left and right posterior cerebral arteries in the P4 segment). A paired t-test was performed to test the statistical significance.

**RESULTS**

The qualitative review showed consistent and superior quality of enhanced TOF over the acquired TOF across all 30 test cases. DL processing largely suppressed the noise/artifacts on CS x2 and CS x5 acquired images, while preserving the signal intensities within the lumen. Superior artery contrast and more small peripheral arterial branches can be observed on the MIP reconstruction in enhanced images. Significant improvement in SNR on TOF slices ($a<0.0001$, 167% over SOC on average) and CNR at peripheral arterial branches on MIP images ($a<0.01$, 188% over SOC on average) were demonstrated.

**CONCLUSION**

The proposed DL enhancement method can significantly improve the quality of accelerated 3D TOF enabling faster acquisition and more small arteries becoming visible with improved contrast on the MIP image.

### CLINICAL RELEVANCE/APPLICATION

DL enhancement methods can significantly improve the quality of TOF images allowing shortened clinical scan time and improved delineation of arteries for cerebrovascular disease assessment.

## R1-SSVA04-4 SUB-1-MINUTE RELAXATION-ENHANCED ANGIOGRAPHY WITHOUT CONTRAST AND TRIGGERING OF THE EXTRACRANIAL ARTERIES BY COMBINING COMPRESSED SENSE WITH DEEP LEARNING BASED RECONSTRUCTION: EVALUATION IN HEALTHY VOLUNTEERS

### PURPOSE

To evaluate the acceleration of Relaxation-Enhanced Angiography without Contrast and Triggering (REACT) using Compressed SENSE (CS) and a newly developed deep learning-based algorithm (CS-AI) for rapid non-contrast MRA of the cervical arteries.

### METHODS AND MATERIALS

This prospective single-center study included 34 healthy volunteers (median age 59 [IQR53-62] years; 14 men), who received carotid imaging using a 3D isotropic flow-independent REACT (reconstructed voxel size: 0.625×0.625×0.75 mm3) sequence at 3T. REACT was acquired threefold: (1) CS factor 7 (CS 7; fixed scan time: 1:20 min), (2) CS factor 10 (CS 10, fixed scan time: 0:55 min), and CS factor 10 with deep learning-based image reconstruction (CS 10-AI, fixed scan time: 0:55 min). Two radiologists rated the image quality of eight different cervical artery segments on a 7-point scale (7=excellent) and assessed overall image noise on a 5-point scale (5=none). Pairwise forced-choice comparison was performed to determine the acquisition technique considered more suitable for vessel evaluation. Apparent signal- and contrast-to-noise ratios (aSNR/aCNR) were measured for the common carotid artery (CCA) and internal carotid artery (ICA, C1 segment).

### RESULTS

Compared to CS 7 and for all arteries combined (5.07 [4.52-5.43]), CS 10 showed lower image quality scores (4.71 [4.38-5.11]; p<.001) while CS 10-AI obtained higher results (5.29 [4.88-5.43]; p=.01). In this context, CS 10-AI achieved significantly higher scores at the aortic arch (p=.004), while CS 10 achieved significantly lower scores at the V1 segment (p=.002) and for all segments of the extracranial carotid arteries combined (p<.001). Forced choice revealed a preference for CS 7 over CS 10 (p<.001), a preference for CS 10-AI over CS 10 (p<.001), but no preference between CS 7 and CS 10-AI (p=1). Image noise was rated similar between CS 7 and CS 10 (p=.14) while CS 10-AI yielded a lower noise than CS 7 (p=.008). Compared to CS 7 and for CCA and ICA combined (aSNR: mean 30.12±5.14, aCNR: 27.49±5.34), values of objective image quality were lower in CS 10 (aSNR: 27.17±5.28, aCNR: 24.67±5.44; all p<.001) whereas CS 10-AI yielded higher results (aSNR: 32.86±5.47, p<.001; aCNR: 29.81±5.79, p=.001).

### CONCLUSION

CS-AI enables rapid acquisition of REACT of the cervical arteries in less than a minute without compromising image quality. Future studies are required to confirm these findings in patients and evaluate its diagnostic performance for vascular findings, e.g. ICA stenosis or dissection.

### CLINICAL RELEVANCE/APPLICATION

CS-AI enables the acquisition of REACT of the neck in less than one minute, indicating its use for rapid imaging of the extracranial arteries without gadolinium contrast.

## R1-SSVA04-5 DEEP LEARNING MODEL FOR AUTOMATED DIAGNOSIS OF MOYAMOYA DISEASE BASED ON MAGNETIC RESONANCE ANGIOGRAPHY: DIFFERENTIAL DIAGNOSIS WITH ATHEROSCLEROTIC DISEASE AND NORMAL CONTROLS

### PURPOSE

Moyamoya disease (MMD) is a rapidly progressing cerebrovascular disease with a high risk of cerebral hemorrhage, making early diagnosis and intervention crucial. Magnetic resonance angiography (MRA) is preferred over DSA and CTA for MMD screening due to its non-invasive and lack of contrast agents. However, the scarcity of MMD coupled with the large number of cerebrovascular examination images present challenges, including time-consuming and risk of misdiagnosis and missed diagnosis. This study explores the potential of the deep learning-based convolutional neural network (CNN) to automatically recognize MMD using MRA images.

### METHODS AND MATERIALS

The dataset comprised MRA images from 600 patients including 200 MMDs, 200 ASDs and 200 NCs, collected from our institution (Ethic ID: 20160411). The images were divided into training (75%), validation (15%), and testing (10%) sets. The performances of 3D CNN models were evaluated using a comprehensive set of metrics such as area under the curve (AUC), accuracy (ACC) and others. The input to the CNN models comprised preprocessed MRA

images, while the output was a tripartite classification label that identified the patient's diagnostic group (Figure 1). Finally, Grad-CAM was used to visualize the CNN's decision-making process in MMD diagnosis by highlighting key areas.

## RESULTS

Table 1 presents the performance metrics for all models in the tripartite classification of MMD, ASD and NC. Notably, DenseNet-121 exhibited superior discrimination capabilities, achieving a macro AUC of 0.980 and an ACC of 0.9444 in the test sets. The per-class area under the receiver operating characteristic curve (ROC) and AUC values are depicted in Figure 2. In the binary classification where ASD and NC were group together, with MMD as the separate group for targeted detection, DenseNet-121 achieved an ACC of 0.983 (Table 2). Additionally, Figure 3 illustrates the Grad-CAM results for the MMD, with areas of intense redness indicating critical areas identified by the model, reflecting decision-making similar to human experts.

## CONCLUSION

This study highlights the efficacy of CNN model in the automated diagnosis of MMD on MRA images.

## CLINICAL RELEVANCE/APPLICATION

The CNN-based deep learning models enhances the accuracy and efficiency of MMD detection, easing the workload on radiologists and promising integration into clinical workflows.

### PURPOSE

Mobile, ultra-low field magnetic resonance imaging (MRI) scanners can vastly improve access to neuroimaging. Implementing MRI techniques to quantify microstructure, particularly myelin, allows monitoring of neurodegenerative diseases as well as myelination trajectories during development. In this study, we developed MRI sequences to measure magnetization transfer ratio (MTR) and T2 relaxation time as surrogate markers for myelin, and assessed their reproducibility at ultra-low field.

### METHODS AND MATERIALS

Five healthy adults underwent MRI using a 0.064T portable MRI scanner (Swoop, Hyperfine Inc., Guilford, CT) using the following scans:• T2-weighted for white matter (WM) segmentation, 1.6x1.6x5 mm3, 3 minutes• MTR imaging: 2 PSIF sequences, ?MToff/?MTon = 60°/300°, TR/tRF = 12 ms/220 µs, 2x2x5 mm3, 4 minutes total• T2 mapping: multi-echo spin echo, 80 echoes, ?TE/TR = 3.93/800 ms, 3x3x5 mm3, 7.5 minutesSubjects were then removed from the scanner, repositioned, and rescanned with the same protocol.MTR maps were calculated as MTR=(MToff-MTon)/(MToff), and T2 was estimated using a mono-exponential fit. Data was assessed for reproducibility by visually comparing maps, using histograms of MTR and T2 values in whole brain and WM voxels, and comparing scan-rescan values for all subjects.

### RESULTS

Mean ± standard deviation for MTR in WM was 0.231±0.010 across all subjects, and T2 in WM was 82.9±2.6 ms. No visible difference between repeated scans were noted, and histograms showed strong overlap between scans. Both measures showed strong correlation between scans (MTR: $r=0.99$, $p<0.001$, T2: $r=0.97$, $p=0.004$). Average scan-rescan coefficient of variation was 1.03% for MTR and 0.33% for T2 mapping.

### CONCLUSION

The ultra-low field myelin-sensitive scans measuring MTR and T2 were successfully implemented and provided values in agreement with expectations. The variability of metrics between, and reproducibility within, subjects was deemed sufficient to track neurodevelopment or neurodegeneration. Metric reproducibility was comparable to higher field strengths.

### CLINICAL RELEVANCE/APPLICATION

Coupled with the increased accessibility of modern mobile ultra-low field MRI scanners, MTR and T2 relaxation time could be used as biomarkers for frequent, non-invasive assessment of myelin-related damage. Applications include detecting and monitoring progression in multiple sclerosis, Alzheimer's disease, leukodystrophies, and traumatic injury. This approach has the potential to extend the reach of clinical trials of new therapies, particularly those aimed at remyelination. It can also be used to track healthy aging during childhood development and through the lifespan into elderliness.

**PURPOSE**

We sought to determine common indications for use of a portable low-field brain MRI (Hyperfine Swoop® 0.064T) and concordance with conventional non-contrast brain MRI (1.5 or 3T).

**METHODS AND MATERIALS**

Patients undergoing low-field brain MRI exams from two sites: 1) Missouri Baptist Medical Center (MBMC, n=293) and 2) Barnes-Jewish Hospital Neuro-ICU (BJH-ICU, n=61), were included. A follow-up non-contrast conventional brain MRI exam (1.5T or 3T) was defined by the following criteria: 1) it was conducted within three days of the low-field exam and 2) there were no new indications or relevant events between the two exams. Concordance between the follow-up and low-field exams was defined as the presence or absence of the same pathology in the same region, whether stable or evolved. The two exams were considered discordant if a positive finding on the follow-up exam was not identified by the low-field exam, or if a positive finding on the low-field exam was contradicted by the follow-up exam.

**RESULTS**

Overall, 354 Hyperfine Swoop MRIs from 351 patients (197/154 female/male, age=69±15 years) were acquired between Sep-2022 and Aug-2024. The most common indication for exam was stroke or stroke-like symptoms [n(%)=269(91.4) in MBMC, 41(67.2%) in BJH-ICU], followed by anoxic brain injury [n(%)=10(2.8) in MBMC and 4(6%) in BJH-ICU. All scans were interpreted by trained neuroradiologists.A total of 36 follow-up conventional MRIs were performed within 3 days of the portable scan. The time elapsed between the low-field and conventional exams varied widely, ranging from 31 minutes to 70 hours and 21 minutes (mean: 24±23 hours). In 20 out of 36 exams (55.5%) findings from the subsequent conventional MR were discordant with low-field, with equal numbers demonstrating unidentified pathology (n=10) or refuting a new/reported positive finding on the low-field study (n=10). From a quality perspective, a total of 24(6.7%) initial low-field scans were noted to be limited or non-diagnostic by the interpreting neuroradiologist, of which only 6 were followed by conventional MRI. This suggests that most of the repeat conventional exams (72.3%) were likely performed for clinical reasons rather than due to a lack of diagnostic quality in the portable MRI scans.

**CONCLUSION**

Point-of-care low-field portable MR with low field strength carries promise for rapid delivery of actionable diagnostic imaging to persons with acute neurological injury.

**CLINICAL RELEVANCE/APPLICATION**

Portable low field MRI should be considered for patients with acute stroke who cannot readily undergo conventional MRI. When clinically indicated, patients may benefit from follow-up conventional 1.5T or 3T MRI exam.

## R2-STCE1-3 A DEEP LEARNING FRAMEWORK FOR GENERATING SYNTHETIC LOW-FIELD IMAGES WITH PAIRED HIGH AND LOW-FIELD DATA

Daniel S. Reich, MD, PhD (*Abstract Co-Author*) Research support, Vertex Pharmaceuticals Incorporated;Research support, sanofi-aventis Group
Serhat Okar (*Abstract Co-Author*) Nothing to Disclose
Thomas C. Arnold, PhD (*Abstract Co-Author*) Nothing to Disclose
Joel M. Stein, MD, PhD (*Abstract Co-Author*) Research Grant, Hyperfine Research, Inc;Consultant, Centaur Diagnostics, Inc
Chetan Vadali (*Abstract Co-Author*) Nothing to Disclose
Alfredo Lucas, PhD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Limited availability of low-field MRI imaging data hampers the development of algorithms and tools tailored for low-field MRI applications. This study introduces a deep learning framework designed to generate synthetic low-field (64mT) MRI images from high-field (3T) data, aiming to create larger datasets necessary for advancing diagnostic applications and understanding the potential uses of low-field MRI in clinical practice.

**METHODS AND MATERIALS**

A total of 50 multiple sclerosis patients were scanned on portable 64mT (Hyperfine) and standard 3T scanners (Siemens) at Penn or NIH with T1-weighted, T2-weighted and FLAIR acquisitions. We previously developed LowGAN, a multi-contrast low-to-high field super resolution generative adversarial network, trained using this paired dataset. In this study we reversed the training process of LowGAN (rLowGAN) such that the input would be the 3T sequences (T1w, T2w, and FLAIR) and the outputs would be synthetic 64mT data. We trained rLowGAN using leave-5-out cross-validation, such that each subject's synthetic 64mT data was created from a rLowGAN model trained without that participant's data. We tested our model in 13 additional MS participants not included during training, as well as on a subset of 20 brain tumor patients from the brain tumor segmentation challenge (BRaTs).

**RESULTS**

We found that rLowGAN produced images that were visually similar to low-field images. rLowGAN synthetic 64mT outputs had a higher structural similarity to actual 64mT images, relative to input 3T images across T1w, T2w and FLAIR contrasts ($p<0.001$). This was the case for both cross-validation and test sets, except for the T2 contrast in the test set where there was no difference in SSIM between rLowGAN vs. 64mT and 3T vs. 64mT ($p=0.304$). We found that rLowGAN made white matter lesions similar to those seen in native 64mT images, and it also introduced venous vascular hyperintense signal on FLAIR images present in 64mT acquisitions. In the external BRaTS dataset, rLowGAN succesfully produced images with the noise and artifact profile of native 64mT images, and simulated brain tumor appearance at low-field.

**CONCLUSION**

Our deep learning framework successfully generates high-fidelity synthetic low-field MRI images from high-field inputs, providing a robust method to create low-field imaging datasets from existing 3T datasets.

**CLINICAL RELEVANCE/APPLICATION**

The ability to produce synthetic low-field MRI images from high-field data using deep learning techniques offers a cost-effective solution to the scarcity of low-field imaging data. Large datasets are necessary for developing algorithms and tools specific to low-field MRI, ultimately enabling the exploration of its diagnostic applications and expanding its clinical utility.

## R2-STCE2-1 LONG-TERM PROGNOSTIC IMPLICATIONS OF AI-BASED THORACIC AORTA CALCIFICATION QUANTIFICATION IN A SCREENING POPULATION: A MULTICENTER STUDY

Nayoung Kim (*Abstract Co-Author*) Nothing to Disclose
Young Joo Suh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yonghan Kwon, MS (*Abstract Co-Author*) Nothing to Disclose
Kyunghwa Han, PhD (*Abstract Co-Author*) Nothing to Disclose
Jong Eun Lee, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the long-term prognostic implication of incidental TAC on non-gated chest computed tomography (CT) in an asymptomatic screening population.

### METHODS AND MATERIALS

This retrospective study included asymptomatic individuals aged 40 years or older who underwent chest CT scans at two health screening centers between 2007 and 2014. CT scans were assessed for thoracic aorta calcification (TAC) status and coronary artery calcification (CAC) status, stratified using both artificial intelligence (AI)-based Agatston score measurement and visual analysis. Multivariable Cox proportional hazards models were used to evaluate the hazard of TAC stratification models for major adverse cardiovascular events (MACE) and all-cause mortality, adjusting for CAC and clinical risk factors. Discriminative ability of TAC stratification models, both quantitative and visual, for the prediction of MACE and all-cause mortality, was measured using C-statistics.

### RESULTS

Of the 7404 participants, 383 experienced MACEs over a median observation period of 7.4 years, and 330 all-cause deaths occurred over a median observation period of 10.9 years. All groups with TAC greater than 0 had a higher hazard of all-cause mortality compared to those without TAC, with the highest in the TAC score > 3000 group (adjusted HR: 2.73; 95% CI: 1.57-4.75; P < .001). The combined TAC and CAC AI-based quantitative stratification with clinical variables model showed the best discriminative ability (C-index: 0.787 and 0.800 for MACE and all-cause mortality, respectively) compared to other models.

### CONCLUSION

TAC has significant long-term potential to predict all-cause mortality. TAC AI-based quantitative stratification, along with CAC and clinical variables, is helpful for the long-term prediction of MACE and all-cause mortality.

### CLINICAL RELEVANCE/APPLICATION

Identifying and quantifying TAC on routine non-gated chest CT scans in asymptomatic individuals significantly enhances long-term risk stratification for all-cause mortality.

## R2-STCE2-2 DEEP LEARNING ANALYSIS OF VOLUMETRIC BODY COMPOSITION IN A MULTI-CENTER TAVR STUDY

Julia Rodighiero (*Abstract Co-Author*) Nothing to Disclose
Jonathan Afilalo (*Abstract Co-Author*) Nothing to Disclose
Ding Yi Zhang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Radiographic assessment of body composition is useful for preoperative risk stratification, notably in frail older adults referred for transcatheter aortic valve replacement (TAVR). Prior studies focused on L3 or L4 single-slice manual measurements of psoas muscle area. Technological advancements in artificial intelligence and deep learning segmentation now enable multi-slice automated measurements of muscle and fat volumes, which are more rapid and reliable for large multi-center implementations.

### METHODS AND MATERIALS

The FRAILTY-TAVR cohort was assembled across 14 centers in the United States, Canada, France, and Ireland. Pre-TAVR CT scans were retrieved in DICOM format and analyzed using our 3-dimensional convolutional neural network (coreslicer.com) to measure the volume and density of the skeletal muscle, subcutaneous fat, and visceral fat. Volumetric measurements were restricted to axial slices between the L1-S vertebral levels using a built-in vertebral classifier. The outcome was all-cause mortality post-TAVR.

### RESULTS

The cohort consisted of 635 patients that underwent TAVR with 39% females, a median age of 83 years (IQR 78-87), and a median follow-up of 466 days (IQR 371-1010). The Cox proportional hazards survival model containing the volumetric body composition measurements outperformed the basic model containing the L3 single-slice psoas muscle area (Harell's C statistic +0.04). Interestingly, the volumetric measurements revealed that low muscle density, indicative of low muscle quality due to intramuscular adiposity, was a superior predictor of mortality compared to low muscle volume (P=0.003).

### CONCLUSION

Opportunistic assessment of body composition using an automated deep learning method identifies patients with higher mortality post-TAVR. Low skeletal muscle density, which is associated with intramuscular adiposity, is particularly predictive.

### CLINICAL RELEVANCE/APPLICATION

Deep learning methods to analyze body composition on preoperative CT scans are more predictive and generalizable than single-slice manual methods, and should be preferred for wide-scale deployment to inform clinical decision making.

## R2-STCE2-3 MULTIOMIC AI-ASSISTED PREDICTION OF LOCAL RECURRENCE AND SURVIVAL AFTER RF ABLATION OF HCC FROM A MULTICENTER TRIAL

### PURPOSE

To evaluate performance of clinical and 3D radiographic ablation margin and tumor features to predict local recurrence and survival in hepatocellular carcinoma (HCC) patients treated with radiofrequency ablation (RFA).

### METHODS AND MATERIALS

550 patients included in the multicenter (39 study sites), multinational (11 countries) OPTIMA trial were considered in this study. Patients with solidary HCC lesions between 3-7cm and with well-defined pre-RFA tumor and 1-month post-RFA devascularized (ablation) zones on enhanced CT were analyzed. AI-assisted 3D tumor and ablation zone segmentation was performed with subsequent elastic registration. Radiomic tumor features were extracted from the segmented tumor and ablation zones in contrast-enhanced CTs, and included: tumor volume, treated and undertreated tumor volume, and tumor morphometrics. Patient clinical features analyzed included sex, age, underlying liver disease, body-mass index, elevated alpha-fetoprotein and number of treatments. Predictive models were built to determine the association of features to local recurrence (incomplete response, local recurrence or local residual disease) and 5-year survival. Three multivariate logistic regression models were built and compared, which included clinical features alone, radiologic features alone, and clinical and radiologic features combined.

### RESULTS

185 patients with corresponding pre-ablation and 28-days post-ablation images were included in the study. When predicting local recurrence in HCC patients, models that included both clinical and radiomic features performed better than clinical features alone (AUC 0.64, [CI95% 0.51, 0.71] vs 0.54 [CI95% 0.36, 0.77], P=0.006). When predicting survival, radiomic features did not improve the predictive performance of clinical features alone (AUC clinical features alone 0.62 [CI95% 0.52, 0.73] vs AUC combined 0.64 [CI95% 0.54-0.74] P=0.4). Amongst all models, 3D tumor metrics showed the highest odds ratios for the prediction of both survival and local recurrence (e.g., tumor flatness OR 8.8 [CI95% 0.36, 305], tumor elongation 4.5 [0.25, 173]).

### CONCLUSION

A machine learning model including both clinical and radiomic tumor and ablation zone features can predict local recurrence after RFA in HCC patients. These analyses suggest the need for the use of both clinical features and 3D evaluation metrics of the tumor to better predict local recurrence, while clinical features alone may best predict survival in HCC patients.

### CLINICAL RELEVANCE/APPLICATION

Together, clinical and image assessment and registration with ablation may support standardization, quality control, and outcome prediction. Understanding the factors contributing to outcome could help tailor treatment approaches.

Miyuko Fujita (*Abstract Co-Author*) Nothing to Disclose
Shintaro Yamaguchi (*Abstract Co-Author*) Nothing to Disclose
Masafumi Takafuji, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Myocardial ischemia arises from different etiologies, including epicardial coronary stenosis and microvascular disease, posing challenges for the efficacy of percutaneous coronary intervention (PCI). Dynamic four-dimensional stress CT perfusion (dCTP) allows to quantify myocardial blood flow (MBF) and is useful for diagnosing myocardial ischemia. Fractal analysis applied to dCTP data shows potential for differentiating ischemia according to etiology, i.e., epicardial stenosis or microvascular disease. This study investigates pre-PCI fractal analysis of dCTP for predicting improvement of myocardial ischemia post-PCI by identifying microvascular ischemia components.

### METHODS AND MATERIALS

Patients with stable coronary artery disease (CAD) who underwent dual-source dCTP within 120 days before PCI and within 400 days after clinically indicated PCI (median interval 308 days) were retrospectively included. Fractal analysis and MBF quantification were performed on dCTP images pre- and post-PCI adhering to the AHA myocardial 17-segment model. To define improvement of perfusion defects after PCI, two experienced observers, blinded to patient clinical information, visually compared pre- and post-PCI short-axis MBF maps for extent of perfusion defects. In a previous study, fractal dimension (FD) classified perfusion defects as either epicardial (FD=4.31) or microvascular (FD>4.31) with the latter being hypothesized to remain unchanged post-PCI. Additionally, we analyzed clinical characteristics and FD by multivariate logistic regression.

### RESULTS

We included 29 patients (24 male, mean age 73.1±9.7 years) and PCI was performed in 36 vessels. Ischemia improvement after PCI in terms of extent of the perfusion defect was observed in 19 of 36 vessels and 84 of 214 myocardial segments. The proportion of vessels and segments with ischemia improvement with low FD (FD=4.31) was significantly higher than those with high FD (FD>4.31) [vessel level; 16/17 (94.1%) vs. 3/19 (15.8%), p<0.001, segment level; 53/58(91.4%) vs. 31/156 (19.9%), p<0.001]. Area under the curve (AUC) of FD for predicting improvement was 0.866. In multivariate analysis, low pre-PCI FD [odds ratio (OR) 77.93; 95% confidence interval (95% CI) 23.17-262.16; p<0.0001], non-smoker status (OR 6.29; 95% CI 2.71-14.62; p<0.0001), and presence of chest pain (OR 4.62; 95% CI 1.63-13.10; p=0.004) were independently associated with ischemia improvement after PCI.

### CONCLUSION

Fractal analysis of dCTP predicts post-PCI improvement of myocardial ischemia in stable CAD by identifying microvascular ischemia components.

### CLINICAL RELEVANCE/APPLICATION

Fractal analysis aids in discerning microvascular disease, potentially guiding PCI decision-making in patients with stable CAD.

## R3-SSCA10-2 A PRELIMINARY STUDY OF CORONARY ARTERY VASCULITIS EVALUATION ON PHOTON-COUNTING CT: STENOSIS AND INFLAMMATION DETECTING

Yining Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Yue Sun (*Presenter*) Nothing to Disclose

**PURPOSE**

To validate the performance of spectral photon-counting detector coronary CT angiography (PCD-CCTA) in stenosis detection and inflammation evaluation in patients with coronary artery vasculitis (CAV).

**METHODS AND MATERIALS**

In this prospective study, patients diagnosed with CAV and referral for hospitalization were enrolled between September 2023 and March 2024. All patients underwent spectral PCD-CCTA examination with virtual monoenergetic images (VMI). Subjective image quality was graded on a scale of 1-5 (1—unacceptable, and 5—excellent). For objective image quality, the contrast-to-noise ratio (CNR) and the signal-to-noise ratio (SNR) per vessel were calculated by CNR = (average luminal HU - average perivascular epicardial HU)/ (aortic root HU standard deviation) and SNR = average luminal HU / (aortic root HU standard deviation). Stenosis evaluation was performed on 55keV VMI and fat attenuation index (FAI) measurement was performed on 70keV VMI. Clinical data during hospitalization were recorded, including percutaneous coronary intervention (PCI), erythrocyte sedimentation rate (ESR) and high sensitivity C-reactive protein (hsCRP). The diagnostic accuracy in detecting obstructive coronary stenosis on PCD-CCTA was determined, with invasive coronary angiography (ICA) serving as the standard of reference. FAI values between obstructive and non-obstructive lesions were compared. The associations of FAI with PCI, ESR and hsCRP were assessed using generalized linear mixed-effects model.

**RESULTS**

41 CAV patients (mean age, 54 ± 12; 35 females) were ultimately included. With a dose of contrast medium 25 mL (interquartile range (IQR), 23.25-30 mL) and effective radiation 3.05 mSv (IQR, 1.73-4.21mSv), the overall image quality was rated as excellent 5 (IQR range, 4-5). The mean overall CNR and SNR were 10.73 ± 2.99 and 8.28 ± 2.44, respectively. PCD-CCTA demonstrated a high diagnostic accuracy in detecting obstructive coronary stenosis at both lesion 0.98 (95% CI: 0.92, 1.00) and vessel level 0.98 (95% CI: 0.91, 1.00). FAI at lesion level displayed significant difference between stents with and without restenosis (-74.82 ± 8.39 vs -83.78 ± 8.88; P = 0.023), as well as between obstructive and non-obstructive stenosis (-78.01 ± 10.75 vs -85.69 ± 7.28; P = 0.003). There was a positive association of FAI with ESR (estimate 0.06 ± standard error 0.01 HU, P < 0.001) and hsCRP (estimate 0.11 ± standard error 0.02 HU, P < 0.001).

**CONCLUSION**

PCD-CCTA appears promising in the stenosis and inflammation status evaluation in patients with CAV, all while utilizing a low dose of contrast medium and radiation.

**CLINICAL RELEVANCE/APPLICATION**

PCD-CCTA allows a comprehensive evaluation of coronary stenosis and inflammatory profile in patients with CAV.

## R3-SSCA10-4 THE DIFFERENCES BETWEEN NON-ST-SEGMENT ELEVATION ACUTE CORONARY SYNDROME AND CHRONIC CORONARY SYNDROME IN CCTA PLAQUE MEASUREMENT

Zhong-Fei Lu, MD (*Abstract Co-Author*) Nothing to Disclose
Bin Lu, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

A high proportion of patients with acute chest pain could not be diagnosed as non-ST-segment elevation acute coronary syndrome (NSTE-ACS) confidently because of inconclusive electrocardiogram and troponin. The study aims to distinguish NSTE-ACS from chronic coronary syndrome (CCS) through comparing the plaque differences in coronary CT angiography (CCTA) images between the culprit plaque in NSTE-ACS patients and the most severe stenosis plaque in CCS patients

**METHODS AND MATERIALS**

This study was a case-control study. The case group were included from a prospective NSTE-ACS cohort. All patients in this cohort underwent CCTA immediately after being diagnosed with NSTE-ACS. The control pair included CCS patients who underwent CCTA examination. Patients with NSTE-ACS and patients with CCS were propensity matched 1:1 for age and gender. The culprit lesion in NSTE-ACS patients and the most severe stenosis plaque in CCS patients were used for comparison. The plaque volume and burden of lipid, fibrous, and calcified constituents were measured. Using stenosis as the baseline model for adjudication of NSTE-ACS (Model 1). CCTA coronary artery plaque variables with statistic significance from multivariate logistic regression analysis were added to the baseline model (Model 2).

**RESULTS**

A total of 258 NSTE-ACS patients (age 58.8 ± 11.1 years, 71.7% male) were included in the study. The NSTE-ACS group and CCS group were completely matched. The degree of stenosis of culprit lesions in NSTE-ACS group is higher than that of the most severe stenosis plaques in CCS group (71.9% vs. 37.4%). The lipid volume (9.8 mm3 vs. 0.4 mm3) and burden (5.0% vs. 0.3%), fibrous volume (50.2 mm3 vs. 19.9 mm3) and burden (36.0% vs. 15.0%) were higher in the NSTE-ACS group. The calcification volume (0.5 mm3 vs. 3.5 mm3) and burden (0.3% vs. 2.8%) was lower in the NSTE-ACS group. In multivariate logistic regression analysis, fibrous burden, calcified burden, and stenosis were independent predictive factors for NSTE-ACS. The AUC (area under curve) of Model 2 composed of stenosis, fibrous burden, and calcified burden was higher than model 1 (0.782 vs 0.699, P<0.001).

**CONCLUSION**

The quantitative information of plaque constituents in CCTA images could provide additional information for the diagnosis of NSTE-ACS.

**CLINICAL RELEVANCE/APPLICATION**

Plaque quantification in CCTA images could be used to diagnose NSTE-ACS.

## R3-SSCA10-5 ROLE OF DUAL ENERGY CT IN QUANTIFYING MYOCARDIAL AND LIVER IRON DEPOSITION IN PATIENTS WITH THALASSEMIA MAJOR: A COMPARISON WITH T2* MRI

Ambuj Roy (*Abstract Co-Author*) Nothing to Disclose
Kartik P. Ganga, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Priya Jagia, MD (*Abstract Co-Author*) Nothing to Disclose
Vineeta Ojha, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Currently, T2 * MRI is considered the gold standard in myocardial and liver iron estimation. Material decomposition techniques using dual energy has been shown to accurately characterize renal and ureteric stones with minimal radiation exposure. The purpose of the proposed study is to elucidate if similar techniques using dual energy CT can be used to identify and quantify iron deposition in myocardium and liver with T2* being the gold standard.

### METHODS AND MATERIALS

Consecutive thalassemia patients were prospectively enrolled. Patients with cardiovascular risk factors were excluded. Control group consisted of 15 patients who were referred for CT scan of the thorax for other unrelated causes. Patients and controls underwent non contrast CT and cardiac MRI using fixed protocol. CT datasets were then be loaded into the Rho/Z application (syngo.via DE Rho/Z Maps, Siemens Healthcare,). Rho/Z and attenuation at 90 kV and 150 kV of the septum, liver, spleen and pancreas were determined with a free-hand region of interest (ROI). Three separate measurements were taken for all the locations and averages of measurements were used for statistical analysis.

### RESULTS

126 patients (mean age-38 years, 65.87% male) were included. The median Serum Ferritin, myocardial and liver T2* were significantly higher in the study group (p<0.001). Myocardial Rho (3.48 vs 3.50; p=0.017), myocardial Z (7.56 vs 7.47; p=0.005) and Myocardial attenuation at 150 kVp (45.4 HU vs 49.08 HU; p=0.02) were significantly different between thalassemia patients and controls. Myocardial Rho with a cut off of 3.497, had a sensitivity and specificity of 46.6 % and of 46.15 %, respectively and myocardial Z with a cut off of 7.51, had a sensitivity and specificity of 69.23 % and 73.33 % respectively for differentiating between thalassemia patients with any myocardial iron (n = 26) and controls. Liver Rho with a cut off of 3.56, had a sensitivity and specificity of 70.97 % and 68.75 % respectively and liver Z with a cut off of 7.66, had a sensitivity and specificity of 92.47 % and 93.75 % respectively for differentiating between thalassemia patients with moderate + severe liver iron (n = 92) and thalassemia patients with mild + no liver iron (n = 34). The average radiation dose per scan was 3.6 +/- 0.84 mSv.

### CONCLUSION

While the sensitivity and specificity of dual energy CT parameters, specifically Liver Z, in identifying liver iron deposition is high, the accuracy of dual energy CT parameters for identifying iron deposition in myocardium is poor.

### CLINICAL RELEVANCE/APPLICATION

DECT can be used to identify liver iron deposition with high accuracy. This may be used as a tool in facilities without availability of T2* MRI or expertise and can also be used as opportunistic screening tool in CTs done for unrelated purposes.

## R3-SSCA10-6 NEW RECONSTRUCTION ALGORITHM ENHANCES IMAGE QUALITY AND DIAGNOSTIC USABILITY OF PHOTON-COUNTING CONTRAST-ENHANCED CORONARY CT ANGIOGRAPHY

Nina Pauline Haag, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The recent ZeeFree (ZF) reconstruction algorithm introduced for the photon counting CT was evaluated to determine its potential to enhance image quality and diagnostic precision compared to Standard (SD) and TrueStack (TS) reconstruction algorithms.

### METHODS AND MATERIALS

79 patients (mean age 63 years ± 13 SD, 55 males) undergoing photon-counting Coronary CT angiography (CCTA) with ZeeFree reconstruction (NAEOTOM Alpha, Syngo.CT VB10, Siemens Healthineers) between July and December 2023 were retrospectively identified. Curved planar reformations were reconstructed for coronary arteries using ZF, SD, and TS. Three blinded readers individually evaluated image quality on a 5-point Likert scale. Results are given as median (IQR). Differences were evaluated using Friedman’s test with pair-wise post-hoc testing. Readers stated whether image quality was diagnostic, presented as percentages, with significance evaluated by the Pearson Chi-Square test. Interrater reliability for image quality used Gwet’s AC2 coefficient with ordinal weights, and Gwet's AC1 coefficient for diagnostic usability.

### RESULTS

Image quality differed among reconstruction algorithms (P<.001). ZF showed superior quality (4 (2)) surpassing SD (4 (2), P=.03), and TS (4 (1), P<.001). Inter-rater agreement was collectively substantial (0.70 - 0.74). ZF had the highest diagnostic usability 438/531 (82.5 %), SD 409/531 (77.0%, P<.001), and TS 401/531 (75.5%, P<.001), with almost perfect inter-rater agreement (0.84).

### CONCLUSION

The exploration of ZF image reconstruction algorithm in photon-counting CCTA reveals improvements in diagnostic quality and usability compared to SD and TS, suggesting its primary use for assessment, supplemented by SD images, while TS may be reserved for cases with severe motion artifacts.

### CLINICAL RELEVANCE/APPLICATION

The ZeeFree reconstruction algorithm for photon-counting CT increases the diagnostic usability of coronary CT angiography images, significantly outperforming Standard and TrueStack reconstructions. Consequently, it can improve diagnostic precision and enhance patient compliance, along with potentially improving clinical outcomes, especially in cases where diagnostic clarity is borderline. This advancement brings us closer to the goal of achieving non-invasive, artifact-free diagnostic coronary CT angiography imaging.

## R3-SSGI17-1 WHAT IS THE IMPACT OF CHANGING GALLBLADDER POLYP RECOMMENDATIONS? SRU VS EUROPEAN GUIDELINES VS CAR VS ACR

Martin Matuszczak, MD (*Abstract Co-Author*) Nothing to Disclose
Aya Kamaya, MD (*Abstract Co-Author*) Royalties, RELX;Research Grant, Canon Medical Systems Corporation
Luyao Shen, MD (*Abstract Co-Author*) Nothing to Disclose
Thodsawit Tiyarattanachai (*Abstract Co-Author*) Nothing to Disclose
Jenny Vo-Phamhi, MS (*Presenter*) Nothing to Disclose

### PURPOSE

To compare follow-up imaging and surgical cost implications of the Society of Radiologists in Ultrasound (SRU) guidelines, 2017 and 2022 European (EUR) guidelines, 2020 Canadian Association of Radiologists (CAR) recommendations, and 2013 American College of Radiology (ACR) White Paper for managing incidentally detected gallbladder polyps.

### METHODS AND MATERIALS

253 consecutive patients with gallbladder polyps identified on ultrasound were independently reviewed by three radiologists for polyp size and morphology. Electronic medical records were reviewed for patient demographics, cholecystectomy (if performed) pathological findings, or any subsequent diagnosis of gallbladder cancer. For each patient, the following were calculated for each of the 5 guidelines studied: 1) number of recommended follow-up ultrasounds based on initial presentation, 2) number of surgical consultations recommended based on initial presentation, 3) number of surgical consultations recommended based on growth, and 4) associated imaging and surgical costs. Interrater agreement was calculated.

### RESULTS

The SRU 2022 guidelines suggested significantly fewer follow-up ultrasounds and surgical consultations, leading to a cost reduction of 96.5% and 96.7% compared to European 2022 and 2017, respectively; 86.5% compared to CAR; and 86.2% compared to ACR guidelines, without compromising sensitivity for gallbladder cancer detection. With SRU Recommendations, the majority of gallbladder polyps would be classified as extremely low risk (68.4%), 30.8% low risk, and 0.8% indeterminate risk. In our cohort, a single case of gallbladder cancer was identified (26 mm) which would be recommended for surgical consult by all guidelines.

### CONCLUSION

The SRU 2022 guidelines offer a cost-effective approach for managing incidentally detected gallbladder polyps without compromising cancer detection.

### CLINICAL RELEVANCE/APPLICATION

The SRU Consensus Conference guidelines can lead to significant savings for patients, health systems, and society, while reducing unnecessary medical interventions.

## R3-SSGI17-2 ARRIVAL TIME ON CONTRAST-ENHANCED ULTRASOUND FOR DIAGNOSIS OF HEPATIC VENOUS CONGESTION AFTER LIVING DONOR LIVER TRANSPLANTATION USING A RIGHT LOBE

Kyowon Gu, MD (*Abstract Co-Author*) Nothing to Disclose
Ji Hye Min, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Woo Kyoung Jeong, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate whether the arrival time of microbubbles was associated with hepatic venous congestion at middle hepatic vein (MHV) tributaries after living-donor liver transplantation (LDLT) with a right lobe

### METHODS AND MATERIALS

A total of 69 patients (55 men, 14 women; mean age, 55.6 years) who underwent LDLT with the right lobe were included. All patients underwent Doppler US and contrast-enhanced ultrasonography (CEUS) on postoperative day 1 (immediate post-op period) and contrast-enhanced CT within 14 days (early

post-op period). Arrival times of HA (HAAT), PV (PVAT), and HA-PV arrival time intervals were compared according to normal, mild, and severe congestion groups. Diagnostic performance was compared before and after adding HA-PV arrival time interval to Doppler US for diagnosis of obstruction at MHV tributaries.

**RESULTS**

In the normal group, HAAT, PVAT, and HA-PV arrival time intervals were 10.6 s ± 3.3, 12.7 s ± 3.3, and 2.1 s ± 0.6, respectively. HA-PV time interval was significantly increased as the severity of congestion increased, 2.1 s, 2.4 s, and 2.8 s, respectively, p = 0.016). After adding the HA-PV arrival time interval (= 3 s), the sensitivity was significantly improved during both immediate and early post-op periods (60.5% to 79.1% and 58.3% to 70.8%, respectively; p = 0.008 and 0.031).

**CONCLUSION**

HA-PV arrival time interval on CEUS was increased according to the severity of hepatic venous congestion. Adding CEUS with increased HA-PV arrival time interval to Doppler US was significantly more sensitive than Doppler US only for the diagnosis of obstruction at MHV tributaries after LDLT.

**CLINICAL RELEVANCE/APPLICATION**

Contrast-enhanced ultrasonography, focusing on the hepatic artery (HA) to the portal vein (PV) arrival time interval, can effectively assess hepatic venous congestion after living-donor liver transplantation (LDLT) using the right lobe. In particular, incorporating the interval between HA and PV arrival times enhances diagnostic accuracy in detecting MHV tributary obstruction, aiding in the management of patients undergoing LDLT.

## R3-SSGI17-3 EFFECT OF MANEUVERS, IV FLUID ADMINISTRATION, AND DIURESIS ON ULTRASOUND LIVER STIFFNESS MEASUREMENTS IN HEALTHY CONTROLS AND PATIENTS WITH FONTAN PHYSIOLOGY

Jonathan R. Dillman, MD, MSc (*Abstract Co-Author*) Research Grant, Perspectum Ltd;Research Grant, Siemens AG;Research Grant, Canon Medical Systems Corporation;Research support, Koninklijke Philips NV;Research support, General Electric Company;Research support, Motilent Ltd
samjhana Thapaliya, MD (*Abstract Co-Author*) Nothing to Disclose
Andrew T. Trout, MD (*Abstract Co-Author*) Author, RELX Author, Wolters Kluwer nv Research Grant, Canon Medical Systems Corporation Research Grant, Siemens AG Research support, Perspectum Diagnostics Ltd Consultant, Lantheus Holdings
Cara E. Morin, PhD (*Abstract Co-Author*) Nothing to Disclose
Julie Bonn (*Abstract Co-Author*) Nothing to Disclose
Clayton Smith (*Abstract Co-Author*) Nothing to Disclose
Adam Lubert (*Abstract Co-Author*) Nothing to Disclose
Pradipta Debnath, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine the effect of stress maneuvers, IV fluid administration, and diuresis on ultrasound liver stiffness measurements (LSM) in Fontan patients and healthy controls.

**METHODS AND MATERIALS**

Ultrasound shear-wave elastography was prospectively performed in ten patients post-Fontan surgery and ten healthy volunteers. LSMs were taken while supine with suspended respiration (baseline) and after/during multiple maneuvers: maximum inspiration, maximum expiration, standing, handgrip exercise, Trendelenburg positioning, exercise (five minutes of walking), normal saline IV infusion (10 mL/kg, maximum of 500 mL), and 15/30/60 minutes after furosemide administration. Clinically indicated abdominal MRI exams from Fontan patients were independently reviewed by three pediatric radiologists and Fontan liver MRI scores were assigned.The absolute and percent change in LSM were compared between baseline and each maneuver and between post-fluid infusion and post-diuretic administration. Patients were also divided into groups based on liver MRI score and LSMs were compared between groups. The Mann-Whitney U test or Wilcoxon signed-rank tests were used to compare groups. Pearson correlation (r) was used to test for an association between baseline LSM and liver MRI score.

**RESULTS**

LSMs in the Fontan group were higher at baseline (median: 2.6kPa vs. 1.3kPa) and for all maneuvers (all $p<0.001$) and had increased variation compared to healthy controls. There was no significant difference in LSM between Fontan patients with high and low liver MRI scores. There was no significant correlation between liver baseline LSM and liver MRI score ($r=-0.53$, $p=0.11$). Fontan LSM did not significantly change versus baseline for any maneuver ($p>0.06$ for all, Figure). Healthy control LSM increased versus baseline only for inspiration (0.02 kPa, 1.6%, $p=0.03$), standing (0.07 kPa, 5.5%, $p=0.03$), and fluid administration (0.10 kPa, 7.8%, $p=0.002$). LSMs post-diuretic were significantly decreased compared to post-fluid infusion for the Fontan group at 30 min (-0.79 kPa, -26.5%, $p=0.004$) and 60 min (-0.78 kPa, -26.2%, $p=0.02$) and for healthy controls at 15 min (-0.12 kPa, -8.70%, $p=0.002$), 30 min (-0.15 kPa, -10.9%, $p=0.003$) and 60 min (-0.15 kPa, -10.9%, $p=0.005$).

**CONCLUSION**

LSM in Fontan patients are higher and have increased variation compared to healthy controls. Diuresis is associated with significantly decreased liver stiffness in both Fontan patients and healthy controls, with suggestion of a greater effect in Fontan patients.

**CLINICAL RELEVANCE/APPLICATION**

Relative euvolemia/hypovolemia impacts ultrasound LSM in Fontan patients and should be further investigated as a potential means to reduce the confounding effect of congestion on LSM.

## R3-SSGI17-4 THE RELEVANCE OF GALLBLADDER POLYPS TO GALLBLADDER CANCER IN A COHORT OF 218,418 PATIENTS

Chelsea Kim (*Abstract Co-Author*) Nothing to Disclose
David R. Urbach (*Abstract Co-Author*) Nothing to Disclose
Brian M. Moloney, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Gonzalo Sapisochin (*Abstract Co-Author*) Nothing to Disclose
Korosh Khalili, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine imaging and clinical variables associated with development of gallbladder cancer (GBCA) and specifically assess the risk of gallbladder polyps (GBP).

### METHODS AND MATERIALS

All patients who underwent a liver ultrasound over 21 years at 3 academic institutions with an intact gallbladder were included and linked at the individual-level to health administrative provincial data in Ontario, Canada. Imaging data (polyp size multiplicity, adenomyomatosis, stones, primary sclerosing cholangitis (PSC), porcelain gallbladder, choledochal cysts) were extracted from reports using natural language processing with I2E (Linguamatics®). Patients with GBP without reported size were excluded. Country of birth/ethnicity (COB/E) was extracted through linkage with the national immigration authority (1985 onwards) and a validated surname-based protocol; patients were divided into low risk and high risk based on global incidence data. GBCA diagnosis was derived from the provincial cancer registry. The primary outcome was time to GBCA after documentation of GB on ultrasound. Multivariate modeling was performed using Cox proportional hazard regression.

### RESULTS

218,418 patients (mean age 50.7, 55.3% female) were included. The prevalence of variables were: High-Risk COB/E 11.4%, GBP 9.2%, stone 10.8%, adenomyomatosis 2.2%, PSC 0.27% choledochal cysts 0.039%, porcelain GB 0.045%. GBP (n=20,033, 34.3% multiple) sizes when quantitively reported were: =6mm 89.4%; 7-9mm 8.2%, = 10 mm 2.3%. 15-year cumulative probability of growth to =10 mm were 2.6% for = 6mm and 18.6% for 7-9mm polyps (HR 10.96, p=0.001). 21,513 (9.8%) patients underwent cholecystectomy in the follow-up period, 15-year cumulative probability of cholecystectomy in patients with GBP and without stones were = 6mm 13.6%; 7-9mm 30.5%; = 10 mm 67.4%. 114 patients were diagnosed with GBCA, 50 of which were>12 months after US scan documenting intact GB. A maximum of 25/114 GBCA patients had a polyp (=21.9%). On multivariate analysis, Age (HR 1.06/year, p<0.001), High-Risk COB/E (HR 2.01,p=0.003), adenomyomatosis (HR 3.36,p<0.001), GBP=10 mm (HR 4.78,p=0.045), stones (HR 4.81,p=<0.001), choledochal cyst (HR 8.55,p=0.03) were directly, and GBP<10mm (HR 0.14,p=0.045) was inversely associated with subsequent GBCA diagnosis.

### CONCLUSION

Development of GBCA from polyps initially measured at <10mm is quite rare and in our cohort, GBP<10mm did not increase the risk of subsequent GBCA.

### CLINICAL RELEVANCE/APPLICATION

New North American and European practice guidelines suggest surveillance of some GBP<1cm. Our study questions the need for surveillance of GBP<10mm in patients without other risk factors.

### PURPOSE

To assess the relationship between the multiparametric US imaging markers shear-wave dispersion slope (DS), attenuation coefficient (AC), and shear-wave speed (SWS) and liver histopathological necroinflammation in patients with metabolic dysfunction-associated steatotic liver disease (MASLD).

### METHODS AND MATERIALS

This international, multicenter prospective study enrolled consecutive biopsy-proven MASLD patients between June 2019 and March 2023. Before biopsy, all participants underwent multiparametric US to obtain DS, AC, and SWS. Multivariable linear regression analyses were performed to assess the association between clinical variables or imaging markers with pathological findings. The diagnostic performance of imaging markers for determining inflammation, steatosis, and fibrosis grades was assessed using the area under the receiver operating characteristic curve (AUC).

### RESULTS

A total of 124 participants (mean age, 53 years ± 15 [standard deviation]; 62 men) were evaluated. Lobular inflammation was associated with DS (P = .02), alanine aminotransferase level (P = .002), and Hispanic ethnicity (P = .047), while AC was associated with steatosis (P <.001), and SWS was

associated with fibrosis (P <.001) and body mass index (P = .02). DS achieved an AUC of 0.72 (95% confidence interval (CI): 0.63, 0.82) for identifying participants with inflammation grade = A2 (moderate). AC showed excellent performance for identifying participants with steatosis grade = S1 (mild) (AUC, 0.92 [95% CI: 0.87, 0.97]) while SWS showed excellent performance for identifying participants with fibrosis stage = F2 (periportal fibrosis) (AUC, 0.91 [95% CI: 0.86, 0.96]). The combination of DS, AC, and SWS showed an AUC of 0.81 (95% CI:0.73, 0.89) for MASH diagnosis.

**CONCLUSION**

Among the three US imaging markers, DS, AC, and SWS, only DS was associated with lobular inflammation grade on histology and demonstrated fair diagnostic performance in distinguishing moderate lobular inflammation grade.

**CLINICAL RELEVANCE/APPLICATION**

Multiparametric US is useful for the management of patients with MASLD.

## R3-SSGI17-6 ULTRASOUND-DERIVED FAT FRACTION FOR HEPATIC STEATOSIS ASSESSMENT: A PROSPECTIVE STUDY WITH MRI PROTON DENSITY FAT FRACTION AS REFERENCE STANDARD

Xiaohui Qiao (*Abstract Co-Author*) Nothing to Disclose
Hong Ding, MD (*Abstract Co-Author*) Nothing to Disclose
Guangwen Cheng (*Abstract Co-Author*) Nothing to Disclose
Liyun Xue, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Metabolic dysfunction-associated fatty liver disease (MAFLD), formerly known as non-alcoholic fatty liver disease (NAFLD), affect approximately 25% of the global population. The noninvasive and accurate assessment of MAFLD is a clinical challenge. We aim to explore the methodology of ultrasound-derived fat fraction (UDFF) and its value for assessing hepatic steatosis, using MRI Proton Density Fat Fraction (MRI-PDFF) as reference standard.

**METHODS AND MATERIALS**

338 MAFLD patients were included in the research between April 2023 and March 2024, and they received the examination of UDFF, MRI-PDFF and laboratory tests. UDFF and MRI-PDFF examinations were performed in the right hepatic lobe. Five measurements of UDFF was collected and the median was recorded, which was compared with the median of the first three measurements as well as the first measurement. 35 patients underwent UDFF examination by two radiologists and the intra- and inter-observe consistency test was performed. The MRI-PDFF results were used to determine the stage of hepatic steatosis: S0, MRI-PDFF< 5%; S1, 5%=PDFF< 16.3%; S2: 16.3%=PDFF<21.7%; S3: PDFF=21.7%. The diagnostic performance of UDFF was evaluated and compared with other non-invasive methods. UDFF performance for hepatic steatosis was showed by the area under the receiver operating characteristic curve (AUC).

**RESULTS**

Intra-observer consistency test showed that the interclass correlation coefficient (ICC) was 0.988, and the inter-observe ICC was 0.965. Paired t-tests showed no statistically significant differences between the median of the first five measurements, the median of the first three measurements, and the first measurement (p all > 0.05). UDFF showed a significant positive correlation with MRI, with a Spearman correlation coefficient of 0.812 (p=0.000). The mean of UDFF in liver steatosis S0-S3 was 5.24±3.06, 13.23±6.42, 20.80±7.90, and 24.02±7.71, respectively. As the degree of steatosis increased, the udff values gradually rise. The difference between any two grades was statistically significant (p all <0.05), with the exception between S2 and S3 (p=0.322). The AUCs of UDFF for diagnosing =S1, =S2, and S3 were 0.927, 0.893, and 0.878, respectively.

**CONCLUSION**

UDFF reliably quantifies liver fat content and provides a accurate, noninvasive and convenient method for hepatic steatosis assessment.

**CLINICAL RELEVANCE/APPLICATION**

As a novel method, UDFF could provide reliable and accurate quantification of liver fat content, offering guidance for the degree evaluation and efficacy assessment of metabolic dysfunction-associated fatty liver disease

### PURPOSE

Bowel damage (BD) critically influences Crohn's disease (CD) prognosis. Gut microbiota and their metabolites play a crucial role in the pathogenesis of BD, while magnetic resonance enterography (MRE) serves as a valuable tool for assessing BD severity. This study aimed to unravel the connections between gut microbiota, metabolites, and MRE phenotypes of BD, with the ultimate goal of developing an optimal diagnostic model for BD by leveraging these biomarkers.

### METHODS AND MATERIALS

A prospective cohort of 230 CD patients were enrolled, who underwent MRE, fecal/blood metabolomic analysis using UPLC-MS/MS, and fecal 16S rRNA gene sequencing. Based on Lémann index (LI) evaluation, patients were categorized into BD (n=103) and non-BD (n=127) groups. We analyzed ten MRE features associated with BD and explored their associations with microbiota and metabolites through correlation and mediation analyses. Significant biomarkers were identified and further confirmed by a random forest algorithm with 10-fold cross-validation. Diagnostic models were constructed using selected gut microbiota, fecal/blood metabolites, and MRE features either independently or in combination, and their efficacy was evaluated using ROC analysis.

### RESULTS

Distinct microbiota, metabolites and MRE phenotypes were observed between CD patients with and without BD. Network graphing detailed the complex interplay among bacterial taxa, metabolites, and MRE phenotypes. Among various pathways, Prevotella_9 potentially contributed to perianal disease through serum PE(38:1). Significant multi-omic features related to BD were further identified, including three bacterial genera (e.g., [Ruminococcus] gnavus group), nine fecal metabolites (e.g., Citrulline), and eight serum metabolites (e.g., N-Acetylneuraminic acid), alongside seven MRE features (e.g., Penetration). The area under the curve (AUC) for the models was 0.620 (95% CI: 0.527-0.712) for microbiota, 0.678 (95% CI: 0.538-0.787) for fecal metabolites, and 0.663 (95% CI: 0.533-0.737) for serum metabolites; while MRE registered an AUC of 0.700 (95% CI: 0.617-0.782). Integrating all parameters in a comprehensive model yielded an improved AUC of 0.761 (95% CI: 0.685 - 0.833) ($P<0.05$).

### CONCLUSION

MRE phenotypes of BD are at least partially attributable to microbial and metabolite factors. The comprehensive model, which integrates macroscopic and microscopic information through simultaneous blood, fecal, and MRE examinations, offers a promising alternative tool for efficient diagnosis of BD in CD patients.

### CLINICAL RELEVANCE/APPLICATION

This study provides a multidimensional diagnostic tool for BD in CD by combining MRE, gut microbiota, and metabolites, minimizing the need for extensive clinical data.

## R3-SSGI18-2 A PROSPECTIVE MULTI-MODEL STUDY FOR COMPARISON OF THE DIAGNOSTIC PERFORMANCE OF MULTI-MODEL MOLECULAR IMAGING TO DETECT INTESTINAL FIBROSIS IN CROHN’S DISEASE

Shi-Ting Feng (*Abstract Co-Author*) Nothing to Disclose
Yang Di Wang (*Abstract Co-Author*) Nothing to Disclose

Zhoulei Li, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate and timely detection of intestinal fibrosis induced by Crohn's disease (CD) is imperative for effective clinical management, yet it remains an unmet need. Magnetization transfer MR Imaging (MTI) has been reported to offer high accuracy in detecting intestinal fibrosis. Recently, the utilization of fibroblast activating protein inhibitor (FAPI) PET/CT has emerged as a promising tool for assessing fibrosis. The diagnostic efficacy of different imaging technique (18F-FAPI and 18F-FDG PET/CT as well as MTI) in detecting intestinal fibrosis was compared with each other.

**METHODS AND MATERIALS**

22 rats were subjected to TNBS treatment for 2-4 weeks, simulating the development of fibrosis, then underwent multi-model quantitative imaging during one week. The standardized uptake values (SUVmean and SUVmeax) were calculated on both 18F-FAPI and 18F-FDG PET/CT scans, while the normalized magnetization transfer ratio (normalized MTR) was determined using MTI. Intestinal histological fibrosis was assessed. Ten patients with a total of 34 intestinal strictures were prospectively recruited and underwent the same imaging protocol.

**RESULTS**

In patients, the accuracy of FAPI uptake (AUCs=0.80-0.87, P=0.01) was comparable to that of MTI (AUCs=0.90-0.91, P=0.05), but superior to FDG uptake (AUCs=0.53-0.82, P=0.01-0.36) in distinguishing non-to-mild from moderate-to-severe fibrosis. In the early phase of the disease (rats treated until week 2), a stronger correlation was detected between fibrotic scores and FAPI uptake (SUVmean: R=0.69) compared to FDG uptake (SUVmean: R=0.17) and normalized MTR (R=0.52). In the late phase (rats treated until week 3 or 4), normalized MTR (R=0.93) exhibited stronger correlations with fibrotic scores than FAPI uptake (SUVmean: R=0.55) or FDG uptake (SUVmean: R=0.19). A strong influence of serve inflammation was detected on both FAPI and FDG uptake, which disturbed their efficiency in diagnosing fibrosis during late phase in patients with CD.

**CONCLUSION**

The 18F-FAPI PET/CT is comparable to MTI and superior to 18F-FDG in terms of characterizing intestinal fibrosis in CD. Notably, 18F-FAPI PET/CT enables accurately identifying early-stage intestinal fibrosis, surpassing the other two imaging modalities, warranting further investigation.

**CLINICAL RELEVANCE/APPLICATION**

18F-FAPI PET/CT is a highly sensitive imaging tool to accurately detect early intestinal fibrosis. Recommendations have been made for selecting non-invasive imaging techniques based on different situations of CD-induced intestinal fibrosis, aiming to improve CD patient management.

## R3-SSGI18-3 PREDICTION OF DISEASE PROGRESSION IN PATIENT WITH CROHN'S DISEASE BASED ON TIME-DEPENDENT DIFFUSION MRI COMBINED WITH MAGNETIZATION TRANSFER IMAGING

Luyao Wu (*Abstract Co-Author*) Nothing to Disclose
Xuehua Li II (*Abstract Co-Author*) Nothing to Disclose
Li Huang (*Abstract Co-Author*) Nothing to Disclose
Qingzhu Zheng (*Abstract Co-Author*) Nothing to Disclose
Shiting Feng, MD (*Abstract Co-Author*) Nothing to Disclose
Xiao Di Shen (*Abstract Co-Author*) Nothing to Disclose
Xinyue Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

Noninvasive evaluation of intestinal fibrosis in Crohn's disease (CD) is crucial for guiding management. Time-dependent diffusion MRI (TD-dMRI) has potential to map cellular characteristics; while magnetization transfer imaging (MTI) has been proven to quantify extracellular collagen. We aimed to evaluate the feasibility of TD-dMRI in detecting intestinal fibrosis and combined it with MTI to predict the risk of disease progression.

**METHODS AND MATERIALS**

This study prospectively enrolled 106 CD patients, with 13 of them later receiving surgery. TD-dMRI indices, including cell diameter, extracellular diffusivity, intracellular volume fraction, cellularity, and diffusivities with different effective diffusion times, were estimated with a two-compartment model. For patients who received surgery, the area ratio of myofibroblasts to fibroblasts was used to depict fibrotic cellular information and then correlated with TD-dMRI indices. Bowel normalized MT ratio (MTR)>0.71 was considered as high collagen deposition. All non-surgical patients were followed up for at least 6 months, unless the disease progressed. Disease progression referred to the development of penetration, strictures, or CD-related surgery.

**RESULTS**

In 45 bowel specimens from 13 surgical patients (lesions, n=22; surgical margins, n=23), TD-dMRI-derived cell diameter was highly correlated with the area ratio of myofibroblasts to fibroblasts (r=0.58; P<0.001). A cutoff value of 11 μm for cell diameter between diseased and normal specimens was obtained using ROC curve analysis. Cell diameter=11 μm indicated the dominance of pro-fibrotic phenotype cells. Based on cell diameter and normalized MTR, 93 non-surgical patients were divided into 4 groups (group1: low cell diameter, low normalized MTR; group2: high cell diameter, low normalized MTR; group3: high cell diameter, high normalized MTR; group4: low cell diameter, high normalized MTR). Group 3 had the highest disease progression rate (33.3%), followed by group 2 (20.0%), group 4 (10.8%), and group 1 (0%). In addition, multivariable Cox regression analysis indicated high cell diameter was the only significant risk factor for disease progression in this study (HR: 4.353; P=0.01).

**CONCLUSION**

TD-dMRI-derived cell diameter effectively characterizes fibrosis-associated cell features. Combing TD-dMRI with normalized MTR enables a comprehensive assessment of fibrosis, allowing prediction of disease progression.

**CLINICAL RELEVANCE/APPLICATION**

TD-dMRI-based microstructural mapping could noninvasively characterize the fibrosis-associated cell features in CD, and the combination with MTI showed promise for comprehensively evaluating the severity of fibrosis, thus accurately predicting disease progression.

## R3-SSGI18-4 ENHANCING RADIOLOGIST'S DETECTION: AN IMAGING-BASED GRADING SYSTEM FOR IDENTIFYING CROHN'S DISEASE IN CLINICALLY SUSPECTED INFLAMMATORY BOWEL DISEASE

Zhen Li, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yaqi Shen, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Ziman Xiong (*Presenter*) Nothing to Disclose

**PURPOSE**

To establish an imaging report and data system of inflammatory bowel disease (IBD-RADS) for the preliminary classification of Crohn's disease (CD) and ulcerative colitis (UC).

**METHODS AND MATERIALS**

This multicenter retrospective study included adult patients diagnosed with IBD and underwent CT enterography scans at three tertiary referral centers between January 2012 and May 2022. Patients were divided into derivation and validation cohorts. The intestinal and perianal inflammatory features were evaluated. Visceral fat information from CT images was extracted, including the ratio of visceral to subcutaneous fat volume (VSR), fat distribution, and attenuation values. The valuable indicators were screened out in the derivation cohort by binary logistic regression and receiver working curve (ROC) analysis to construct the IBD-RADS, which was tested in the validation cohort.

**RESULTS**

The derivation cohort included 606 patients (365 CD, 241 UC), and the validation cohort included 155 patients (97 CD, 58 UC). Asymmetric enhancement (AE) (OR = 88.87 [37.65, 209.78]; P < 0.001), perianal fistula (OR = 5.024 [2.154, 11.71]; P < 0.001) and VSR (OR = 1.579 [1.090, 2.287]; P = 0.02) were independent predictors of CD. VSR improved the efficiency of imaging signs (AUC: 0.929 vs. 0.901; P < 0.001), with a threshold greater than 0.97 defined as visceral fat predominance (VFP). In IBD-RADS, AE was the major criterion, VFP and perianal fistula were auxiliary criteria, and inter-intestinal fistula and limited small bowel disease were special favoring items as their 100% specificity. Grade 3 to 5 correctly classified approximately 80% of CD patients (derivation: 78.6% (287/365), validation: 86.6% (84/97)), and more than 97% of those were eventually diagnosed with CD (derivation: 97.3% (287/295), validation: 97.7% (84/86)).

**CONCLUSION**

IBD-RADS can help radiologists distinguish between CD and UC in patients with suspected IBD.

**CLINICAL RELEVANCE/APPLICATION**

The IBD-RADS proposed in the present study is helpful for radiologists to make a preliminary classification, to shorten the diagnosis time of Crohn's disease.

## R3-SSGI18-5 MRI NEUROPHENOTYPE REFLECTING BRAIN-GUT INTERACTIONS TO PREDICT INTESTINAL DISEASE PROGRESSION IN PATIENTS WITH CROHN'S DISEASE

Xuehua Li II (*Abstract Co-Author*) Nothing to Disclose
Yang Di Wang (*Abstract Co-Author*) Nothing to Disclose
Lili Huang, MD (*Abstract Co-Author*) Nothing to Disclose
Shiting Feng, MD (*Abstract Co-Author*) Nothing to Disclose
Ruonan Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

There is considerable recent interest in the role of brain-gut axis in the pathogenesis and manifestations of Crohn's disease (CD). We developed a multimodal neuroimaging-based model to characterize the neurophenotype of CD patients and predict intestinal disease progression, using multi-omics data to demonstrate its validity.

**METHODS AND MATERIALS**

This prospective study enrolled 109 CD patients who underwent baseline tests (including multimodal neuroimaging, psychological scales, MR enterography, ileocolonoscopy) and fecal/blood samples collection within one week. The neurophenotype of patients with different intestinal inflammation levels was characterized using a radiomics model, developed from 13 out of 13,870 neuroimaging features. This neurophenotype in predicting disease progression during follow-up was evaluated using Kaplan-Meier curves and Cox regression analysis. Multi-omics data (including fecal microbiome, fecal/blood metabolomics, intestinal/blood-brain-barrier permeability, and blood neurotransmitter) were used to elucidate how this neurophenotype reflecting brain-gut interactions.

**RESULTS**

The model enabled accurate characterization of neurophenotypes in patients with different intestinal inflammation levels in training and test cohorts (AUC=0.824-0.842, both P<0.05). Neurophenotype was the most important predictor of disease progression (HR=29.05, P=0.033), surpassing psychological traits (HR=0.95-1.09, all P>0.05). Multi-omics analysis revealed that elevated intestinal inflammation was correlated with increased intestinal permeability and specific gut microbiota (e.g., Enterococcus) and metabolites (e.g., caproic acid), which collectively contributed to high-risk neurophenotype (all P<0.05). High-risk neurophenotype subsequently associated with intestinal disease progression by establishing correlations with six blood neurotransmitters (e.g., tryptophan) (all P<0.05).

**CONCLUSION**

The neurophenotype varies among CD patients with different intestinal inflammation levels and can predict intestinal disease progression. Multi-omics data offer biological evidence to support its validity.

**CLINICAL RELEVANCE/APPLICATION**

Our neurophenotype characterization model effectively illuminates these brain changes and accurately stratifies their neurophenotypic risk, paving the way for the implementation of new strategies to initiate transformative advancements.

### PURPOSE

Establish the feasibility of a single-acquisition 3D quantitative and qualitative multi-contrast, zero echo time (ZTE) based sequence for rapid clinical face MR imaging.

### METHODS AND MATERIALS

This prospective study included two aims: 1) phantom validation of T1 and T2 quantitative relaxometry map accuracy; 2) IRB-approved and HIPAA-compliant application of the sequence in human patients undergoing clinical face MRI. The sequence combines T2 and T1 magnetization preparation with 3D ZTE segmented readout. The obtained raw data are Deep Learning (DL) reconstructed into five echo images of variable contrast weighting which are then fitted into quantitative T1 and T2 parameter maps. For enhanced visualization of bone anatomy, the PD-weighted ZTE was inverted (using an inverse gray scale). Quantitative T1 and T2 accuracy and reproducibility was assessed using the NIST/ISMRM phantom. In clinical MRI examinations, the sequence was scanned in coronal orientation with 1mm isotropic resolution, 5mins01sec scan time, and prior to intravenous contrast injection. All clinical examinations were performed on a 3T GE Premier system with a 21-channel head and neck coil.

### RESULTS

Quantitative T1 and T2 ROI measurements had excellent accuracy and precision on par with other parameter mapping methods. SNR was similar or favorable to SNR of the clinical T1- and T2-weighted images (study sequence echo 3 SNR: 81.6 for muscle and 122.6 for fat; clinical 3D T1 TSE SNR: 25.7 for muscle and 123.4 for fat). Images were of visually adequate clinical quality and nicely showed pathology, including a left submandibular sialocele.

### CONCLUSION

The study sequence provides similar SNR and similar spatial resolution compared with current standard-of-care face MRI with the benefits of a substantially shortened examination, addition of quantitative parameters that could serve as biomarkers, and the addition of bone images that could potentially suffice for bone evaluation in place of CT.

### CLINICAL RELEVANCE/APPLICATION

A single-acquisition 5-minute, 1 mm isotropic, comprehensive clinical sinus MRI examination including bone images appears feasible pending further validation.

## R3-SSHN03-3 QUANTITATIVE HIGH-DEFINITION MICROVASCULATURE IMAGING FOR DIFFERENTIATION OF SMALL CHOROIDAL MELANOMAS FROM BENIGN NEVI

Mostafa Fatemi, PhD, PhD (*Abstract Co-Author*) Nothing to Disclose
Azra Alizad, MD (*Abstract Co-Author*) Nothing to Disclose
Nicholas B. Larson, PhD (*Abstract Co-Author*) Nothing to Disclose
Shaheeda Adusei (*Abstract Co-Author*) Nothing to Disclose
Lauren Dalvin (*Abstract Co-Author*) Nothing to Disclose
Soroosh Sabeti, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate differentiation of early-stage (thickness=2mm) melanoma cases from choroidal nevi is of high clinical importance. The purpose of this study is to determine the effectiveness of a contrast-free ultrasound-based technique called high-definition microvasculature imaging (qHDMI) in discriminating malignant from benign small intraocular tumors.

**METHODS AND MATERIALS**

An in-vivo study approved by our institutional review board (IRB) and compliant with Health Insurance Portability and Accountability Act, consisting of 36 participants with suspicious intraocular masses was conducted. Diagnoses made based by ocular oncologist through clinical evaluation of the results of multimodal imaging were used as the gold standard reference. Microvasculature images were generated through post-processing of the data, in a series of clutter filtering, denoising, and vessel enhancement steps. The qHDMI biomarkers extracted included number of vessel segments (NV), number of branch points (NB), vessel density (VD), Murray's deviation (MD), fractal dimension (FD), diameter (D), bifurcation angle (BA) and tortuosity (t). Distributional differences across the malignant and benign cases were tested using a non-parametric Wilcoxon rank-sum test and statistical significance was assumed for biomarkers with p-values $< 0.05$.

**RESULTS**

Out of the 36 lesions (from 36 participants, 21 male and 15 female) included in the study, 21 were clinically diagnosed as choroidal melanoma (malignant) and 15 were determined to be choroidal nevus (benign). Participants with malignant lesions had their age ranging from 30 to 86 years with mean age ± standard deviation of 60.48±15.75 years. Ages of participants with benign masses ranged from 34 to 89 years with a mean ± standard deviation of 67.47±14.31 years. The mean thickness of benign and malignant masses was 1.70±0.40 mm and 3.81±2.63 mm, respectively. Five qHDMI biomarkers exhibited significant distributional differences between the two groups. These biomarkers and their corresponding p-values are vessel density (p-value = 0.011), number of vessel segments (p-value = 0.003), number of branch points (p-value = 0.003), maximum tortuosity (p-value = 0.002), and fractal dimension (p-value = 0.001).

**CONCLUSION**

The proposed qHDMI technique can be utilized as a complementary tool for characterization of small ocular tumors and early detection of choroidal melanoma.

**CLINICAL RELEVANCE/APPLICATION**

In an extremely sensitive organ such as eye, where biopsies are accompanied by high-morbidity, the proposed method can noninvasively and objectively diagnose small ocular melanomas that could lead to better patient outcome.

## R3-SSHN03-6 PROGNOSTIC VALUE OF DIFFUSION RELAXATION CORRELATED SPECTROSCOPIC IMAGING IN IDENTIFYING CERVICAL LYMPH NODE METASTASIS IN ORAL TONGUE SQUAMOUS CELL CARCINOMA

Yongming Dai (*Abstract Co-Author*) Nothing to Disclose
Yingwei Wu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Siyu Li (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine the feasibility of DR-CSI to predict the pathological T (pT) stage and cervical lymph node metastasis (CLNM) in oral tongue squamous cell carcinoma (OTSCC).

**METHODS AND MATERIALS**

Patients with a new diagnosis of OTSCC were enrolled from January 2023 to December 2023. Preoperative head and neck MR scan including DWI and DCE-MRI were performed. DR-CSI scan conducted by multi b-values and multi-TE based diffusion imaging were acquired for all patients. Tumor dimension features and MRI-based depth of invasion (DOI) were measured. For each patient, a D-T2 spectrum was fitted and segmented into 5 compartments, and the volume fractions VA, VB, VC, VD, VE were obtained. The tumor-stroma ratio (TSR) was determined based on HE specimens. All MRI and histopathologic metrices were compared between CLNM and non-CLNM OTSCCs. The relationship between Vi fraction or TSR to CLNM was calculated by Spearman's correlation test.

**RESULTS**

58 patients (age: 54.3±13.9 years; 38 male) with OTSCC were evaluated; 28 in CLNM group while other 30 in non-CLNM group. Max tumor diameter(MTD) and MRI-based DOI was larger in CLNM group than that in non-CLNM group (MTD 3.4±1.2cm vs. 2.6±1.0cm, p=0.006, DOI:11.6±1.2mm vs. 7.3±1.0mm, p<0.01). CLNM group exhibited increased VB(CLNM vs non-CLNM, 29.9±12.2% vs 19.0±12.6%, p<0.01), decreased VA(CLNM vs non-CLNM, 30.3±16.7% vs 41.5±22.8%, p<0.05) and decreased VD(LNM vs non-LNM, 24.0±10.1 vs 17.1±13.2, p<0.01). VB, VD, MTD and high TSR were independent preoperative factors for CLNM.VB+VD+MTD model yielded an excellent performance in predicting CLNM (area under AUC:81.5%). VB was positively correlated with TSR (p<0.01, with correlation coefficients of 0.71(95% CI:0.62-0.83).

**CONCLUSION**

DR-CSI can detect microstructural changes between CLNM and non-CLNM groups. VB was correlated with Higher TSR, offering potential for subtype identification in OTSCC. DR-CSI may serve as a useful imaging biomarker for tailoring individual treatment regimens in OTSCC.

**CLINICAL RELEVANCE/APPLICATION**

Subclinical lymph node (LN) metastasis is associated with poor survival outcome in oral tongue squamous cell carcinoma (OTSCC), and a subset of patients with aggressive disease experiences treatment failure. DR-CSI has emerged to discern sub-voxel level environments by resolving the entangled MR signal of diffusion and relaxation time weights, offering useful information for distinguishing intra-tumor components such as TSR. DR-CSI would serve as a useful imaging modality to identify subtypes of OTSCC and tailor individual treatment regimens in OTSCC.

## R3-SSIN07-1 INITIAL SPEED AND ACCURACY MEASUREMENTS OF 3D PRINTED MEDICAL PARTS USING A NEW-TECHNOLOGY DESKTOP INVERTED VAT POLYMERIZATION PRINTER

Summer J. Decker, PhD (*Abstract Co-Author*) Nothing to Disclose
Prashanth Ravi, PhD (*Abstract Co-Author*) Nothing to Disclose
Aisling McEleney, MPH (*Abstract Co-Author*) Nothing to Disclose
Jonathan M. Ford, PhD (*Abstract Co-Author*) Nothing to Disclose
Rayna Debellevue (*Abstract Co-Author*) Nothing to Disclose
Frank J. Rybicki III, MD, PhD (*Presenter*) Medical Director, Imagia Cybernetics Inc

### PURPOSE

Patient-specific 3D printing from medical images is time consuming, and faster 3D printing will save resources. This project tests the hypothesis that 3D printing with a new-technology desktop inverted vat polymerization printer is faster and more accurate than a commonly used legacy printer.

### METHODS AND MATERIALS

This initial evaluation tests a new-technology (Form 4B, Formlabs, Sommerville, MA) that incorporates masked liquid crystal display based optics versus a legacy printer (Form 3B) that incorporates laser-based optics. Using three new-technology printers, five previously validated clinical anatomic models were 3D printed with a 15mm cube; the same surface mesh files were also printed once with the legacy printer. All print, wash, and cure settings were harmonized for the new-technology and legacy printers. For each patient, there was one 3D printed part. Four of the 5 parts were printed in Clear (V5, Form 4B and V4, Form 3B) resin with 0.05mm layers; the fifth (cardiac - flexible) model was printed in Elastic (50A V2, Form 4B and 50A V1, Form 3B) with 0.1mm layers. Print time, material consumption, and post-processing (wash, support removal, post-cure) times were recorded; accuracy was meticulously measured using calipers.

### RESULTS

The mean print time (hr:min) for the new-technology printer was 4:44 versus 12:19 for the legacy technology. For the new-technology compared to the legacy technology, for the models, the maximum deviation among the parts was 0.387mm (new) versus 1.06mm (legacy) on the same part (a mandible 3D printed to pre-bend plates); for all 5 parts, the mean absolute error was 0.77% (new) versus 2.3% (legacy), p=0.0087, unpaired t-test. For the 15mm cube, there was no significant difference in the mean absolute error along any of the three dimensions. Material consumption for the new-technology printer (mean 133ml) was not significantly different than the legacy technology (126ml). Similarly, the mean post-processing time for the new technology printer (30 min) was not significantly different from that of the legacy technology (38 min).

### CONCLUSION

This initial study of a new-technology desktop inverted vat polymerization printer shows an acceleration of 2.5x (250% faster) when comparted to its precursor 3D printer commonly used to fabricate medical devices. The accuracy of the parts is improved roughly 3x. The rationale for these improvements is a liquid crystal display with integrated heating and temperature sensors. Further research is warranted to validate these initial measurements across a larger cohort of 3D printed parts used for patient care.

### CLINICAL RELEVANCE/APPLICATION

Improved print speed with more accurate parts is expected to improve clinical 3D printing throughput and efficiency.

## R3-SSIN07-2 ROBUST SEGMENTATION OF 40 DIFFERENT ORGANS IN MAGNETIC RESONANCE IMAGING

Lina Xu (*Abstract Co-Author*) Nothing to Disclose
Lisa C. Adams, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Marcus R. Makowski (*Abstract Co-Author*) Nothing to Disclose
Alessa Hering, PhD (*Abstract Co-Author*) Nothing to Disclose
Hartmut Hantze (*Abstract Co-Author*) Nothing to Disclose
Mathias Prokop, MD, PhD (*Abstract Co-Author*) Speakers Bureau, Canon Medical Systems Corporation;Research Grant, Siemens AG;Speakers Bureau, Siemens AG
Keno K. Bressem, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To introduce a deep learning model capable of multi-organ segmentation in MRI scans, offering a solution to the current limitations in MRI analysis due to challenges in resolution, standardized intensity values, and variability in sequences.

**METHODS AND MATERIALS**

The model was trained on 1,200 manually annotated MRI scans from the UK Biobank and 221 in-house MRI scans, leveraging cross-modality transfer learning from CT segmentation models. A human-in-the-loop annotation workflow was employed to efficiently create high-quality segmentations. The model's performance was evaluated on the AMOS22 dataset containing 60 MRI scans. Dice Similarity Coefficient (DSC) was used to assess segmentation accuracy. The model will be open sourced.

**RESULTS**

The model showcased high accuracy in segmenting well-defined organs, achieving Dice Similarity Coefficient (DSC) scores of 0.932 and 0.934 for the right and left lungs, respectively, and 0.919 for the heart. It also demonstrated robustness in organs like the liver (DSC: 0.875) and kidneys (DSC: 0.882 left, 0.909 right), which present more variability. However, segmentation of smaller and complex structures such as the portal and splenic veins (DSC: 0.548) and adrenal glands (DSC: 0.596 left, 0.648 right) revealed the need for further model optimization.

**CONCLUSION**

The proposed model is a robust, tool for accurate segmentation of 40 anatomical structures in MRI and CT images. By leveraging cross-modality learning and interactive annotation, the model achieves strong performance and generalizability across diverse datasets, making it a valuable resource for researchers and clinicians.

**CLINICAL RELEVANCE/APPLICATION**

The model can facilitate the extraction of quantitative imaging biomarkers, improve diagnostic algorithms, and support treatment planning by providing detailed anatomical context in MRI. Its open-source availability will accelerate research on MRI-based biomarkers and AI diagnostic systems.

## R3-SSIN07-3 SEGMENTING TUMORS ON 3D AUTOMATED BREAST ULTRASOUND (ABUS) WITH SELF-CONFIGURING HYBRID TRANSFORMER

Chulhong Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Chiho Yoon (*Abstract Co-Author*) Nothing to Disclose
Namkug Kim, PhD (*Abstract Co-Author*) Stockholder, Anymedi, Inc
Jongjun Won, BS (*Abstract Co-Author*) Nothing to Disclose
Hyunseok Lim, MS (*Abstract Co-Author*) Nothing to Disclose
Hyunsu Jeong, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

To propose a self-configuring hybrid transformer to segment tumors on 3D automated breast ultrasound (ABUS) by automatically creating the network for a large model in small graphic processing unit (GPU) memory.

**METHODS AND MATERIALS**

A total of 200 GE Invenia ABUS scans with breast tumors in TDSC-ABUS 2023 public dataset in MICCAI 2023 challenge with anonymized patient information were used. A tumor boundary was labeled by a breast clinic doctor with 5-year experiences. Our network mainly consists of hybrid transformer blocks with an efficient self-attention module by reducing the dimension of features and a channel-cross gate that considers long-range dependency among channels. In addition, multi-task learning was performed by classifying whether the patch includes tumors or not. All configurations (the size of model, the degree of dimensional reduction, etc) on the hybrid transformer were automatically created and evaluated. Quantitative evaluation was performed on dice similarity coefficient (DSC) and precision. Comparing our network with the conventional models, paired T-test was used. Segmentation results were analyzed according to whether the tumor size was T1 (=2cm ) or more advanced (>2cm ) stages. All experiments are conducted on five-fold cross validations with training and validation (160 scans) and test sets (40 scans).

**RESULTS**

Mean tumor size for the dataset was 2.5cm± 1.3cm. 80 and 120 cases were included in the T1 and more advanced T stages, respectively. In the five-fold cross validations, DSCs of Unet, SwinUNet, nnUNet, and our network were 33.90% (95% confidence interval, CI: 29.65 - 38.15), 32.54% (95% CI: 29.11 - 35.96), 54.70% (95% CI: 50.77 - 58.62), 58.26% (95% CI: 54.03 - 62.5), respectively. Our model significantly outperformed UNet and SwinUNet ($P<0.001$), except nnUNet ($P=0.185$). Our network significantly outperformed the other networks with precision of 62.71% (95% CI: 58.12 - 67.30). Our model showed better DSC (mean: 42.26%, 95% CI: 34.75 - 49.77), precision (mean: 42.16%, 95% CI: 34.19 - 50.12) at T1 stage, and DSC (mean: 68.93%, 95% CI: 64.96 - 72.90), precision (mean: 76.41%, 95% CI: 72.48 - 80.34)) at more advanced T stage than other models.

**CONCLUSION**

Our model maximizes the capability of self-attention for the characteristics of 3D ABUS data. Our network with self-attention for the characteristics of 3D ABUS data is relatively robust to the size variance of tumors by quantitatively better results than the other models in both T1 and more advanced stages.

**CLINICAL RELEVANCE/APPLICATION**

Our model could be expected to improve the performance of quantification of tumor volumetry and computer-aided diagnosis for reducing radiologists' fatigue by reducing false positive rates and automated segmentation.

## R3-SSIN07-4 ASSESSING THE EFFECTIVENESS OF AN INTEGRATED QUALITY ASSURANCE PROTOCOL ON LUNG CT SEGMENTATION ACCURACY ACROSS A LARGE MULTICENTER STUDY

Thomas J. Vogl, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ricarda Elisabeth Fischbach (*Abstract Co-Author*) Nothing to Disclose
Andreas Bucher, MD (*Abstract Co-Author*) Travel support, Bayer AG Travel support, Guebert SA Travel support, Pharmacept
Eric Frodl, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the impact of a structured quality assurance protocol (QAP) on the accuracy and consistency of lung CT scan segmentations in a multicenter setting. Our objective was to monitor segmentation consistency and accuracy using an integrated QAP developed for large multicenter datasets in the extraction of image-based biomarkers from chest CT studies.

**METHODS AND MATERIALS**

In this retrospective multicenter study, part of the nationwide RACOON project, we enrolled 75 readers from 36 sites, including all university hospitals in the country. Each reader performed voxel-wise segmentation (labels: ground-glass opacity [GGO], consolidation [CONS]) on chest CT image series. Participation in the QAP took place in three rounds, corresponding to progress milestones in each reader's worklist (R1: 0%, R2: 50%, R3: 100%). Segmentations were evaluated using an integrated analysis workflow within our annotation software, focusing on accuracy and inter-reader consistency. Quantitative evaluation was performed using Sụrensen's Dice Coefficients (SDC) and Root-Mean-Square Distance (RMSD). A structured survey assessed the readers' experience in each round. A robust linear mixed effects model was used for statistical analysis.

**RESULTS**

From July 2021 to June 2022, 2961 image series were labeled across the entire training dataset, of which 519 were specifically analyzed within our QAP (R1: 205, R2: 171, R3: 143). Most readers (57%) had minimal experience with segmentation (intermediate: 25%, expert: 17%). We observed significant improvements in segmentation accuracy for both labels, with mean SDC increasing from 0.376±0.214 to 0.584±0.340 for GGO ($p < 0.0001$) and from 0.313±0.301 to 0.556±0.311 for CONS ($p < 0.0001$). RMSD improvements were also significant for GGO (from 8.18±3.28 to 6.04±6.47, $p < 0.0001$) and CONS (from 4.83±2.25 to 3.96±4.25, $p = 0.0009$). Mean reading time decreased by 25% (from 96.6±77.5 min to 78.01±65.9 min, $p = 0.02558$). There was no significant correlation between readers' prior segmentation experience and their quality improvements for GGO ($p = 0.9622$) and CONS ($p = 0.9685$).

**CONCLUSION**

Implementing a comprehensive quality assurance process can provide critical metrics on the reliability of training datasets, reducing reliance on full expert review. Our QAP, integrated into the annotation software, supports systematic monitoring of training success across different levels of reader experience.

**CLINICAL RELEVANCE/APPLICATION**

In multicenter studies, a dedicated QAP efficiently ensures dataset quality and provides critical metrics that reflect reader accuracy.

## R3-SSIN07-5 IMPROVING FOUNDATION MODELS WITH DEEP LAYER ADAPTERS FOR MEDICAL IMAGE SEGMENTATION

Matthew S. Brown, PhD (*Abstract Co-Author*) Nothing to Disclose
Dan Ruan, PhD (*Abstract Co-Author*) Nothing to Disclose
Jin Kim, BEng, MEng (*Presenter*) Nothing to Disclose

**PURPOSE**

Foundation models, such as the Segment Anything Model (SAM), have shown strong general performance in image segmentation tasks. However, the optimal approach to adapting these models for domain-specific applications, such as medical image segmentation, remains an open question. In this work, we investigate the effectiveness of introducing adapters to deep layers of foundation models for medical image segmentation.

**METHODS AND MATERIALS**

Experiments were conducted using the VinDr-RibCXR dataset, consisting of 245 Chest X-ray images focusing on rib segmentation. The dataset was split into a training set of 196 images and a validation set of 49 images. ViT-B and ViT-H architectures were employed as backbones for the SAM-Adapter model, which adds fully-connected adapters as inputs to the transformer blocks. Models were trained for 50 epochs using a batch size of 2, the AdamW optimizer, and IoU as the loss function. The number of adapters, starting from the deepest blocks, was systematically varied to investigate their impact.

**RESULTS**

For the ViT-B architecture (12 transformer blocks), performance plateaued with adapters at the 7 deepest blocks, with an F1 score of 0.824. This surpassed the no-adapter baseline of 0.777 and the full-adapter configuration of 0.821. For the ViT-H architecture (32 transformer blocks), performance plateaued with adapters at the 20 deepest blocks, with an F1 score of 0.847. This surpassed the no-adapter baseline of 0.770 and the full-adapter configuration of 0.837.

**CONCLUSION**

Adding adapters to the deepest 60% of layers in both ViT-B and ViT-H architectures led to the most improved performance compared to the baseline and the full-adapter configuration. This finding highlights the importance of infusing domain-specific information into the SAM foundation model for specific medical image segmentation tasks and shows that adapters can be focused on the deeper layers to reduce the training burden and model size.

**CLINICAL RELEVANCE/APPLICATION**

Foundation models such as Segment Anything Model (SAM) require refinement for medical image segmentation if they are to provide automation and improve clinical workflows and patient care. This study investigates an adapter approach and provides insights into the benefits of adding adapters to the deeper layers only, thus reducing the training burden and model size. Further research is needed to validate these findings across a broader range of medical imaging tasks, datasets, and foundation models.

## R3-SSIN07-6 ENHANCED CHOROID PLEXUS SEGMENTATION WITH 3D UX-NET AND ITS ASSOCIATION WITH DISEASE PROGRESSION IN MULTIPLE SCLEROSIS

Xiaohua Wang (*Abstract Co-Author*) Nothing to Disclose
Li Yongmei, PhD (*Abstract Co-Author*) Nothing to Disclose
Qi Hao (*Presenter*) Nothing to Disclose

**PURPOSE**

The choroid plexus (CP) is suggested to be closely associated with the neuroinflammation of multiple sclerosis (MS). We aim to develop a reliable deep learning (DL) model for the automatic segmentation of CP and further validate its clinical significance in MS.

**METHODS AND MATERIALS**

The 3D UX-Net model (3D U-Net used for comparison) was trained and validated on a cohort of 216 relapsing-remitting MS (RRMS) patients and 75 healthy subjects. Among these, 53 RRMS with baseline and 2-year follow-up scans formed an independent internal test set (dataset1b). Another 58 RRMS from multi-center data served as an external test set (dataset2). Dice coefficient was computed to assess segmentation performance. Compare the correlation of CP volume segmented using 3D UX-Net and manual methods with clinical outcomes. Disability and cognitive function in MS were assessed using the expanded disability status scale (EDSS) and symbol digit modalities test (SDMT).

## RESULTS

The 3D UX-Net model achieved Dice coefficients of 0.875 and 0.870 for CP segmentation on dataset1b and dataset2, respectively, outperforming 3D U-Net's scores of 0.809 and 0.601. Furthermore, CP volumes segmented by the 3D UX-Net model aligned consistently with clinical outcomes compared to manual segmentation. In dataset1b, both manual and automatic segmentation revealed a significant positive correlation between normalized CP volume (nCPV) and EDSS score at baseline($r = 0.285/0.287$, $p = 0.045/0.044$) and a negative correlation with SDMT score ( $r = -0.331/-0.329$, $p = 0.020/0.021$). Similar correlation with EDSS score was found in dataset2 ($r = 0.337/0.346$, $p = 0.021/0.017$). Meanwhile, in dataset1b, both manual and automatic segmentation revealed a significant increase in nCPV from baseline to follow-up ($p < 0.05$). The increase of nCPV was more pronounced in patients with disability worsened compared to stable patients for both manual ($0.50 \pm 0.43$ vs $0.14 \pm 0.30$, $p = 0.023$) and automatic segmentation ($0.44 \pm 0.31$ vs $0.15 \pm 0.26$, $p = 0.018$). Disease-modifying therapy (DMT) patients exhibited a significantly lower nCPV increase compared to untreated patients for both manual segmentation ($0.13 \pm 0.36$ vs $0.38 \pm 0.31$, $p = 0.004$) and automatic segmentation ($0.13 \pm 0.25$ vs $0.34 \pm 0.33$, $p = 0.004$).

## CONCLUSION

The 3D UX-Net model demonstrated outstanding segmentation performance for the CP, yielding consistent results in clinical investigations compared to manual segmentation in MS.

## CLINICAL RELEVANCE/APPLICATION

The 3D UX-Net model exhibited excellent performance for choroid plexus (CP) segmentation on T1-weighted images of multiple sclerosis (MS), and the CP volume obtained can serve as an imaging marker for disease progression and post-treatment monitoring in patients with MS.

### PURPOSE

Cancer and cancer treatments induce profound depletion of serum estrogen levels and can lead to an increased risk of vertebral fractures (VF). This study aimed to evaluate the performance of artificial intelligence (AI) in detecting vertebral fractures in cancer patients compared with radiological assessment. The secondary objective was to determine to what extent the detection of these VF, particularly for severe fractures, could have modified treatment management by offering an interventional radiology procedure.

### METHODS AND MATERIALS

Chest, abdominal and pelvis CT follow-up exams acquired from September to December 2023 for adult patients treated for stage IV cancer were retrospectively reviewed to evaluate the performance of an AI tool, CINA-VCF, to detect incidental VF. The AI tool quantifies intra-vertebral height loss and height loss relative to neighboring vertebrae. VF were categorized into three stages according to the degree of height loss: grade 1 with a loss of 20-25%; 26-40% for grade 2 and > 40% for grade 3. Grade 3 were considered as severe fractures. AI also calculated the mean value of L1 trabecular attenuation using a fully automated tool on healthy L1 vertebrae - to estimate bone mineral density and identify patients at risk of osteoporosis. We also collected relevant demographic and clinical information such as age, sex, type of cancer, type of treatment, bone metastatic status, and spinal treatment history. Two expert interventional radiologists in cancer treatment (IR1 and IR2), with over 10 and 2 year's experience respectively, assessed whether or not they would have treated severe fractures with vertebroplasty.

### RESULTS

We included 1501 patients over a three-month period. Among these patients, AI detected VF in 501, with 436 true positives (TP) and 65 false positives (FP). The Predictive Positive Value was 87%. 51 % of patients were at risk of osteoporosis and 32 % had vertebral metastasis. 81 % of fractures detected by the AI tool had not been described on the initial radiological report, including 10 severe fractures, with 9 requiring an interventional treatment. Overall, based on expert opinion, 89.6 % of severe fractures had an indication for cementoplasty.

### CONCLUSION

AI detects more incidental VF than radiologists in cancer patients, including severe VF that, according to expert opinion, could have benefited from specific management.

### CLINICAL RELEVANCE/APPLICATION

AI could assist radiologists to detect more incidental vertebral fractures in adult cancer patients, optimizing timely treatment and reducing associated morbidity and economic burden. Automated assessment of L1 trabecular attenuation offers potential for osteoporosis screening, facilitating early identification of at-risk individuals.

## R3-SSMK11-2 ARTIFICIAL INTELLIGENCE MEASURES COBB ANGLES WITH HIGH ACCURACY

Ali Guermazi, MD, PhD (*Abstract Co-Author*) Consultant, Novartis AG;Consultant, Pfizer Inc;Consultant, AstraZeneca PLC;Consultant, Merck KGaA;Consultant, TissueGene, Inc;Consultant, Regeneron Pharmaceuticals, Inc;Shareholder, Boston Imaging Core Lab, LLC
Andrew J. Kompel, MD (*Abstract Co-Author*) Nothing to Disclose

Boston Center (*Abstract Co-Author*) Nothing to Disclose
Daichi Hayashi, MD, PhD (*Abstract Co-Author*) Author with royalties, Wolters Kluwer nv
Jeanne Ventre, PhD (*Abstract Co-Author*) Researcher, GLEAMER
Nor-Eddine Regnard, MMed (*Presenter*) Founder, GLEAMER;Officer, GLEAMER;Stockholder, GLEAMER

**PURPOSE**

Radiographic Cobb angles are routinely measured by radiologists, orthopedic surgeons, and pediatricians treating patients with spinal scoliosis. Although it is a relatively simple task, repetitive Cobb angle measurement on a large number of radiographs can be tedious for human readers. Accordingly, artificial intelligence (AI) with its ability to automate angles' measurements, can be valuable. Consequently, our study aims to evaluate the accuracy and reliability of an AI-based software (BoneMetrics, Gleamer) in automatic Cobb angle measurements using full spine radiographs.

**METHODS AND MATERIALS**

The radiology reports of 400 full spine radiographs of patients =4 years of age were screened using a Natural Language Processing algorithm to identify the studies performed for Cobb angle measurements. Two US board-certified experienced musculoskeletal radiologists and one US board-certified experienced orthopedic surgeon independently annotated Cobb angles exceeding 7°, and indicated the curves' location as either proximal thoracic (apices between T3 and T5), main thoracic (apices between T6 and T11), or thoraco-lumbar (apices between T12 and L4). If at least two annotators agreed on the number of coronal curves, their respective locations, and the difference between the corresponding curves was less than 8°, then the ground truth was defined as the mean of their measurement. Otherwise, the radiograph was reviewed by the three annotators in consensus.The AI used was BoneMetrics (Gleamer), an automated image-processing software for conventional and EOS radiographs. The software includes a deep learning algorithm that detects key points used for the computation of the Cobb angles. The AI was evaluated against the manual annotation with the mean absolute error (MAE) for the major Cobb angle and the minor ones.

**RESULTS**

A total of 345 patients were included in the study (age: 33±24 years, range: 4-85 years, 221 women): 179 pediatric (< 22 years old), and 166 adult patients. 53 cases were reviewed in consensus. The MAE of the AI for the main Cobb angle was 2.6° (95% CI: [2.0; 3.3]). For the subgroup of pediatric patients, the MAE was 1.9° (95% CI: [1.6; 2.2]) versus 3.3° (95% CI: [2.2; 4.8]) for adults with no significant statistical difference (p=.09). The MAE for the minor angles was 2.8° (95% CI: [2.3; 3.3]).

**CONCLUSION**

The AI predicted the Cobb angle of scoliotic patients with high accuracy regardless of patients' age. The main limitation was that one radiograph was not processed by the AI due to low confidence in key point placement.

**CLINICAL RELEVANCE/APPLICATION**

AI demonstrates accuracy in measuring Cobb angles for scoliosis assessment across various age groups, offering a prospective support to physicians in busy clinical setting.

## R3-SSMK11-3 AI GENERATED SYNTHETIC STIR IMAGING IN THE LUMBAR SPINE

Zenas Igbinoba, MD (*Abstract Co-Author*) Nothing to Disclose
Ek Tsoon Tan, PhD (*Abstract Co-Author*) Research Grant, General Electric Company Research Grant, Siemens AG Research Grant, Medtronic Inc Research Grant, AMAG Pharmaceuticals
Mark Fontana (*Abstract Co-Author*) Nothing to Disclose

Alice Santilli, MSc, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Generative adversarial networks (GANs) can be used to generate MRI series to allow for faster acquisitions with less opportunity for motion artifacts while lowering costs. This study uses a continuous dataset to synthetically create STIR series from T1 and T2 sequences and evaluates the models both mathematically and using radiology experts.

**METHODS AND MATERIALS**

Sagittal T1, T2, and STIR images were extracted from lumbar MRIs from patients over a three-month period and randomly divided into a training, validation, and testing sets. No patients were excluded, including patients with and without spine surgery, spinal instrumentation, and scoliosis. A Pix2Pix GAN backbone was optimized using the training and validation sets to select appropriate loss function and model hyperparameters. The optimal model was then used to generate a synthetic STIR volume for 100 test patients. These volumes, real and synthetic, were assessed by three radiologists with expertise in musculoskeletal imaging and neuroradiology. Each radiologist was blinded to the imaging technique and reviewed all volumes, divided into two sessions, with a two week wash out period between them. Radiologists evaluated image quality, degree of motion artifacts, confidence in whether the evaluated image was real or synthetic, and whether a short list of pathologies existed in the inspected volume.

**RESULTS**

The dataset was comprised of 1817 examinations acquired sequentially. Of the 100 test set patients, radiologists were able to tell a synthetic volume from a real volume in most cases. However, the synthetic volumes were graded with equal or better quality than the real volumes in 77% of test patients; moreover, the synthetic volumes had equal or reduced motion artifacts in 78% of test patients. Assuming that a diagnosis was present if the majority (2/3) of reviewers noted it in a given real or synthetic volume, we found that the synthetic volumes had high positive predictive value (>75% across diagnoses) but relatively lower sensitivity (23-77%, depending on the diagnosis).

**CONCLUSION**

GAN-generated STIR imaging from T1 and T2 volumes using sequentially collected data are of high-quality and reproduce many of the important features and pathologies seen in the real images from our institution. Our research creates a key link between objective computer vision performance metrics and subject clinical performance metrics. The conservative nature of our model requires further refinement to achieve diagnostic equivalency, however this project provides a promising first step in expediting imaging protocols.

**CLINICAL RELEVANCE/APPLICATION**

AI synthetic MRI sequence generation holds promise in reducing image acquisition times and increasing patient throughput while retaining diagnostic accuracy.

### PURPOSE

To evaluate the accuracy of the lesion-to-cord signal-intensity ratio in differentiation of multiple myeloma and metastases on T1-weighted magnetic resonance (MR) imaging of the spine.

### METHODS AND MATERIALS

Forty-one patients with pathologically proven focal multiple myeloma of the spine and 59 patients with pathologically proven vertebral metastases were included in the study. Patients with vertebral metastases included 26 patients with breast carcinoma, 11 patients with bronchogenic carcinoma, 7 patients with prostatic carcinoma, 5 patients with hepatocellular carcinoma, 3 patients with renal cell carcinoma, 2 patients with gastric carcinoma, 1 patient with thyroid carcinoma, 1 patient with neuroendocrine carcinoma, 1 patient with nasopharyngeal carcinoma, 1 patient with colon carcinoma, and 1 patient with tongue carcinoma. The signal intensity of focal lesions and that of the spinal cord were measured by operator-determined region of interest (ROI). The signal intensity of the vertebral focal lesions to that of the spinal cord was calculated for each patient. Statistical analysis was done by the Student's t-test and by the Receiver-Operating-Characteristic (ROC) curve analysis.

### RESULTS

The lesion-to-cord signal-intensity ratio was significantly higher in multiple myeloma (1.39±0.24) than that of metastases (0.85±0.31) ($p<0.0001$). It had a diagnostic accuracy of 76% at the threshold of =1 for multiple myeloma and an area under the ROC curve of 0.78. One type of metastases, those of hepatocellular carcinoma, showed a statistically significant higher lesion-to-cord signal-intensity ratio (1.33±0.4) than that of the rest of metastases (0.80±0.27) ($p<0.0002$). There was no statistically significant difference between lesion-to-cord signal-intensity ratio of multiple myeloma and hepatocellular carcinoma metastases ($p<0.6268$). On re-analysis of the ROC curve after exclusion of hepatocellular carcinoma metastases, diagnostic accuracy for multiple myeloma at the threshold of =1 increased to 80% and the area under the curve increased to 0.82.

### CONCLUSION

On sagittal T1-weighted MR images, focal multiple myeloma lesions appear hyperintense to the spinal cord while vertebral metastases appear hypointense to the spinal cord in most cases. Hepatocellular carcinoma metastases represent a unique category of metastases which, like multiple myeloma, appear hyperintense to the spinal cord.

### CLINICAL RELEVANCE/APPLICATION

In patients with vertebral focal lesions without a recognized primary neoplasm, T1-weighted MR imaging can differentiate between multiple myeloma and metastases after exclusion of hepatocellular carcinoma by imaging of the liver. Machine learning of the results may further improve the diagnostic accuracy.

## R3-SSMK11-6 AI-ASSISTED RADIOLOGIC INTERPRETATION: EVALUATING DIAGNOSTIC AGREEMENT AND CLINICAL EFFICACY IN MULTI-VENDOR LUMBAR-SPINE MRI

Young Han Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Youngho Won (*Abstract Co-Author*) Nothing to Disclose
Jiwoo Park, MD (*Abstract Co-Author*) Nothing to Disclose
SOOHO AHN, MS (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate diagnostic agreement and clinical efficacy of commercially available artificial intelligence (AI) solution for L-spine MRI in clinical real-world by analyzing AI-generated radiologic interpretation and by comparing radiologists' reading time with and without AI support.

### METHODS AND MATERIALS

First session, 101 cases of L-spine MRI (GE Healthcare, Philips Healthcare, Siemens Healthineer) were evaluated by board-certified radiologists and by Columbo software (Smart Soft Healthcare, Varna, Bulgaria). Qualitative analysis used the board-certified radiologist's readings as a gold standard and recorded agreements in scale of 0, 25, 50, 75 and 100%. For quantitative analysis, the number of words deleted from AI reading and the number of words for missed findings were counted, and errors from each reading were categorized. These errors were then categorized again to see which findings were missed. Second session, in clinical settings, reading times of 11 cases of L-spine MRI with and without Colombo software were recorded by two radiologists (board-certified radiologist and radiologist in training).

### RESULTS

AI radiologic interpretations were successful in most cases (n=92/101) with three different MRI images. Agreements of major findings showed 0% (n=8/92), 25% (n=11), 50% (n=28), 75% (n=41), and 100% agreement (n=4). The numbers of deleted words from AI interpretations were average 44.3 (SD=26.45), and words for missed findings were average 6.3(SD=4.64). Most common types of errors were incorrect severity (n=37), followed by false prediction (n=35) and missed findings (n=29). Lesion location and positions were correct in all cases. False predictions were found in disc bulging (n=13), fracture (n=11), central stenosis (n=6), and antero/retrolisthesis (n=4). Omission of finding was seen in central stenosis (n=12), disc bulging (n=7), instrumentation (n=7), and post operative status (n=2). The average radiologic reading time was decreased from 178.9 to 109.0sec in certified radiologist ($p=0.0169$) and decreased from 296.6 sec to 75.8 sec in radiologist-in-training ($p=0.0015$).

### CONCLUSION

Use of AI software shows acceptable agreements with major findings in lumbar spine MRI, but revealed some weaknesses in measuring severity, false findings, and missed findings of findings. Combining the strengths of AI and radiologists could lead to better diagnostic performance and efficient radiologic reading workflow.

**CLINICAL RELEVANCE/APPLICATION**

This study highlights the benefits of AI radiologic reading software into radiologic workflows. The radiologists assisted with AI software would reduce the burden of radiologists and would lead to better patient outcomes and more efficient use of healthcare resources.

### PURPOSE

Multiple sclerosis (MS) is characterized by central nervous system lesions visible on MRI. The diagnostic criteria include typical MS lesions, but specificity can be improved using MS-specific, pathologically-validated imaging biomarkers, including paramagnetic rim lesions (PRLs) and central vein sign (CVS). However, manual segmentation of MS lesions, PRLs, and CVS is time-consuming and subjective. We propose a fully automated method for segmenting MS lesions, PRLs, and CVS, called Automated Lesion, PRL, and CVS Analysis (ALPaCA).

### METHODS AND MATERIALS

ALPaCA uses an intensity-based, voxel-wise lesion segmentation method to identify a large set of lesion candidates. Lesion candidates are input into a multi-contrast 3D CNN as 24x24x24 voxel patches from four MRI contrasts: T1-weighted, FLAIR, echo planar imaging (EPI) magnitude, and EPI phase. ALPaCA then jointly makes multi-label predictions of lesion, PRL, and CVS status of the candidate inside each patch. Since PRL and CVS status depend on lesion status, ALPaCA first predicts lesion status and then uses this prediction for PRL and CVS status. When multiple lesions exist within a patch, an attention mechanism allows ALPaCA to identify which lesion candidate to classify.

### RESULTS

We trained ALPaCA with subject-level cross validation in a multi-site dataset of 47 adults with MS and 50 with radiological MS mimics. Medians and interquartile ranges (IQRs) of lesions, PRLs, and CVS for individuals with MS were 36 [20, 71], 1 [0.5, 4], and 9 [3, 15], respectively. For individuals with radiological MS mimics, median and IQRs were 40 [20, 106], 0 [0, 0], and 2 [0, 3]. At the lesion candidate level, ALPaCA achieves areas under the receiver-operator curve (AUROCs) of 0.95, 0.91, and 0.87 for lesion, PRL, and CVS classification when run on validation data. These AUROCs are higher than those of automated competitors run on the same dataset - 0.72, 0.78, and 0.67 (all $p < 0.001$). In logistic regression models where MS diagnosis was the outcome and age and sex were controlled for, when ALPaCA subject-level PRL and CVS percentages increased by 10, the odds for MS were 28.5 (95% CI: [6.8, 120.2], $p < 0.001$) and 4.9 (95% CI: [2.2, 11.2], $p < 0.001$) times as high. These odds increases were comparable to those from manual labels. Meanwhile, neither ALPaCA nor manual lesion count was associated with MS diagnosis ($p = 0.08$ and $p = 0.44$), reflecting the specificity of PRL and CVS biomarkers over lesion count.

### CONCLUSION

ALPaCA provides a fully-automated pipeline for voxel-wise segmentation of standard MS lesions, PRLs, and CVS using clinically-feasible scans.

### CLINICAL RELEVANCE/APPLICATION

Automated segmentations may allow for translation of PRL and CVS biomarkers to clinical practice and advancement of quantitative lesion-based research.

**PURPOSE**

The 2024 Brain Tumor Segmentation (BraTS) challenge on post-treatment glioma aims to create a large public database of annotated post-treatment diffuse glioma MRIs and a benchmarking environment for the development and evaluation of deep learning segmentation algorithms towards addressing challenges in disease monitoring and treatment planning.

**METHODS AND MATERIALS**

The challenge, launched in April 2024, brings together a new multi-institutional dataset of patients diagnosed with diffuse gliomas that have undergone treatment (i.e., surgery, radiation, and/or systemic therapy). All MRI scans include pre-contrast T1 weighted, contrast enhanced T1 weighted, T2 weighted, and T2 weighted Fluid Attenuated Inversion Recovery (FLAIR) sequences. Data preprocessing and annotation protocols follow established BraTS standards, ensuring consistency across multi-site contributions. Ground truth reference annotations are approved by expert neuroradiologists with test data annotated by two independent expert neuroradiologists to assess interrater reliability. Annotations comprise four labels: enhancing tissue, surrounding non-enhancing FLAIR hyperintensity, non-enhancing tumor core, and resection cavity. These data will be used by participants to develop, containerize, and evaluate their automated segmentation models, predicting the four distinct sub-regions on validation data through July 2024. In August, participants that submit a formal methods paper will be invited to submit containerized solutions to one hidden testing data.

**RESULTS**

The dataset comprises approximately 2400 MRIs from six different contributing sites. The winner of the challenge will be announced at the Medical Image Computing and Computer Assisted Intervention (MICCAI) Conference in October 2024. Algorithm performance will be evaluated using common segmentation metrics, including lesion-wise Dice Similarity Coefficient, 95% Hausdorff distance for different tumor subregions and will be compared to neuroradiologist interrater reliability.

**CONCLUSION**

The 2024 BraTS challenge on post-treatment glioma establishes a benchmark for automated segmentation on post-treatment MRI, leveraging the largest expert-annotated glioma dataset available to date. The developed state-of-the-art models will provide a crucial tool for objectively assessing residual tumor volume for follow-up and treatment planning.

**CLINICAL RELEVANCE/APPLICATION**

Automated segmentation algorithms developed through BraTS 2024 challenges have significant clinical relevance in neuro-oncology practice. By providing accurate and efficient tools for tumor volume assessment on MRI, these algorithms have the potential to improve patient management and outcome.

## R3-SSNR14-3 DEVELOPMENT AND VALIDATION OF A RADIOMICS-BASED TREATMENT RESPONSE PREDICTIVE MODEL FOR BRAIN METASTASES RECEIVING STEREOTACTIC RADIOSURGERY THERAPY

Peng Du, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The selection of the initial treatment strategy for brain metastases (BM) plays a crucial role in the prognosis of patients, and stereotactic radiosurgery (SRS) is considered one of the promising therapies. Therefore, we developed and validated a radiomics-based predictive model to prospectively identify BM patients that are insensitive to SRS, especially those with potential risk of local failure (LF) after treatment.

**METHODS AND MATERIALS**

A total of 337 BM patients (247, 60, and 30 in the training set, internal validation set, and external validation set, respectively) were enrolled in this study. 12918 radiomics features [2 masks × 3 MRI sequences (T2-FLAIR, DWI and CE-T1WI) × 2153 features] extracted from 9 ROIs were filtered through LASSO and Max-Relevance and Min-Redundancy (mRMR) algorithms. The selected radiomics features were combined with four clinical features to establish a model for the prediction of BM patients' response to SRS using SVM classifier. The performance of the model was evaluated by its accuracy, specificity, sensitivity, and AUC curve.

**RESULTS**

In the training set, the SVM classifier that uses a combination of clinicaland radiomics features shows excellent discriminative performance (AUC=0.95, 95% CI: 0.93-0.97). Moreover, this model also achieves satisfactory results in the validation sets (AUC=0.95 in the internal validation set and AUC=0.93 in the external validation set), demonstrating outstanding generalizability.

**CONCLUSION**

The predictive model established in this study can non-invasively predict the response of BM patients to SRS, thus helping neuro-oncologists to develop a more refined and individualized first treatment plan for patients.

**CLINICAL RELEVANCE/APPLICATION**

We present a novel non-invasive SRS treatment response prediction model of BM patients based on an machine learning approach. The model combines the pre-treatment multimodal MRI radiomics features and relevant clinical risk factors, and is capable of accurately identifying BM patients at risk of LF after treatment, thus helping neuro-oncologists to develop a more refined and individualized first treatment plan for patients.

## R3-SSNR14-4 USING THE BLACK BOX OF AI TO FIND RADIOLOGIST BLINDSPOTS IN DETECTING CERVICAL SPINE FRACTURES ON CT

**PURPOSE**

To use machine learning (ML) models to retrospectively identify cervical spine fractures that were missed by radiologists; describe and categorize fracture types, and assess their clinical significance.

**METHODS AND MATERIALS**

Emergency department adult cervical spine CTs between 2018 and 2022 were included. CT scans reported as negative based on radiology reports were identified and processed by seven of the award-winning ML models from the RSNA 2022 Cervical Spine Fracture Detection Challenge. CT scans that were classified as positive by a majority of the ML models but reported as negative by a radiologist underwent independent review by two neuroradiologists, who identified the true missed fractures and documented their cervical spine segment, specific anatomical locations, and fracture patterns. Two spine surgeons blinded to clinical data evaluated the clinical significance of missed fractures based on CT images only and determined whether the misses warranted any of the following interventions: surgery, MRI, CTA, or cervical collar immobilization. Inter-observer agreement was measured with a weighted kappa statistic. Disagreements in clinical significance were resolved with discussion.

**RESULTS**

A total of 6,979 cervical spine CT studies of 6,671 patients were included in the study. Out of these, 6,378 studies were reported negative for cervical spine fractures by the initial reporting radiologist. 350 studies of these negative scans were classified as positive by a majority of the ML models. 30/350 (8.6%) ML model-identified studies were positive for fracture on secondary review by neuroradiologists. 24/30 patients had one missed fracture location, 5 patients had two missed fracture locations, and 1 patient had three missed fracture locations. The most common vertebral level for missed fractures was C7 while the most common fracture types were of spinous processes and transverse processes. 11/30 missed fractures were considered clinically significant by spine surgeons (kappa 0.93): 1 for potential surgery, 8 for immobilization, 9 for MRI evaluation, and 5 for CTA evaluation.

**CONCLUSION**

We demonstrate that missed cervical spine fractures can be reliably identified using ML models. Understanding these misses and their clinical significance is of educational value. This information can be used to help improve radiologist search patterns, reducing future diagnostic errors and mitigating the potentially negative consequences associated with them.

**CLINICAL RELEVANCE/APPLICATION**

We are pioneering the use of ML models to retrospectively identify and qualify radiology misses on cervical spine CT. Our results can help radiologists refine their search patterns and highlight the clinical importance of prone-to-miss fractures.

## R3-SSNR14-5 EXPLORING THE UTILITY OF ARTIFICIAL INTELLIGENCE AUGMENTED FUNCTIONAL CONNECTOMICS APPROACH IN BRAIN TUMOURS TO EVALUATE THE INVOLVEMENT OF NON-ELOQUENT AREAS - A PROSPECTIVE COHORT STUDY

Sunitha P Kumaran, MD (*Abstract Co-Author*) Nothing to Disclose
Akshay Kumaar M (*Abstract Co-Author*) Nothing to Disclose
Sachin Patalasingh (*Abstract Co-Author*) Nothing to Disclose
Rimjhim Agrawal, PhD (*Abstract Co-Author*) Nothing to Disclose
Radha Kumari (*Abstract Co-Author*) Nothing to Disclose
Shreyas Reddy K, MBBS, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The primary goal of brain tumour surgery is to maximize tumour removal for better survival, but this can cause new neurological problems and lower quality of life. While surgeons use fMRI to map basic brain functions like language and movement, and might not have information on the location of personalized higher-order functions. These higher-order complex functions such as the default mode network (DMN), central executive network (CEN), salience network (SN), dorsal attention network (DAN), and ventral attention network (VAN), are often compromised to achieve adequate resection, leading to deficits in attention, memory, and emotions. Computational algorithms with the augmentation of machine learning offer a promising individualized reconstruction of these complex brain networks, potentially improving surgical outcomes.

**METHODS AND MATERIALS**

This is part of the ongoing study (CTRI/2022/11/046964) to retrospectively assess the utility of rs-fMRI in presurgical planning for glioblastomas. Several assessments were performed, including the Adenbroke cognitive examination (ACE), the Edinburgh handedness inventory (EHI), and muscle strength using the Oxford muscle scale. Of the 35 patients, 5 patients demonstrated low ACE scores and were evaluated for non-eloquent area involvement (DMN, CEN, VAN, SN, and DAN).

**RESULTS**

In all 5 patients (45-55, 4 M, and 1 F), low ACE scores were associated with the involvement of at least 3 of the non-eloquent areas, most commonly involving DAN, SN, and VAN. ACE scores ranged from 21 to 54. Involvement in all 5 networks corresponded to the highest discrepancy in scores ranging from 21 to 45. When 3 areas were involved, scores ranged from 51 to 54.

**CONCLUSION**

Our study reveals that non-eloquent areas are often involved in brain tumours, as evidenced by low ACE scores. The involvement of these areas could potentially result in decreased overall quality of life during the post-operative period. Using ML algorithms, the integration of these non-traditional eloquent network maps may help in the preservation of higher mental functions.

### CLINICAL RELEVANCE/APPLICATION

In neuro-oncology, preserving complex higher cognitive functions during brain tumour surgery is crucial for maintaining a patient's overall quality of life. However, traditional surgical approaches may compromise cognitive networks like default mode, salience, executive, and attention networks. Our ongoing study highlights the prevalence of low cognitive assessment scores in patients with involvement in these non-eloquent areas. Integration of machine learning algorithms for individualized mapping of these complex brain networks may aid in preserving higher mental functions, thereby enhancing patients' quality of life following surgery.

### PURPOSE

Translation of AI generated brain metastases (BM) segmentation into clinical practice is dependent on the availability and quality of diverse annotated medical imaging datasets. BraTS-METS 2023 challenge has gained momentum for testing and benchmarking algorithms using rigorously annotated internationally compiled real-world datasets. We present the segmentation challenge results and characterize the challenging cases that affected winning algorithm performance.

### METHODS AND MATERIALS

Untreated brain metastases on standard anatomic MRI sequences (T1, T2, FLAIR, T1PG) from 8 contributed international datasets were annotated in stepwise method: published UNET algorithms, student, neuroradiologist, final approver neuroradiologist. Segmentations were ranked based on lesion-wise Dice and Hausdorff distance (HD95) scores. False positives (FP) and false negatives (FN) were rigorously penalized, receiving a score of 0 for Dice and a fixed penalty of 374 for HD95. The mean scores for the teams were calculated.

### RESULTS

Datasets from 8 international institutions containing 1303 studies were reviewed and 966 were annotated after meeting the inclusion criteria. Of these, 402 studies (3076 lesions) were released on Synapse as publicly available datasets to challenge participating teams. Additionally, 31 studies (139 lesions) were held out for validation and 59 studies (218 lesions) were used for testing. The Dice for the winning team was 0.65 ± 0.25 with an average rank across subjects being 7.9. Common errors by leading teams included false negative for small lesions and misregistration of masks in space. The Dice scores and lesion detection rates of all algorithms were found to diminish with decreasing tumor size, especially for those noticeably less than 100 mm3.

### CONCLUSION

Algorithms for BM segmentation need to be refined to effectively balance a high sensitivity of lesion detection and the need to minimize false positive and false negatives.

### CLINICAL RELEVANCE/APPLICATION

BraTS-METS 2023 challenge curated well annotated diverse datasets and identified common errors in developing generalizable algorithms. This approach will allow translation of BM segmentation across varied clinical environments and provide personalized volumetrics reports to patients undergoing BM treatment.

## R3-SSNR15-1 EVALUATION OF CEREBROVASCULAR REACTIVITY BY MULTIPHASE ASL PERFUSION IN CHRONIC CEREBROVASCULAR STENO-OCCLUSIVE DISEASE: COMPARISON WITH TC-99M HMPAO SPECT

Tae Jin Yun, MD (*Abstract Co-Author*) Nothing to Disclose
Chul-Ho Sohn, MD (*Abstract Co-Author*) Nothing to Disclose
Inpyeong Hwang, MD (*Presenter*) Research Consultant, AIRS Medical Inc.

### PURPOSE

In chronic steno-occlusive disease, impaired cerebrovascular reactivity (CVR) is related to not only increased future stroke risk but also risk factors of hyperperfusion syndrome after carotid endarterectomy or stenting. We evaluated cerebrovascular reactivity by multiphase ASL perfusion with acetazolamide challenge and compared the diagnostic performance to detect CVR impairment with 99mTc-HMPAO SPECT.

### METHODS AND MATERIALS

This IRB-approved, single center study prospectively enrolled participants with unilateral moderate or severe stenosis at proximal internal carotid artery or proximal middle cerebral artery, between July 2021 to April 2022. The participants underwent acetazolamide-challenged multiphase ASL perfusion-weighted imaging and 99mTc-HMPAO SPECT within 1 week interval to evaluate CVR. patient-specific gray matter segmentation masks were obtained from 3D T1-weighted images using freesurfer software, then further divided according to major vascular territory. The basal and acetazolamide-challenged transit time-corrected cerebral flow (CBF), arterial transit time (ATT) and SPECT CBF were measured, then normalized by cerebellum (nCBF). CVR index (CVRI) were calculated as follows: CVRI = (nCBFacetazolamide - nCBFbasal)/ nCBFbasal×100%. Correlation analysis and the ROC curve analysis were performed to evaluate diagnostic performance of CVRIASL and non-normalized CVRASL to detect CVR impairment, defined as CVRISPECT < -10%.

### RESULTS

We enrolled 11 participants (2 women, 69 ± 6 years, 3 proximal MCA stenosis and 8 proximal ICA stenosis). The CVRIASL showed lower value than CVRISPECT (mean difference, -10.1%). The mean difference of CVRIASL, CVRISPECT, CVRASL in MCA territory cortical gray matter between stenosis and contralateral side were -9.6%, -5.0%, and -17.0%, respectively. The correlation coefficient between CVRISPECT and CVRIASL was 0.604, while that between CVRISPECT and CVRASL was slightly lower (0.411). For detection of CVR impairment region of interest, the AUC of CVRIASL and CVRASL were 0.970 and 0.959, respectively (optimal threshold, -27.7% and 4.3%, respectively).

### CONCLUSION

The acetazolamide-challenged multiphase ASL perfusion can be used to assessment of CVR impairment region in cerebrovascular chronic steno-occlusive disease in replacement of 99mTc-HMPAO SPECT. ASL CVR without normalization also could be used to detect CVR impairment region.

### CLINICAL RELEVANCE/APPLICATION

Evaluation of CVR impairment can be performed precisely by acetazolamide-challenged multiphase ASL without radiation hazard for decision of treatment plan in chronic steno-occlusive disease. The impaired CVR might be directly perceivable on the ASL CBF images in routine clinical practice.

## R3-SSNR15-2 PREDICTION OF MALIGNANT CEREBRAL EDEMA FOLLOWING THROMBECTOMY IN ACUTE ISCHEMIC STROKE DUE TO LARGE VESSEL OCCLUSION USING A DEEP LEARNING MODEL BASED ON CT PERFUSION

Zhifang Pan (*Abstract Co-Author*) Nothing to Disclose
Heng Lin (*Abstract Co-Author*) Nothing to Disclose
Yunjun Yang (*Abstract Co-Author*) Nothing to Disclose
Haoli Xu, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Malignant cerebral edema (MCE) is a severe complication following endovascular thrombectomy (EVT) in patients with acute ischemic stroke due to large vessel occlusion (AIS-LVO). This study aimed to develop and test deep-learning (DL) models based on computed tomography perfusion (CTP) imaging to predict MCE automatically in AIS-LVO patients undergoing EVT.

**METHODS AND MATERIALS**

CTP and clinical data from AIS-LVO patients undergoing EVT between August 2018 to June 2023 from two stroke centers were utilized. Cohort 1 (n = 160) was used for model training and validation (10-fold cross-validation), cohort 2 (n = 50) served for external testing. The DL models incorporated whole maps of each CT perfusion parameter without distinguishing between the infarct core and ischemic penumbra. Among ShuffleNet, ViT, MobileNet, ResNet34, and ResNet50, the network with the best prediction performance was selected for DL modeling. Models based on single CTP maps and multi-maps were trained and validated to predict MCE post-EVT. Data augmentations for CTP images of the MCE group were performed using random affine transformation via Monai libraries to deal with data imbalance and prevent the prediction model from over-fitting. A clinical model comprising baseline NIHSS, age, net water uptake, collateral circulation status and other parameters was established, and fusion models were established by integrating DL features and clinical parameters. Model performance was evaluated by the area under the receiver-operating characteristic curve, accuracy, sensitivity, specificity, negative predictive value, and positive predictive value.

**RESULTS**

During the follow-up, 38 patients developed MCE in cohort 1 within 48 hours after EVT, and 15 patients developed MCE in cohort 2. In the validating cohort, the performance of single map models based on CBF (AUC = 0.782, ACC = 0.806) and Tmax (AUC = 0.773, ACC = 0.819) were better than the other single map models. The fusion model based on CBF, Tmax, MTT, CBV, TTP, and Clinical data (FaxMVPC) showed the best performance for predicting MCE (AUC = 0.857, ACC = 0.844). The performance of FaxMVPC model in predicting MCE was better than that of clinical model (AUC = 0.768, ACC = 0.806, $p < 0.05$). The FaxMVPC model in the external testing cohort achieved comparable performance (AUC = 0.812, ACC = 0.761).

**CONCLUSION**

Our study indicates that incorporating DL features derived from CTP can enhance the predictive ability of clinical model for MCE following EVT in AIS-LVO. Moreover, this DL-clinical fusion model demonstrates a certain degree of generalizability.

**CLINICAL RELEVANCE/APPLICATION**

The proposed model has potential for identifying patients at risk of developing MCE post-EVT, facilitating timely intervention and improving patient outcomes.

## R3-SSNR15-5 MR FINGERPRINTING DYNAMIC CONTRAST ENHANCED: TEMPORAL VARIATION CHARACTERISTICS OF BRAIN TUMOR

Jingliang Cheng (*Abstract Co-Author*) Nothing to Disclose
Yanglei Wu (*Abstract Co-Author*) Nothing to Disclose
Gaoyang Zhao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Heterogeneity in brain tumors influences clinical decisions and prognosis. However, the temporal variations in T1 during contrast agent perfusion are understudied. Here, we employed MR Fingerprinting (MRF) to obtain time-T1 curves following the injection of contrast agent with the aim of exploring its temporal characteristics and its potential value in assessing the properties and diagnosis of brain tumors.

**METHODS AND MATERIALS**

We enrolled 12 patients with intracranial lesions with a mean age of 51.6 years (range 31-73 years), who underwent preoperative MRI scans follow by surgical resection. The MRF sequence was acquired following routine scans, with a focus on the axial level of the lesion as determined by T2 FLAIR images. The time resolution of MRF is 27 seconds and scanning were repeated 12 times during contrast agent injection. Commencing with the third scan, Single dose (0.1 ml/kg of body weight) of Gadobutrol (Bayer Schering Pharma, Berlin, Germany) was administered via antecubital intravenous access at the rate of 2.0 mL/s. This was followed by a 20 mL saline flush at the same rate. The moment at which the signal curve reached its minimum was determined as the time to peak (TTP). The corresponding T1 relaxation times at this point were recorded as T1peak. The initial T1 relaxation times were recorded as T10, and the T1 relaxation times of last stage were recorded as T1end.

**RESULTS**

Among the 12 patients, 8 had been confirmed pathological types, including four meningiomas, one low-grade glioma, one diffuse large B-cell lymphoma (DLBCL), one hemangioblastoma (HB), and one is grey matter (GM) heterotopia. Meningiomas exhibited the fastest TTP with the lowest T1peak, while the T1peak of low-grade glioma was higher than that of GM. DLBCL displayed slightly slower signal changes with T1peak values closer to normal white matter (WM) signals. Nodules formed by GM heterotopia were showed similarities to normal GM signals. HB exhibited two distinct signal components.

**CONCLUSION**

In this study, we adapted the MRF sequence to dynamically quantify the changes in T1 relaxation time during contrast enhancement. Temporal curves of different brain tumors revealed substantial heterogeneity, both among various tumor types and within the same tumor type.

**CLINICAL RELEVANCE/APPLICATION**

For the first time, our work reveals the temporal patterns of T1 during contrast enhancement in various brain tumors, providing a wealth of dynamic information. These findings present a promising approach for exploring the "Bio-MRI features" associated with tumor heterogeneity, and they hold the potential to advance the clinical adoption of T1 quantitative imaging techniques.

## R3-SSNR15-6 CEREBRAL PERFUSION IN PATIENTS WITH SICKLE CELL ANEMIA ASSESSED THROUGH TRANSCRANIAL CONTRAST ENHANCED ULTRASOUND COMPARED TO MAGNETIC RESONANCE IMAGING

Alessandra R. Chiovatto (*Abstract Co-Author*) Nothing to Disclose
Emanoel R. Melo, MD (*Abstract Co-Author*) Nothing to Disclose
Claudio C. Castro (*Abstract Co-Author*) Nothing to Disclose
Mateus Esmeraldo, MD (*Abstract Co-Author*) Nothing to Disclose
Renato D. Chiovatto, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate whether transcranial contrast-enhanced ultrasound (CEUS) can detect cerebral perfusion alterations in adult sickle cell anemia (SCA) patients, comparing its effectiveness with brain magnetic resonance imaging (MRI).

## METHODS AND MATERIALS

A comparative study was designed with two participant groups: a case group consisting of adults diagnosed with SCA (HbSS genotype) and a control group without SCA. Each participant underwent a series of diagnostic tests including transcranial CEUS, transcranial color-coded Doppler (TCCD), and brain MRI utilizing both dynamic susceptibility contrast (DSC) and arterial spin labeling (ASL) protocols. Transcranial CEUS was performed using both bolus and flash-replenishment technique. Multiple perfusion parameters from these imaging techniques were collected and analyzed.

## RESULTS

The bolus technique of the transcranial CEUS, the TAMAX parameter of the TCCD, and the DSC and ASL techniques of the brain MRI were able to differentiate the SCA patients from the control individuals, with $p < 0,05$. SCA patients had a larger area under the bolus curve on transcranial CEUS, higher TAMAX on TCCD, higher cerebral blood flow (CBF) and shorter mean transit time (MTT) than controls on brain MRI.

## CONCLUSION

Transcranial CEUS has demonstrated potential as an effective screening tool to detect cerebral perfusion anomalies in adults with SCA. While brain MRI continues to be the definitive method for evaluating cerebral perfusion, its high cost and limited availability highlight the need for alternative approaches. Transcranial CEUS, with its lower resource demands, offers a promising complement to MRI, potentially increasing the accessibility of diagnostic evaluations and providing information about cerebral hemodynamics.

## CLINICAL RELEVANCE/APPLICATION

Identifying cerebral perfusion deficits early in patients with SCA is crucial for preventing severe complications such as stroke and cognitive deficits. The ability of transcranial CEUS to provide rapid and reliable perfusion assessments could transform the standard of care, given its cost-effectiveness and simpler learning curve. Additionally, the contrast agent used in CEUS (microbubbles) is not limited by renal function, offering a significant advantage for SCA patients who may face restrictions with MRI contrast agents. This positions transcranial CEUS as a promising initial screening tool and a follow-up imaging modality for SCA patients.

## R3-SSPH13-2 A NOVEL ENERGY-MODULATED SCATTER CORRECTION METHOD FOR DUAL-LAYER FLAT-PANEL DETECTOR BASED CBCT IMAGING

Dong Liang (*Abstract Co-Author*) Nothing to Disclose
Ting Su, PhD,PhD (*Abstract Co-Author*) Nothing to Disclose
Xin Zhang (*Abstract Co-Author*) Nothing to Disclose
Yongshuai Ge, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a rapid and precise scatter correction method for cone-beam CT (CBCT) imaging using a dual-layer flat-panel detector (DL-FPD).

### METHODS AND MATERIALS

In this work, a new scatter estimation model is established for DF-FPD based CBCT imaging, in which the primary and scattered X-ray photons having lower energy are captured by the top detector layer, while the primary and scattered X-ray photons having higher energy are captured by the bottom detector layer. With these two independent measurements, the scattered X-ray signals on both detector layers can be analytically extracted. To validate this energy-modulated scatter correction method, phantom experiments are conducted on our DL-FPD CBCT imaging benchtop.

### RESULTS

Experimental results show that the newly proposed energy-modulated scatter correction method is able to grealy reduce the shading artifacts in both low-energy and high-energy CBCT images acquired from a DL-FPD. On average, image non-uniformity is reduced by over 77% in low-energy CBCT images and by over 66% in high-energy CBCT images.

### CONCLUSION

The newly proposed scatter correction method based on the dual-layer flat-panel detector is able to effectively and rapidly reduce shading artifacts, resulting in significantly improved CBCT image quality.

### CLINICAL RELEVANCE/APPLICATION

In the future, the performance of CBCT imaging in interventional C-arm modalities can be greatly enhanced, resulting in improved CBCT images for more precise intra-operative navigation.

## R3-SSPH13-3 IMPACT OF BOWTIE SCATTER ON IODINE QUANTIFICATION IN PHOTON-COUNTING CT

Wojciech Zbijewski, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Medtronic plc
Donghyeon Lee (*Abstract Co-Author*) Nothing to Disclose
Katsuyuki Taguchi, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Canon Medical Systems Corporation;Consultant, Suzhou Bowing Medical Technologies
Xiaohui Zhan, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Yang Tai (*Presenter*) Research Grant, Canon Medical Systems Corporation

### PURPOSE

We investigate the impact of scatter from the bowtie (BT) on the quantitative accuracy of energy channel reconstructions in photon-counting CT (PCCT) to establish whether BT scatter needs to be included in subtraction-based correction.

### METHODS AND MATERIALS

A high-fidelity Monte Carlo (MC) simulator was used to obtain PCCT projections of a digital abdomen phantom with spherical iodine inserts (2, 5, 10mg/mL) of 10 and 20mm diameters placed in the liver. The PCCT configurations involved 4cm and 16cm collimations (isocenter), 1mm detector pixels, 6 energy channels per pixel with thresholds of 20/30/45/55/65/80keV, a 1-dimensional 20:1 anti-scatter grid (ASG), and a realistic aluminum BT for body imaging. HU accuracy of the iodine inserts was compared in energy channel reconstructions between (i) a reference PCCT simulation without scatter, (ii) a simulation contaminated by BT and object scatter, and (iii) a simulation contaminated by BT scatter only, including absorption and secondary scattering of BT scatter in the object. A beam-hardening (BH) correction incorporating BT attenuation was applied.

**RESULTS**

Overall, scatter leads to appreciable biases in reconstructions of low-energy channels. In the presence of object and BT scatter, the relative iodine HU errors wrt. the scatter-free reference in the 30-44keV channel were up to 35% for 2mg/mL, 25% for 5mg/mL, and 20% for 10mg/mL inserts (20mm dia.) at 4 cm collimation and increased to 80%, 66% and 54% at 16 cm collimation. BT scatter is a substantial contributor to these biases, especially at large collimations: the relative errors in simulations with BT scatter alone were 2%, 12%, and 5% for the 2, 5, 10mg/mL inserts, respectively, in the 30-44keV channel at 4 cm collimation, and 17%, 29%, and 16% at 16 cm collimation. The biases are reduced in higher energy channels but remain substantial, especially at 16 cm collimation (relative iodine HU errors of 20% - 60% in the presence of object+BT scatter and 2%-10% due to BT scatter alone). These results are consistent with projection-domain data that show that BT scatter contributes ~80% of the scatter signal in the periphery of the abdomen for the 30-44keV channel and ~50% for the 65-79keV channel.

**CONCLUSION**

For abdominal PCCT imaging, BT scatter is an appreciable contributor to the total low-energy scatter, especially at wide collimations. It needs to be accounted for in scatter correction to ensure accurate material quantification, in particular in future PCCT generations with wide axial coverage.

**CLINICAL RELEVANCE/APPLICATION**

We show that scatter from the bowtie is a non-negligible contributor to iodine quantification bias caused by x-ray scatter in PCCT imaging. The results are relevant for the development of correction algorithms.

## R3-SSPH13-4 SCATTER CORRECTION USING A HALF GRID IN CBCT IMAGING

Dong Liang (*Abstract Co-Author*) Nothing to Disclose
Han CUI (*Abstract Co-Author*) Nothing to Disclose
Ting Su, PhD,PhD (*Abstract Co-Author*) Nothing to Disclose
Yongshuai Ge, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

This work aims at developing a cost effective and fast Compton scatter correction method for cone-beam CT (CBCT) imaging using a new grid design.

**METHODS AND MATERIALS**

In this study, we propose the use of a half anti-scatter grid (h-ASG) that covers only half of the full detector surface. This setup allows for the estimation of Compton scatter distribution through two distinct measurements: one captures the full primary and scatter signals not shielded by the ASG, and the other captures a portion of the primary and scatter signals that are shielded by the ASG. To validate the feasibility of this novel scatter correction method using h-ASG, physical phantom experiments are conducted on our benchtop system.

**RESULTS**

Experimental results demonstrate that the distribution of Compton scatters can be accurately and quickly estimated from the h-ASG, resulting in a significant reduction of shading artifacts. Notably, it is found that the newly proposed h-ASG method outperforms the conventional ASG method, enhancing the uniformity of CBCT images by more than 75%.

**CONCLUSION**

Compton scatter correction in a CBCT imaging system can be simply and quickly performed using a half anti-scatter grid.

**CLINICAL RELEVANCE/APPLICATION**

The use of a novel half anti-scatter grid is able to remove the Compton scatter artifacts, significantly improving the image quality of CBCT imaging systems such as C-arm, O-arm and dental CBCT modalities.

## R3-SSPH13-5 THERMAL ANALYSIS OF AN ARCHITECTURE TO IMPROVE X-RAY SOURCE POWER IN HIGH RESOLUTION PHOTON COUNTING DETECTOR CT

Scott S. Hsieh, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The spatial resolution of photon counting detector (PCD) CT is limited by the power of the small focal spot of the X-ray source. In a conventional X-ray source, increasing power would melt or damage the tungsten anode. We propose a new CT system architecture in which the focal spot is multiplexed across multiple tracks to increase effective power without increasing maximum anode temperature.

**METHODS AND MATERIALS**

In focal spot multiplexing, the PCD circuitry is modified so that recorded photons are assigned according to the active focal spot track in addition to the photon energy, effectively creating "spatial bins" that coexist alongside conventional energy bins. The X-ray source toggles between tracks much more quickly than in conventional focal spot wobble to allow tracks to cool momentarily before continued bombardment. This requires fast electromagnetic or electrostatic control, or field emission cathodes. The thermal implications of this architecture were simulated using the heat equation to determine the maximum possible power, assuming (1) an ideal, 0.4 mm square focal spot, (2) a maximum allowed surface track temperature increase of 1500 K [i.e., a strictly track-limited source], (3) an 8 degree anode angle with anode track velocity of 100 m/s, (4) instantaneous track switching, and (5) that the heat equation could be linearized at 2000 K.

**RESULTS**

Without focal spot multiplexing, the maximum power was estimated to be 28 kW. Focal spot multiplexing provides no benefit whatsoever at switching frequencies below 250 kHz, which includes conventional focal spot wobble (<10 kHz). When using two tracks and switching at 500, 2000, or 8000 kHz, power could be increased to 39, 46, or 53 kW, respectively. When using four tracks, the power could be increased to 40, 69, or 92 kW, respectively. Note that at high power, the anode bulk must be considered and the source will no longer be strictly track-limited. The maximum power with infinitely fast switching is proportional to the number of tracks used (e.g., 56 and 112 kW for 2 and 4 tracks, respectively), but the electron steering apparatus response time and PCD charge drift time set upper limits.

**CONCLUSION**

Focal spot multiplexing is a potential architecture for PCD CT to overcome the tube power limitations that are currently intrinsic to small focal spots. Increases in power could also be translated to further decreases in focal spot size. Fast track switching times and modifications to the PCD circuitry would

be necessary to achieve these gains.

**CLINICAL RELEVANCE/APPLICATION**

High resolution PCD CT is currently limited to low power protocols. This architecture could increase power or further shrink the size of the focal spot.

## R3-SSPH13-6 TO BIN OR NOT TO BIN: EFFECT OF DETECTOR PIXEL BINNING IN DEEP-SI PHOTON-COUNTING CT

Lusik Cherkezyan (*Abstract Co-Author*) Employee, General Electric Company
Arnaud Choux (*Abstract Co-Author*) Nothing to Disclose
Jiahua Fan, PhD (*Abstract Co-Author*) Employee, General Electric Company
Zhye Yin (*Abstract Co-Author*) Employee, General Electric Company
Amir Pourmorteza, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon-counting detector (PCD) CT have improved the quality of CT images by providing ultra-high-resolution (UHR) images and spectral information.While PCD-CT can resolve high spatial frequencies, many routine clinical applications do not require such detailed features.UHR imaging in these cases poses a challenge in data transfer, processing, and storage especially when spectral data is also present. Some PCD-CT scanners avoid this by binning detector pixel data in standard-resolution (SR) acquisition modes. Although this binning reduces the size of CT projection data, it has been shown to decrease the sampling frequency of the imaging system, consequently increasing image noise in high-z PCDs and flat panel detectors. In this paper, we explore the effect of binning on the image quality of spectral deep-Si PCD-CT images.

**METHODS AND MATERIALS**

A cylindrical water phantom (d=20cm) was scanned on a prototype deep-Si PCD-CT scanner at 120 kVp and 250 mAs with 8-energy thresholds at UHR. The two adjacent pixels in the projection data were averaged together to create 1-D (2-pixel) binned data. Virtual monoenergetic images (VMIs) were calculated from filtered-backprojection (FBP) reconstruction of basis material images after projection-based material decomposition. Three linear convolution kernels with matched modulation transfer functions (MTF) with increasing sharpness (MTF10% = 7.3, 9.8, 12.3 lp/cm) were used. We compared CT number accuracy and image noise in large circular regions of interest (area>120 mm2) placed in water in 5-mm thick VMIs.

**RESULTS**

Binning did not significantly affect the CT numbers and the average deviation between original and binned images were 0.2, 0.5, and 1.5 HU for the three kernels for all VMI energies. Image noise was significantly higher in binned images and the difference increased with the sharpness of reconstruction kernels: 5.0%, 9.9%, 19.5%. For example, the standard deviation of noise was 14.5 HU vs 17.4 HU for original vs binned VMI at 65 keV.

**CONCLUSION**

While binning of UHR PCD projection data may help alleviate the cost of large data storage, transferring, and processing of SR images in soft kernels, the noise tradeoff at sharper kernels may need to be considered. The noise increase may adequately be compensated with advanced denoising techniques so that sharper kernels are not significantly impacted by effective pixel size.

**CLINICAL RELEVANCE/APPLICATION**

Processing UHR data without binning may reduce image noise in applications where sharp kernels are required at the cost of increased workflow burden. This may be alleviated by advanced denoising. Soft kernel applications may benefit from the speedup offered by binning without noise penalty.

### PURPOSE

To develop a radiomics model to assess the treatment response to neoadjuvant chemotherapy in bladder cancer patients from CT Urogram (CTU) images, and perform a pilot validation study of model generalizability on multi-institutional sequestered test sets.

### METHODS AND MATERIALS

With Institutional Review Board (IRB) approval, 835 patients with bladder cancer treated with neoadjuvant chemotherapy between 2003 and 2020 at three U.S. institutions were identified. Patient selection criteria included having CTU scans before and after neoadjuvant chemotherapy treatment and a pathological cancer stage determined by post-radical cystectomy. The criteria outlined above were met by 295 patients. The ground truth of treatment response was established based on pathological cancer stages: a stage of pT0 indicated a complete responder (CR), while any stage above pT0 was classified as a non-complete responder (NCR). The model development data set was sourced from Institution A and was split into three sets: training (56%: 35 CRs, 113 NCRs); validation (4%: 5 CRs, 5 NCRs); and a held-out internal test set (40%: 19 CRs, 87 NCRs). Institution B data (3 CRs, 16 NCRs) and Institution C data (4 CRs, 8 NCRs) were used as external test sets, which were sequestered from the developer until the model development was completed and frozen. Radiomics features, including morphology, texture, and intensity-based features were extracted from the pre- and post-treatment CTU scans. A random forest algorithm was utilized to perform classification and the area under the receiver operating characteristic curve (AUC) was used to evaluate the classification performance on the test sets.

### RESULTS

The selected features included morphology features (lesion area and surface) and intensity-based features. The developed model achieved an AUC of 0.77±0.05, 0.85±0.13, and 0.84±0.12 on the test set of Institution A, B, and C, respectively.

### CONCLUSION

While larger data sets are needed for further validation, this study demonstrates the potential generalizability of a developed radiomic model based on CTU images to assess the treatment response to neoadjuvant chemotherapy for bladder cancer patients across different institutions. Efforts to expand the external test sets are underway.

### CLINICAL RELEVANCE/APPLICATION

Accurate treatment response assessment to neoadjuvant chemotherapy can help identify NCR who may benefit from alternative treatments, potentially avoiding side effects and toxicities from ineffective chemotherapy.

## R3-SSPH14-2 HARMONIZATION OF LUNG DENSITY QUANTIFICATION FOR RELIABLE CLINICAL INSIGHTS

Ehsan Abadi, PhD (*Abstract Co-Author*) Nothing to Disclose
Ehsan Samei, PHD (*Abstract Co-Author*) Research Grant, General Electric Company;Advisory Board, General Electric Company;Research Grant, Siemens

AG;Advisory Board, Siemens AG;Advisory Board, medInt Holdings, LLC;Advisory Board, Metis Health Analytics;Research Consultant, Nanox Imaging Ltd;Royalties, General Electric Company;Royalties, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Mirion Technologies, Inc;Royalties, Cambridge University Press;Royalties, John Wiley & Sons, Inc
Saman Sotoudeh Paima, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

To improve the reproducibility of lung density quantification in Computed Tomography (CT) and its correlation with clinical endpoints via a harmonization framework (i.e., CT-HARMONICA).

**METHODS AND MATERIALS**

Reproducibility of lung density CT quantification is vital for reliable assessment of patient lung health. However, variations in acquisition protocols (e.g., radiation dose levels, reconstruction algorithms) and patient attributes (e.g., patient size, breath-hold volumes) limit this reproducibility. To alleviate this, we recently developed a harmonization framework, composed of image resampling, spatial resolution, and noise matching, followed by lung volume adjustment. This study aims to demonstrate the clinical benefit of this harmonization framework on a cohort of clinical subjects. A total of 448 subjects were selected from the COPDGene study, scanned using both the full-dose (FD) and reduced-dose (RD) protocols. The image acquisitions are reconstructed across one or more reconstruction kernels (e.g., smooth, and sharp). The 15th percentile of lung density histogram (Perc15) was used as the metric to evaluate measurement reproducibility. The quantification results are correlated with the diffusing capacity of the lungs for carbon monoxide (DLCO % predicted) adjusted for both hemoglobin and altitude.

**RESULTS**

CT-HARMONICA improved the reproducibility across different reconstruction kernels and radiation dose levels, from 44.0 ± 1.5 HU to 12.5 ± 0.4 HU. Similarly, the Bland-Altman plot demonstrates the improved bias (before: -13.9 HU, after: 3.0 HU) and limits of agreement (before: [-48.6, 20.9] HU, after: [-8.2, 14.1] HU) of the measurements. Harmonization also improved the linear relationship between the Perc15 imaging biomarker and DLCO % predicted as shown by the improved Pearson correlation coefficient (before: 0.06-0.13, after: 0.27-0.31, across three variations of reconstruction kernel and radiation dose).

**CONCLUSION**

CT-HARMONICA offered a robust solution for harmonizing CT images, enhancing the reliability of lung density quantification. This approach facilitates better comparison of images under different conditions, enabling robust longitudinal and multi-center studies.

**CLINICAL RELEVANCE/APPLICATION**

Confounding factors like imaging and patient variabilities have hindered the practical use of lung density in monitoring lung health. Our harmonization approach improves reproducibility, translating into better clinical insight.

## R3-SSPH14-3 CORONARY ARTERY CALCIUM SCORE - LUNG CANCER SCREENING VERSUS CORONARY ARTERY CALCIUM SCAN: A QUANTITATIVE STUDY OF DIFFERENT CHEST SIZES WITH DYNAMIC CARDIAC PHANTOM

Yifang Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Alexander W. Scott II, PhD (*Abstract Co-Author*) Nothing to Disclose
Christina M. Lee, BS,ARRT (*Abstract Co-Author*) Nothing to Disclose
Chao Guo, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Lung cancer CT screening (LCS) is gaining wider clinical use. It will significantly benefit the diagnostic process if it can also contribute to the evaluation of the patient's coronary artery calcification. Currently, there have been no well controlled studies about the quantitative correlation of the coronary artery calcium score between LCS scans and gated coronary artery calcium scans (CACs). The purpose of this study was to examine the quantitative relationship between the calcium score from LCS and CACs with different chest sizes considered.

**METHODS AND MATERIALS**

A CIRS dynamic cardiac phantom was used with 12 calcification (hydroxyapatite) inserts of various densities and diameters. A fat ring was added to the phantom to simulate a large chest. The phantoms were set in motion according to the ECG with heart rates ranging from 50 to 100 beats per minute. For the phantom of the medium chest size, gated scans (CTDIvol = 1.74 mGy) were performed with the above ECG to obtain the ground truth calcium score. Non-gated LCS scans were then performed with CTDIvol = 2 mGy for the medium size and with CTDIvol = 6.69 mGy for the large size with similar SNR. The LCS results were later compared with ground truth CACs results. A FOV of 200 mm was used throughout this study. Siemens SyngoVia was used to score the calcifications by three individual readers.

**RESULTS**

The LCS calcium scores were affected by blurring and distortion induced by cardiac motion. With regular patient size phantom, the Agatston score was found to have a linear relationship to the score from LCS. The averaged slope on regular chest size was 1.44, with an intercept of 21.47. The results varied for different heart rates, with the slope from 1.48 to 1.58 and the intercept from 6.80 to 19.19. With the large phantom, the averaged slope for large size was 1.12, with an intercept of 18.66. The results varied for different heart rates, with the slope from 1.11 to 1.21, and the intercept from 3.32 to 14.68. Compared with the large size's result, the calcium score of regular size chest from LCS was lower than the Agatston score with a larger variance.

**CONCLUSION**

When compared with the ground truth, the results from non-gated LCS were underestimated; however, this can be compensated by a factor especially for regular size chest. Calcifications of higher density will be scored more accurately in the LCS, irrespective of heart rate. Despite the potential impact of heart rate on calcium scoring, it is still feasible to reliably assess major calcifications by substantially reducing the patient's dose.

**CLINICAL RELEVANCE/APPLICATION**

The study verifies the feasibility of incorporating coronary artery calcium scoring into LCS scans. The incorporation allows for simultaneous diagnosis with lower dose, and potentially earlier diagnosis of CAC.

## R3-SSPH14-4 AUTOMATED EMPHYSEMA SEGMENTATION BY ACTIVE LEARNING: CLOSER CONCORDANCE WITH CLINICAL VISUAL SCORES COMPARED TO THE CONVENTIONAL LAA-950 IMAGING BIOMARKER

**PURPOSE**

This study aimed to evaluate the concordance of two automated techniques (1- AI-based emphysema segmentation, 2- conventional method of low attenuations below -950 HU (LAA-950)) with clinical visual scoring.

**METHODS AND MATERIALS**

A cohort of COPD patients underwent chest CT scans, which were scored by two clinical experts using the Fleischer Society classification system. Same CT cases were used to measure LAA-950 and to automatically segment emphysema using our developed automated emphysema detection algorithm leveraging active learning. The performance of the AI-based and LAA-950 emphysema measurements were evaluated by comparing them against the visual scores. Since the visual scores were ordinal variables, an ordinal logistic regression was used. The goodness of regression fits was quantified in terms of Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC).

**RESULTS**

We investigated 99 patients (54 males, 45 females, 72% white, 28% black) with various severities according to the Global Initiative for Obstructive Lung Disease (GOLD) stages (32, 12, 26, 20, and 6 cases for GOLD 0,1,2,3, and 4, respectively, and 3 subjects with persevered ratio). The AIC and BIC were 261 and 276 for the AI-based segmentation algorithm, and 277 and 292 for the LAA-950 technique. These values showed a significant superior performance for the AI-based emphysema segmentation algorithm compared to the conventional LAA-950 measurements in terms of concordance with the manual visual scoring of emphysema.

**CONCLUSION**

Our findings showed that the AI-based emphysema detection better reflects clinical visual scoring of emphysema compared to the LAA-950 measurements which are susceptible to image acquisition variabilities such as noise and resolution. Such robust automated methods can boost the precision of emphysema assessment in a timely manner, leading to better patient care and outcomes in COPD management.

**CLINICAL RELEVANCE/APPLICATION**

The AI-based detection provided accurate assessment of emphysema severity. By integrating this automated technique into routine practice, clinicians can assess the emphysema severity in a rapid and standardized manner.

## R3-SSPH14-5 IMPACT OF RADIOLOGIST ANNOTATION VARIABILITY ON RADIOMICS-PREDICTED BREAST CANCER PROGRESSION RISK

Qian Cao (*Abstract Co-Author*) Nothing to Disclose

Subrata Mukherjee (*Abstract Co-Author*) Nothing to Disclose
Ravi K. Samala, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Reproducible prediction of drug response to cancer therapy is important for improving clinical care. We developed a radiomics-based model of metastatic breast cancer (MBC) progression risk based on a retrospective analysis of the MONALEESA clinical trials, in which radiomic features were derived from radiologist annotations of target lesions across sequential CT exams. In this work, we focus on quantifying the uncertainty in risk score output associated with radiologist annotations.

**METHODS AND MATERIALS**

Consecutive CT imaging studies from 191 patients in the MONALEESA-3 and MONALEESA-7 trials were partitioned by patient into 106 and 85 patients for training and testing, respectively. Most of the target lesions in the dataset were annotated by multiple radiologists. Each annotation includes the target lesion segmentation at the RECIST slice. Radiomic features at the baseline (screening and week 8 follow-up) were extracted from each annotation. This includes 98 radiomic features and 98 delta radiomic features (ratio of features from screening and week 8). For patients with multiple target lesions at a single timepoint, the radiomic features were summed to produce an aggregate feature vector for the timepoint. Random survival forest models were then trained to predict a patient's risk of breast cancer progression, with high risk interpreted as shorter progression free survival (PFS) time. To evaluate the impact of radiologist annotation variability on risk score output, we randomized the selection of annotation for the same target lesion across multiple radiologists during model training, testing, and in both phases. We carried out 50 repeats of the analysis for each randomization scheme and characterized the distribution of the concordance indices from all repeats.

**RESULTS**

The coefficient of variation for all radiomic feature values was 0.126±0.009 with respect to the selection of radiologist annotation. Randomization of annotation during model training, testing, and both phases resulted in concordance indices of 0.66±0.00, 0.67±0.01, and 0.66±0.01, respectively, over all repeats of the analysis.

**CONCLUSION**

Variability in multiple radiologists' annotation impacts radiomic feature values. However, this variability does not significantly affect model training but can have a much larger impact on testing performance.

**CLINICAL RELEVANCE/APPLICATION**

Radiomic models of MBC progression risk trained from multiple annotators and reference standards are consistent. However, the variability in annotation still contributes to uncertainty in real-world performance.

## R3-SSPH14-6 EARLY ASSESSMENT OF PROGRESSION-FREE SURVIVAL IN METASTATIC BREAST CANCER: RADIOMIC ANALYSIS FROM INITIAL POST-TREATMENT CT DATA

Tingting Hu (*Abstract Co-Author*) Nothing to Disclose
Subrata Mukherjee (*Abstract Co-Author*) Nothing to Disclose
Ravi K. Samala, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop an interpretable model for early assessment of metastatic breast cancer progression-free survival based on clinical features and early serial chest computed tomography (CT) scans obtained from the MONALEESA clinical trial.

**METHODS AND MATERIALS**

We considered CT data, with target lesions annotated by radiologists, from 213 breast cancer patients participating in the MONALEESA-3 and 7 clinical trials. The data is divided into 112 and 101 patients for training and testing, respectively. For each target lesion, 98 radiomics features were computed at baseline and at the first post-treatment tumor assessment at week 8. Delta radiomics features were computed as the ratio of week 8 and baseline radiomic features. Appending baseline radiomics features with delta radiomics and 9 baseline clinical variables resulted in 205 total features to predict progression-free survival (PFS) for the patients in trials, 55% of which were either censored due to lost-to-follow-up or no event. We reduced the dimensionality of the baseline and delta radiomics features through principal components and fitted a Cox proportional hazard model using the reduced 15-dimensional covariate vector. Interactions between the delta-radiomics features and the clinical features were also included in the Cox model to understand how interaction terms might improve early prediction of progression. We used concordance index (C-index) to evaluate the performance of the fitted Cox models on the test data.

**RESULTS**

The mean C-index increased from 0.52 using only the baseline radiomics features to 0.61 when delta radiomic features were added. The C-index when treatment arm and other clinical variables were added to the above model increased to 0.625. On adding interactions among significant effects, the C-index of the resulting Cox model further increased to 0.63 (0.55-0.71). We next considered Pearson and Spearman’s rank correlation coefficient among the uncensored and predicted survival times for patients in the test data with events. We found that the interaction model provides 24.92% and 20.28% improvement in these metrics over the Cox model without interaction.

**CONCLUSION**

A principal component-based Cox proportional hazard model with clinical and delta radiomic features from baseline and week 8 follow-up achieved high predictive performance of cancer progression. Modeling interactions between the delta radiomic features and treatment arm information further increased predictive performance. The features driving the model's performance warrants further investigations.

**CLINICAL RELEVANCE/APPLICATION**

This study shows that a radiomics PFS model can be an early indicator of treatment response in metastatic breast cancer.

## R3-STCE1-2 ARTERIAL MUCOSAL LINEAR ENHANCEMENT AT CONTRAST-ENHANCED MRI TO EXCLUDE RESIDUAL TUMOR AFTER NEOADJUVANT CHEMO AND RADIATION THERAPY FOR RECTAL CANCER

Gengyun Miao (*Presenter*) Nothing to Disclose

### PURPOSE

A watch-and-wait regimen for locally advanced rectal cancer after neoadjuvant chemo and radiation therapy (NCRT) relies on identifying complete tumor response. However, the concordance between a complete response at T2-weighted and diffusion-weighted MRI (DWI) and pathologic complete response (pCR; ie, ypT0N0) in the tumor is unsatisfactory. To assess whether identification of mucosal linear enhancement (MLE) at arterial-phase contrast-enhanced (CE) T1-weighted MRI is associated with ypT0 status in patients with locally advanced rectal cancer after NCRT and to evaluate whether combining MLE at CE T1-weighted MRI and negative lymph node metastasis (LNM) at T2-weighted DWI can improve identification of pCR.

### METHODS AND MATERIALS

This retrospective study included patients with locally advanced rectal cancer who underwent total mesorectal excision after NCRT between July 2020 and July 2023 at a tertiary referral academic center. Restaging MRI included T2-weighted DWI and arterial-phase CE T1-weighted MRI for primary tumor assessment, and T2-weighted DWI for evaluation of LNM status. Imaging features associated with ypT0 status were identified at multivariable regression analysis.

### RESULTS

In total, 239 patients (mean age, 58 years ± 12 [SD]; 180 male patients) were assessed. MLE was more common in ypT0 group than in ypT1-4 group after NCRT (73% vs 4%, respectively; $P < .001$). MLE was associated with higher odds of ypT0 status in an adjusted analysis (odds ratio, 137; 95% CI: 25, 767; $P < .001$). The combination of MLE and negative LNM status achieved an area under the receiver operating characteristic curve of 0.84 (95% CI: 0.79, 0.88) for pCR.

### CONCLUSION

MLE at CE MRI was associated with higher odds of complete tumor response. Combining MLE and negative LNM status showed good performance for identifying complete tumor response and may exclude residual tumors after NCRT in patients with locally advanced rectal cancer.

### CLINICAL RELEVANCE/APPLICATION

The study highlights the potential of mucosal linear enhancement (MLE) at arterial-phase contrast-enhanced T1-weighted MRI as a key indicator of complete tumor response (ypT0) in patients with locally advanced rectal cancer after neoadjuvant chemoradiotherapy (NCRT). The combination of MLE and negative lymph node metastasis (LNM) on T2-weighted diffusion-weighted imaging (DWI) significantly improves the accuracy of predicting pathologic complete response (pCR), achieving an area under the receiver operating characteristic curve (AUC) of 0.84. This non-invasive imaging approach can guide clinical decisions for a watch-and-wait regimen, potentially reducing the need for invasive surgeries and improving patient outcomes by precisely assessing residual tumor presence.

## R3-STCE1-3 MULTIDIMENSIONAL DIFFUSION MRI FOR THE PREDICTION OF HER2 STATUS IN BREAST CANCER

Yaqin Zhang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Yuxi Tao (*Presenter*) Nothing to Disclose

### PURPOSE

Breast cancer patients with different HER2 expression status are suitable for different treatment options. This study aims to explore the performance of multidimensional diffusion imaging (MDD) in predicting HER2 expression in breast cancer and assist in the precise classification and treatment of breast cancer

### METHODS AND MATERIALS

The study included women with breast cancer who underwent MRI between December 2023 and July 2024. Three sets of b-values (100, 1000, and 2000 s/mm2) were acquired using gradient waveforms targeting 29 isotropic linear encoding directions and 26 spherically encoded signals. The quantitative parameters reflecting tissue microscopic heterogeneity were calculated by diffusion tensor distribution (DTD) model and encoding scheme for diffusional variance decomposition (DIVIDE), including microscopic normalized shape variance (Cμ), normalized size variance (CMD), microscopic fractional anisotropy (μFA), total mean kurtosis (MKT), microscopic anisotropy (MKA) and isotropic heterogeneity (MKI), axial diffusivity (AD), radial diffusivity (RD), and mean diffusivity (MD). Mann-Whitney U test and t-tests were used to determine the difference of mdd-MRI parameters between benign and

malignant breast lesions. The differences in these parameters were compared between different pathological grading of breast cancer by Kruskal-Wallis H test. Receiver operating characteristic (ROC) analysis was used to evaluate the performance of various parameters.

**RESULTS**

Forty-nine patients with breast lesions who received preoperative 3.0T MRI were enrolled. There are 9, 11, and 29 samples in the HER2-negative, HER2-low, and HER2-positive groups, respectively. CMD (P<.034) and MKI (P<.027) were significantly different in HER2 expressions. The area under the ROC curve (AUC) for distinguishing HER2-low status versus HER2-negative and HER2-positive group was 0.701 and 0.703 of CMD and MKI, respectively. MKI reflects variable cell density (such as necrotic areas) and CMD indicates the change in the size of the average diffusion tensor in the microenvironment.

**CONCLUSION**

Several parameters, such as normalized size variance and isotropic heterogeneity, reflect tissue heterogeneity and change significantly in different HER2 expression levels in breast cancer.

**CLINICAL RELEVANCE/APPLICATION**

By measuring these parameters in multidimensional diffusion MR sequences, HER2 status could be distinguish noninvasively and quantitatively, which is helpful for screening patients for HER2 targeted therapy.

### PURPOSE

Drawbacks of invasive contrast-enhanced MRA (CE-MRA) such as potential allergic reactions, nephrogenic systemic fibrosis, and long-time deposition of gadolinium, a metal element, have led to the introduction of non-contrast-enhanced MRA (non-CE-MRA) techniques. This study aimed to evaluate a novel flow-independent sequence (Relaxation-Enhanced Angiography without Contrast and Triggering (REACT)) for imaging of the extracranial arteries in acute ischemic stroke (AIS) at 1.5 T.

### METHODS AND MATERIALS

This retrospective single-center study included 47 AIS patients (median age 67 [53-80] years; 34 men), who received a standardized protocol in clinical routine including REACT (fixed scan time: 3:01 min) and CE-MRA of the extracranial arteries at 1.5 T. Two radiologists assessed scans for the presence of proximal internal carotid artery (ICA) stenosis and stated their diagnostic confidence using a 3-point scale (3=good). Image quality of cervical arteries as well as the impact of artifacts and image noise were scored on 5-point scales (5=excellent/none). Apparent signal- and contrast-to-noise ratios (aSNR/aCNR) were measured for the common carotid artery and ICA.

### RESULTS

REACT achieved a sensitivity of 95.0% and a specificity of 97.3% for ICA stenoses in high agreement with CE-MRA (?=0.83) with equal diagnostic confidence (both: 3[3-3]; p=.22). Subjective image quality was comparable between both techniques (CE-MRA: 4 [3.57-4.43] vs. REACT: 3.79 [3.43-4.14]; p=.03), with higher scores for CE-MRA at the aortic arch (4 [4-4.5] vs. 4 [3-4]; p=.002) and vertebral arteries (e.g., V1 segment: 3 [3-4] vs. 3 [2.5-3]; p<.001), whereas REACT provided superior results for the C1 segment of the ICA (4 [4-5] vs. 5 [4.5-5]; p=.008). Both sequences were only slightly affected by artifacts (both: 5 [4-5]; p=.60), while image noise was more pronounced in CE-MRA (4 [3-4] vs. 4.5 [4-5]; p<.001) in line with higher aSNR (18.3±6.7 vs. 34.1±15.1; p<.001) and aCNR (12.8±5.4 vs. 27.6±12.7; p<.001) values in REACT for both vessels combined.

### CONCLUSION

Given its short acquisition time and good diagnostic performance while yielding to CE-MRA comparable image quality, REACT is suitable for the imaging of the extracranial arteries in acute ischemic stroke at 1.5 T. Avoiding gadolinium as a contrast agent is sustainable for both human health and the environment.

### CLINICAL RELEVANCE/APPLICATION

Based on the study results, REACT proves to be a suitable, more cost-effective, and sustainable alternative to contrast-enhanced MRA of the neck at 1.5 T, e.g. to rule out vascular pathologies in acute ischemic stroke.

Alexander Cypro, MD (*Abstract Co-Author*) Nothing to Disclose
Roshun Sankaran, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

Bronchiolitis obliterans syndrome (BOS) is the most common form of chronic lung allograft dysfunction (CLAD) after lung transplantation, affecting 50% of recipients within 5 years. Quantitative inspiratory-expiratory chest CT has emerged as a potential technique to facilitate diagnosis, and novel artificial intelligence algorithms can be used to automate analysis of air trapping. However, in clinical practice, these exams may be uninterpretable if the expiratory phase is not performed at full expiration. We sought to define criteria for diagnostic adequacy of expiratory phase CT and, after applying these criteria, determine what quantitative CT thresholds correlate with FEV1 decline and spirometric evidence of BOS progression.

### METHODS AND MATERIALS

We conducted a retrospective chart review of all lung transplant patients with at least two inspiratory-expiratory chest CT acquired at our institution between March 2020 and November 2023. Diagnostic adequacy of expiratory phase CT was defined as the presence of concave tracheal morphology or flat tracheal morphology with volume change with between inspiration and expiration (VCCT) =1.5L. We applied a previously developed deep learning lung segmentation and deformable co-registration algorithm to automate measurements of lung volumes and voxelwise air trapping. Linear regression analysis was used to compare CT lung volumes with spirometry. ROC analysis was used to determine the optimal threshold to detect concurrent FEV1 decline, defined as a =10% decrease, and confirmed with a Chi-squared test.

### RESULTS

We identified 192 patients with 527 inspiratory-expiratory CTs. Of these, 311 (59%) CTs were diagnostically adequate based on tracheal morphology and VCCT criteria. Diagnostic quality scans showed improved correlation between spirometry and CT volumes, including between forced vital capacity and VCCT ($r=0.75$, $p<0.001$) and between residual volume and expiratory volume ($r=0.76$, $p<0.001$). Area under ROC for increase in air trapping between CT exams to predict FEV1 decline was 0.66, and at a threshold of =20% increase in air trapping, specificity was 95% and sensitivity was 26.1% ($X2=11.85$, $p=0.0006$).

### CONCLUSION

Diagnostically adequate CTs exhibited good correlation with spirometry for lung volumes. Increased air trapping by =20% is highly specific for concurrent FEV1 decline. However, air trapping measurements may not be reliable with suboptimal expiratory phase imaging.

### CLINICAL RELEVANCE/APPLICATION

Quantitative inspiratory-expiratory chest CT can be a useful adjunct for monitoring CLAD and can complement spirometry for diagnosis of BOS. Dedicated efforts to enhance technologist training are necessary to ensure diagnostic value of these exams.

## R4-SSCH10-3 THE STUDY OF QUANTITATIVE PARAMETERS OF ENHANCED CT TO DISTINGUISH THE ANTERIOR MEDIASTINAL CYSTS FROM TYPE B1 AND B2 THYMOMAS

Lulu Liu I, RT, RT (*Abstract Co-Author*) Nothing to Disclose
Xiaoyun Liang (*Abstract Co-Author*) Nothing to Disclose
Yuchi Tian (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of quantitative parameters based on CT in differentiating anterior mediastinal cyst from type B1 and type B2 thymoma.

### METHODS AND MATERIALS

From January 2019 to May 2023, a total of 102 cases (76 cases of anterior mediastinal cyst and 26 cases of B1 and B2 type thymostoma confirmed by routine surgery and pathology below 3cm) were retrospectively collected from Zhejiang Cancer Hospital. Quantitative parameter data were collected on CT images of mediastinal window in unenhanced phase and enhanced phase before surgery, respectively. The target nodules and the area of interest of subscapular muscle at the same level were delineated, the unenhanced and enhanced CT values and their standard deviations in the area of interest were measured, and the relative enhancement rate of nodules, nodular non-uniformity and relative non-uniformity rate were calculated, and the quantitative parameters between the two groups were analyzed by univariate analysis and multivariate logistic regression analysis. Receiver operating characteristic (ROC) curve was drawn to evaluate the diagnostic efficiency of each parameter.

### RESULTS

There were statistically significant differences in unenhanced and enhanced CT values, relative enhancement rate, enhanced nodular inhomogeneity and relative heterogeneity between the two groups (all $P < 0.05$), while no statistically significant differences in unenhanced inhomogeneity and relative heterogeneity between the two groups (all $P > 0.05$). The ROC curve showed that the area under ROC curve of enhanced CT values was the largest among the quantitative parameters, and the AUC values were 0.849 (95% CI: 0.754-0.943). respectively. The sensitivity was 80.8%(21/26) and the specificity was 88.2%(68/76). Multivariate logistic regression analysis showed showed enhanced CT value and enhanced inhomogeneity of nodule were independent predictors, and the combined AUC value of both was 0.929 (95% CI: 0.880, 0.977).

### CONCLUSION

It is valuable to distinguish anterior mediastinal cysts below 3cm and thymoma type B1 and B2 based on preoperative quantitative CT parameters, in which combined enhanced CT value and inhomogeneity is the highest.

### CLINICAL RELEVANCE/APPLICATION

This study reveals that quantitative CT parameters such as unenhanced and enhanced CT values and standard deviation of CT value means heterogeneous degree of nodule in conventional CT images can quickly and accurately distinguish anterior mediastinal cysts and thymomas below 3cm, and avoid preoperative misdiagnosis of anterior mediastinal cysts as thymomas and unnecessary surgical treatment, which has great clinical value.

## R4-SSCH10-4 EVALUATING TUMOR SIZE AND VOLUME AS A PROGNOSTIC FACTOR IN LIMITED STAGE THYMIC EPITHELIAL TUMORS: IS THERE A NEED FOR VOLUMETRIC MEASUREMENT OR DIFFERENT THRESHOLDS ACCORDING TO HISTOLOGIC SUBTYPES?

Joon Beom Seo, MD, PhD (*Abstract Co-Author*) Stockholder, Promedius Inc;Stockholder, Coreline Soft, Co Ltd;Stockholder, Anymedi Inc
Jooae Choe, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Eun Jin Chae, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shinhyeong Nam (*Presenter*) Nothing to Disclose

### PURPOSE

The recent proposal for 9th edition of the TNM staging system for thymic epithelial tumors (TETs) incorporates tumor size, specifically the longest tumor diameter (LTD), to differentiate between T1a and T1b. However, the prognostic value of tumor size in TETs remains controversial, potentially due to non-standardized measurement methods and variability across histologic subtypes. This study aimed to evaluate and compare the prognostic significance of tumor size and tumor volume (TV) in TETs and assess the need for different threshold values based on histologic risk groups.

### METHODS AND MATERIALS

This retrospective study included patients with surgically resected limited-stage TETs from January 2006 to December 2019. Tumor size was measured on axial, coronal, and/or sagittal images for LTD, and volumetric analysis was performed using software. Optimal cutoff values were selected using a maximally selected log-rank statistic which were also evaluated based on each histologic subtype. Prognostic value was evaluated for recurrence-free survival (RFS) using univariable and multivariable Cox proportional hazard models. Interreader agreement for LTD and TV between two readers was evaluated using the intraclass correlation coefficient (ICC).

### RESULTS

Of 253 patients (median age 52 years, 140 male [55%]), 80 (32%) were classified as low-risk (A and AB), 123 (49%) intermediate-risk (B1 and B2), and 50 (20%) high-risk (B3 and thymic carcinoma [TC]) based on histologic subtypes. LTD (HR, 1.02; P = .006) and TV (HR, 1.00; P = .007) were significant independent predictors for RFS on both univariable and multivariable analysis, but LTD > 5.0 cm was not. TV performance was comparable to LTD for RFS (C-index 0.60 vs. 0.62; P = .18). The optimal cutoffs for RFS were >7.0 cm for tumor size and >140 cm2 for TV. According to risk groups, the cutoff value differed for TV (32 cm2 for B3 and TC vs. 130-140 cm2 for A, AB, B2, and B2) but less for LTD (6.5 cm for high-risk, 4.3 cm for intermediate-risk, and 7.4 cm for low-risk). Interreader agreement was excellent, although slightly higher for TV than LTD (ICC, 0.997 vs. 0.942).

### CONCLUSION

Tumor size and volume are independent prognostic factors in limited-stage TETs, with comparable performance and high interreader agreement. The identified optimal cutpoints for RFS—over 7.0 cm for tumor size and over 130 cm2 for tumor volume—were slightly higher than 5.0 cm suggested by the recent update for TET staging.

### CLINICAL RELEVANCE/APPLICATION

The recent update for staging TET incorporating tumor size based on longest diameter is a reasonable and robust approach that can improve patient risk stratification for recurrence, but the cutoff value suggested should be further validated.

## R4-SSCH10-5 NEW IMAGING PROTOCOL TO ASSESS ET TUBE PLACEMENT

Daniela M. Tridente, MD (*Abstract Co-Author*) Nothing to Disclose
Ronald L. Eisenberg, MD (*Abstract Co-Author*) Nothing to Disclose
Diana Litmanovich, MD (*Abstract Co-Author*) Nothing to Disclose
Rokas Liubauskas, MD (*Abstract Co-Author*) Nothing to Disclose
Nihara Chakrala, MBBS (*Abstract Co-Author*) Nothing to Disclose
Yuval Liberman, MD, MMedSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Following intubation, a frontal chest radiograph is obtained to assess endotracheal tube (ETT) position by measuring the ETT tip to carina distance. ETT tip location changes with neck position and can be determined by assessing the position of the mandible. Since the mandible is typically not visualized on standard chest radiographs, we developed a new protocol where the mandible is seen on the chest radiograph, hypothesizing that it will improve the accuracy of the ETT position assessment

**METHODS AND MATERIALS**

Two groups of intubated patients studied (2/9/2021-5/4/2021): chest radiograph taken in either standard or new protocol (visible mandible required). Two observers independently assessed the images for neck position (neutral, flexed, extended) based on mandible position relative to the vertebral bodies. With the mandible absent (i.e., neck position unknown), we established terms: "gray-zone" (difficult to assess the ETT position adequately) and "clear-zone" (confident recommendation to retract, advance, or maintain ETT position). We compared the rate of confident assessment of the ETT in the standard vs the new protocol.

**RESULTS**

Of 308 patients, 155 had standard chest radiographs and 153 the new protocol. Inter-rater agreements for the distance between the ETT and the carina and mandible height based on vertebral bodies were 0.986 ($p<0.001$) and 0.955 ($p<0.001$), respectively. The mandible was visualized significantly more often ($p<0.001$) with the new protocol (92%; 141/153) than with standard protocol (21%; 32/155). By visualizing the mandible or the presence of the ETT within the clear zone, a reader could confidently assess the ETT position more often using the new protocol (96.7% vs 51.6%, $p<0.001$).

**CONCLUSION**

Mandible visibility on post-intubation chest radiograph is helpful for assessing ETT position.

**CLINICAL RELEVANCE/APPLICATION**

The new protocol resulted in a significant increase in both visualizing the mandible and accurately determining ETT position on post-intubation chest radiograph.

Akinori Hata, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

We previously developed an AI for automated chest CT three-dimensional quantification of body composition. The objectives were to validate the performance of the AI and investigate the significance of the quantification for mortality in patients with esophageal cancer.

**METHODS AND MATERIALS**

Patients with esophageal cancer from January 2011 to December 2015 were investigated in this retrospective study. The AI segmented adipose tissue and paravertebral muscle in the whole slices on unenhanced chest CT. Subcutaneous and visceral (mediastinal) adipose tissue was segmented separately (SAT and VAT, respectively) and the volume of SAT and VAT was quantified. Muscle area, mean CT value, and the percentage of intermuscular adipose tissue (IMAT%) were calculated in the muscle quantification. Three radiologists independently and manually segmented adipose tissue and paravertebral muscle in 15 patients. The Dice score and Pearson correlation coefficient were used as the metric for assessing the similarity between the manual and AI segmentations. The association between the quantifications in AI segmentation and overall survival in five years was evaluated by multivariable Cox proportional hazards models.

**RESULTS**

Overall, 464 patients were included. The Dice score for SAT between AI and each radiologist (reader#1, #2, and#3) was 0.91, 0.91, and 0.92, those for VAT were 0.84, 0.79, and 0.82, those for muscle other than IMAT were 0.90, 0.89, and 0.89, and those for IMAT were 0.85, 0.82, and 0.83, respectively. In the Cox proportional hazard model, higher VAT volume (HR=1.26 [95%CI: 1.06, 1.51], P=0.010) and lower CT value in the muscle (HR=0.86 [95%CI: 0.74, 0.997], P=0.046) were significant factors for worse OS adjusting for age, sex, body mass index, NYHA status, smoking history, and clinical cancer stage. In the Cox proportional hazard model using quantification variables with stepwise selection, VAT volume, VAT/SAT ratio, and IMAT% were selected and VAT volume was a significant factor for worse OS (HR=1.29 [95%CI: 1.07, 1.57], P=0.009) adjusting for age, body mass index, NYHA status, smoking history, and clinical cancer stage.

**CONCLUSION**

Automated three-dimensional quantification of body composition by AI was successfully performed. VAT volume was significantly associated with shorter survival in patients with esophageal cancer.

**CLINICAL RELEVANCE/APPLICATION**

VAT volume may be a useful prognostic factor in patients with esophageal cancer.

## R6-SSBR11-1 CRYOABLATION AS A PRIMARY TREATMENT FOR LOW-RISK BREAST CANCERS LESS THAN 1.5CM WITHOUT SURGICAL EXCISION: FINAL RESULTS OF THE ICE3 TRIAL

Kenneth R. Tomkovich, MD (*Presenter*) Consultant, IceCure Medical, Inc;Speakers Bureau, IceCure Medical, Inc

### PURPOSE

The ICE3 trial was the first large scale multi-center trial in the world with the primary endpoint to assess ipsilateral breast tumor recurrence (IBTR) rates following image guided breast cancer cryoablation for low-grade breast cancers less than 1.5cm without surgical excision. Secondary endpoints included evaluation of adverse events and cosmetic satisfaction rates. We report final results and important imaging findings.

### METHODS AND MATERIALS

This HIPPA compliant IRB approved single arm prospective trial sought enrollment of 150-200 females ages 50 and over with unifocal invasive ductal carcinoma 1.5cm or less and ER+/PR+ or ER+/PR- and HER2-. Patients underwent ultrasound-guided cryoablation using the ProSense system (IceCure Medical). A freeze, thaw, freeze cycle was performed with the goal of a visible cryosphere with at least a 10mm margin of ice. Patients did not undergo surgical lumpectomy. Patients were followed with mammography at 6 and 12 months and then annually for 5 years. Additional imaging with MRI or ultrasound was optional. Adjuvant therapy was offered. Adverse events were recorded and classified. Patient and physician satisfaction with cosmetic results was evaluated.

### RESULTS

Enrollment began in October 2014 at 19 sites across the United States. 5-year follow up was completed in March 2024. 194 patients met inclusion criteria. The ages were 55-94 years (mean 74.9). The tumor sizes were 2.5mm-14.9mm (mean 8.1mm). There were no serious procedure related adverse events. A total of 7 recurrences were reported. The mean time to recurrence was 46.4 months. 162 patients were included in the final 5 year follow up analysis for an IBTR rate of 4.3%. There were 4 recurrences out of 108 patients who received adjuvant hormone therapy following cryoablation for an IBTR rate of 3.7%. Physician's and patient's satisfaction with cosmetic results were 100%. The most common imaging findings included fat necrosis, dystrophic calcifications, and fibrosis.

### CONCLUSION

Cryoablation of low-risk breast cancers is safe and well tolerated and yielded an overall 5-year recurrence rate of 4.3%. These results are similar to reported results for surgical lumpectomy. Performed in an outpatient setting using local anesthesia with only minor adverse events reported and 100% satisfaction with cosmetic outcomes, breast cancer cryoablation provides significant benefits when compared to breast cancer surgery.

### CLINICAL RELEVANCE/APPLICATION

Results of the ICE3 trial suggest that cryoablation for women with small low-risk breast cancers is a safe and effective primary treatment option offering this group of patients a new alternative to surgical lumpectomy. Additional trials are encouraged to validate these findings.

## R6-SSBR11-2 AN MRI-BASED INTERPRETABLE MODEL DECODING BREAST TUMOR HETEROGENEITY THROUGH MULTI-DIMENSIONAL INFORMATION FOR PREDICTING TREATMENT RESPONSE TO NEOADJUVANT CHEMOTHERAPY

Yanting Liang (*Abstract Co-Author*) Nothing to Disclose
Yanfen Cui (*Abstract Co-Author*) Nothing to Disclose
Zaiyi Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Chu Han (*Abstract Co-Author*) Nothing to Disclose
Chinting Wong (*Abstract Co-Author*) Nothing to Disclose
Zhenwei Shi, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a predictive model using pretreatment MRI scans for predicting pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) in patients with breast cancer.

**METHODS AND MATERIALS**

Retrospective data from 3156 patients with breast cancer, collected between January 2000 and September 2022 from 8 international cohorts, were used. Pretreatment MRI scans were analyzed using three different imaging biomarkers: deep learning (DL) based on a pretrained foundation model, radiomics (Rad), and imaging tumor microenvironment (ITM) assessment on intratumor and peritumor regions. A multivariable logistic regression model, incorporating the three imaging biomarkers, was used to generate a Breast cancer Treatment Response to NAC (BTRnac) score. The performance of the model was evaluated using the area under the receiver operating characteristic curve (AUC) and other metrics.

**RESULTS**

The training dataset comprised 1481 patients (median age: 45.4 years [IQR: 38.6-62.7 years]) from centers A-D, while the four external test datasets included 1675 patients (median age: 43.2 years [IQR: 39.4-60.5 years]) from centers E-H. All three imaging biomarkers showed a significant association with the odds ratio of achieving pCR. The final model demonstrated good performance in predicting pCR to NAC in both the training dataset (AUC: 0.92) and the external test datasets (AUC range: 0.81-0.86). The BTRnac score, quantifying tumor ecological diversity and heterogeneity, successfully stratified patients into high and low-risk groups with significant differences ($P<0.001$).

**CONCLUSION**

This study developed a predictive model that effectively utilized multi-information from DCE-MRI scans. The model exhibited strong performance in predicting pCR to NAC in patients with breast cancer. Genetic analysis provided further insights into the underlying interpretation of the model. These findings highlight the potential of the model as a valuable tool for predicting treatment response in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

The developed predictive model has significant potential in accurately stratifying patients, aiding in optimal treatment decision-making before NAC. This has important implications for guiding treatment strategy modifications and selections in clinical practice.

## R6-SSBR11-3 BACKGROUND BREAST TISSUE CHARACTERISTICS IN MAMMOGRAPHY, US, AND MRI AND RELATIONSHIP WITH BREAST CANCER RECURRENCE: INSIGHTS FROM LONG-TERM FOLLOW-UP RESULTS

Arim Yeom (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the association between background breast tissue characteristics (BTC) in mammography, ultrasound, and magnetic resonance imaging and in-breast tumor recurrence (IBTR).

**METHODS AND MATERIALS**

We retrospectively reviewed preoperative images and clinicopathologic data of the patients who underwent breast cancer surgery in 2008 to 2009 at our institution, and follow-up data for up to 14 years following breast cancer surgery. BTC (mammographic (MG) breast density, background echotexture, glandular tissue component (GTC), and background parenchymal enhancement (BPE)) was assessed in the contralateral breast of proven cancer, and bilateral breast cancer patients were excluded. Relationship between MG density, background echotexture, GTC, and BPE was assessed using Spearman's correlation. Kaplan-Meier survival analysis and Cox proportional hazards model were used to assess association of the BTC and IBTR, and tumor staging was adjusted. Subgroup analysis was conducted according to the tumor subtype and menopausal status. We also evaluated the relationship between each BTC and clinicopathologic parameters. Statistical analysis was performed using SAS version 9.4.

**RESULTS**

A total of 2,268 female patients were included in the study (mean age, 48.5±9.6 years), and median follow-up was 10.8 years (interquartile range, 6.9-12.9 years). Among them, 128 patients (5.6%) developed IBTR. There was no significant association among MG density, background echotexture, GTC, and BPE. High BPE was associated with IBTR ($p<0.001$), while other BTCs were not. In subgroup analysis, in patients with triple-negative breast cancer, there was statistically significant association between GTC and IBTR ($p=0.03$) and BPE and IBTR ($p=0.001$). Also, high MG density, high GTC, and high BPE were associated with extensive intraductal component ($p=0.03$). High MG density and high BPE were correlated with hormone receptor positivity, but GTC was not.

**CONCLUSION**

High BPE is associated with IBTR. High BPE and GTC are associated with increased risk of developing IBTR in triple-negative breast cancer patients.

**CLINICAL RELEVANCE/APPLICATION**

By assessing background breast tissue characteristics in preoperative images, personalized postoperative surveillance considering the possibility of in-breast recurrence can be performed.

## R6-SSBR11-4 A ROBUST DEEP LEARNING FRAMEWORK FOR AUTOMATIC MOLECULAR SUBTYPES ASSESSMENT IN BREAST CANCER BASED ON MRI

Jiuquan Zhang (*Abstract Co-Author*) Nothing to Disclose
Yao Huang (*Abstract Co-Author*) Nothing to Disclose
Xiaoxia Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

To build a novel deep learning framework using pretreatment dynamic-contrast enhanced (DCE) MRI for lesion segmentation and automatic molecular subtypes assessment in breast cancer without any human interaction and validate the robustness by multicenter data.

**METHODS AND MATERIALS**

In this multicenter study, eligible patients who had biopsy-proven breast cancer were recruited. And their pretreatment breast DCE-MRIs were collected for analysis. We designed an automatic segmentation model for lesions from DCE-MRI, using the 3D-ResU-Net as the backbone. We used dice to evaluate the lesion segmentation performance. Moreover, we further proposed an ensembled molecular subtypes classification model (Ensembled ResNet) merging both 2D and 3D features from lesion from a training cohort. The accuracy of Ensembled ResNet for the prediction of molecular subtypes in breast cancer was verified in one internal and two external validation cohorts. Model performances were evaluated using area under the curve (AUC).

**RESULTS**

A total of 632 patients were retrospectively recruited. Our proposed segmentation method had high accuracy among the three validation cohorts (dice scores: 0.8606, 0.8530, 0.8451) and four molecular subtypes (dice scores: 0.8525, 0.8432, 0.8290, 0.8559). Ensembled ResNet had favourable accuracy for the prediction of Luminal A subtypes (AUC of 0.7485), Luminal B subtypes (AUC of 0.6854), HER2-enriched subtypes (AUC of 0.7792) and triple negative breast cancer (AUC of 0.7999), superior than 2D-ResNet, 3D-ResNet and radiomics models in all validation datasets (with all $p < 0{\cdot}05$, except for the comparison between Ensembled ResNet and the 2D-ResNet model in Luminal B and TNBC subtypes).

**CONCLUSION**

Our proposed novel deep learning framework can fully automatically assess molecular subtypes with high accuracy and robustness in patients with breast cancer. And this proposed framework may be a noninvasive decision-making tool with great potential in clinical application.

**CLINICAL RELEVANCE/APPLICATION**

In this study, we built a novel deep learning framework using pretreatment dynamic-contrast enhanced MRI for lesion segmentation and automatic molecular subtypes assessment in breast cancer without any human interaction. The framework can fully automatically assess molecular subtypes with high accuracy superior to 2D-ResNet, 3D-ResNet and Radiomics models. The prediction performance of the proposed framework was validated in a multicenter cohort, and the robustness and generalization are highlighted. In clinical practice, such a deep learning framework could non-invasively and accurately assess breast cancer molecular subtypes to guide clinical individualized drug treatment, thereby reducing complications caused by biopsy.

## R6-SSBR11-5 ACCURACY OF MAGNETIC RESONANCE IMAGING IN PREDICTING PATHOLOGICAL RESPONSE IN PATIENTS WITH TRIPLE-NEGATIVE BREAST CARCINOMAS UNDERGOING NEOADJUVANT CHEMOTHERAPY AND IMMUNOTHERAPY

Mariah C. Wanderley (*Abstract Co-Author*) Nothing to Disclose
Solange Sanches (*Abstract Co-Author*) Nothing to Disclose
Almir Bitencourt, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Vinicius C. Felipe SR, PhD (*Abstract Co-Author*) Nothing to Disclose
Fabiana B. Makdissi (*Abstract Co-Author*) Nothing to Disclose
Bianca M. Lago, MD (*Abstract Co-Author*) Nothing to Disclose
Soraia Damiao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Compare the diagnostic performance of magnetic resonance imaging (MRI) in predicting the pathological response in patients with invasive triple-negative invasive breast carcinomas undergoing neoadjuvant chemotherapy (NAC) with and without immunotherapy.

**METHODS AND MATERIALS**

A retrospective, single-center study, which included female patients diagnosed with triple-negative invasive breast carcinoma who underwent neoadjuvant chemotherapy (NAC group) or neoadjuvant chemotherapy combined with immunotherapy (NACI group), followed by surgery, from 2021 to 2024. Patients underwent two MRI scans: one before and one after neoadjuvant treatment (preoperative). The diagnostic performance of MRI to predict treatment response was calculated, considering the pathological response as the gold standard. Radiological complete response (CR) was defined as the absence of residual abnormal enhancement in the tumor bed at preoperative MRI. The pathological response was assessed using the Residual Cancer Burden (RCB), and pathological complete response (pCR) was defined as the absence of invasive carcinoma in the tumor bed and axillary lymph nodes at histology after surgery (RCB-0).

**RESULTS**

The study included 106 patients, 61 in the NAC group (mean age: 44 years; mean tumor size: 33mm) and 45 in the NACI group (mean age: 46 years; mean tumor size: 39 mm). There was no statistically significant difference between the two groups in terms of age, clinical staging, tumor size, and lesion type at MRI (mass vs. non-mass enhancement). Regarding treatment response, the NACI group showed higher rates of rCR (75.6% x 44.3%; p=0.003) and pCR (68.9% x 45.6%; p=0.025). In the NAC and NACI groups, MRI showed a sensitivity of 74% and 85%, specificity of 73% and 81%, positive predictive value of 69% and 93%, negative predictive value of 78% and 64%, and accuracy of 73% and 84% to predict pCR, respectively. The positive predictive value to detect a complete response was higher in the NACI group (p=0.016).

**CONCLUSION**

Our preliminary results show that MRI has an excellent diagnostic performance in predicting pCR in patients with triple-negative breast cancer treated with NAC associated with immunotherapy. These patients showed a higher rate of pCR, and preoperative MRI showed better diagnostic performance in predicting pCR in this population compared with patients treated without immunotherapy.

**CLINICAL RELEVANCE/APPLICATION**

By highlighting the diagnostic performance of MRI in this specific context, the study supports the use of MRI as a non-invasive method to tailor therapeutic planning, optimize treatment efficacy, and potentially improve patient outcomes in this challenging subset of breast cancer patients.

Farah Cadour, MD, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Several genes have been identified as pathogenic in arrhythmogenic cardiomyopathy (ACM) including desmosomal and non-desmosomal genes. However, there is currently limited data on the association between imaging findings and genotypes in ACM. The purpose of this study was to evaluate genotype-phenotype associations between desmosomal and non-desmosomal variants using cardiac MRI.

### METHODS AND MATERIALS

In this retrospective cohort study, consecutive adult patients with a pathogenic or likely pathogenic variant in a gene associated with ACM and at least one cardiac MRI between 2004-2023 were included. Cardiac MRI evaluation included quantification of left ventricular (LV) and right ventricular (RV) volumes and function, evaluation of regional wall motion abnormalities, late gadolinium enhancement (LGE) and native T1/T2 mapping.

### RESULTS

Of the 224 included ACM patients (105 women, mean age 39±15 years), pathogenic or likely pathogenic variants in desmosomal genes were identified in 104 (46%, most frequently plakophilin-2 PKP2 in 23% and desmoplakin DSP in 17%) and non-desmosomal genes in 120 (54%, most frequently titin TTN in 28% and lamin A/C LMNA in 11%). The proportion of women was higher in the desmosomal group compared to the non-desmosomal group (59% vs 37%, p=0.002), however there was no difference in age (38±15 years vs 40±16 years, p=0.38). Patients with non-desmosomal variants had higher prevalence of RV abnormalities (RV dilation, low RVEF, RV regional wall motion abnormality, or RV LGE), LV abnormalities (LV dilation, low LVEF, LV regional wall motion abnormality, or LV LGE) and bi-ventricular abnormalities (62% vs 44%, p=0.01; 73% vs 35%, p<0.001; and 65% vs 27%, p<0.001, respectively) and significantly lower RVEF and LVEF (44±13% vs 52±8%, p<0.001 and 42±16% vs 56±8%, p<0.001, respectively) compared to those with desmosomal variants. The prevalence of LV LGE and native T1 and T2 Z-scores did not differ between non-desmosomal and desmosomal variants (48% vs 55%, p=0.52; 0.24 [IQR -0.55-0.90] vs. 0.70 [IQR -0.13, 1.67], p=0.15; 0.13 [IQR -0.34-0.80] vs. 0.48 [IQR -0.19, 0.94], p=0.55, respectively). However, desmosomal variants were associated with more extensive LGE (median 3 segments [IQR 0-10] vs. 0 [IQR 0-4], p=0.001) and more frequent ring-like pattern of LGE (41% vs 12%, p<0.001).

### CONCLUSION

Non-desmosomal ACM variants are associated with worse biventricular function; however, desmosomal variants are associated with higher extent of LGE and more frequent ring-like LGE.

### CLINICAL RELEVANCE/APPLICATION

Cardiac MRI identifies clinically relevant phenotypic differences in gene-positive ACM. Futher study is needed to evaluate genotype relationships with respect to disease progression trajectory and risk of future adverse events.

## R6-SSCA11-2 PROGNOSIS AND RISK STRATIFICATION IN DILATED CARDIOMYOPATHY WITH LVEF ≤ 35%: CARDIAC MRI INSIGHTS FOR BETTER OUTCOMES

Minjie Lu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Di Zhou (*Presenter*) Nothing to Disclose

### PURPOSE

Current guidelines categorize implantable cardioverter-defibrillators as a Class I recommendation for primary prevention of sudden cardiac death (SCD) in dilated cardiomyopathy (DCM) patients with left ventricular ejection fraction (LVEF) = 35%. However, its effectiveness is hindered by the inability to

reliably discriminate between the risk of SCD and competing death of heart failure (HF) deterioration, thereby limiting its clinical utility. We aimed to refine a risk stratification model based on cardiac magnetic resonance imaging (MRI) for DCM patients with LVEF = 35%.

**METHODS AND MATERIALS**

A total of 1272 DCM patients with LVEF = 35% who underwent cardiac MRI were consecutively enrolled in this study. The primary endpoint is SCD-related endpoint, which is a composite of SCD or aborted SCD and the second endpoint is HF-related endpoint, which is a composite of HF death or heart transplantation. The risk models were validated in a prospective temporal validation cohort (n = 301).

**RESULTS**

Over a median follow-up of 87.4 months, 104 patients reached the SCD-related endpoints, and 131 patients reached the HF-related endpoints. Late gadolinium enhancement (LGE) = 7.5% was associated with a greater rate of the SCD-related endpoints (adjusted hazard ratio [HR]: 3.6; $p < 0.001$), while left atrial volume index (LAVi) = 75.6 ml/m2 was associated with a greater rate of the HF-related endpoints (adjusted HR: 2.1; $p < 0.001$). High-risk SCD patients with LVEF < 20% and LGE = 7.5% had a 9.29-fold higher risk of SCD events, compared with low-risk SCD patients with LVEF of 20-35% and without LGE. Patients with LVEF < 20% and LAVi = 75.6ml/m2 had the highest risk of HF-related endpoints.

**CONCLUSION**

DCM patients with LGE = 7.5% were at heightened risk of SCD events, which may potentially benefit from prompt implantable cardioverter-defibrillator therapy. Physicians should prioritize addressing worsening heart failure in patients with LGE < 7.5% and LAVi = 75.6 ml/m2, as the escalation in the risk of HF death/HTx surpasses that of SCD or aborted SCD.

**CLINICAL RELEVANCE/APPLICATION**

In this cohort study, patients with late gadolinium enhancement (LGE) = 7.5% showed a 3.6-fold greater risk of sudden cardiac death composite events.The risk categories and stratification models, integrated by LVEF, LGE, and LAVi, hold promise for guiding interventions like implantable cardioverter-defibrillators, heart transplantation, LV assist device therapy, and referral for heart failure specialty care, ultimately improving outcomes. This endeavor can enhance targeted therapeutic decision-making and potentially alleviate the economic burden on patients with DCM and severely reduced LVEF.

## R6-SSCA11-3 STRAIN CMR CAN PREDICT REGIONS OF INFLAMMATION ON PET/CT IN PATIENTS WITH CARDIAC SARCOIDOSIS

Hubert J. Vesselle, MD, PhD (*Abstract Co-Author*) Consultant, MIM Software Inc
Wei Wu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mohamed M. Abdelmotleb, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Avanti Gulhane, MD (*Abstract Co-Author*) Nothing to Disclose
Mehrzad Shafiei, MD (*Abstract Co-Author*) Nothing to Disclose
Hamid Chalian, MD (*Abstract Co-Author*) Nothing to Disclose
Murat Sadic, MD (*Abstract Co-Author*) Nothing to Disclose
Karen G. Ordovas, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Ganesh Raghu, MD (*Abstract Co-Author*) Nothing to Disclose
Negar Firoozeh, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine if cardiac magnetic resonance (CMR) strain parameters can identify regional myocardial inflammation in cardiac sarcoidosis (CS).

**METHODS AND MATERIALS**

This single-institution, HIPAA-compliant, IRB-approved, retrospective study included consecutive patients with confirmed or probable cardiac sarcoidosis per the updated Japanese Circulation Society Guideline, with both CMR and F18-FDG PET/CT within 90 days of each other in the past 5 years. Comparison of strain CMR parameters between left ventricular (LV) myocardial segments with and without inflammation on PET/CT was performed using t-test and nonparametric test of hypothesis depending on variable distribution. To assess if strain association with inflammation was independent from the presence of late gadolinium enhancement (LGE), multivariable logistic regression models were employed, adjusting for key demographic and clinical characteristics as covariates.

**RESULTS**

Among 125 patients with cardiac sarcoidosis (mean age 59.45 years, 58% male), segmental analysis identified inflammation in 385 out of 2125 myocardial segments (18.11%) on PET/CT. LGE was present in 89 (4.2%) of all segments and in 23.11% of inflamed segments. Segments with inflammation had significantly decreased Peak Circumferential Strain (PCS) mean -14.1, SD 5.7) and Peak Longitudinal Strain (mean -10.3, SD 5.4) compared to non-inflamed segments (mean -18.4, SD 3.5 and mean -13, SD 3.6, respectively; both $p < 0.001$). Multivariable logistic regression showed that PCS (OR: 1.406; p=0.011) and PLS (OR: 1.020; p=0.011), where independent from LGE to predict inflammation, while adjusting for potential confounders including age, sex, LV ejection fraction, and LV end-diastolic volume index. Additional strain parameters investigated did not differ between segments with and without inflammation.

**CONCLUSION**

The presence of abnormal peak circumferential and longitudinal strains remained significantly associated with myocardial inflammation as detected by PET/CT, irrespective of the concurrent presence of LGE, underscoring the independent diagnostic value of strain measures in this context.

**CLINICAL RELEVANCE/APPLICATION**

CMR strain parameters were independently associated with inflammation, suggesting their potential utility for non-invasive assessment in detecting active sarcoidosis.

## R6-SSCA11-4 TOWARDS PHENOTYPING CHARACTERISTICS AND MECHANISM OF QRS DURATION AND MORPHOLOGY IN PATIENTS WITH NON-ISCHEMIC HFREF: INSIGHTS FROM CMR IMAGING

Minjie Lu, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Di Zhou (*Presenter*) Nothing to Disclose

**PURPOSE**

As the cornerstone of decision-making and prognosis, there is currently a lack of data focusing on the association between phenotype and underlying mechanisms among various conduction delay patients. We aimed to elucidate the phenotyping characteristics among different QRS duration and

morphology in patients with non-ischemic heart failure and reduced ejection fraction(HFrEF) and explore predictive metrics for survival outcomes following cardiac resynchronization therapy (CRT).

**METHODS AND MATERIALS**

A retrospective analysis was conducted on 887 consecutive patients with non-ischemic HFrEF and prolonged QRS duration who underwent cardiac magnetic resonance (CMR) imaging, as well as 200 subjects with HFrEF and normal QRS duration as the control group. Survival estimates for patients who underwent CRT were determined using Kaplan-Meier curves with the log-rank test.

**RESULTS**

Patients with left bundle branch block (LBBB) had a higher right ventricular ejection fraction (RVEF) and worse LV torsion and strains compared to controls and patients with right bundle branch block (RBBB). Late gadolinium enhancement (LGE) percentage was significantly larger in patients with RBBB and non-specific intra-ventricular conduction delay (IVCD) than in controls and LBBB patients (LBBB vs. RBBB vs. IVCD vs. controls: 4.5% ± 6.7 vs. 8.9% ± 9.1 vs. 8.3% ± 8.0 vs. 4.9% ± 7.0). Multivariable logistic regression revealed that LGE presence and torsion were independent determinants of IVCD. Over a median follow-up of 4.7 years, RVEF = 48.1% (HR [95% CI]: 6.247 [1.923-20.294]), torsion = 0.1°/cm (HR [95% CI]: 2.692 [1.310-5.532]), and LGE = 2.3% (HR [95% CI]: 7.948 [3.108-20.328]) were associated with reduced survival after CRT.

**CONCLUSION**

RBBB is associated with reduced RVEF and larger LGE burden, indicating a worse prognosis after undergoing CRT. LV torsion was notably impaired in patients with LBBB and IVCD, suggesting decreased LV synchrony, which may benefit from CRT.

**CLINICAL RELEVANCE/APPLICATION**

As the cornerstone of decision-making and prognosis, we found that left ventricular dyssynchronous was evident in patients with left bundle branch block or non-specific intra-ventricular conduction delay, which may indicate an improved clinical outcome after CRT. Right bundle branch block patients may not benefit from CRT due to right ventricular dysfunction and relatively preserved left ventricular synchronous contraction. Based on cardiac magnetic resonance, reduced right ventricular ejection fraction, preserved left ventricular torsion, and larger late gadolinium enhancement are associated with worse outcomes following CRT. CMR imaging may assist clinicians in assessing patients who could benefit from CRT and those who might have less favorable outcomes.

## R6-SSCA11-5 CARDIAC MAGNETIC RESONANCE-DERIVED LEFT ATRIOVENTRICULAR COUPLING INDEX AS A NOVEL PROGNOSTIC MARKER FOR LIGHT-CHAIN AMYLOIDOSIS

Yinqiu Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the prognostic value of left atrioventricular coupling index (LACI) in patients with light-chain (AL) amyloidosis.

**METHODS AND MATERIALS**

We prospectively enrolled 170 patients with biopsy-proven AL amyloidosis who underwent cardiac magnetic resonance (CMR) imaging between December 2011 and January 2020. LACI was defined as the ratio between the left atrial volume and the left ventricular volume in end-diastole. The primary endpoint was all-cause death. Youden's Index was used to identify the optimal cut-off for LACI in predicting all-cause mortality. Association between LACI and all-cause mortality was analyzed with univariable and multivariable Cox proportional hazards models. The Kaplan-Meier curve was depicted and compared using the log-rank test.

**RESULTS**

LACI was significantly higher in patients with primary endpoint compared to those without primary endpoint (55.9%, interquartile range: 29.9%-72.0% vs. 39.4%, interquartile range: 23.8%-51.8%, p=0.002). Among 170 patients with AL amyloidosis, 113 (66.5%) experienced primary endpoint during a median follow-up of 30 months. The optimal cut-off for LACI to predict mortality was 51.9%. Multivariate Cox analysis demonstrated LACI=51.9% (HR 1.807, 95% CI 1.171-2.788, p=0.008) was an independent predictor of all-cause mortality after adjusting for baseline confounders, left ventricular and left atrial functional parameters. On Kaplan-Meier analysis, LACI assessment enabled further risk stratification in patients at advanced Mayo stage (IIIa and IIIb) (log-rank p=0.002, p=0.038, respectively).

**CONCLUSION**

CMR-derived LACI is a powerful independent predictor of all-cause mortality in patients with AL amyloidosis and it offers incremental prognostic information for all-cause mortality in patients at advanced Mayo stage.

**CLINICAL RELEVANCE/APPLICATION**

LACI is independently associated with all-cause mortality in AL amyloidosis and it can further improve risk stratification in patients with AL amyloidosis.

## R6-SSCA11-6 PARAMETRIC MAPPING USING CARDIOVASCULAR MAGNETIC RESONANCE FOR THE DIFFERENTIATION OF LIGHT CHAIN AMYLOIDOSIS AND TRANSTHYRETIN-RELATED AMYLOIDOSIS

Daniel Kuetting, MD (*Abstract Co-Author*) Nothing to Disclose
Leon Bischoff, MD (*Abstract Co-Author*) Nothing to Disclose
Narine Mesropyan, MD (*Abstract Co-Author*) Nothing to Disclose
Julian A. Luetkens, MD (*Abstract Co-Author*) Speakers Bureau, Koninklijke Philips NV;Research Consultant, Bayer AG
Alexander Isaak, MD (*Abstract Co-Author*) Nothing to Disclose
Dmitrij Kravchenko, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate different cardiovascular magnetic resonance (CMR) parameters for the differentiation of light chain amyloidosis (AL) and transthyretin-related amyloidosis (ATTR).

**METHODS AND MATERIALS**

In total, 75 patients, 53 with cardiac amyloidosis (20 patients with AL (66±12 years, 14 males [70%]) and 33 patients with ATTR (78±5 years, 28 males [88%])) were retrospectively analyzed regarding CMR parameters such as T1 and T2 mapping, extracellular volume (ECV), and late gadolinium enhancement (LGE) distribution patterns, and myocardial strain, and compared to a control cohort with other causes of left ventricular hypertrophy (LVH; 22 patients (53±16 years, 17 males [85%])). One way-ANOVA and receiver operating characteristic analysis were used for statistical analysis.

## RESULTS

ECV was the single best parameter to differentiate between cardiac amyloidosis and controls (area under the curve [AUC]: .97, 95% confidence intervals [CI]: .89-.99, p<.0001, cutoff: >30%). T2 mapping was the best single parameter to differentiate between AL and ATTR amyloidosis (AL: 63±4 ms, ATTR: 58±2 ms, p<.001, AUC: .86, 95% CI: .74-.94, cutoff: >61 ms). Subendocardial LGE was predominantly observed in AL patients (10/20 [50%] vs. 5/33 [15%]; p=.002). Transmural LGE was predominantly observed in ATTR patients (23/33 [70%] vs. 2/20 [10%]; p<.001). The diagnostic performance of T2 mapping to differentiate between AL and ATTR amyloidosis was further increased with the inclusion of LGE patterns (AUC: .96, 95% CI: .86-.99]; p=.05).

## CONCLUSION

ECV differentiates cardiac amyloidosis from other causes of LVH. T2 mapping combined with LGE differentiates AL from ATTR amyloidosis with high accuracy on a patient level.

## CLINICAL RELEVANCE/APPLICATION

CMR findings such as ECV, T1 and T2 mapping can speed up diagnosis of cardiac amyloidosis in a clinical setting while also differentiating between ATTR and AL amyloidosis, the two most common causes of cardiac involvement.

Meiri Silva (*Abstract Co-Author*) Nothing to Disclose
Camila Wiethan (*Abstract Co-Author*) Nothing to Disclose
Joao Manoel M. Santos, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This meta-analysis aims to evaluate the diagnostic accuracy of computed tomography (CT) for local staging of colon cancer and identifying associated poor prognostic factors.

### METHODS AND MATERIALS

Conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA-DTA) guidelines and the Cochrane Handbook for Diagnostic Test Accuracy, this review searched relevant databases from January 2010 to assess the efficacy of CT in diagnosing locally advanced colon cancer (stage pT3 or higher). Additionally, lymph node involvement (N+) and extramural vascular invasion (EMVI+) were evaluated.

### RESULTS

Out of 117 studies reviewed in full, 31 met the inclusion criteria, encompassing a total of 222,838 patients. CT demonstrated a sensitivity and specificity of 0.78 (95% CI: 0.72 - 0.83 and 0.67 - 0.86, respectively) for identifying pT = 3 stages, with an Area Under the Curve (AUC) of 0.85 (95% CI: 0.79 - 0.88). For detecting lymph node involvement, the sensitivity and specificity were both 0.62 (95% CI: 0.55 - 0.68 and 0.53 - 0.70, respectively), and the AUC was 0.65 (95% CI: 0.59 - 0.69). For EMVI+, the sensitivity was 0.36 (95% CI: 0.18 - 0.59), the specificity was 0.78 (95% CI: 0.64 - 0.88), and the AUC was 0.64 (95% CI: 0.49 - 0.75).

### CONCLUSION

CT is effective for staging locally advanced colon cancer, confirming its utility in clinical decision-making. This study underscores the need for further research to refine diagnostic criteria and explore new diagnostic approaches.

### CLINICAL RELEVANCE/APPLICATION

Given the FOxTROT trial results, which indicate potential benefits of neoadjuvant chemotherapy for locally advanced colon cancer, accurate preoperative staging becomes crucial. CT has proven effective for patient stratification and demonstrating diagnostic accuracy, essential for selecting appropriate treatment plans.

## R6-SSGI19-2 DIAGNOSTIC ACCURACY AND INTERREADER AGREEMENT OF NODE REPORTING AND DATA SYSTEM (NODE-RADS) IN CT-BASED STAGING OF REGIONAL LYMPH NODES IN GASTRIC CANCER

Fabian Elsholtz, MD (*Abstract Co-Author*) Nothing to Disclose
Bernd K. Hamm III, MD (*Abstract Co-Author*) Research Consultant, Canon Medical Systems Corporation;Research Grant, Canon Medical Systems Corporation;Stockholder, Siemens AG;Research Grant, Siemens AG;Stockholder, General Electric Company;Research Grant, General Electric Company;Research Grant, Koninklijke Philips NV;Research Grant, Elbit Imaging Ltd;Equipment support, Elbit Imaging Ltd;Research Grant, Bayer AG;Research Grant, Guerbet SA;Research Grant, Bracco Group;Research Grant, B. Braun Melsungen AG;Research Grant, Krauth Medical KG GmbH & Co;Research Grant, Boston Scientific Corporation;Investigator, CMC Contrast AB
Moritz Tronser (*Abstract Co-Author*) Nothing to Disclose
Carsten Kamphues (*Abstract Co-Author*) Nothing to Disclose

Florian Loch (*Abstract Co-Author*) Nothing to Disclose
Rolf O. Reiter, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The current assessment of regional lymph nodes in gastric cancer lacks precision, prompting a growing need for standardized oncologic imaging through "reporting and data systems" (RADS). Our goal was to evaluate the diagnostic accuracy of Node-RADS in comparison to specific criteria for regional lymph nodes in gastric cancer, employing CT scans and histopathology as reference.

**METHODS AND MATERIALS**

This retrospective study examined 91 consecutive patients (median age 66, range 33-91, including 37 women) diagnosed with histologically confirmed gastric adenocarcinoma who underwent surgery. CT scans were used to assess the Node-RADS score, ranging from 1 to 5, indicating the probability of regional lymph node metastases based on combined size and configuration criteria as follows: 1 (very low), 2 (low), 3 (equivocal), 4 (high) and 5 (very high). Additionally, individual evaluations of Node-RADS criteria were conducted, along with assessments of long-axis diameter and specific subcategories of altered border contour (such as lobulated, spiculated, and indistinct).

**RESULTS**

Representative examples of Node-RADS scores are shown in figure 1. The highest diagnostic accuracy was observed in Node-RADS scores of =3 and =4, exhibiting a sensitivity/specificity/Youden index of 56.8%/90.7%/0.47 and 48.6%/98.1%/0.47, both with good interreader agreement (? = 0.73 and 0.67, $p < 0.01$). Among the individual criteria, optimal performance was associated with a short-axis diameter of 10 mm, demonstrating a sensitivity/specificity/Youden index of 56.8%/87.0%/0.44 (? = 0.65, $p < 0.01$).

**CONCLUSION**

Our findings indicate that employing a structured blend of size and configuration criteria for regional nodal staging in gastric cancer marginally improves the overall diagnostic accuracy compared to several individual criteria, including short axis diameter. This improvement reflects an increase in specificity, while sensitivity remain consistent. The Node-RADS assessment showed good interreader agreement.

**CLINICAL RELEVANCE/APPLICATION**

Evaluation of lymph nodes in gastric cancer remains limited, with a lack of agreement on radiological assessment. In gastric cancer, Node-RADS slightly increases diagnostic accuracy when compared to individual criteria, such as short-axis diameter. For structured reporting of regional lymph nodes in gastric cancer, Node-RADS holds promise as a potential tool.

## R6-SSGI19-4 PRELIMINARY RESULTS ON INTER-RATER AGREEMENT BETWEEN FULLY AUTOMATED TUMOR SEGMENTATION MODEL AND RADIOLOGIST RECIST RESPONSE ASSESSMENT IN PATIENTS WITH COLORECTAL LIVER METASTASES

**PURPOSE**

Automated tumor segmentation (TS) models have potential in the development of quantitative imaging biomarkers for treatment response in cancer patients. This study aims to compare the agreement between an automated novel TS model and two radiologists applying RECIST to patients with colorectal liver metastases (CRLM) undergoing systemic chemotherapy.

**METHODS AND MATERIALS**

In this IRB approved retrospective study, treatment naḭve patients with CRLM who underwent chemotherapy were included if they had baseline and one follow-up CECT available for response assessment by RECIST 1.1. A ScaleNAS TS model trained on liver metastases across a range of primary cancers was applied to an independent data set to obtain total tumor volumes (TTV) in the liver. Response categories were then automatically generated based on changes in TTV. A threshold of +/- 65% was used to define Progressive Disease (PD), Stable Disease (SD), and Partial Response (PR). Complete Response (CR) and PR categories were combined. Inter-rater agreement was measured by weighted kappa statistics for 1) RECIST 1.1 response categories generated by two expert radiologists (R1 and R2), and 2) the response categories generated from TTV by the TS model compared to R1.

**RESULTS**

189 patients (mean age 59.3 y, 54.0% male) from a single cancer center were included. For 52 patients evaluated by both radiologists, 37/52 (71.2%) RECIST categories were in agreement (19 PR, 15 SD, and 3 PD) with weighted kappa = 0.58. For 189 patients evaluated by R1 and processed by the automated TS model, there was agreement in 133/189 (70.4%) RECIST categories (55 PR, 66 SD, 12 PD), with weighted kappa = 0.54.

**CONCLUSION**

In this preliminary study of patients with colorectal liver metastases on chemotherapy, automated calculation of treatment response by a novel ScaleNAS TS model showed a moderate level of inter-rater agreement with an expert radiologist, similar to the moderate agreement between two expert radiologists applying RECIST 1.1.

**CLINICAL RELEVANCE/APPLICATION**

Preliminary results suggest the potential of using automated TS model to achieve expert radiologist level performance in identifying responders to chemotherapy. Further multi-center multi-reader validation is required.

## R6-SSGI19-6 A HUMAN IN THE LOOP DEEP LEARNING APPROACH FOR SEMI-AUTOMATED RECTAL TUMOR SEGMENTATION ON MULTI-PLANE MRI

**PURPOSE**

Precise segmentation of rectal tumors on pre-treatment MRI can enable accurate clinical staging toward personalized treatment selection. However, the accuracy of clinical staging can vary based on reader experience, and developing deep learning models to assist in this regard requires laborious manual annotation of tumor extent. We present initial results of an integrated human-in-the-loop (HITL) refinement learning model for semi-automated segmentation of rectal tumors on axial and coronal pre-treatment MRI scans.

**METHODS AND MATERIALS**

Baseline staging MRI scans from locally advanced rectal cancer patients were accrued from 4 institutions, for all of which consensus radiologist annotations of tumor extent had been obtained as surrogate "ground truth". A deep learning (DL) nnUNet tumor segmentation model was trained on axial and coronal T2w MRIs from two institutions, with segregated training and internal validation cohorts. Two rounds of HITL refinement learning were conducted, where model-generated segmentations were refined by two novice radiology readers. Refined annotations were used to re-optimize the nnUnet model. Model-generated segmentations were evaluated before HITL and after each HITL round against "ground truth" in two external validation cohorts, with performance quantified via dice similarity coefficient (DSC) and time taken for human annotation.

**RESULTS**

A total of 381 MRI scans from 231 rectal cancer patients were considered. The optimized HITL informed DL model yielded the best overall tumor segmentation performance on the external validation cohort (N=20, two institutions) for both axial (DSC = 0.76) and coronal scans (DSC=0.68), with no further improvement in model performance after a second round of HITL refinement. By comparison, the pre-HITL DL tumor segmentation model yielded significantly worse performance on both axial (DSC=0.60, p=0.0362) and coronal (DSC=0.62, p=0.0186) MRI scans. This HITL-informed DL model also yielded robust performance on a second validation cohort across both axial (DSC=0.65) and coronal views (DSC = 0.65). HITL refinement for rectal tumor annotation was also found to significantly improve reader efficiency by requiring only 18 minutes/scan compared to manual de novo annotations which took up to 38 minutes/scan ($p<0.001$).

**CONCLUSION**

Human-in-the-loop deep learning models can enable accurate and efficient semi-automated rectal tumor segmentations on pre-treatment MRI scans across axial and coronal acquisition planes

**CLINICAL RELEVANCE/APPLICATION**

Semi-automated tumor segmentation approaches could enable more accurate and reproducible staging of rectal cancers as well as improved treatment selection, regardless of reader experience.

## R6-SSGI20-1 EXTRAMURAL VENOUS INVASION MEDIATED BY HSA_CIRC_0097977 IN ORTHOTOPIC MOUSE MODEL OF GASTRIC CANCER—A MR IMAGING-HISTOPATHOLOGICAL CORRELATION STUDY

Jin Cheng, MD (*Abstract Co-Author*) Nothing to Disclose
Yiqun Liu (*Abstract Co-Author*) Nothing to Disclose
Yi Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Caizhen Feng, MBChB (*Abstract Co-Author*) Nothing to Disclose
Xinyi Gou (*Presenter*) Nothing to Disclose

### PURPOSE

To perform a magnetic resonance imaging (MRI)-histopathological correlation study of extramural venous invasion (EMVI) and to investigate the relationship between EMVI and the expression of hsa_circ_0097977 on orthotopic gastric cancer (GC) mouse model.

### METHODS AND MATERIALS

We first retrospectively collected samples from patients with locally advanced GC for circRNA sequencing and found that hsa_circ_0097977 was significantly related with EMVI status. On animal level, orthotopic GC mouse model was constructed by implanting GC cells (BGC-823 and NCI-N87) with/without knock-down (KD) of hsa_circ_0097977, and followed by 9.4 Tesla (T) MRI scan. MRI-histopathological correlation study on EMVI, analysis of the association between EMVI and metastasis were performed respectively. Subsequently, cell function experiments were conducted to confirmed the effect of hsa_circ_0097977 on cell level.

### RESULTS

EMVI could be accurately detected by 9.4T MRI on orthotopic mouse model with pathological confirmation as the reference standard, with the area under the curve (AUC) of 0.843 (sensitivity 78.57%, specificity 90.0%). MRI detected EMVI was the only imaging factor associated with distant metastasis (p=0.04). Furthermore, KD of hsa_circ_0097977 was the only factor associated with EMVI (p=0.043, 0.038). Cell function test identified that KD of hsa_circ_0097977 could decrease the invasion and migration of GC cells.

### CONCLUSION

EMVI of GC, the risk factor of distant metastasis, could be detected by 9.4T MRI and confirmed by histopathological analysis. At the same time, the expression of EMVI can be regulated by KD of hsa_circ_0097977.

### CLINICAL RELEVANCE/APPLICATION

Extramural venous invasion of gastric cancer could be detected by 9.4T MRI, confirmed by histopathological analysis, and modulated by knock-down of hsa_circ_0097977 on the orthotopic mouse model, which could be a foundation of further research on extramural venous invasion.

## R6-SSGI20-2 DEEP LEARNING PREDICTION FOR EARLY RECURRENCE AND SURVIVAL IN PATIENTS WITH LOCALLY ADVANCED GASTRIC CANCER USING CT IMAGES

Jiansong Ji, MD (*Abstract Co-Author*) Nothing to Disclose
Mingzhen Chen (*Abstract Co-Author*) Nothing to Disclose
Xinyu Guo (*Presenter*) Nothing to Disclose

### PURPOSE

Early recurrence (ER) in patients with locally advanced gastric cancer (LAGC) portends aggressive biological characteristics and a dismal prognosis. To develop and validate a deep learning-based ER prediction model in patients with LAGC (DLER) using multiphase CT images along with other clinical factors, and further explore the underlying biological basis under its prediction.

### METHODS AND MATERIALS

In this retrospective multicentre study, we enrolled 594 patients with LAGC underwent curative surgery from three institutions between January 1, 2015 to March 31, 2023. Patients were divided into the training set (n = 284), internal validation set (n = 71), external test set 1 (n =155), and external test set 2 (n = 84). DenseNet169-based features of 2.5dimensional (2.5D) CT image from the primary tumour were employed to develop the DLER, and then

clinical factors were integrated within the model (DLERinteg). The discrimination performance of different models was measured by the area under the curve (AUC), accuracy, sensitivity, and specificity. The log-rank test was used to analyze early recurrence-free survival (ERFS), disease-free survival (DFS) and overall survival (OS) based on low versus high model-derived score. The genetic analysis was performed based on 41 patients with RNA-sequencing data from The Cancer Image Archive (TCIA).

**RESULTS**

Early recurrence (ER) rates were 9.9% (35/355), 16.1% (25/155) and 10.7% (9/84) in the three centers, respectively. DLER had a consistently high performance in the training set (AUC = 0.950), internal validation set (AUC = 0.852), external validation set 1 (AUC = 0.766), and external validation set 2 (AUC = 0·816). DLERinteg further improved the prediction performance with AUCs of in the four sets, respectively. In multivariable analysis, the deep learning score remained an independent predictor for early recurrence-free survival, DFS and OS ($P < 0.001$ for all). In the biological basis exploration, a high deep learning score was related with the upregulation of pathways facilitating tumour proliferation and the suppression of immune cell infiltration in the tumor microenvironment.

**CONCLUSION**

The deep learning model could allow accurate prediction of early recurrence and survival in patients with LAGC.

**CLINICAL RELEVANCE/APPLICATION**

Our approach enables noninvasive assessment of the ER, which opens the door for longitudinal monitoring response to cancer therapy and predicting cancer outcomes. Given the routine use of radiologic imaging in oncology, our approach can be extended to many other solid tumor types.

## R6-SSGI20-3 BASELINE VIRTUAL MR ELASTOGRAPHY AND EXTRACELLULAR VOLUME FRACTION IN THE PREDICTION OF RESPONSE TO NEOADJUVANT IMMUNOCHEMOTHERAPY IN GASTRIC CANCER

Ying Li (*Abstract Co-Author*) Nothing to Disclose
Liming Jiang, MD (*Abstract Co-Author*) Nothing to Disclose
Yongjian Zhu, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Although neoadjuvant immunochemotherapy (NAIC) showed great potential for improving the prognosis of gastric cancer (GC), only about 40% patients could achieve pathological response. Accurate prediction of the NAIC response is crucial for patients' benefits. To evaluate the predictive performance of virtual MR elastography (vMRE) and extracellular volume (ECV) for predicting the response to of NAIC in GC patients.

**METHODS AND MATERIALS**

Consecutive patients with pathologically confirmed gastric adenocarcinoma and received NAIC plus radical gastrectomy were prospective collected. The patients underwent three cycles of the NAIC and received radical surgery within 4 weeks of completion of NAIC. Pathologic tumor regression was assessed using the Mandard tumor regression grade (TRG) standard. All patients underwent MR examination including DWI with four b-value. T1 mapping was performed before and 5 min after contrast agent injection, using variable flip angle VIBE sequence. The shifted ADC (sADC), DWI-based virtual shear modulus (μDiff), and ECV maps were calculated via an in-house developed software written in MATLAB .Diffusion parameters were compared by Mann-Whitney U test. Logistic regression analyses were performed to construct the combined model for MTM prediction. The receiver operating characteristic (ROC) curve was performed to evaluate the prediction performance.

**RESULTS**

A total of 68 LAGC patients were finally enrolled. After gastrectomy, 44.12% were pathologic responders (Table 1). Non-responders showed a higher tumor stage ($p = 0.027$) than responders. Statistical differences were observed for histopathological type, histological grade, and Lauren type between responders and non-responders ($p < 0.05$). The differences in the vMRE and ECV parameters between the two groups are listed in Table 2 and Figure 1A-E. Table 3 and Figure 1F-K summarize and displayed the predictive performance of the parameters for discriminating responders from non-responders. sADC and μDiff exhibited the highest predictive performance with an AUC of 0.833. The combination of μDiff and ECV could further improve predictive performance to an AUC to 0.968. Figure 2 illustrative examples of vMRE and ECV imaging for a responder and non-responder, respectively.

**CONCLUSION**

Tumor stiffness determined by vMRE and ECV exhibited good performances in predicting response to NAIC and may be used to guide clinical treatment in LAGC patients.

**CLINICAL RELEVANCE/APPLICATION**

Our result revealed that DWI-based virtual shear modulus (μDiff) and ECV exhibited promising predictive ability for predicting response to NAIC. This would aid in identifying responders before treatment, reducing unnecessary toxicity and side effects, and guiding individualized treatment.

## R6-SSGI20-4 PREDICTING COMBINED POSITIVE SCORE IN ESOPHAGEAL CANCER PATIENTS USING MULTIPARAMETRIC CEST-MRI

Xin Li, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Yuan Liu (*Abstract Co-Author*) Nothing to Disclose
Chuansheng Zheng, MD (*Abstract Co-Author*) Nothing to Disclose
Peng Sun, MD,MD (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Ziwei Jin (*Abstract Co-Author*) Nothing to Disclose
Si Xu (*Abstract Co-Author*) Nothing to Disclose
Quan Chen (*Presenter*) Nothing to Disclose

**PURPOSE**

Combined Positive Score (CPS), based on the expression of PD-L1, has emerged as a potential predictor of immunotherapy response in various cancers, including esophageal cancer. The objective of this study is to assess the potential of multiparametric chemical exchange saturation transfer magnetic resonance imaging (CEST-MRI) in predicting CPS in patients with esophageal cancer.

**METHODS AND MATERIALS**

A prospective study was conducted on esophageal cancer patients who underwent CEST-MRI imaging between August 2023 and April 2024. Demographic and clinical data, including age, BMI, gender, tumor location, TNM staging, and pathology, were collected. CPS was calculated based on PD-L1 expression in tumor tissues. Multiparametric CEST-MRI technology yields a total of 12 quantitative parameters, including Amide, NOE, Amine, MT, DS, AmideVsAmine, MTR35, MTRrex-amide, AREX-admide, DNS-AREX, pH-weighted and AACID maps. The data are fitted using in-house MATLAB scripts. A

statistical analysis, including correlation analysis and multivariate regression, was conducted to assess the relationship between CEST-MRI parameters and CPS.

**RESULTS**

A total of 28 patients of esophageal cancer divided into 2 group (CPS <10 and CPS = 10). Significant correlations were observed between specific CEST-MRI parameters (AACID, MT, AREX-amide, DNS_AREX and MTR3.5) and CPS = 10 ($p < 0.05$). Furthermore, multivariate regression analysis demonstrated the independent predictive value of CEST-MRI parameters for CPS.

**CONCLUSION**

Multiparametric CEST-MRI has the potential to serve as a non-invasive imaging modality for predicting CPS in patients with esophageal cancer.

**CLINICAL RELEVANCE/APPLICATION**

The correlation between CEST-MRI parameters and CPS indicated that CEST-MRI may be a useful tool in guiding immunotherapy strategies and patient management. Further prospective studies are required to validate these findings and elucidate the clinical utility of CEST-MRI in a personalized treatment approach for esophageal cancer.

## R6-SSGI20-5 RADIOGRAPHIC CHARACTERIZATION TO NONINVASIVELY DIFFERENTIATE TRUE DISEASE PROGRESSION FROM PSEUDOPROGRESSION IN LYMPH NODES

Qingling Zhang (*Abstract Co-Author*) Nothing to Disclose
Ziyu Ning (*Abstract Co-Author*) Nothing to Disclose
Yihuai Hu, MD (*Abstract Co-Author*) Nothing to Disclose
Zaiyi Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Chenyi Xie, BMBS, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The therapeutic landscape for locally advanced esophageal squamous cell carcinomas (ESCC) is remarkably evolving. This study aims to differentiate lymph nodal disease progression from immune-activated responses by systematically analyzing sematic imaging features based on routine workup and re-assessment CT images

**METHODS AND MATERIALS**

We retrospectively enrolled 232 ESCC patients receiving neoadjuvant immunochemotherapy (nICT) plus surgery from three medical centers. CT images were evaluated by experienced radiologists and enlarged LNs after immunotherapy were further analyzed for size measurement and morphological appearances. Subsequently, we correlated radiological features with well-established clinicopathological characteristics and overall survival for clinical significance. Last, we profiled lymph nodal T cell abundance and spatial distribution by using the multiplexed immunofluorescence (mIHC) profile to explore the potential mechanisms in radiologically LN enlargement.

**RESULTS**

The nICT yielded radiologically enlarged LN in 60/232 (25.9%) of patients. We observed that changes in long-axis diameters, the imaging-identified extranodal extensions, and shapes are predictive for LN involvement status. A cutoff value of <32% change in the long axis was a significant predictor of malignancy (AUC = 0.709). The presence of enlarged metastatic LNs is independently associated with poor overall survival for ESCC receiving nICT (hazard ratio: 2.25 [95% CI: 1.16,4.35], $P < 0.001$). The benign enlargements are more likely to occur in patients with favorable prognostic biomarkers receiving nICT. The mIHC staining reveals differences in the composition of T helper and T cytotoxic cells between the metastatic and nonmetastatic groups. The enlarged uiLNs presented more prominent elevated PD-1 expression in the germinal follicles and highly proliferative CD4+ T cells.

**CONCLUSION**

The systematic assessment of LNs in ESCC responses to ICIs remains inadequately defined. This study represents the initial preliminary report documenting radiologically enlarged regional and distant LN in locally advanced ESCC subjected to nICT. We emphasize the critical importance of a precise evaluation approach for suspected progression LNs following nICT before finalizing treatment decisions. We expected that the multidimensional evaluation of tumor-draining LNs in this study might facilitate the improved decision-making in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

Radiologist-evaluated semantic features continue to have diagnostic values in differentiating metastatic status of tumor-draining lymph nodes, revealing the potential mechanism and clinical significance of immune-related responses in ESCC.

## R6-SSGI20-6 BASELINE HIGH-RESOLUTION MRI FOR PREDICTING PROGNOSIS IN PATIENTS WITHLOCALLY ADVANCED ESOPHAGEAL SQUAMOUS CARCINOMA UNDERGOINGDEFINITIVE CHEMORADIATION THERAPY

Linlin Wang, MEd, MEd (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to assess the performance of baseline high-resolution MRI in predicting progression-free survival (PFS) among patients with locally advanced esophageal squamous cell carcinoma (ESCC) treated with definitive chemoradiation therapy (CRT).

**METHODS AND MATERIALS**

We retrospectively analyzed 30 patients with locally advanced ESCC between June 2019 and May 2021. Pretreatment high-resolution MRI data were comprehensively evaluated. Multivariate Cox proportional hazards models were employed to identify independent prognostic factors. Time-dependent receiver operating characteristic (ROC) curve analysis was performed to assess the prognostic accuracy of the MRI model. Survival analysis was calculated using the Kaplan-Meier method and log-rank tests.

**RESULTS**

In multivariate Cox regression analysis, tumor thickness (HR 1.20, 95% CI 1.01-1.43, $P = 0.036$), the evaluation of aorta invasion [clear boundary, suspicious involvement (HR 4.20, 95% CI 1.01-17.40, $P = 0.048$), definite involvement (HR 11.00, 95% CI 1.20-101.00, $P = 0.034$)], and the change ratios of signal intensity of lymph nodes in the delayed enhancement phase (HR 0.04, 95% CI 0.01-0.31, $P = 0.002$) were significant prognostic factors for PFS. The MRI model exhibited excellent prognostic accuracy, with AUC values of 0.924 and 0.920 for 1-year and 3-year PFS, respectively. Kaplan-Meier analysis demonstrated that patients in the high-risk group exhibited significantly poorer PFS than those in the low-risk group (log-rank test, $P < 0.001$).

## CONCLUSION

Baseline high-resolution MRI could predict the prognosis of locally advanced ESCC patients receiving CRT.

## CLINICAL RELEVANCE/APPLICATION

This MRI model had the potential to guide clinical decision-making and achieve individualized treatment for patients with locally advanced esophageal cancer.

## R6-SSGU07-2 DEVELOPING A ROBUST DEEPLEARNING MODEL FOR ADRENAL GLAND SEGMENTATION IN LARGE-SCALE NON-CONTRAST CT IMAGES

Tuo Zhang (*Abstract Co-Author*) Nothing to Disclose
Feng Shi (*Abstract Co-Author*) Employee, Shanghai United Imaging Healthcare Co, Ltd
Yinghui Ge (*Abstract Co-Author*) Nothing to Disclose
Yuwei Xia (*Abstract Co-Author*) Nothing to Disclose
Fanxing Meng (*Presenter*) Nothing to Disclose

### PURPOSE

Quantifying the adrenal glands is crucial for research into related diseases, as they are vital endocrine organs in the human body. The challenge of accurately segmenting adrenal glands due to their changing positions, size and low contrast in non-contrast CT examinations. The purpose of our study is to overcome these challenges by developing a non-contrast CT-based deep learning algorithm for precise adrenal gland segmentation.

### METHODS AND MATERIALS

This retrospective study included 1,220 CT examinations. The data were further divided to training set (n= 960), test set (n=240) and inter-reader set (n=20). Furthermore, an independent test set (n=81) were also collected. Two radiologists manually segmented the adrenal parenchyma of each side in axial images, and then these results were checked and modified by a senior radiologist. For the inter-reader set, five board-certified radiologists provided annotations on a subset of 20 random cases, performed in a multi-blind manner. A 3D nnU-net based model was utilized to build an automatic segmentation model of the adrenal glands from the CT scans, enabling automatic positioning, volume, and diameter quantitative analysis of the left and right adrenal glands. Model performance was assessed through Dice Similarity Coefficient (DSC), Hausdorff Distance (HD), and Average Symmetric Surface Distance (ASSD). In light of the need for robust validation, we further evaluated the performance of our segmentation model by gauging its consistency against the expertise of human radiologists.

### RESULTS

The developed segmentation models yielded median DSC scores of 0.899 and 0.904 for the left and right adrenal glands respectively in the test set, and similar scores of 0.900 for the left and 0.896 for the right gland in the independent test set. Furthermore, no significant difference was found between inter-reader DSC for manual segmentation by radiologists and the automatic segmentation by our machine (P=0.541). It has showcased a superior degree of adaptability and precision compared to enhanced CT-based models.

### CONCLUSION

This robust deep learning model provides a quick and precise method to measure adrenal quantitative parameters.

### CLINICAL RELEVANCE/APPLICATION

This automatic process has the capacity to screen patients with abnormal adrenal manifestations (such as adrenal enlargement) during regular CT examinations. The automaticity and precision of this model could enhance clinical diagnosis and decision-making. Given the potential impact on renal healthcare, further validations of the proposed model in multi-center studies with a larger sample volume will increase its robustness and applicability in the real-world setting.

## R6-SSGU07-3 UNLOCKING THE MYSTERY: BODY COMPOSITION TWEAKS REVEALED IN CT IMAGING - MACS AND NFAI IN ADRENAL INCIDENTALOMAS. WHAT TO DO?

Emilio Quaia, MD (*Abstract Co-Author*) Speakers Bureau, Bracco Group

Francesco Bigolin, MD (*Abstract Co-Author*) Nothing to Disclose
Matteo Scordari, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Adrenal incidentalomas (AI) are adrenal masses found during unrelated imaging procedures. Roughly 50% are classified as non-functioning adrenal incidentalomas (NFAI), while 30 to 50% as exhibit mild autonomous cortisol secretion (MACS). According to the clinical guidelines from the European Society of Endocrinology, surgery might be considered as an option for patients with significant co-morbidities who have MACS, with careful consideration of individual factors. Our aim was to investigate whether a more prompt and specific approach to surgery could be applied to differentiate between MACS and NFAI.

**METHODS AND MATERIALS**

We examined 117 patients with AI. 54 patients with MACS were compared with 63 patients with NFAI. CT scans were conducted on patients with MACS at baseline and following a median duration of 5 years, while patients with NFAI underwent CT scans at baseline and after a median duration of 4.1 years. Measurements were performed at the 3rd lumbar spine level. We analyzed total body surface and body circumference, total fat area (TFA), visceral and parietal areas (VFA, PFA), visceral-total and visceral- parietal ratios, muscle surface and perimeter. Additionally, liver, spleen, muscle, and bone attenuation were registered. For our analysis, we utilized ImageJ, a Java-based software derived from NIH Image. Statistical comparisons were conducted using Student's t-test or Mann-Whitney test.

**RESULTS**

In the MACS group, our analysis revealed a statistically significant increase in total body area (Median pre 710cm2, IQR 584-829; Median post 765cm2, IQR 615-867; p=0.03) and in visceral fat (Median pre 174cm2, IQR 113-278; Median post 183cm2, IQR 133-276; p=0.05), a reduction in mean densitometry of the spleen (Median pre 47.1HU, IQR 42-51; Median post 45.3HU; IQR 40-48; p=0.02), and a decrease in densitometry at the L1 level (Median pre 106HU, IQR 84-142; Median post 100HU, IQR 76-134; p=0.02). Conversely, in the NFAI group, our analysis did not reveal any statistically significant difference between the baseline and follow-up CT scans concerning the total body area, the visceral fat, and the HU of the spleen, while, we identified a statistically significant reduction of the mean densitometry at the L1 level (Median pre 125HU, IQR 100-159; Median post 114HU, IQR 86-159; p=0.04).

**CONCLUSION**

Surgery should be considered as the primary treatment option for MACS in order to reduce cardiovascular, stroke, and osteoporotic risks.

**CLINICAL RELEVANCE/APPLICATION**

Analyzing body composition alterations via CT scans aids in better patient management, guiding surgical decisions and reducing cardiovascular and stroke risks.

## R6-SSGU07-5 APPLICATION VALUE OF CT LYMPHANGIOGRAPHY IN THE GRADING OF PRIMARY CHYLURIA

Qi Hao (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of CT lymphangiography (CTL) in the grading of primary chyluria.

**METHODS AND MATERIALS**

The clinical and CTL imaging data of 77 patients diagnosed with primary chyluria were collected retrospectively.Referring to the clinical grading criteria,seventy-seven patients were divided into mild and severe groups, and CTL indexes were recorded separately for each group.CTL indexes include: Abnormal deposition of lipiodol in the urinary system, chest, abdomen and pelvis, image manifestations of the two groups were statistically analyzed. ?2 test was used for counting data, and independent sample t test was used for measurement data. $P < 0.05$ was considered statistically significant.

**RESULTS**

Among 77 cases of primary chyluria, 27 cases were in mild group and 50 cases were in severe group. Among the 27 patients with mild primary chyluria, CTL showed abnormal deposition of iodide in renal parenchyma in 10 cases (37.0%), perivascular in 23 cases (85.2%), subcapsular in 2 cases (7.4%), extracapsular in 7 cases (25.9%), adiposicular in 8 cases (29.6%), adrenal in 5 cases (18.5%), and extracapsular in 6 cases (22.2%). There were 6 cases in bladder (22.2%) and 1 case in peribladder (14.8%). Among the 50 patients with severe primary chyluria, CTL showed abnormal deposition of iodide in renal parenchyma in 25 cases (50.0%), perivascular in 47 cases (94.0%), subcapsular in 2 cases (4.0%), extracapsular in 14 cases (28.0%), adiposicular in 6 cases (12.0%), adrenal in 7 cases (14.0%), and extracapsular in 4 cases (8.0%). There were 23 cases (46.0%) within the bladder and 8 cases (16.0%) around the bladder.The difference of whole kidney type was statistically significant (P=0.009), and the incidence of severe group (68.0%) was higher than that of mild group (37.0%).There were statistically significant differences in abnormal lipiodol deposition in renal parenchyma and bladder between 2 groups ($P < 0.05$), and the incidence of abnormal lipiodol deposition in severe group was higher than that in mild group.

**CONCLUSION**

CTL can show the distribution, extent and severity of abnormal dilated lymphatic vessels in primary chyluria, and the abnormal distribution of iodide in kidney and bladder has clinical significance for the classification of primary chyluria.In addition, it can also show systemic lymphatic abnormalities.

**CLINICAL RELEVANCE/APPLICATION**

CTL can provide an important image basis for the diagnosis,classification and treatment of primary chyluria.

## R6-SSGU07-6 RETROSPECTIVE ANALYSIS OF ANNUAL TRENDS IN PROSTATE CANCER GRADING: A COMPREHENSIVE RESEARCH STUDY

Robert E. Reiter, MD (*Abstract Co-Author*) Nothing to Disclose
Holden H. Wu, PhD (*Abstract Co-Author*) Institutional research support, Siemens AG
Steven S. Raman, MD (*Abstract Co-Author*) Consultant, Johnson & Johnson;Consultant, Bayer AG;Consultant, Merck & Co, Inc;Consultant, Amgen Inc;Consultant, Profound Medical Inc

Kyunghyun Sung, PhD (*Abstract Co-Author*) Nothing to Disclose
Sohaib Naim, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to examine the impact of evolving prostate cancer (PCa) screening guidelines for a patient population with both multiparametric MRI (mpMRI) and histopathological (HP) data by analyzing annual PCa grade distribution, detection rate (DR), and positive predictive value (PPV) trends.

## METHODS AND MATERIALS

For this retrospective study, our study group consisted of 902 male subjects whose data was collected at our single institution between 2010 and 2021. Eligibility criteria for this study included available clinicodemographic data, mpMRI scans acquired via standardized protocol, and prostate whole-mount HP (WMHP), all retrieved with HIPPA and IRB approval. Genitourinary (GU) pathologists and GU radiologists performed monthly matching workflows to determine concordance for detected and graded PCa true positive (TP), false negative (FN), and false positive (FP) lesions. Information from TP, FN, and FP lesions were used to calculate DRs and PPVs for every patient. All TP, FN, and FP lesions were then grouped by acquisition year to estimate annual trends. Reviewed clinical features included mean and standard deviation for subject age, PSA level, prostate volume, PSA density, and MRI lesion size. All PCa grading guidelines were issued by PI-RADS for mpMRI lesions and ISUP for WMHP lesions. A weighted chi-square test correlated statistical differences for DR and PPV at each annual cutoff point.

## RESULTS

Annual trends are presented for MRI, WMHP, clinical, and statistical findings. Total MRI scans acquired per year gradually increases from 2010-2013 before stabilizing from 2014 onwards and peaking in 2015. The same trend is reflected for PI-RADS grades, where from 2010-2013 there is a gradual increase in grades 3-5 lesions per year. Although grades 4 and 5 lesions stabilize from 2014 onwards, grade 3 lesions gradually decrease. ISUP annual trends reflect PI-RADS trends, showing steady growth in total findings from 2010-2013 at every grade. Like PI-RADS grade 3 lesions, ISUP lesions grade 1 gradually decrease 2014 onwards whereas grade 2-5 lesions per year stabilize. Included clinical features were largest in 2018 and 2020, and our statistical findings showed DR and PPV before and after 2018 and 2014, respectively, were the most significantly different.

## CONCLUSION

Our study has confirmed significant DR and PPV differences for several annual groupings while also confirming the impact of evolving PCa screening guidelines through annual PI-RADS and ISUP grading trends for TP, FN, and FP lesions, all of which should be closely monitored for prospective studies.

## CLINICAL RELEVANCE/APPLICATION

Understanding annual PCa grading and clinical trends can lead to key findings that can contribute to improving PCa diagnosis rates and screening guidelines.

## R6-SSMK12-1 FUTILITY OF PREOPERATIVE US-GUIDED SENTINEL LYMPH NODE BIOPSY IN ACRAL MELANOMA: A 5-YEAR RETROSPECTIVE STUDY

Jung Han Kim (*Abstract Co-Author*) Nothing to Disclose
Kee-Taek Jang, MD (*Abstract Co-Author*) Nothing to Disclose
Harim Kim, MD (*Abstract Co-Author*) Nothing to Disclose
Sang-Hee Choi, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Preoperative evaluation of nodal status is crucial for treatment and prognosis in acral melanoma patients. While clinical guidelines for surgical sentinel lymph node biopsy (SLNB) are well established, clinical indications for preoperative sentinel lymph node ultrasound (US) and US-guided SLNB are relatively obscure. This study explores clinical usefulness of preoperative sentinel lymph node US and US-guided SLNB.

### METHODS AND MATERIALS

In this single-center retrospective study, 90 acral melanoma patients who underwent both preoperative sonographic lymph node evaluation and surgical lymph node dissection were identified from 2015 to 2018. Patients were categorized into four groups based on the preoperative US findings and the performance of US-guided SLNB. Preoperative US score was measured by presence of loss of hilar fat, cortical irregularity, increased cortical echogenicity, increased cortical Doppler, and mass-forming morphology. The medical records including body mass index (BMI), pathologic report and images were reviewed. The survival of groups was analyzed with the preoperative US findings and the performance of preoperative US-guided SLNB. Subgroup analysis was performed for surgical SLNB negative patients to find out risk factors for 5-year recurrence. Uni- and multivariable analysis including Cox regression were performed to identify risk factors for 1- and 5-year recurrence and death within 5 years.

### RESULTS

Regardless of preoperative US abnormality, US-guided SLNB did not yield difference in patient survival ($p = 0.346$ and 0.556 respectively). Higher US score correlated with both 1- and 5-year recurrence ($p = 0.002$ and 0.013 respectively), and hematogenous metastasis within 5 years after surgery ($p = 0.008$). The thickness of tumor and lymphatic metastasis at initial surgery was related to local tumor recurrence within 5 years after surgery ($p = 0.001$ and 0.002 respectively). Tumor size and the presence of hematogenous metastasis ($p = 0.002$, and 0.003 respectively) were closely correlated with 5-year survival. In subgroup analysis, the thickness of tumor was statistically significant factor for 5-year recurrence after surgery among surgical SLNB negative patients ($p = 0.0013$). Preoperative BMI did not show any significant correlation with recurrence nor metastasis.

### CONCLUSION

Preoperative US-guided SLNB did not affect the postoperative patient prognosis. However, applying preoperative US scoring criteria can help predict 1- and 5-year recurrence.

### CLINICAL RELEVANCE/APPLICATION

Preoperative US-guided SLNB is not necessary for identification of micro-metastasis as it does not affect patient prognosis. However, preoperative sentinel lymph node US has clinical value in that it helps predict 1- and 5-year recurrence.

## R6-SSMK12-2 MRI OF ATYPICAL LIPOMATOUS TUMOR: DOES GADOLINIUM HELP? A MULTICENTER STUDY

Hande Nalbant, MD, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance of Magnetic Resonance Imaging (MRI) with and without gadolinium-based contrast agents (GBCA) for differentiating atypical lipomatous tumor (ALT) from benign lipoma (BL) in a large dataset.

**METHODS AND MATERIALS**

This multicenter (5 different institutions) retrospective study included subjects with a histopathologic diagnosis of BL or ALT and a preoperative MRI study with contrast.A musculoskeletal radiologist of 10 years of experience reviewed all the images in two sessions (at least 4 weeks apart), the first session with non-contrast only, and the second session, including postcontrast sequences.At each session the radiologist scored the probability of being ALT or BL using as a binary decision and as a 5-point grading scale to mimic the clinical reporting language (Fig. 1). Pathology reports were used as the gold standard.McNemar's test was used to evaluate the statistical significance of the differences in sensitivity and specificity. Intraclass correlation coefficient (ICC) was used to compare the ordinal diagnostic scores.

**RESULTS**

466 cases (228 ALT, 238 SL) were eligible for analysis.In the first session (no contrast- WOC), 239 lesions were assessed as BLs (77.4% were true negative) and 227 lesions were assessed as ALTs (76.7% were true positive).In the second session (with contrast images -WC), 234 lesions were assessed as BLs (77.8% were true negative) and 232 lesions were assessed as ALTs (75.9% were true positives).The agreement on assigning the exact score between the two sessions, as measured by ICC, was 0.883 (95%CI: 0.863 - 0.901).There were no significant differences between the two readings in sensitivity or specificity on analysis.

**CONCLUSION**

Our study demonstrated no significant difference in radiologic readings between with contrast and without contrast MRIs in the assessment of BL and ALT.

**CLINICAL RELEVANCE/APPLICATION**

Most MRI examinations include post contrast sequences to improve image quality. On the other hand, GBCAs may cause some adverse reactions such as allergic reaction, nephrogenic systemic fibrosis or long-term accumulation in the organs including bones and brain. Therefore, the use of contrast administration should be carefully prescribed, especially when the clinical indication is differentiation between BL vs ALT.

## R6-SSMK12-3 REVISED BONE REPORTING AND DATA SYSTEM (BONE-RADS): PERFORMANCE AND RELIABILITY COMPARED WITH THE ORIGINAL BONE-RADS

Atefe Pooyan, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Sara Haseli, MD (*Abstract Co-Author*) Nothing to Disclose
Majid Chalian, MD (*Abstract Co-Author*) Grant, The Boeing Company
Arash Azhideh, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Ehsan Alipour, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Chankue Park, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The Bone Reporting and Data System (Bone-RADS) has some limitations due to biased clinical factors. We aimed to propose a revised Bone-RADS and to compare its diagnostic performance and inter-reader reliability with the original algorithm for solitary bone lesions on CT.

**METHODS AND MATERIALS**

This retrospective analysis included 159 patients (mean age, 56 ± 19 years; 88 men) who underwent bone biopsies between March 2005 and September 2021. Patients with solitary bone lesions on CT and sufficient histopathology results were included. In the revised Bone-RADS, the criteria of pain attributable to the lesion and a history of malignancy were omitted. Two radiologists categorized the bone lesions in the original and revised Bone-RADS (1, likely benign; 4, suspicious for malignancy or need for treatment). The diagnostic performance of the Bone-RADS was calculated using histopathology results as a standard reference and compared with each other. Inter-reader reliability was assessed.

**RESULTS**

Bone lesions were categorized into two groups: 96 lucent and 63 sclerotic/mixed lesions. For the original and revised Bone-RADS in reader 1, algorithms in lucent lesions demonstrated sensitivities of 93% and 93%, specificities of 11% and 50%, positive predictive values of 72% and 82%, negative predictive values of 38% and 74%, and accuracies of 69% and 80%, respectively. In sclerotic/mixed lesions, they exhibited sensitivities of 73% and 65%, specificities of 32% and 92%, positive predictive values of 43% and 85%, negative predictive values of 63% and 79%, and accuracies of 49% and 81%, respectively. For the original and revised Bone-RADS in reader 2, algorithms in lucent lesions showed sensitivities of 82% and 94%, specificities of 11% and 46%, positive predictive values of 69% and 81%, negative predictive values of 20% and 76%, and accuracies of 61% and 80%, respectively. In sclerotic/mixed lesions, they had sensitivities of 69% and 73%, specificities of 32% and 86%, positive predictive values of 42% and 79%, negative predictive values of 60% and 82%, and accuracies of 48% and 81%, respectively. Inter-reader reliability in the revised algorithm was higher than in the original algorithm (? = 0.744 vs. 0.854).

**CONCLUSION**

In comparison with the original Bone-RADS, the revised Bone-RADS demonstrated increased specificity and accuracy while maintaining sensitivity.

**CLINICAL RELEVANCE/APPLICATION**

The original Bone-RADS has some limitations, where there are many ambiguous cases distinguishing whether the pain is caused by the tumor itself or by general condition such as internal degeneration or trauma. Revised Bone-RADS, excluding clinical factors from original Bone-RADS, performed better in evaluating solitary bone tumor on CT.

## R6-SSMK12-4 DETECTIVE ABILITY OF PH IN OSTEOSARCOMA MICROENVIRONMENT USING CHEMICAL EXCHANGE SATURATION TRANSFER(CEST) IMAGING

Songtao Ai (*Abstract Co-Author*) Nothing to Disclose
Zhengjia Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this study is to investigate the ability of ioversol chemical exchange saturation transfer (CEST) imaging in detecting pH in the microenvironment of rat osteosarcoma.

**METHODS AND MATERIALS**

In vitro, we used 15 phantom tubes filled with PBS solution with different pH and different concentration of ioversol to verified the relation between pH and CEST ratiometric values. And in vivo, ten rats were used to test whether ioversol could be used as contrast agent for pH imaging on osteosarcoma. Rat osteosarcoma cells were injected subcutaneously into the hind limbs of SD rats. 2 weeks after cell implantation, the rats were scanned by a 3T MR system with a 32-channel head coil. For 9 out of 10 rats, ioversol (4g I/kg body weight) was injected through tail vein. CEST images were acquired using a 2d turbo spin echo sequence with the saturation duration of 1.5s and saturation powers of 1μT and 3μT. All CEST images were postprocessed via MATLAB. The pH weighted ratiometric values were calculated by the ratio of MTRasym (3.5 ppm) in 1 μT to MTRasym (3.5 ppm) in 3 μT using a custom Matlab code.

**RESULTS**

To test whether CEST imaging could distinguish the ioversol solutions at different pH level, 10 tubes of 30mM ioversol at pH 5.0 to 8.2 were used. The result showed that the pH value and CEST effect were linearly correlated in the pH range of 5.8-7.0 ($R2=0.86$, $p<0.0001$). To test the relationship between ioversol concentration and ratiometric value, 5 tubes of pH 7.2 with different ioversol concentrations (30, 50, 70, 90, 110 mM) were prepared, the result showed that the ratiometric values of ioversol solution were not concentration-dependent on in the concentration range tested. In addition, the results of rat osteosarcoma models showed that the calculated ratiometric value of the majority of the tumor region was relatively low, suggesting the acidic and solid part of the tumor, while there was also small region with high value, suggesting the necrotic and cystic portion of the tumor. This finding was confirmed by histopathology.

**CONCLUSION**

Our findings provide the first evidence that ioversol-enhanced CEST imaging can actually measure pH-related ratiometric value in osteosarcoma in a concentration-independent manner, with excellent spatial resolution. Furthermore, the CEST effect is heterogeneous in the tumor ROI, it can be expected to become one of the methods for early evaluation of the effect of preoperative neoadjuvant chemotherapy in cancer patients.

**CLINICAL RELEVANCE/APPLICATION**

By using CEST imaging, the status of osteosarcoma can be correlated with the actual pH value. CEST imaging potentially can be a novel method for assessing the early effect of preoperative neoadjuvant chemotherapy in the future.

## R6-SSMK12-5 NESTED HABITAT ANALYSIS BASED ON MRI FOR THE PREDICTION OF PROGRESSION-FREE SURVIVAL IN AGGRESSIVE SPINAL TUMOR

Tongyu Wang (*Abstract Co-Author*) Nothing to Disclose
Dapeng Hao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yang Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Ning Lang, MD (*Abstract Co-Author*) Nothing to Disclose
Qizheng Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the feasibility of MRI-based Nested Habitat Radiomics for predicting the progression-free survival (PFS) of aggressive spinal tumors to aid early personalized treatment decisions.

**METHODS AND MATERIALS**

Clinical, pathological and imaging data of 211 patients underwent spinal tumor resection from March 2010 and January 2021 were retrospectively analyzed. The primary outcome was 3-year PFS. Fuzzy C-means algorithm was used to perform clustering on T1-weighted images (T1WI) and T2-weighted images (T2WI) to segment ROIs of the lesions. Then a Nested Habitat Analysis Method was employed to evaluate the heterogeneity of the lesions. For the first round of habitat analysis, a Support Vector Machine (SVM) is then developed to classify the lesions based on global features extracted from ROIs. Following the global analysis, the local radiomics features were extracted from smaller patches inside ROIs of patients with poor prognosis. We applied this SVM model to these local features to generate probability maps that indicate areas of potential aggressiveness, followed by k-means clustering to segment the ROIs into 2 sub-ROIs. Then an updated SVM model were trained to identify these sub-ROIs of poor prognosis. For each poor prognosis patients, another round of habitat analysis was applied and each of sub-ROI was divided into 2 micro-ROIs using k-means clustering. The final radiomics model were established based on the each patient's mico-ROI with highest probability. A nomogram was developed by radiomics signatures and the clinical independent parameter for personalized PFS prediction. The performance was primarily evaluated using the area under the receiver operating characteristics curve (AUC) via the DeLong test. Meanwhile, survival analysis was conducted to explore the hierarchical guidance significance.

**RESULTS**

Compared with texture features extracted from the whole tumor, the features generated by the Nested Habitat method can better predict the recurrence ($p < 0.05$). At the same time, the Habitat model combined with clinical characteristics showed best performance in postoperative PFS evaluation, with AUC of 0.93 and 0.88 in the training and external test cohort, respectively. Kaplan-Meier survival analysis showed the Nested Habitat Rad-score were independent risk factors for 3-year PFS.

**CONCLUSION**

The Nested Habitat Rad-score is a noninvasive imaging predictor that could guide the stratification of prognosis in aggressive spinal tumor.

**CLINICAL RELEVANCE/APPLICATION**

The Nested Habitat model to predict PFS could be useful in clinical decision-making associated with personalized selection of surgical interventions and therapeutic options for patients with aggressive spinal tumor as a noninvasive and less costly approach.

## R6-SSMK12-6 DIAGNOSTIC PERFORMANCE AND INTER-READER RELIABILITY OF BONE REPORTING AND DATA SYSTEM (BONE-RADS) ON COMPUTED TOMOGRAPHY

Ehsan Alipour, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Atefe Pooyan, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Sara Haseli, MD (*Abstract Co-Author*) Nothing to Disclose

Majid Chalian, MD (*Abstract Co-Author*) Grant, The Boeing Company
Chankue Park, MD (*Abstract Co-Author*) Nothing to Disclose
Arash Azhideh, MD, MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance and inter-reader reliability of the Bone Reporting and Data System (Bone-RADS) for solitary bone lesions on CT.

**METHODS AND MATERIALS**

This retrospective analysis included 179 patients (mean age, 56 ± 18 years; 94 men) who underwent bone biopsies between March 2005 and September 2021. Patients with solitary bone lesions on CT and sufficient histopathology results were included. Two radiologists categorized the bone lesions using the Bone-RADS (1, benign; 4, malignant). The diagnostic performance of the Bone-RADS was calculated using histopathology results as a standard reference. Inter-reader reliability was calculated.

**RESULTS**

Bone lesions were categorized into two groups: 103 lucent (pathology: 34 benign, 12 intermediate, 54 malignant, and 3 osteomyelitis) and 76 sclerotic/mixed (pathology: 46 benign, 2 intermediate, 26 malignant, and 2 osteomyelitis) lesions. The Bone-RADS for lucent lesions had sensitivities of 95% and 82%, specificities of 11% and 11%, and accuracies of 57% and 50% for readers 1 and 2, respectively. The Bone-RADS for sclerotic/mixed lesions had sensitivities of 75% and 68%, specificities of 27% and 27%, and accuracies of 45% and 42% for readers 1 and 2, respectively. Inter-reader reliability was moderate to very good (? = 0.744, overall; 0.565, lucent lesions; and 0.851, sclerotic/mixed lesions).

**CONCLUSION**

Bone-RADS has a high sensitivity for evaluating malignancy in lucent bone lesions and good inter-reader reliability. However, it has poor specificity and accuracy for both lucent and sclerotic/mixed lesions. A possible explanation is that proposed algorithms heavily depend on clinical features such as pain and history of malignancy.

**CLINICAL RELEVANCE/APPLICATION**

Bone-RADS has the merits of high sensitivity and inter-reader reliability, but it showed poor specificity and accuracy. We speculate that Bone-RADS heavily depend on clinical factors such as pain. Further studies comparing the performance of the original with the revised algorithm, excluding clinical factors, are needed.

### PURPOSE

To assess the diagnostic value of combined hybrid cardiac magnetic resonance (CMR) and 18F-fluorodeoxyglucose positron emission tomography (FDG-PET) for the detection and differentiation of chronic active versus healed myocardial injury in patients with a history of confirmed SARS-CoV-2 infection and persistent symptoms.

### METHODS AND MATERIALS

Twenty-six patients presenting with persistent symptoms since the onset of COVID-19 infection, with a median symptom duration of 7.5 months and a mean age of 39 ± 12 years (50% female), were prospectively enrolled in this study. Following dietary preparation for the suppression of myocardial glucose metabolism, patients underwent evaluation using a 3 Tesla hybrid PET/MR scanner. The CMR protocol comprised T1 and T2 mapping, assessment of myocardial function, and LGE imaging. Myocardial FDG uptake was categorized as negative (successful suppression), positive (focal or focal-on-diffuse uptake), or excluded if diffuse and homogenous myocardial FDG uptake exceeded liver uptake and affected the entire left ventricle, suggesting unsuccessful suppression. FDG uptake was quantified as the ratio of normal myocardium to blood pool (TBRmax) and the ratio of target to normal myocardium (TNMRmax).Chronic active myocardial injury was assumed if both PET and CMR findings were positive, healed myocardial injury if PET was negative but CMR findings were positive, and no myocardial injury if patients were CMR-negative regardless of PET findings.

### RESULTS

Myocardial FDG uptake was successfully suppressed in all patients with TBRmax 1 ± 0.2. Chronic active myocardial injury with focal FDG uptake was diagnosed in 9 (35%) patients, healed myocardial injury in 8 (30%) patients, and no myocardial injury in 9 (35%) patients. TNMRmax was significantly higher in patients with chronic active myocardial injury 2.6 ± 0.9 vs. healed or no myocardial injury 1.1 ± 0.2 ($p<0.0001$). Left ventricular ejection fraction was preserved overall (66 ± 5%). Non-ischemic LGE was present in 8 (31%) patients, while T1 mapping abnormalities were observed in 16 (62%) patients and T2 mapping abnormalities in 15 (58%) patients.

### CONCLUSION

The combined CMR/FDG-PET imaging approach appears to be valuable not only for the detection of myocardial injury but also for the differentiation between chronic active and healed myocardial injury in patients with long COVID.

### CLINICAL RELEVANCE/APPLICATION

Combined CMR/FDG-PET holds promise in evaluating myocardial injury in long COVID, potentially guiding management decisions and long-term monitoring strategies.

## R6-SSNMMI08-2 ASSESSING PRECISION IN HEPATOCELLULAR CARCINOMA (HCC) TREATMENT RESPONSE ASSESSMENT: INTER-READER AND INTRA-READER RELIABILITY USING $^{68}$GA PSMA PET/CT VERSUS CROSS-SECTIONAL IMAGING

Aashna M. Karbhari, MD (*Abstract Co-Author*) Nothing to Disclose

Nandakumar Patnam, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Ajith Antony, MBBS, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Precise HCC treatment response evaluation is vital for optimizing therapies and trial designs. 68Ga-PSMA, a theranostic radiotracer, is hyper-expressed in HCC neovasculature. We tested its measurement reliability against CT/MRI across and within readers.

**METHODS AND MATERIALS**

We prospectively enrolled treatment-naļve HCC patients qualified for loco-regional therapy (LRT) or immunotherapy (IT) who underwent 68Ga-PSMA PET before and after treatment, alongside a multiphasic CT/MR. Lesions with PSMA uptake less than (grade 1) or equal to liver (grade 2) were excluded, while those with uptake higher than liver (grade 3) or spleen (grade 4) were included. Three radiologists independently evaluated the imaging response, applying mRECIST and LR-TR to the LRT cohort, and mRECIST with RECIST 1.1 to the IT group, with a minimum 2-week gap between CT/MR and PET assessments. Post-treatment uptakes of PSMA at grades 1 and 2 indicated response; grades 3 and 4 were categorized as non-response. For intra-reader assessment, a minimum 3-week gap was observed with randomized scans for each review session. Reader agreement was evaluated using Gwet's AC1 and 2.

**RESULTS**

Of 88 patients screened with PSMA PET, 69 (78%) had PSMA-avid HCC. Thirteen patients (mean age:75.1, range:30-84; 11 males) with 29 lesions (mean size:3.6 cm, range:1-20 cm) qualified for the study, split into seven (54%) for LRT with 10 lesions and six (46%) for IT with 19 lesions. Average interval between pre-treatment PET and CT/MRI was 19-days (range:0-46), and post-treatment was 10-days (range:0-56). Pre-treatment mean SUVmax was 11.4 (range: 4.7-17.7), with a tumor-to-liver SUVmax ratio of 3.1 (range:1.5-5.3). Inter-reader agreement was moderate (?=0.54) using mRECIST, but intra-reader was higher (?=0.72-0.86). With treatment stratification, both inter- and intra-reader agreements in the LRT group were nearly perfect (?>0.8) using mRECIST and LR-TR. For the IT group, inter-reader agreement was fair (?=0.37) with mRECIST and substantial (?=0.66) with RECIST 1.1; intra-reader varied from moderate to almost perfect (?=0.47-0.82) with mRECIST and was substantial to almost perfect (?=0.69-0.93) with RECIST 1.1. PSMA-based assessments showed almost perfect inter- and intra-reader agreement (?>0.8) across all cohorts.

**CONCLUSION**

HCC treatment response assessment using 68Ga-PSMA PET demonstrates high repeatability and reproducibility, particularly higher than CT/MR for the immunotherapy group.

**CLINICAL RELEVANCE/APPLICATION**

68Ga-PSMA PET offers precise HCC response evaluation across treatments, meriting larger studies to correlate with oncologic outcomes.

## R6-SSNMMI08-3 COMBINED LONG-AXIAL FIELD-OF-VIEW PET AND SPECTRAL CT TO ENABLE INNOVATIVE SCAN PROTOCOLS FOR IMPROVED QUANTIFICATION IN ONCOLOGY

Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation
Elizabeth Li (*Abstract Co-Author*) Nothing to Disclose
Florence Marie Muller (*Abstract Co-Author*) Nothing to Disclose
Joel Karp, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV
Austin Pantel, MD (*Presenter*) Institutional research support, Lantheus Holdings;Consultant, Blue Earth Diagnostics Ltd;Consultant, General Electric Company;Consultant, Lantheus Holdings

**PURPOSE**

Independent advances in PET and CT technology have led to improvements in image quality and expanded clinical applications. Truly integrated systems utilizing both state-of-the-art PET and CT, though, have not been realized. Recently, we have combined a long axial field-of-view (LAFOV) PET with a detector-based spectral CT (IQon Spectral CT, Philips Healthcare). We aim to leverage the strengths of these two high performance instruments (PET: functional information/quantification, and Spectral CT: reduced metal artifacts, iodine concentration mapping, detection of bone metastases etc.) to improve malignancy characterization. More specifically, we aim to develop clinically accessible protocols for improved quantification in oncology, by utilizing spectral CT to measure tumoral perfusion and to provide a surrogate for the input function peak for PET kinetic modelling. Initial protocol developments for this new integrated instrument are included here.

**METHODS AND MATERIALS**

A multi-modal flow phantom was developed for protocol refinement to limit radiation dose in vivo. An insert was added into a NEMA Image Quality phantom to create plasma and tissue compartments, with a peristaltic pump used to induce flow. Fluorine-18 and CT iodine concentration in the plasma compartment were compared. Preliminary in vivo perfusion studies in a porcine model were then performed, using iodinated contrast for CT and two PET tracers (82Rb and an experimental 18F-labeled tracer).

**RESULTS**

Dynamic flow phantom studies capture the bolus shape with 5-second frames, supporting harmonization between modalities for in vivo studies. Preliminary studies in a ventilated pig demonstrated similar blood input between three different iodine injections and two PET tracer injections. Consistent hepatic perfusion measurements were realized across the three CT acquisitions with different injection rates. These perfusion measurements were greater than that estimated from 82Rb, as expected given differences in extraction fraction.

**CONCLUSION**

Early results from this combined LAFOV PET/spectral CT demonstrate the ability to measure a blood input function and tissue perfusion from both modalities. We expect to have human studies in the coming months. Additional benefits of this combined system (e.g., reduced metal artifacts, detection of bone metastases) for clinical imaging will also be assessed.

**CLINICAL RELEVANCE/APPLICATION**

By leveraging a LAFOV PET/spectral CT, clinically translatable protocols can be developed to measure tumoral perfusion and PET radiotracer uptake/kinetics, with potential for translation to standard AFOV PET. Such data will better characterize malignancy, and in turn guide personalized treatment approaches, advancing precision medicine.

## R6-SSNMMI08-4 UPDATE ON DEAUVILLE SCORING WITH THE USE OF DIGITAL PET-CT SCANNERS

Stephen Graves (*Abstract Co-Author*) Research Consultant, RayzeBio
Michael M. Graham, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Sinan Akay, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Since introduction of the Deauville five-point scale in 2009, digital PET-CT scanners have been widely adopted. The improved sensitivity, time-of-flight performance, and smaller detector element size have enabled clinical image reconstruction with improved spatial resolution which could impact the Deauville scoring of small lesions. The goal of this study was to investigate the clinical significance of Deauville scores on digital PET-CT scanners in patients with diffuse large B-cell lymphoma (DLBCL).

### METHODS AND MATERIALS

Digital FDG PET-CT of patients with newly diagnosed DLBCL, who underwent standard first-line treatment between April 2019 and Jan 2024, were retrospectively reviewed. The reported Deauville scores (1-5) on interim (after 2nd or 3rd cycle) and end-of-therapy (after 6 cycles) PET-CTs were recorded. Subsequently, therapy response on post first-line treatment and disease status based on 6-month clinical follow-up were evaluated based on review of patient charts. The predictive value of Deauville scores for treatment outcome at 6-month follow-up were analyzed.

### RESULTS

The study group comprised 80 patients. Forty-six patients had Deauville scores 1, 2 or 3 on end-of-therapy PET/CT scan; amongst these patients 42 (91%) patients had no evidence of disease (NED) at 6 months post-therapy. Thirty-four patients had end-of-therapy Deauville 4 or 5 scans; 10 (29%) of them patients had NED on 6-month follow-up. Further analysis of Deauville 4 revealed that 7/10 (70%) of end-of-therapy and 10/17 (60%) of interim PET-CT scans revealed NED at 6-month follow-up. The probability of having recurrent/persistent disease at the 6th month follow-up was found to be 16.4 times lower in patients categorized as Deauville 4 on end-of-therapy scan compared to those categorized as Deauville 5.

### CONCLUSION

A majority of patients with Deauville 4 scores on digital PET-CT interim or end-of-therapy scans did not have persistent disease at follow-up. Therefore, it is crucial to obtain a tissue sample or follow-up PET-CT scans for patients with DLBCL with Deauville 4 score before a possible change in therapy.

### CLINICAL RELEVANCE/APPLICATION

There is a score migration of Deauville five-point scale with the use of digital PET-CT scanners. In contrast to initial scoring, our data shows that the majority of patients with Deauville score 4 PET-CT scans did not have persistent disease and showed good outcomes.

## R6-SSNMMI08-5 $^{18}$F-FDG PET/CT: CORRELATION OF IMAGING MARKERS AND CAR-T CELL THERAPY ASSOCIATED ADVERSE EVENTS

Julian Kirchner (*Abstract Co-Author*) Nothing to Disclose
Daniel Weiss (*Abstract Co-Author*) Nothing to Disclose

Christina Antke (*Abstract Co-Author*) Nothing to Disclose
Vivien Lorena Ivan, MD (*Abstract Co-Author*) Nothing to Disclose
Helena A. Peters, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study is to evaluate the predictive potential of pre -CAR-T [18F]FDG PET/CT in patients with diffuse large B-cell lymphoma (DLBCL) concerning Cytokine Release Syndrome (CRS) and Immune Effector Cell-associated Neurotoxicity Syndrome (ICANS) and their correlation with treatment response in post-CAR-T [18F]FDG PET/CT.

### METHODS AND MATERIALS

Eighteen DLBCL-patients (mean age: 60 ± 12 years) were retrospectively included who underwent CAR-T therapy and [18F]FDG-PET/CT at predefined time points (t0 -t2). Median follow-up time was ten months (IQR 6 - 16) after CAR-T cell infusion. Following clinical parameters were obtained: age, sex, serum lactate dehydrogenase (LDH) and Interleukin-6 (IL-6). The occurrence of CRS / ICANS has been recorded. SUVmax, Deauville score and Lugano response criteria (LC) were evaluated. Pearson correlations, group comparisons (Mann-Whitney-U-test) and chi-quadrat test were calculated. P values below 0.05 were defined as statistically significant. 95%-confidence intervals (CI) were defined.

### RESULTS

SUVmax at t0 correlates positive with LDH ($r = 0.5$, $p = 0.02$) and grade of CRS ($r = 0.5$, $p = 0.04$) and ICANS ($r = 0.6$; $p < 0.01$). Appearance of ICANS was significantly associated with SUVmax at t0 ($p = 0.03$, $U = 7.0$, $Z = -2.2$). Using ROC analysis and Youden's index a SUVmax threshold of 17 at t0 (AUC: 0.865, $p < 0.01$) could be defined. Patients exceeding SUVmax of 17 had a significant higher risk of CRS > 1 (OR = 22, CI 2 - 314, $p = 0.03$) and ICANS > 1 (OR = 18, CI 1 - 271, $p = 0.04$). There was a significant difference between patients with progressive disease (PD) and patients with a best response of complete remission (CR), partial remission (PR), or stable disease (SD) with respect to the presence of an ICANS > 1 ($p < 0.01$).

### CONCLUSION

SUVmax at t0 could be a useful marker for identifying DLBCL-patients with an increased risk of CRS > 1 and ICANS > 1. Patients with ICANS > 1 were significantly associated with a PD at t1.

### CLINICAL RELEVANCE/APPLICATION

• Pre-therapeutic SUVmax could be a useful imaging marker for risk stratification of CAR-T therapy-associated adverse events.• An ICANS > 1 could be a relevant indicator for a progressive disease at t1.

## R6-SSNMMI08-6 EVALUATION OF THE QUALITY OF IMAGES AND THE SENSITIVITY OF DETECTION OF SUB-CENTIMETER LESIONS OF A NEW GENERATION OF PET-CT

## PURPOSE

The Omni Legend 32cm (Omni6R) represents a cutting-edge PET/CT scanner showing high sensitivity, small crystal size, and a deep learning (DL) based PET reconstruction algorithm, Precision DL. Precision DL was designed to emulate Time of Flight (TOF) enhancement on a "non TOF" PET scanner. The Omni6R is expected to enhance image quality while reducing acquisition duration without impairing detection and quantitation in comparison to standard of care (SOC) systems. We conducted a single-blinded, prospective, non-randomized clinical study (NCT05154877), comprising of 2 phases, to evaluate the Omni6R.

## METHODS AND MATERIALS

Subjects underwent a BMI based FDG PET scan (~2 MBq/kg), performed on Discovery-MI 25cm (DMI5R) or Discovery-IQ 25cm (DIQ5R) using 10-minute scanning protocol. Subjects were then scanned on the Omni6R, and data were reconstructed into 8- and 6-minute images, Standard (Omni6R-S) and Reduced Time (Omni6R-RT). Phase 1 focused on a qualitative assessment of images from the Omni6R compared to SOC for 30 patients. PET images were evaluated by 3 physicians using 4 clinical indexes (image quality, diagnostic confidence, sharpness, and noise), each scored on a 5-point Likert and summed for a total score out of 20. We chose the optimal SOC and the acquisition duration for the Omni6R for phase 2 based on the Likert score obtained. In Phase 2, 15 patients were recruited, following the same consecutive scan pattern. A software provided by the scanner-vendor is used to synthesize 150 spherical lesions with diameters from 6-10 mm and contrast from 3-15. The synthetic lesions were inserted into sinograms at clinically relevant locations and reconstructed into PET images. 3 physicians assessed lesion detectability and reported PET metrics for each lesion during the review. We calculated the true positive ratio (TPR) of synthetic lesions by dividing the number of detected lesions by their total number and compared it across scanners.

## RESULTS

During phase 1, the DMI5R obtained the highest Likert scores among the SOCs, which were still lower than the scores obtained by the Omni6R-RT (DIQ5R: 13.2 ± 1.5 / DMI5R: 14.8 ± 1.5 / Omni6R-S: 17.1 ± 1.4 / OmniI6R-RT: 16.4 ± 1.3). Therefore, we used the DMI5R and Omni6R-RT, i.e. acquisition with a 40% duration reduction when compared with the SOC protocol, for the lesion detectability study. The averaged TPR across the 3 readers were 84.4% and 84.6% for the Omni6R-RT and the DMI5R, respectively.

## CONCLUSION

Omni6R showed better qualitative results over all SOC studied. Lesion detectability analysis demonstrated equivalency between the Omni6R-RT and the DMI5R. Omni6R provides performance equivalent to high-performance TOF systems while enabling optimization for acquisition durations.

## R6-SSNR16-1 REVEALING HEMODYNAMIC HETEROGENEITY IN GLIOBLASTOMA AND MEDULLOBLASTOMA BY DEEP-ANALYSIS OF DYNAMIC SUSCEPTIBILITY CONTRAST-ENHANCED MRI DATA

Hui Mao, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Kartik M. Reddy, MD (*Abstract Co-Author*) Nothing to Disclose
Farid Hajibonabi, MD (*Abstract Co-Author*) Nothing to Disclose
Quanquan Gu (*Abstract Co-Author*) Nothing to Disclose
Leonardo Tang, MS, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Intratumoral heterogeneity is a hallmark of malignant tumors, such as glioblastoma (GBM) and medulloblastoma (MB). It is presentation of cellular, genetic and epigenetic variations within the tumor microenvironment (TME) and is directly linked to the poor prognosis and treatment failure. While intratumoral heterogeneity can be described based on morphological features of tumor tissue derived from structural MRI, physiological and hemodynamic heterogeneity is largely overlooked. Dynamic susceptibility contrast-enhanced magnetic resonance imaging (DSC MRI) is a clinically available non-invasive tool for analyzing blood supply and vascular permeability of tumors. Wholistically analyzing time course profiles from DSC MRI can improve the segmentation of the tumors while revealing the intertumoral hemodynamic heterogeneity of tumors and TME in GBM and MB.

### METHODS AND MATERIALS

Data for 31 MB patients, consisting of 3D T1-MPRAGE, T1 contrast-enhanced, and 4D DSC MRI, were acquired from Children's Healthcare of Atlanta. Data for 103 GBM patients, consisting of 3D T2-FLAIR and 4D DSC MRI images, was acquired from the University of Pennsylvania glioblastoma cohort (UPENN-GBM) in the Cancer Imaging Archive (TCIA). Tumor region of interest (ROI) on 3D structural MRI was obtained by U-Net tumor segmentation convolutional neural network in GBM patients and by expert radiologist review in MB patients. A hybrid method of HDBScan was then performed on 4D DSC MRI to perform density-based clustering based on hemodynamic responses derived from the patterns of time course profiles within ROIs.

### RESULTS

Across 103 GBM patients, our approach revealed an average of 5.32 distinct subtypes of tumor tissue with 67.93% hemodynamically active tissue within the tumor ROI. Conversely, analysis of 31 MB patients identified an average of 4.67 hemodynamically distinctive tumor tissue subtypes with 62.53% active tissue. Representative features for the average signal profile of each cluster were extracted for additional quantitative analysis.

### CONCLUSION

We demonstrated that proposed neural network is capable of delineating tumor tissue subtypes within the TME and extracts relevant time course signal features. MB exhibits fewer hemodynamically distinctive tumor tissue subtypes, suggesting a lower degree of intratumoral heterogeneity compared to GBM.

### CLINICAL RELEVANCE/APPLICATION

This study leverages machine learning and routinely obtained 4D DSC MRI data to improve the tumor segmentation and analyze intratumoral heterogeneity within and between MB and GBM, complementing traditional morphological assessments of tumor heterogeneity. Furthermore, features extracted from DSC time course profiles offer data-driven quantification of hemodynamic parameters.

## R6-SSNR16-2 AI IN ROUTINE USE - RESULTS OF A LARGE-SCALE TEST ACROSS GERMANY AND AUSTRIA

Torsten B. Moeller, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The study was conducted to answer the question of whether the use of artificial intelligence is already having a quality-improving effect in routine teleradiological reporting throughout Germany and Austria.

### METHODS AND MATERIALS

We performed a study of over 3000 native cranial CT scans (CCT) from CT departments of 140 hospitals in Germany and Austria between MArch and April 2022. Of these scans, 2707 CCT were analyzed using AI with hemorrhage analysis. The results were compared with the findings of more than 70

teleradiologists who did not have the AI results at that time. Possible discrepant findings were evaluated by two full radiologists with specific neuroradiological CCT experience including controls or previous findings.

**RESULTS**

Of the 2707 CCT examined by both radiologists and AI, 189 cases (approximately seven percent) were found to have ICB (intracranial hemorrhage) described by both radiologists and AI. In 30 patients (approximately one percent) there was a discrepancy: the AI had seen a hemorrhage that the radiologist had not described. These cases were subsequently reevaluated by two experienced radiologists. 12 of the 30 unclear examinations were classified as false positives by the AI, eight cases as questionablepositives, and 10 cases as true positives. Thus, there were 199 cases with ICB in the studied patient group, of which more than 5 percent were primarily missed by radiologists without AI support.

**CONCLUSION**

The positive effect of AI on the quality of radiological reporting postulated in several studies can also be confirmed in practice and especially in the teleradiological context.

**CLINICAL RELEVANCE/APPLICATION**

Our study provides evidence that, at least in the field of teleradiology, AI is already a valuable tool, particularly with regard to improving quality and speed.

## R6-SSNR16-3 COMPARISON OF 2D & 3D DEEP LEARNING MODELS FOR HEAD CT TISSUE SEGMENTATION

Septian Hartono, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Automated brain volumetry is vital for detecting brain atrophy. CT has lower soft tissue contrast than MRI but is more affordable, accessible and time-saving. Limited works exist on CT segmentation for brain volumetry. In this study, we developed 3D deep learning (DL) models for semantic segmentation of gray matter (GM), white matter (WM) and cerebrospinal fluid (CSF) tissue classes on head CT in a multi-ethnic Southeast Asian population, leveraging on paired MRI labels as a benchmark to enhance accuracy.

**METHODS AND MATERIALS**

The study was approved by the institutional ethics committee. Participants underwent CT scan on a Siemens Somatom Force CT system with tube voltage = 120 kVp, acquisition matrix = 512 × 512, number of slices = 225, voxel size 0.4 × 0.4 × 1.0 mm3. MR scan was performed on the same day as the CT scan, on a Siemens Vida 3T using sagittal T1-MPRAGE sequence with following parameters: TR/TE/TI = 2300/3.0/900 ms, matrix = 256 x 256, number of slices = 176, voxel size = 1 × 1 × 1.1 mm3.CT and MRI images were skull-stripped using Synthstrip and FSL BET respectively. GM, WM, and CSF labels were derived from the MR images using FSL FAST. CT and MR images were co-registered with FSL FLIRT. The resulting transformations were then applied to the MR labels. The alignment of the MR labels with the CT image was visually assessed for each data set.The final pre-processed datasets consisting of CT images and their paired, co-registered MR labels were split with a train-test ratio of 4:1. There were 234 subjects (mean age 64.6 ± 6.1 years) in total with 187 CT-MRI pairs for training and 47 pairs for testing.We trained and tested various 2D and 3D models and compared their accuracy with Dice score and complexity in terms of number of parameters and floating point operations (FLOPs).

**RESULTS**

Spatially-Aware Swin-Unet outperformed other 2D models with Dice scores of 0.865, 0.776 and 0.787 in WM, GM and CSF, respectively, and overall Dice score of 0.809 (Figure 1). UNETR++ was the best performing 3D model with Dice scores of 0.849, 0.824, and 0.818 for WM, GM, and CSF, respectively, and an average dice score of 0.830.

**CONCLUSION**

We showed the feasibility of 2D and 3D DL models for direct and accurate head CT tissue segmentation. 2D Spatially-Aware Swin-Unet with its added inter-slice contextualization and 3D UNETR++ with its efficient paired attention block offers both accuracy as well as efficiency within their respective classes.

**CLINICAL RELEVANCE/APPLICATION**

While brain MRI offers highly precise segmentation, CT is more readily available. Deep learning facilitates CT-based brain tissue segmentation, bridging the gap between MRI and CT. This enables rapid brain tissue assessment, aiding in early neurodegenerative disease detection and precision medicine in Southeast Asia.

## R6-SSNR16-4 OPTIMIZING 3D T1 MPRAGE PROCESSING FOR ROBUST DIFFERENTIATION OF ALZHEIMER'S DISEASE FROM COGNITIVELY NORMAL IN OLDER ADULTS: THE IMPACT OF ADVANCED DEEP LEARNING-BASED RECONSTRUCTION AND SEGMENTATION

Seoyoung Lim, MS, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Structural MRI with brain segmentation is crucial in detecting early anatomical changes indicative of Alzheimer's diseases (AD), but challenges like low resolution, noise, and inaccurate segmentation limit its efficacy. This study aimed to enhance differentiation of AD from cognitively normal (CN) in older adults by using two deep learning (DL)-based algorithms for image reconstruction and segmentation.

**METHODS AND MATERIALS**

This study leveraged the OASIS-2 open dataset, consisting of 3D T1w MRI scans of 150 subjects aged 60-96. The dataset includes 373 MRI sessions from AD/CN subjects, with each subject undergoing multiple sessions at least a year apart. In each session, 3~4 T1w scans were acquired. Excluding scans from subjects with a change in diagnosis, 585 AD scans and 724 CN scans were analyzed. In each scan, 22 region of interest (ROI) volumes were measured by applying DL-based image reconstruction (DLR) that functions denoising and super resolution (SwiftMR, AIRS Medical), and DL-based volumetry (DLV) for segmentation, developed using a U-net-based architecture trained on 1336 T1w scans with manually corrected labels from FastSurfer. Comparative analysis was performed across four frameworks combining two image reconstructions (before and after DLR) and two segmentations (FastSurfer and DLV). The volume measures were applied to a machine learning classifier comprising an ensemble of XGBoost, Random Forest, and TabNet. The classifier was evaluated with 5-fold nested cross-validation, calculating AUC-ROC for each session to assess inter-session variability, and for each scan during the first session to assess inter-scan variability. Additionally, feature importance was estimated to select the top 2 significant ROIs.

**RESULTS**

In inter-session analysis, the average AUC-ROC of after DLR was higher than before DLR regardless of segmentation algorithm (before/after DLR = 96.8%/97.5% in FastSurfer; before/after DLR = 98.1%/99.0% in DLV). On the other hand, DLV showed higher average AUC-ROC than FastSurfer in both before and after DLR. The improvement of after DLR and DLV were also demonstrated in inter-scan analysis (before/after DLR = 60.2%/62.2% in FastSurfer; before/after DLR = 67.7%/71.5% in DLV). Overall, DLR + DLV marked a significant advancement over the whole frameworks. In addition, only DLR+DLV consistently identified the top 2 significant ROIs as hippocampus and amygdala except session 4 which had a small number of samples, revealing high reproducibility.

**CONCLUSION**

Our framework combining DLR and DLV enhances AD differentiation from CN in older adults using 3D MRI.

**CLINICAL RELEVANCE/APPLICATION**

A deep learning-based framework for MRI reconstruction and segmentation improves AD classification with high reproducibility.

## R6-SSNR16-5 ENHANCING GLIOMA SEGMENTATION AND KI-67 BIOMARKER CORRELATION WITH SHAP ANALYSIS

Sakib Abrar Hossain (*Abstract Co-Author*) Nothing to Disclose

Muge Karaman, PhD (*Abstract Co-Author*) Nothing to Disclose
Muhammad E. H. Chowdhury (*Abstract Co-Author*) Nothing to Disclose
Enamul Bhuiyan, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To enhance glioma tumor segmentation accuracy in MRI scans through deep learning techniques. We also aim to correlate bottleneck features extracted from glioma brain tumor MR images with Ki-67 biomarkers using SHapley Additive exPlanation (SHAP) analysis.

**METHODS AND MATERIALS**

The study involved 103 patients with glioma from an internal dataset and 110 patients from the Cancer Genome Atlas (TCGA) lower-grade glioma collection. Ground truth data were provided through manual segmentation by radiologists. Models were trained and validated using MATLAB for preprocessing and PyTorch on Google ColabPro for 2D segmentation, with consistent hyperparameters across all networks (learning rate: 0.00001, Dice loss function, Adam optimizer). Performance was assessed using Dice Score (DSC) and Intersection over Union (IoU). Additionally, 256 explainable AI (XAI) features were extracted from glioma brain tumor MR images, with the top 10 features selected via Principal Component Analysis (PCA). SHAP analysis explored the association among Ki-67 biomarkers, patient demographics, and XAI features.

**RESULTS**

We explored the effectiveness of convolutional neural networks (CNNs), including UNet, UNet++, and FPN, combined with various backbones such as ResNet152, DenseNet201, and a novel Self-ONN architecture. Our results indicated that UNet with ResNet152 backbone achieved the highest performance, with a DSC of 89.13% and IoU of 86.46%. UNet with ResNet152_Self-ONN backbone followed closely with a DSC of 88.91% and IoU of 86.24%. Other configurations also showed competitive results, such as ResNet152_Self-ONN_UNet++ with a score of 88.89%. Our preliminary results reveal that the top 10 XAI extracted features have strong correlations with Ki-67 biomarkers having p-value range 0.04-0.001 with 95% confidence interval.

**CONCLUSION**

Our study highlighted the effectiveness of ResNet152_UNet in tumor segmentation and the slight improvement achieved with the inclusion of Self-ONN characteristics. These findings suggest the potential benefits of investigating different backbone networks and segmentation topologies. Future research could focus on optimizing image enhancement parameters to further improve segmentation accuracy. Additionally, combining demographics (age, sex), histological tumor grade, and XAI features' SHAP analysis indicates a strong association between XAI features and Ki-67 biomarkers. However, a rigorous study of a large cohort is mandatory to validate the preliminary results.

**CLINICAL RELEVANCE/APPLICATION**

The correlation among the Ki-67 biomarker, patient demographics, and explainable AI features in glioma tumors can enhance existing diagnosis, prognosis, and treatment planning with meticulous precision.

## R6-SSPD05-1 ABDOMINAL IMAGING IN PEDIATRIC NON-ACCIDENTAL TRAUMA: INCIDENCE OF POSITIVE FINDINGS ON ABDOMINAL CT

Edward J. Richer, MD (*Abstract Co-Author*) Nothing to Disclose
Sanjeev Chilukuri, MD (*Abstract Co-Author*) Nothing to Disclose
Susan D. Taylor, DO (*Abstract Co-Author*) Nothing to Disclose
Geetika Khanna, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Erica Riedesel, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Retrospective observational study to evaluate incidence of positive findings on Computed Tomography (CT) of the abdomen/pelvis performed as part of evaluation for suspected pediatric non-accidental trauma (NAT).

### METHODS AND MATERIALS

This was an IRB approved, single institution, retrospective review of patients under age 6 years old who had both a skeletal survey and CT abdomen/pelvis with IV contrast in the same admission for the workup of suspected NAT between 2013-2023. The EMR was reviewed for each patient, and note was made of findings on imaging, physical exam, and laboratory analysis.

### RESULTS

Between 2013 and 2023, a total of 2429 patients under age 6 yrs underwent skeletal survey due to clinical concern for NAT. Of those, 133 patients (5.4%, 133/2429) had additional CT imaging of the abdomen/pelvis to evaluate for possible intra-abdominal injury. The largest total number of CT abdomen/pelvis studies were performed in patients under age 4mos (n=50). 30% (40/133) of CT studies had positive imaging findings. The most common imaging finding was presence of free fluid (n = 23, 57.5% [23/40]). Liver injury was the second most common imaging finding (n=14, 40% of studies [16/40]). Bowel injury was seen in 27.5% (11/40). Multiple positive findings were seen in 45% (18/40) of patients. Positive findings on CT were seen least in patients <4mos of age (14%, 7/50) and most in patients age >2 yrs (52%, 12/23).

### CONCLUSION

In this 10-year, single institution retrospective review, approximately 5% of patients under age 6 yrs with concern for NAT underwent additional imaging with CT abdomen/pelvis for possible intrabdominal injury. However, positive findings concerning for traumatic intrabdominal injury were seen in only 1% of all patients. Types of intrabdominal injury seen were relatively similar at all ages. While CT imaging was performed most in the youngest members of this population (<4mos), these patients also had the lowest percentage of positive imaging findings on CT.

### CLINICAL RELEVANCE/APPLICATION

A high number of abdominopelvic CT scans are performed in pediatric patients with suspected NAT despite low prevalence of intrabdominal injury. While reduction of unnecessary CT scans in pediatric blunt trauma patients has been a topic of high interest in pediatric trauma, emergency medicine, and radiology literature there has been little evaluation of how to "image gently" for intra-abdominal injury in suspected NAT. Further investigation into the role of clinical and laboratory markers in guiding appropriate imaging is needed. In addition, there is potential for alternative imaging such as ultrasound or contrast-enhanced ultrasound to be used as a screening evaluation prior to CT which may be beneficial in this vulnerable patient population.

## R6-SSPD05-3 STANDARD USE OF 3D CLOACAGRAMS WITH PRINTED MODELS FOR COMPLEX CLOACA REPAIR

Rex M. Pillai, MD (*Abstract Co-Author*) Nothing to Disclose
Osama A. Raslan, MD, MBBCh (*Abstract Co-Author*) Research Grant, Bracco Group;Contract, Shanghai United Imaging Healthcare Co, Ltd
Steven Lucero (*Abstract Co-Author*) Nothing to Disclose
Neha Antil, MD (*Abstract Co-Author*) Nothing to Disclose
Eric Kurzrock (*Abstract Co-Author*) Nothing to Disclose
Zoe Saenz (*Presenter*) Nothing to Disclose

### PURPOSE

Cloacas are complex congenital malformations that involve the urinary, reproductive, and colorectal tracts. Due to their multisystem involvement, they present significant technical challenges to surgical repair. Routine 3D cloacagrams have been advocated for surgical planning as they allow improved

characterization of spatial relationships. However, while 3D printed models from these cloacagrams are feasible, they have yet to become standard in the repair of cloacas. Our objective is to evaluate our institution's experience in the routine use of 3D cloacagrams with printed 3D models in operative planning and education.

**METHODS AND MATERIALS**

We performed a retrospective review of cloacal patients who underwent 3D printed modeling for their malformation based upon a 3D cloacagram from 2020 to 2024. Demographics, imaging, measurements, pre-operative planning, repair time and findings, and follow-up were assessed.

**RESULTS**

Five patients with a 3D cloacagram were identified. The median age was 30.52 months (SD 12.61). All underwent cloacal repair. Common co-morbidities were cardiac (80%), renal (80%), and vertebral anomalies (60%). The median age at 3D cloacagram was 5.98 months (SD 2.14) with an average procedure time of 1 hour, 8 mins. Two patients were managed preoperatively with clean intermittent catheterization (CIC) and one required vaginostomy and suprapubic vesicostomy tube placement. Median age at repair was 9.13 months (SD 2.89) with an average repair time of 7 hrs, 42 mins. The common channel length measurements correlated best between the 3D cloacagram and intraoperative findings. All five patients had 3D printed models used for surgical planning and education which were utilized in preoperative counseling with families and trainees. Median follow-up time was 12 months (SD 8.43). One patient underwent appendicostomy requiring flushes, one patient requires CIC, and one requires suprapubic tube with persistent bilateral severe hydronephrosis and reflux. 25% are on medications for bowel management.

**CONCLUSION**

3D cloacagrams are provide accurate measurements with minimal intraoperative discrepancy.

**CLINICAL RELEVANCE/APPLICATION**

3D printed models can supplement imaging findings while reinforcing operative management and education.

## R6-SSPD05-4 DUODENUM INVERSUM: IS IT A VARIANT OF NORMAL ANATOMY?

Ellen Park, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Anthony Deross (*Abstract Co-Author*) Nothing to Disclose
Jennifer Bullen, MSc (*Abstract Co-Author*) Nothing to Disclose
Brooke S. Lampl, DO (*Abstract Co-Author*) Nothing to Disclose
Deborah D. Brahee, MD, DC (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the clinical outcomes of patients diagnosed with duodenum inversum and to determine if this diagnosis requires further investigation or if it can confidently be considered a variant of normal anatomy.

**METHODS AND MATERIALS**

There were 1662 upper GI exams between January 2016 and December 2020. Repeat exams on the same patient were excluded, so that only the patient's earliest exam remained in the sample. Additionally, post-operative exams, non-diagnostic exams, and other exams meeting various exclusion criteria were excluded, ie. heterotaxy). A total of 1490 exams (from 1490 unique patients) remained. All upper GI's were reviewed and categorized by 3 fellowship trained pediatric radiologists (EP, BL, and DB) with 18, 15, and 5 years experience as DI, WD, malrotation, and normal. Duodenum inversum was defined as the distal duodenum ascending to the right of midline to the level of the bulb and then crossing to the left with the duodenal jejunal junction in normal location, fixed by the ligament of Treitz. Any cases that were of unclear diagnosis, WD, and DI were reviewed by 3 pediatric radiologists for consensus. Patients diagnosed with DI on upper GI exam, had a retrospective chart review performed by pediatric radiology (BL) and pediatric surgery (AD) (15 and 18 years experience) to evaluate clinical and/or surgical outcomes.

**RESULTS**

Of the 1490 patients identified, 11 (0.7%) were marked DI, 23 (1.5%) were marked malrotation, and 1456 (97.7%) were marked normal (n=1433) or WD (n=23) (i.e. without DI or malrotation). Mean patient age at exam was 5.6 years (median: 2.5 years, IQR: 4.4 months to 10.6 years, full range: 0 to 18.9 years). Of the 11 patients with DI on upper GI exam, seven went to the operating room. Of the seven patients, five had abnormalities including abnormal peritoneal attachments, cocooning of the peritoneum, and Ladd's bands with all 5 patients undergoing Ladd's procedures. One of the 7 had a genitourinary finding of endometriosis and paratubal cyst. A second patient had a pylorotomy and no other intraoperative findings.

**CONCLUSION**

Duodenum inversum is an uncommon diagnosis seen in 0.7% (11/1490) patients in this study. Traditionally, DI has been considered a variant of normal anatomy in the radiology literature. Of the 11 patients, 5 went on to Ladd's procedure and had other findings concerning for malrotation. In a symptomatic patient, we propose that the diagnosis of duodenum inversum on upper GI may warrant further investigation and not be considered a variant of normal anatomy.

**CLINICAL RELEVANCE/APPLICATION**

Duodenum inversum has classically been taught to be a variant of normal anatomy. We suggest that further investigation is warranted in the symptomatic patient.

## R6-SSPD05-5 MAGNETIC RESONANCE CHOLANGIOPANCREATOGRAPHY (MRCP) FOR SUSPECTED CHOLANGIOPATHY IN CHILDREN: A MULTI-READER AGREEMENT STUDY

Leticia Khendek (*Abstract Co-Author*) Nothing to Disclose
Pradipta Debnath, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess inter-radiologist agreement when interpreting Magnetic Resonance Cholangiopancreatography (MRCP) examinations in pediatric patients with known or suspected cholangiopathy.

**METHODS AND MATERIALS**

This was a retrospective, multi-reader study of clinically obtained MRCP examinations performed in patients less than 21 years-old due to known or suspected cholangiopathy between January 2018 and September 2023. Based on review of clinical records, patients were classified as having Primary Sclerosing Cholangitis (PSC), Autoimmune Sclerosing Cholangitis (ASC), or other diagnosis. Images were reviewed in a HIPAA-compliant, cloud-based image viewing platform by nine blinded fellowship-trained pediatric radiologists who independently documented biliary and liver findings. Kappa (?) statistics and intra-class correlation coefficients (ICC) with 95% confidence intervals (CIs) were used to quantify inter-reader agreement.

**RESULTS**

Seventy-five unique patients were included [median age=16.8 years (IQR: 13.8 to 18.7 years); 48 boys]. Within our study cohort, 22.7% (17/75) had PSC, 22.7% (17/75) had ASC, and 41/75 (54.7%) had other diagnoses. Among observers, agreement was slight for presence of cholangiopathy (?=0.15 [95% CI: 0.073 to 0.23]) and presence of PSC/ASC (?=0.13 [0.062 to 0.21]). For all patients, there was no agreement for intrahepatic stricture number (?=-0.002 [(-0.158 to 0.153]) and stricture extent (?=-0.056 [-0.093 to -0.019]). Agreement was slight for presence of intrahepatic stricturing disease (?=0.08 [0.04 to 0.12]). Most other findings had fair agreement between readers [including intrahepatic biliary dilation without stricture, intrahepatic focal/segmental dilations, intrahepatic and extrahepatic diverticula, “floating” bile ducts, diffuse extrahepatic dilation without stricture, extrahepatic stricture, bile duct mural thickening, intrahepatic peribiliaryT2-weighted signal, and biliary obstruction (?=0.22 to 0.34). There was moderate agreement on measured extrahepatic stricture length (? =0.46 [-0.113 to 1.00]) and presence of extrahepatic biliary dilation (?=0.53 [0.40 to 0.65]). There was good agreement for measured extrahepatic bile duct diameter (ICC=0.89 [0.85 to 0.92]).

**CONCLUSION**

Inter-radiologist agreement while interpreting MRCP in children is poor to fair for most findings of cholangiopathy, including the diagnosis of PSC/ASC.

**CLINICAL RELEVANCE/APPLICATION**

Suboptimal inter-radiologist agreement related to findings of pediatric cholangiopathy, including the diagnosis of PSC/ASC suggests, the need for education and more objective diagnostic tools.

## R6-SSPH15-1 VALIDATING AN AI-POWERED AUTOMATED TOOL FOR DELINEATING METASTATIC BONE DISEASE AND EXTRACTING QUANTITATIVE RESPONSE BIOMARKERS FROM WHOLE-BODY DIFFUSION WEIGHTED IMAGING (WBMRI)

Christina Messiou, MD, BMBS (*Abstract Co-Author*) I am a co-founder of Diafora (alongside the Institute of Cancer Research and The Royal Marsden) that has formed a joint venture, Celescan, with Sopra Steria
Nina Tunariu, MD (*Abstract Co-Author*) Nothing to Disclose
Dow-Mu Koh, FRCR (*Abstract Co-Author*) Nothing to Disclose
Matthew Blackledge, MSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Ricardo Donners, MD (*Abstract Co-Author*) Nothing to Disclose
Richard P. Holbrey, PhD (*Abstract Co-Author*) Software developer, Mint Medical GmbH
Antonio Candito, PhD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

WBMRI is an established technique used to assess bone metastases in patients with Advanced Prostate Cancer (APC), allowing quantification of two response biomarkers: (i) Total Diffusion Volume (TDV, in millilitres), and (ii) the Apparent Diffusion Coefficient (ADC), which is inversely correlated to tumour cellularity. However, manual delineations to measure ADC and TDV typically takes 1-2 hours, depending on disease volume. To overcome this challenge, we propose an AI-powered automated tool that can generate a detailed report on WBMRI biomarkers and their changes post-treatment within two minutes for APC patients.

### METHODS AND MATERIALS

The core technologies of the automated tool include: (i) a previously developed semi-supervised deep learning model with 2-channel inputs (calculated ADC map and b=0 s/mm2 image), which generates a skeleton probability map and a normalised b900 signal image; (ii) a convolutional neural network, which processes the output from (i), in order to generate a mask for suspected bone metastases, characterised by high b900 signal intensity and low ADC values (>500 mm2/s). This mask is applied to the ADC map to extract ADC statistics and TDV. Thresholds for changes in median ADC and TDV were established to assess response to treatment. The tool's segmentation and diagnostic accuracy were validated through an IRB approved multi-centre retrospective cohort study of 94 patients and single-centre prospective trial with 16 patients. Manual disease delineations (66 scans from the retrospective cohort) and clinical standard for response were defined by experienced radiologists for both cohorts.

### RESULTS

Our tool showed an average relative error below 5% for median ADC and 8.5% for TDV (after log-transform), compared to expert delineations. The diagnostic accuracy in classifying response/stable/progression disease across the retrospective and prospective cohorts yielded 81%, with sensitivity of 84% and specificity of 74%.

### CONCLUSION

WBMRI allows assessments of early treatment changes in metastatic bone disease. Our automated tool provides fast and reproducible delineations and measurements of ADC and TDV from restricted diffusion bone lesions on WBMRI scans. This solution could assist clinicians in shifting towards a quantitative paradigm for assessing treatment response, potentially improving clinical decision-making for APC patients.

### CLINICAL RELEVANCE/APPLICATION

Our automated tool enables fast delineations of suspected bone disease and measurement of WBMRI response biomarkers, potentially assisting clinicians in tailoring treatment plans for APC patients.

## R6-SSPH15-2 DECOUPLING ITERATIVE ALGORITHM FOR RAPID CALCULATION OF STANDARD TOFTS MODEL PARAMETERS

Wei Qian (*Abstract Co-Author*) Nothing to Disclose
Shouliang Qi (*Abstract Co-Author*) Nothing to Disclose
Shu Chang (*Abstract Co-Author*) Nothing to Disclose
Xiaobing Fan, PhD (*Abstract Co-Author*) Nothing to Disclose
Ying Ma (*Abstract Co-Author*) Nothing to Disclose
Dianning He, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The standard Tofts model (STM) is an important pharmacokinetic (PK) model for analyzing dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) data. However, it is time-consuming to perform pixel-by-pixel analysis of three-dimensional DCE-MRI data using the STM. Here, we introduced a decoupling iterative algorithm, prediction-correction method (PCM), for rapid calculation of the STM parameters.

**METHODS AND MATERIALS**

We utilized the QIBA_v6_Tofts dataset from the Quantitative Imaging Biomarkers Alliance and public prostate DCE-MRI dataset (n = 11) (QIN-PROSTATE). Our PCM eliminates the need for fitting the entire contrast agent concentration as function of time (C(t)) curve to calculating the volume transfer constant (Ktrans) and volume fraction (ve). The PCM is beginning with predicted ve=C(tN)/Cp(tN), where tN is the last time point and Cp(t) is artieral input function (AIF). Then utilizing earler part of C(t) (0 = t = tp) and predicted ve to predict Ktrans, where tp is the time when the AIF reached peak value. Subsequently, ve is fitted with the later part of C(t) (tL = t = tN, tL is 15 or 30 second before tN) with above prediced Ktrans. This process were repeated until the changes of Ktrans and ve were less than given error. This method relies on fitting one parameter by leveraging a small amount of data to reduce the computation time.

**RESULTS**

The PCM is verified with QIBA data and calculated Ktrans and ve values are close to values obtained from the STM. Validation using clinical data confirmed that the prediction-correction method significantly enhances the speed of parameter fitting. The results demonstrate that the speed of parameter fitting by PCM is enhanced by an average of 690% in comparison to the traditional method.

**CONCLUSION**

The PCM is significantly accelerates the calculations of Ktrans and ve with the accuracy close to the STM. By using the PCM, physiological parameters Ktrans and ve can be calculated rapidly for 3D DCE-MRI data.

**CLINICAL RELEVANCE/APPLICATION**

The novel PCM was significantly reduced the computation time required to fit entire C(t) used in the STM. There is a significant advance to use PCM for physicians accessing PK parameters maps in diagnosing cancers.

## R6-SSPH15-3 3D FAT BODY MASS QUANTIFIED FROM CT SCANS USING AI PREDICTS SURVIVAL IN EARLY PHASE CLINICAL TRIALS IN PATIENTS TREATED WITH ANTIBODY-DRUG-CONJUGATES

Capucine Baldini (*Abstract Co-Author*) Nothing to Disclose
Littisha Lawrance (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore if the body mass quantified in 3D from CT scans are able to predict the survival for patients in early phase clinical trials for patients treated with Antibody Drug Conjugates(ADCs).

**METHODS AND MATERIALS**

In this retrospective cohort 136 patients treated with ADCs in early phase clinical trials were included. A deep learning software (Anthropometer3DNet) automatically quantified the multi-slice measurements of muscle body mass (MBM), fat body mass (FBM), subcutaneous fat mass (SFM) and visceral fat mass (VFM), which was normalized according to the height of the patient. Clinical and biological parameters such as the RMH (Royal Marsden Hospital) score, Charlson Comorbidity and ECOG PS were also retrieved. Primary endpoints were progression free survival (PFS) and overall survival (OS).The anthropometric parameters were also used to predict duration spent in the clinical trial. Survival analysis was performed using Cox regression models and Kaplan-Meier (KM) estimator. Cut-offs were determined using the maximally ranked selected statistics method. The effect of the anthropometric parameters with respect to the toxicity observed was also evaluated using ROC analysis. Correlation between these anthropometric parameters and the clinical and biological parameters was also examined to see if they provided the same kind of information.

**RESULTS**

The most frequent primary cancers were non-small cell lung cancer (41%) and colorectal cancer (23%). The median PFS and OS were 2.6 and 7.9 months respectively. A higher SFM (>3.34 kg/m2) (p=0.03) and higher FBM (>3.63 kg/m2) (p=0.01) were significantly associated with longer PFS .Similarly, A higher SFM (p=0.04) and a higher FBM (p=0.04) was significantly associated with longer OS. A higher FBM also predicted a longer duration spent in clinical trial significantly (p=0.01). About 90 (66%) patients had experienced toxicity, of which 46 were high grade (3-4). All anthropometric parameters were significantly associated with toxicity in the univariate but not in the multivariate analysis, none were associated significantly with high grade toxicity.The correlation of anthropometric and clinical parameters, was also examined. None of them showed a significant linear correlation with the anthropometric parameters.

**CONCLUSION**

In this mono-center cohort, anthropometric parameters measured in 3D from CT scan (high SFM and high FBM) were significantly associated with survival and duration in the clinical trial.

**CLINICAL RELEVANCE/APPLICATION**

The measuring of anthropometric parameters with a CT scan in 3D at baseline can be advantageous for patients when recruiting them to a clinical trial.

## R6-SSPH15-4 KNOWLEDGE DISTILLATION FOR LYMPH NODE METASTASIS CLASSIFICATION IN ESOPHAGEAL CANCER WITH PATHOLOGY-GUIDED LABEL SHARPENING AND TWO-STREAMED MULTI-SCALE FEATURE FUSION

Dakai Jin, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Diagnosis of lymph node (LN) metastasis in CT scans is crucial for esophageal cancer staging and treatment planning. Deep learning can potentially address it by learning from large-scale, accurately labeled data. However, due to the surgery procedure in LN dissection, it is difficult to pair the metastasis of individual LN reported in the pathology report to the LN instance found in CT. In addition, even for experienced physicians, only partial LN metastases can be accurately determined in CT. In this study, we propose a two-streamed multi-scale feature fusion network and leverage the teacher-student paradigm with pathology prior to explore the potential of large-scale unlabeled LNs in performance improvement.

### METHODS AND MATERIALS

We collected 1052 esophageal cancer patients who underwent treatment. Each patient has a preoperative contrast-enhanced CT and pathology report indicating the metastasis status of resected LN-stations. Among them, 310 patients had their LNs manually delineated and confirmed the metastasis status (benign or metastasis) by one radiologist (5 years experiences) and reviewed by another radiologist (15 years experiences), while the rest patients only had automatically segmented LN instance masks without the metastasis status. We first developed a supervised two-stream (local and global stream) classification network with 2.5D multi-scale feature fusion, which better characterized LN's global (size, shape) and localized features (intensity, textures). Then, for unlabeled data, we adopted the teacher-student mechanism with pathology prior, where hard pseudo labels were assigned to unlabeled LNs if the model generated high confident predictions that were consistent with the corresponding LN-station metastasis derived from pathology report. Four-fold cross-validation was conducted to evaluate the model’s performance, reporting sensitivity, specificity, and AUC as classification metrics.

### RESULTS

LN classification results are shown in the Table and Figure. Our supervised model exhibited the AUC of 0.9068, outperforming the 2nd-best compared supervised method (DualNet_3D) by 4.20% (0.9068 vs. 0.8648). For our semi-supervised method, the AUC can be further increased to 0.9318, with an improvement of 2.50% compared to our supervised model and outperforming other semi-supervised method by at least 2.95% in AUC.

### CONCLUSION

This study established a supervised and a semi-supervised model for predicting LN metastasis of esophageal cancer patients on CT scan, and showed high predictive performance on a large patient cohort.

### CLINICAL RELEVANCE/APPLICATION

Our developed LN classification model may be applied in the clinical workflow to assist the diagnosis and treatment for esophageal cancer patients.

## R6-SSPH15-5 3D QUANTITATIVE ANGIOGRAPHY USING SPARSE PROJECTION DATA WITH VIRTUAL ANGIOGRAPHY-INFORMED CONVOLUTIONAL NEURAL NETWORK RECONSTRUCTION

**PURPOSE**

Traditional quantitative angiography (QA) during neurovascular interventions relies on 2D digital subtraction angiography, which is limited by its lack of comprehensive spatial information, leading to inaccuracies in disease assessment and treatment guidance. In theory, 3D-QA would address the 2D limitation, however, capturing reliable 3D-QA is challenging due to the rapid contrast bolus transit. These factors emphasize the need for improved 3D-QA. This study explores the feasibility of using sparse projection cone beam computed tomography (CBCT) for 3D angiographic reconstruction using computed fluid dynamics (CFD) data.

**METHODS AND MATERIALS**

This study utilizes CFD with patient-specific 3D vascular geometries to generate a set of 3D virtual angiograms. Sparse reconstructions were derived from 15 projections using the Feldkamp-Davis-Kress algorithm and created a corresponding ground truth for each slice from the 3D virtual angiogram. A modified U-Net convolutional neural network (CNN) architecture was trained to reconstruct full angiographic data from these sparse projections. Training involved 4,100 axial slices with an 80:20 training-testing split (by geometry). Augmentation techniques, including rotation and mirroring of the vessel image, were utilized to enhance model robustness. C-arm based CBCT acquisitions operating at 25 frames per second with a 200-degree rotation, capturing 108 projections with 10 ms integration time and a 30 ms inter-projection gap, employing a cone beam projection geometry were acquired from 3 patients. Finally, the trained U-Net was applied to actual patient CBCT data to evaluate the model’s ability to recover full reconstructions from sparse data. We employed metrics like the Dice coefficient, precision, recall, and F1-score to gauge our performance.

**RESULTS**

Evaluation of our U-Net model across the dataset yielded a Dice coefficient of 0.71, indicating good model-to-ground truth alignment, with an F1-score of 71%. Despite a modest precision of 56%, the model's recall was high at 97%, demonstrating its capability in capturing relevant features critical for clinical diagnosis and intervention planning.

**CONCLUSION**

Our findings demonstrate the feasibility of using CNNs for accurate 3D quantitative angiography reconstruction. Trained on virtual CFD data, the model effectively applied these insights to real patient CBCT data, demonstrating promising clinical applicability.

**CLINICAL RELEVANCE/APPLICATION**

This study underscores the potential of machine learning algorithms, trained on virtually generated data, to address the challenges of acquiring accurate 3D quantitative angiography from CBCT scans, improving clinical assessments and vascular intervention planning.

## R6-SSPH15-6 A NOVEL DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM FOR LOW-DOSE CDTE PHOTON-COUNTING BREAST CT

Sabee Y. Molloi, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Huanjun Ding (*Abstract Co-Author*) Nothing to Disclose
Hamidreza Khodajou-Chokami, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

We present a novel deep learning (DL)-based framework designed to rapidly generate high-quality CT images for low-dose breast CT applications.

**METHODS AND MATERIALS**

Our deep learning model, RecGAN-Net, combines generator and discriminator networks to optimize CT image reconstruction. The generator employs a multi-receptive field densely connected convolutional neural network with an encoder-decoder structure and dense skip connections to expand the receptive field and enhance performance. The discriminator utilizes a traditional architecture with binary cross-entropy loss, enhanced by leaky ReLUs with a slope of 0.2, culminating in a sigmoid-activated output layer to determine the final probability assessment. Our data were experimentally collected using a cone-beam breast CT system, equipped with a Cadmium Telluride (CdTe) photon-counting detector, operating at a maximum tube voltage of 70 kVp and set at a source-to-detector distance of 62.5 cm. To harness the advantages of transfer learning, RecGAN-Net was initially trained on the AAPM challenge dataset, and subsequently fine-tuned on our in-house dataset, containing high-dose breast CT images (12 mGy, 1480 projections) and the corresponding low-dose CT images (1.5 mGy, 180 projections), featuring embedded microcalcifications ranging from 140 μm to 500 μm.

**RESULTS**

Transitioning from the high-dose reference image to an approximately eightfold reduction in projection data, RecGAN-Net achieved a Structural Similarity Index (SSIM) of 0.989 and a Root Mean Square Error (RMSE) of 0.007 HU as compared with Feldkamp-Davis-Kress (FDK) reconstruction with SSIM of 0.533 and an RMSE of 0.04 HU. This demonstrates that the low-dose CT image maintains a high level of similarity to the high-dose reference image, significantly outperforming the FDK reconstruction. Preliminary postmortem breast results have demonstrated RecGAN-Net's capability to detect 140 μm microcalcifications with a low radiation dose of 1.5 mGy.

**CONCLUSION**

Integrating our deep learning algorithm into a photon-counting breast CT system not only yields high-quality images but also significantly reduces the radiation dose. Microcalcifications can be detected at a mean glandular dose level comparable to that of clinical mammography.

**CLINICAL RELEVANCE/APPLICATION**

RecGAN-Net advances breast CT imaging by maintaining high image quality while reducing radiation to levels comparable with mammography (1.5 mGy). This enables the detailed detection of critical microcalcifications (140 μm), essential for early breast cancer diagnostics. By minimizing radiation without compromising diagnostic quality, RecGAN-Net can transform breast cancer screening, enhancing patient safety and facilitating earlier interventions.

Nastaran Khalili, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Hannah Anderson (*Abstract Co-Author*) Nothing to Disclose
Sina Bagheri, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Magnetic resonance imaging (MRI) has become a powerful, non-invasive method for visualizing and tracking labeled cells. Superparamagnetic iron oxide nanoparticles (SPIONs), valued for their biocompatibility and magnetic properties, hold potential for cellular labeling. This study employed microfluidic devices to precisely label human T-cells with SPIONs through mechanoporation, enhancing the accuracy and efficiency of the labeling process.

### METHODS AND MATERIALS

Experiments were conducted using a novel, custom-engineered microfluidic device designed to enhance the delivery of SPIONs through volume exchange and convective transfer. Within the device, human T-cells traverse multiple ridged channels, undergoing a series of rapid and high-intensity deformations that transiently open cellular pores, facilitating the convective transport of SPIONs into the cells. The uptake of nanoparticles by the cells was assessed using Prussian blue staining and a colorimetric iron assay. Both labeled and unlabeled T-cells were imaged in vitro using MRI. T2 relaxation times were compared between labeled and unlabeled T-cells using a Student's t-test, with significance set at $p<0.05$.

### RESULTS

The uptake of SPIONs was significantly greater in labeled T-cells compared to unlabeled ones (0.250 ± 0.048 pg/cell versus 0.009 ± 0.003 pg/cell, $p<0.001$). This cellular nanoparticle uptake was further verified using Prussian blue staining. Additionally, T-cells labeled with nanoparticles exhibited significantly shorter T2 relaxation times (50.49 ± 7.19 ms) compared to unlabeled cells (89.35 ± 11.03 ms) as determined by MRI ($p=0.007$).

### CONCLUSION

This study successfully demonstrated the labeling of human T-cells with SPIONs, establishing a foundation for the labeling of therapeutic T-cells, including CAR T-cells.

### CLINICAL RELEVANCE/APPLICATION

The methodology developed enables non-invasive in vivo tracking of therapeutic T-cells using MRI, thereby offering significant potential for monitoring the distribution and migration of therapeutic T-cells in clinical applications. This advancement could greatly enhance the precision and efficacy of T-cell-based therapies.

## R6-STCE1-3 UTILIZING 19F NANOEMULSIONS IN MRI TO MONITOR CANCER PROGRESSION POST-IMMUNOTHERAPY AND RADIATION THERAPY IN BREAST AND COLON CANCER MODELS

Emily Qi, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Colon and breast cancer are 2 of the most prominent and aggressive forms of cancer. While magnetic resonance imaging (MRI) is commonly used alongside biopsies to diagnose and monitor cancer progression, biopsies are invasive and time intensive. A novel method of tracking tumor growth after immunotherapy or radiation therapy is the use of fluorine (19F) nano-emulsions as contrast agents for MRI, which label systemic macrophages. Macrophages flock to the tumor site to initiate tumor resistance, and there is an increase in immune response, and thus, macrophages, when treatment is used.

### METHODS AND MATERIALS

Anti-PD-L1 immunotherapy was used to block the PD-L1 protein found on the surface of various types of cancer cells, which work to inhibit immune response. Female mice were injected with murine breast (4T1) or colon cancer (MC38) cell lines in the mammary fat pad, followed by intravenous injections of the 19F contrast agent, and finally, a baseline 19F MRI. The study then diverged into 2 primary directions: radiation therapy (RT) and

immunotherapy. In the first study, half of the mice underwent 8 Gy of localized RT while the other half remained untreated; they were monitored for 14 days to elucidate tumor growth and 19F signal. In the second study, 12 mice received anti-PD-L1 immunotherapy and 3 remained untreated. MRI was performed on days 3, 7, 10, 14, and 17 of the study to evaluate response rate.

**RESULTS**

The RT study yielded a significantly higher fluorine signal and tumor growth reduction in treated mice versus untreated. The immunotherapy study showed a response rate of 75%, allowing us to quantify responders versus non-responders using MRI as the primary diagnostic modality.

**CONCLUSION**

19F MRI is a promising method for diagnosing and tracking cancer through noninvasive precise tracking of macrophage activity during radiation therapy and immunotherapy.

**CLINICAL RELEVANCE/APPLICATION**

This novel approach shows great potential for improving clinical outcomes through more consistent and accurate monitoring.

## R6-STCE2-2 DEEP LEARNING-ACCELERATED MR IMAGING IN MUSCLE INJURIES OF PROFESSIONAL SOCCER ATHLETES: ENHANCING EFFICIENCY AND REDUCING COSTS IN RADIOLOGY

Ibrahim Yel, MD (*Abstract Co-Author*) Nothing to Disclose
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Simon S. Martin, MD (*Abstract Co-Author*) Nothing to Disclose
Jan-Erik Scholtz, MD (*Abstract Co-Author*) Nothing to Disclose
Vitali Koch, MD (*Abstract Co-Author*) Nothing to Disclose
Leon D. Gruenewald, MD (*Abstract Co-Author*) Nothing to Disclose
Jennifer Gotta (*Abstract Co-Author*) Nothing to Disclose
Scherwin Mahmoudi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

MRI has become a relevant diagnostic imaging method for evaluating muscle injuries in professional athletes, aiding in treatment planning and rehabilitation management. The purpose of this study was to investigate the impact of deep learning-accelerated PD-weighted sequences on acquisition time, image quality, and operational costs in muscle injuries of professional soccer athletes.

### METHODS AND MATERIALS

22 professional male soccer athletes (mean age 25.4±3.4) who underwent 3-Tesla MRI of the lower limb due to suspicion of structural muscle injuries were included in this study. Standard sequences were acquired according to a dedicated protocol comprimising PD-weighted imaging in axial, paracoronal and parasagittal plane, as well as T1-weighted imaging in axial plane. Additionally, PD-weighted imaging sequences were acquired using the deep learning algorithm (PDDL). Subjective evaluation was independently performed by three blinded radiologists. 5-point Likert scales were utilized to subjectively assess diagnostic confidence, image quality, and lesion sharpness. Objective analysis encompassed time efficiency and quantitative imaging parameters, including signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR), as well as operational costs including electricity and personnel.

### RESULTS

MRI analysis revealed structural injuries in 18 patients (81.1%). Subjective evaluations of PDDL sequences revealed excellent diagnostic confidence (median 5, interquartile range (IQR): 5-5), image quality (median 5, IQR: 5-5), and lesion sharpness (median 5, interquartile range: 4-5). PDDL was preferred over conventional PD sequences in 90.9% of cases. Objective image analysis of PDDL revealed significant higher SNR (115.0±9.1) and CNR values (80.5±12.8) when compared to conventional PD sequences (81.3±5.9 and 54.3±5.4, respectively; $p < 0.05$). Acquisition times could be reduced by an average of 39.7% using PDDL sequences, leading to relevant cost savings in terms of electricity and personnel.

### CONCLUSION

Our findings suggest that deep learning-accelerated PD sequences in MRI imaging of muscle injuries among professional athletes allow a reduction in acquisition time while additionally improving both subjective and objective image quality. The integration of these sequences may enhance operational efficiency and reduce ongoing costs, promoting a more sustainable and value-based approach in radiology.

### CLINICAL RELEVANCE/APPLICATION

The integration of deep learning sequences into MRI protocols for muscle injury evaluation not only facilitates prompt treatment and rehabilitation in professional sports medicine but also underscores the potential for substantial cost savings and increased efficiency, contributing to a more equitable and sustainable healthcare system.

## R7-STCE1-1 TRANSCRIBING MULTILINGUAL RADIOLOGIST-PATIENT DIALOGUE INTO MAMMOGRAPHY REPORTS USING AI: A STEP TOWARDS PATIENT-CENTRIC RADIOLOGY

Mohak Narang, MD,MBBS (*Abstract Co-Author*) Nothing to Disclose
Neha Rani (*Abstract Co-Author*) Nothing to Disclose
Amit Gupta, MD, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the efficiency of generating mammography reports using artificial intelligence (AI)-based transcription and information extraction from simulated radiologist-patient conversations in vernacular language.

### METHODS AND MATERIALS

A curated dataset of 50 mammograms (10 normal, 20 benign, 20 malignant) was used in this retrospective study. A radiologist (10 years' experience) discussed mammogram findings with paramedical staff in vernacular language to simulate patient conversations. Conversation for each mammogram was transcribed using OpenAI's large-v2 whisper model at different temperature (temp) settings (0, 0.3, 0.5 and 0.7). The generated transcript versions were processed by Generative Pre-trained Transformer-4o (GPT-4o) to generate reports in a predetermined JSON format, displayed as editable files in HTML. Time taken for conversation, transcription, GPT-4o response and radiologist editing was measured. Accuracy metrics, including word error rate (WER) and character error rate (CER) for AI-generated transcriptions were compared to manual transcriptions. Concordance rates for JSON fields in AI-generated versus radiologist-edited reports were calculated.

### RESULTS

The mean WER and CER for AI-generated transcripts respectively, were: 0.577 and 0.379 at temp 0; 0.641 and 0.428 at temp 0.3; 0.604 and 0.380 at temp 0.5; and 0.622 and 0.395 at temp 0.7. The concordance rates for various fields in the json format report varied from 0.96 (for 'recommendation') to 0.54 (for 'left breast. parenchyma'); with a mean concordance of 0.81 for all the fields. The mean time for report generation was 206.7s, with conversation 113.8s, transcription 45.6s, GPT-4o response 4.3s, and editing 43.1s.

### CONCLUSION

AI-driven transcription for vernacular languages using automated speech recognition along with feature extraction by language model for radiology report generation provides an efficient method to establish a radiologist-patient dialogue and advance a patient-centric and equitable radiology practice.

### CLINICAL RELEVANCE/APPLICATION

Traditional radiology reports, designed for physicians, are seldom understandable to the patients especially in non-English-speaking populations. While radiologist-generated summaries offer some assistance, they contribute to an already heavy workload and are not widely practiced. AI-enhanced report generation from vernacular-language dialogues between radiologists and patients, promises not only a more engaging and empathetic experience for patients but also the potential for comparable efficiency with current radiology workflows. This approach could transform how information is conveyed, making radiology more accessible and patient-centered.

## R7-STCE1-2 CARBON FOOTPRINT OF CT COLONOGRAPHY VERSUS OPTIC COLONOSCOPY

Christina A. LeBedis, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Clara Kerwin, MD (*Abstract Co-Author*) Nothing to Disclose
Kevin J. Chang, MD (*Abstract Co-Author*) Speaker, RELX;Speaker, Koninklijke Philips NV
Monica Kassavin, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The growing awareness of climate change and the need for sustainable practices have led to increased scrutiny of the carbon footprint associated with medical procedures . This study focuses on comparing the carbon footprint of CT colonography versus optic colonoscopy, two procedures used for colorectal cancer screening and diagnosis with similar sensitivities in detecting colorectal lesions.

### METHODS AND MATERIALS

A comprehensive review of peer-reviewed articles was undertaken to evaluate the carbon footprint associated with CT colonography and optical colonoscopy. Studies were chosen based on data on carbon emissions and procedural methodologies. In the absence of studies specifically addressing the carbon footprint of CT colonography, general emissions data for CT procedures were used as a proxy. The carbon footprint was measured in carbon emissions equivalent (CO2eq).

## RESULTS

Existing literature suggests that CT colonography has a lower carbon footprint compared to optical colonoscopy. The average carbon footprint for colonoscopy ranges from 15.0 to 28.4 kg CO2eq , while CT ranges from 2.6 to 9.2 kg CO2eq. This difference is largely due to the lower resources required, including fewer staff, no need for anesthesia, shorter procedure times, less disposable waste and minimal equipment and laundry requirements. Additionally, technological advancements in imaging have enhanced the efficiency of CT, reducing scanning time and, consequently, energy consumption, which is the largest contributor to greenhouse gas emissions in diagnostic imaging.

## CONCLUSION

Incorporating environmental impact assessments into medical decision-making is crucial for sustainable healthcare practices. Although CT colonography and optical colonoscopy offer comparable diagnostic accuracy, the lower carbon footprint of CT colonography presents an opportunity for reducing the environmental impact of colorectal cancer screening. Limitations to existing literature include no specific quantification of CT colonography footprint and most studies from countries outside the United States which may have a different energy grid. Future research should focus on national and institutional-level carbon footprint analysis to validate these findings and guide healthcare policies. By prioritizing sustainability, healthcare providers and policymakers can align medical practices with global climate goals?.

## CLINICAL RELEVANCE/APPLICATION

Given that gastrointestinal endoscopies are the third-largest source of medical waste in healthcare facilities, it is important to consider the comparative carbon footprint of CT colonography to drive sustainable medical practices.

# R7-STCE1-3 REDUCING MRI ENVIRONMENTAL IMPACT THROUGH AI: COMPARATIVE ANALYSIS OF DL AND NON-DL MPRAGE IMAGE QUALITY AND IMPACT ON MRI PRACTICE SUSTAINABILITY

Salil Soman, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Christopher J. MacLellan, PhD (*Abstract Co-Author*) Stockholder, NNOX
Blake Foster, MD (*Abstract Co-Author*) Nothing to Disclose
Ibraheem Shaikh, MD (*Abstract Co-Author*) Nothing to Disclose
Eugene Milshteyn, PhD (*Abstract Co-Author*) Nothing to Disclose
Semyon Chulsky, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To compare pathology visibility, morphometry, and the need for repeat sequences between DL and non-DL MPRAGE at 1.5T, and to determine how AI in MRI enhances diagnostic accuracy and sustainability, supporting equitable healthcare delivery.

## METHODS AND MATERIALS

35 patients were scanned on a 1.5T Voyager MR system (GE HealthCare, WI, USA) from May to August 2023, under an IRB-approved protocol. 13 had abnormalities. Images were reconstructed using a commercial DL method (AIR™ Recon DL, GE HealthCare), which reduced noise by 75%, and conventional non-DL methods. Qualitative analysis involved a neuroradiologist, a neuroradiology fellow, and 2 radiology residents with 19, 8, 2, and 1 years of experience, respectively. Preference for DL or non-DL images was scored on a scale of 0 (non-DL), 1 (DL), and 2 (no difference), with inter-rater agreement measured by Fleiss' Kappa. Morphometric analysis used FreeSurfer (v7.4.0). Volumes and cortical thickness were compared using a paired t-test ($p<0.05$). Two neuroradiologists assessed the need to repeat scans on a 5-point scale from -2 (not repeating) to 2 (repeating) and patient callbacks. Inter-rater agreement was measured, and differences were calculated using a two-tailed t-test ($p<0.05$).

## RESULTS

Preference for DL images was 78%, non-DL images 13%, and no preference 9.5%, with a Fleiss Kappa of 0.9, indicating strong agreement. Morphometric comparisons remained within a 5% mean value difference. A significant difference in rescan recommendations between DL and non-DL images was found ($p<0.001$). Non-DL images scored -0.03 with an inter-rater reliability of 1, while DL images scored -1.62 and -1.48 with an inter-rater reliability of 0.895. Callback rates differed significantly ($p=0.04$); 17% for non-DL with inter-rater reliability of 1, compared to 3.4-6.9% for DL with inter-rater reliability of 0.651.

## CONCLUSION

This study shows that DL MPRAGE images provide equal or better diagnostic quality than non-DL images while decreasing repeat scans. This reduction lowers greenhouse gas emissions from energy use, patient travel, and MRI waste, highlighting environmental benefits. Improved imaging efficiency enhances health equity by reducing patient burden. However, the environmental impact of training advanced AI models should be considered.

## CLINICAL RELEVANCE/APPLICATION

Concerns about climate change highlight the significant energy consumption of MRI scans and their environmental impact. This necessitates strategies for environmental sustainability while maintaining imaging quality. AI applications show promise but require further investigation into their effects on imaging quality and sustainability through reduced scan times and fewer repeat exams.

## R7-STCE2-2 PEDIATRIC RADIOLOGY DEPARTMENT ENVIRONMENTAL FOOTPRINT: AWARNESS AMONG EMPLOYEES AND COMPREHENSIVE QUANTITATIVE ENERGY EXPENDITURE

Francoise Rypens, MD (*Abstract Co-Author*) Nothing to Disclose
Juliana Arnoldo (*Abstract Co-Author*) Nothing to Disclose
Ramy El-Jalbout (*Abstract Co-Author*) Nothing to Disclose
Joanna J. Abi Ghosn, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Health care facilities have a major impact on climate change since they contribute to important greenhouse gas emissions. Medical imaging contributes greatly to this pollution through its energy consumption from imaging equipment, workstations, monitors and the production of medical waste including contrast agents. Although the climate change's issue was highlighted since decades, a well-organized action plan was not adopted quickly by the health care systems. The purpose of the study is to promote the need to reduce the environmental footprint of a pediatric radiology department, by first determining the level of knowledge and the personal attitude of the medical imaging staff and employees with respect to radiology environmental footprint, and second by measuring the energy consumption of the different imaging equipment and electronic devices.

### METHODS AND MATERIALS

Prospective study in which a survey of 18 questions with multiple choices and open-ended questions was distributed to the radiology staff, residents, technologists and administrative agents. The mean kilowatt-hour energy expenditure per equipment was collected with an energy consumption meter in every sector and exam room of the radiology department to measure energy expenditure.

### RESULTS

A total of 31 employees responded to the survey of whom 51.6% were technologists, 32.2% aged 31 to 40 years old and 83.8% women. While the majority believe that Radiology Department consumes up to 50 % of total energy expenditure of the hospital and all the respondents do green actions to decrease environmental impact in their daily lives, only 42 % turn off their computer stations and radiology equipment daily. On the other hand, 67.7% believe that working from home decreases environmental impact and 48.4% do not know whether Artificial Intelligence (AI) has an impact on radiology department environmental impact. As expected, the majority of energy expenditure in the radiology department was from radiology equipment. Among the latter, energy consumption of MRI (25 kWh) dropped significantly after working hours (5kWh).

### CONCLUSION

Most of radiology staff and employees are aware of the environmental impact of the radiology department. However, actions that could have decreased energy expenditure are overlooked because of lack of awareness. We intend to launch an awareness campaign via a memory aid based on our survey results and objective energy expenditure in the department and then do a follow up survey at institution's level in 3 months to assess the behavioral changes.

### CLINICAL RELEVANCE/APPLICATION

Radiology is a major source of greenhouse gas emissions mostly from imaging equipment. However informed staff and employees can drive change by simple daily actions at bedside and in exam rooms.

## S1-SSCH01-1 VOLUMETRIC AIRWAY-TO-LUNG DYSANAPSIS: ASSOCIATIONS WITH RESPIRATORY MORBIDITY AND MORTALITY IN COPD

Sandeep Bodduluri, MS, PhD (*Abstract Co-Author*) Nothing to Disclose
Surya Bhatt (*Abstract Co-Author*) Nothing to Disclose
Venkata Sthanam (*Abstract Co-Author*) Nothing to Disclose
Arie Nakhmani (*Abstract Co-Author*) Nothing to Disclose
Stephanie Marie Aguilera, BSc (*Presenter*) Nothing to Disclose

### PURPOSE

Airway-to-lung dysanapsis is associated with increased risk of developing chronic obstructive pulmonary disease (COPD) and premature mortality. It has been quantified by the ratio of the geometric mean of segmental airway lumen diameters to the cube root of the lung volume. We derived a more anatomically accurate 3D volumetric measure of dysanapsis using airway to-lung volume ratio. We hypothesize that greater volumetric dysanapsis, indicated by lower airway-to-lung volume ratios, is associated with respiratory morbidity and mortality in COPD.

### METHODS AND MATERIALS

Inspiratory CT scans from 8102 subjects enrolled in the multicenter COPDGene study were included. Airways and lungs were segmented using a UNet-based segmentation model. Volumetric dysanapsis is defined by the airway to lung volume ratio scaled to 1000. Multivariable regression analyses were used to test associations between volumetric dysanapsis and lung function measures (FEV1, FEV1/FVC) adjusted for age, race, sex, BMI, smoking status, pack-years of smoking, Pi10 and %CT emphysema. We also tested associations between volumetric dysanapsis with 6-minute walk distance, SGRQ score for quality of life, mMRC dyspnea score, and annualized change in FEV1 over 5 years with additional adjustments for baseline FEV1. We categorized volumetric dysanapsis into quartiles and performed multivariable Cox proportional hazards analysis to test its association with mortality.

### RESULTS

Airway-to-lung volume ratio was lower with disease progression ($p<0.001$): 6.21(1.80), 5.25(1.49), 4.70(1.52), 4.23(1.32), 3.65(0.98) through GOLD severity stages 0-4 respectively. In adjusted multivariable analyses, volumetric dysanapsis was independently associated with FEV1 (ß = -0.03 L, 95%CI -0.01 to -0.04, $P<0.001$), FEV1/FVC (ß = -0.025 , 95%CI -0.022 to -0.027; $P<0.001$), 6-min-walk distance (ß = -2.68 m; 95%CI -3.55 to -1.81; $P<0.001$), SGRQ score (ß = 0.74 , 95%CI 0.23 to 1.25, $P=0.004$), mMRC dyspnea score (ß = 0.03, 95% CI 0.01 to 0.06, $P =0.003$), and lung function decline (ß = -3.48 ml/year; 95%CI -5.28 to -1.69; $P <0.001$). When divided by quartiles, there were 831(10%) subjects with moderate dysanapsis and 304 (4%) subjects with severe dysanapsis in GOLD 0. Moderate (adjusted HR= 1.37, 95%CI 1.21 to 1.56, $P<0.001$) and severe volumetric dysanapsis (adjusted HR= 2.25, 95%CI 2.00 to 2.54, $P<0.001$) were significantly associated with increased mortality.

### CONCLUSION

Volumetric airway-to-lung dysanapsis increases with COPD severity, and is independently associated with lung function, respiratory morbidity, and mortality.

### CLINICAL RELEVANCE/APPLICATION

Volumetric dysanapsis significantly enhances early COPD screening before major symptoms arise.

## S1-SSCH01-2 CHEST CT-BASED CHARACTERIZATION OF OSTEOPOROSIS AND SARCOPENIA IN COPD

Eric A. Hoffman, PhD (*Abstract Co-Author*) Founder, VIDA Diagnostics, Inc;Shareholder, VIDA Diagnostics, Inc;Advisory Board, Siemens AG

Alejandro Comellas, MD (*Abstract Co-Author*) Nothing to Disclose
Punam K. Saha, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Osteoporosis and sarcopenia are major comorbidities in chronic obstructive pulmonary disease (COPD). We compute thoracic bone and muscle metrics from chest CT data and retrospectively characterize osteoporosis and sarcopenia in COPD.

**METHODS AND MATERIALS**

Deep learning-based automated algorithms were applied to inspiratory chest CT images of participants from the Genetic Epidemiology of COPD (COPDGene) Iowa cohort at baseline visits to compute their pectoral muscle area (PMA) and spinal volumetric bone mineral density (BMD). A generalized additive model (GAM) was built by accounting for possible nonlinear effects of demographics and risk variables, specifically, the model formula being: log(Y) ~ Sex + Smoking + Race + s(Age) + s(Height) + s(Weight) + s(PackYears), where s(·) are variable-specific smooth natural cubic spline functions determined by the data based on generalized cross validation, and Y could be the PMA or BMD metric. The GAMs were built using data from participants with preserved lung function. For each model, the corresponding residual standard deviation s measures the typical variation around the predicted value. For each participant, BMD (PMA) was predicted with the model and the computed prediction residual was standardized by s.

**RESULTS**

Study participants (n=1,127; age (mean±standard deviation): 60.2±9.1 years; 572 (50.7%) females) were grouped according to COPD severity: 1) preserved lung function (n=520); 2) mild COPD (n=214); 3) moderate COPD (n=212); and 4) severe COPD (n=181). A gradual decline in PMA with COPD severity was observed in Figure 1(a), while a relatively sharper fall in BMD between mild and moderate COPD group was noted. Participants with increasing COPD severity had greater negative shifts in BMD and PMA falling in the osteoporosis, sarcopenia, and osteosarcopenia quadrants, which indicates adverse relations of bone and muscle features with COPD (Figure 1(b)). Also, the distribution suggests that a large proportion of patients with COPD in Quadosteoporosis and Quadsarcopenia have divergent negative findings in bone and muscle outcome metrics. Welch's t-test shows that prediction residuals for BMD and PMA in moderate and severe COPD groups are significantly lower compared to the preserved lung function group (Figure 1(c)).

**CONCLUSION**

Bone density and muscle mass are reduced with increasing COPD severity, and spherical distributions of shifts in bone and muscle metrics are suggestive of different pathways of bone and muscle loss in COPD.

**CLINICAL RELEVANCE/APPLICATION**

CT-based automated characterization of osteoporosis and sarcopenia in COPD will facilitate the understanding of multi-pathway bone and muscle loss in COPD and their associations and impacts on disease progression and clinical outcomes.

## S1-SSCH01-3 INCREASING FREQUENCY OF CHEST CT ACQUISITION IN ELDERLY PATIENTS WITH PNEUMONIA: ASSOCIATION WITH INCIDENCE RATE AND PROGNOSIS IN POPULATION-BASED COHORT

Eui Jin Hwang, MD, PhD (*Presenter*) Research Grant, Lunit Inc;Research Grant, Coreline Soft, Co Ltd;Research Grant, Monitor Corporation Inc

**PURPOSE**

The accessibility to diagnostic imaging such as chest CT, which is essential for diagnosing pneumonia, has continuously improved. This study investigated the temporal trend of chest CT acquisition in elderly patients with pneumonia and associated incidence rate and prognosis of pneumonia.

**METHODS AND MATERIALS**

A population-based cohort comprising a randomly sampled Korean population aged 60 to 80 in January 2008 was investigated. The age- and sex-adjusted incidence rate of pneumonia was evaluated in each year from 2009 to 2018. Incidence rates of hospitalized and non-hospitalized pneumonia, as well as pneumonia with and without chest CT acquisition, were separately evaluated. Among patients with pneumonia, the frequency of chest CT acquisition was evaluated each year after adjustment of potential confounding variables (age, sex, severity of pneumonia, and comorbidities). The 30-day mortality rate of pneumonia patients was also evaluated each year after adjustment of confounding variables.

**RESULTS**

The entire cohort comprised 511,931 individuals (mean age 69 years in 2009; 56% female), representing 8% of the Korean population with the same age. The age- and sex-adjusted incidence rate of pneumonia showed mild growth (53 to 58 per 1000 person-year from 2009 to 2018). The incidence rates of non-hospitalized pneumonia (32 to 44 per 1000 person-year) and pneumonia with chest CT (9 to 15 per 1000 person-year) showed a clear tendency to increase, while the incidence rates of hospitalized pneumonia (19 to 18 per 1000 person-year) and pneumonia without chest CT (44 to 45 per 1000 person-year) remained stable. The frequency of chest CT acquisition in pneumonia patients showed a trend of continuous increase (12% to 29%, from 2009 to 2018), both in hospitalized (38% to 68%) and non-hospitalized pneumonia (5% to 12%). The 30-day mortality rate of pneumonia patients remained stable between 2009 and 2018 (1.2% to 1.1%), regardless of hospitalization (8.9% to 9.4% for hospitalized pneumonia; 0.18% to 0.07% for non-hospitalized pneumonia) and chest CT acquisition (3.7% to 3.6% for pneumonia with chest CT; 0.93% to 0.85% for pneumonia without chest CT).

**CONCLUSION**

Between 2009 and 2018, the incidence rates of non-hospitalized pneumonia and pneumonia with chest CT acquisition increased in elderly individuals. Despite the increased frequency of chest CT acquisition in pneumonia patients, the 30-day mortality rate of pneumonia patients remained similar.

**CLINICAL RELEVANCE/APPLICATION**

The increased accessibility to chest CT may have contributed to the increased diagnosis of mild pneumonia, which did not require hospitalization. However, the increased frequency of obtaining chest CT in pneumonia patients may not have improved the prognosis.

## S1-SSCH01-4 AUTOMATIC CLASSIFICATION OF PARENCHYMAL CLUSTERS AS INDICATORS OF PULMONARY EMPHYSEMA IN LUNG CANCER SCREENING

**PURPOSE**

Quantifying emphysema holds potential for asymptomatic smokers in lung cancer screening(LCS) population. This study aims to optimize Hounsfield Unit(HU) threshold for emphysema quantification and severity classification through the analysis of low-attenuation(LA) clusters of lung parenchyma in LCS.

**METHODS AND MATERIALS**

In this study, 352 individuals (170 females) had low-dose chest CT scans(120 kVp and 35 mAs) for lung cancer screening[3]. Images were reconstructed with a B30f kernel at 2.0mm slice thickness. A commercial AI software was used to perform lung segmentation for excluding pulmonary vessels and bronchi. LA cluster were calculated and classified by size, under HU thresholds(-950HU, -960HU, -970HU, -975HU). The severity of emphysema was divided into four groups based on the diameter of the largest cluster: trace(3-6mm), mild(6-12mm), moderate(12-16mm), and confluent(>16mm). Clusters measuring less than 3mm in diameter were identified as typical lung parenchyma. Two experienced radiologists and two trainees visually assessed CT images for emphysema according to Fleischner criteria. Inter-reader agreement and correlation with quantified emphysema were evaluated using Spearman analysis.

**RESULTS**

Using a 6mm LA cluster size cutoff, agreement between automatic classification and visually scored emphysema scores exceeded 79%. Peak agreement occurred at -975 HU, reaching 89.7%, 89.5%, 79.2%, and 88.3% for readers A, B, C, and D, respectively. For the 12mm cutoff, agreements between automatic classification and readers' emphysema scores were above 89%. Peak agreement occurs at -960HU, 95.2%, 93.5%, 89.2%, and 92.0% for readers A, B, C, and D, respectively.

**CONCLUSION**

Utilizing cluster analysis during lung cancer screening, the threshold from -960HU to -975HU was found to be the optimal choice for a dichotomous emphysema severity classification of the lung parenchyma in lung cancer screening. Strong agreement between visual severity scores and LA cluster classification suggests visual scoring based on the largest emphysema regions may be more objective in estimating severity.

**CLINICAL RELEVANCE/APPLICATION**

LA cluster analysis seems effective for objective emphysema quantification and severity classification. In LCS, the application of LA-cluster analysis has the potential to automate emphysema scoring.

## S1-SSCH01-5 ASSESSING THE FEASIBILITY OF AN AI REPORT GENERATION MODEL IN DETECTING TUBERCULOSIS ON CHEST RADIOGRAPHS

Byungseok Roh (*Abstract Co-Author*) Nothing to Disclose
Ok Kyu Song (*Abstract Co-Author*) Nothing to Disclose
Eun Kyoung Hong, MD,PhD (*Abstract Co-Author*) Research Consultant, VUNO Inc
Kyu-Chong Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Hae Won Kim (*Abstract Co-Author*) Nothing to Disclose
Dong Kyu Kim (*Abstract Co-Author*) Nothing to Disclose
Woong Bae, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Advances in multimodal generative Artificial Intelligence (AI) have the potential to improve radiologic workflow by automating radiological reporting processes. Utilization of AI report generation model can enhance the efficiency of tuberculosis (TB) detection on Chest Radiographs (CR), especially in areas of high prevalence of TB and shortage of radiologists. The current study aims to assess the feasibility of a multimodal AI report generation model for CR in detecting TB.

**METHODS AND MATERIALS**

Two public datasets (Shenzhen, Mongomery) from US National Library of Medicine, and an AI report generation model, available online for research purposes (karacxr.ai), were utilized for the analysis. From the AI-generated reports, text descriptions of all lung and pleural abnormalities were extracted by one radiologist, except findings related to lung inflation status. The stand-alone performance of the AI model in detecting TB-related abnormalities was compared to independent readings of 3 radiologists, in terms of sensitivity, specificity, positive and negative predictive values and accuracy. Additionally, the autonomous reporting rate of the AI model was analyzed by 2 radiologists, by assessing the acceptability of the AI-generated reports.

**RESULTS**

The AI model demonstrated sensitivity, specificity, and accuracy of 0.944, 0.892, and 0.918, respectively, where that of 3 radiologists' ranged between 0.919-0.947, 0.894-0.968 and 0.920-0.945, respectively in detecting abnormalities in TB patients (Table 1). The most commonly mentioned abnormalities in the CRs are, in the following order: nodular lesion, 138; patchy, hazy, focal opacity/density, 135; consolidation, 120; and scarring, 106 cases. (Figure 1). The AI-generated reports achieved autonomous reporting rates of 73.13% (585/800) and 61.38% (491/800), as assessed by two radiologists.

**CONCLUSION**

The result of this study demonstrated the AI report generation model's comparable performance in detecting TB-related abnormalities on CRs to radiologists and the majority of AI-generated reports were accepted by radiologists, suggesting a potential for autonomous reporting on CRs in the specific clinical setting.

**CLINICAL RELEVANCE/APPLICATION**

The multimodal AI report generation model showed promising performance in detecting TB-related abnormalities, with a potential for autonomous reporting of CRs. However, further validation is necessary to fully establish its clinical efficacy and ensure its reliability in broader clinical practice.

## S1-SSCH01-6 PLEURAL EFFUSION AS A PROGNOSTIC MARKER IN COVID-19: INSIGHTS FROM A NATIONWIDE MULTICENTER STUDY

**PURPOSE**

This study evaluates the prognostic value of pleural effusion (PE) in predicting clinical outcomes in COVID-19 patients at thirteen centers in Germany. This nationwide multicentric analysis aims to fill this gap by evaluating the prognostic significance of PE in COVID-19 patients.

**METHODS AND MATERIALS**

In this retrospective analysis within the RACOON (Radiological Cooperative Network of the COVID-19 pandemic) project, 1,183 patients (29.3% women, 70.7% men) underwent chest CT to evaluate for PE. We examined the association of PE with 30-day mortality, ICU admission, and the need for mechanical ventilation. All CT scans were evaluated by a team of experienced radiologists who applied standardized criteria to identify and measure pleural effusion, ensuring consistency across all evaluations. Data regarding patient outcomes were meticulously recorded, including mortality rates, ICU admissions, and the necessity for mechanical ventilation, to assess the impact of pleural effusion on patient prognosis effectively.

**RESULTS**

The patient sample consisted of 1183 patients, 347 (29.3%) women and 836 (70.7%) men. Mean age was 62.5 ± 15.2 years; median age, 63 years. PE was detected in 31.5% of patients and was significantly correlated with higher 30-day mortality (47.5% in non-survivors vs. 27.3% in survivors, $p<0.001$), yielding a hazard ratio of 2.22 (95% CI 1.65-2.99, $p<0.001$). Moreover, the volume of the PE was larger in cases with fatal outcome compared to non-fatal cases (5417 ± 34514 mm$\acute{N}$ versus 1461 ± 8359 mm$\acute{N}$, $p<0.001$). There was no significant association between PE volume or density and mortality outcomes. ICU admission was reported in 46.8% of patients and 26.7% required mechanical ventilation. The prevalence of PE was lower in male patients compared to female (n=236, 28.2% versus n=137, 39.4%, $p=0.008$).

**CONCLUSION**

Pleural effusion is a significant independent predictor of increased 30-day mortality in COVID-19 patients, highlighting its importance as a prognostic marker. The presence of PE, regardless of its volume or density, should be highlighted in radiological reports to aid clinical decision making.

**CLINICAL RELEVANCE/APPLICATION**

This study confirms pleural effusion as an independent prognostic factor for increased 30-day mortality in COVID-19 patients. Recognition of PE, regardless of volume or density, is critical to improve patient management and target treatment strategies more effectively.

## S1-SSGU01-1 A MULTI-TASK DEEP LEARNING MODEL INCORPORATING CT RADIOLOGICAL FEATURES FOR IDENTIFYING CLEAR CELL RENAL CELL CARCINOMA IN SOLID RENAL MASSES: MULTICENTER DEVELOPMENT AND EXTERNAL VALIDATION

Yanlin HE (*Abstract Co-Author*) Nothing to Disclose
Yaqin Zhang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Jiayue Han (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a multi-task deep learning model incorporating CT radiological features (hereafter, MMulti) for diagnosing clear cell renal cell carcinoma (ccRCC) in solid renal masses and identifying radiological features of the masses and to compare the performance of MMulti, radiologists, a radiomic model (hereafter, MRadomic), and a model trained without incorporating radiological features (hereafter, MDiag).

### METHODS AND MATERIALS

This retrospective study included 597 surgically proven renal masses from four centers. Multivariate logistic regression analyses were employed to identify radiological features associated with ccRCC. These features were then introduced into a multi-task deep learning model based on residual networks as the radiologist's domain knowledge. MMulti, MDiag and MRadiomic were trained on contrast-enhanced CT images of 402 masses (Data from Centers I, II, and III). The performance of MMulti was compared with that of MDiag, MRadiomic and radiologists with different experience levels on the external test dataset (195 masses, data from Centers IV) with the DeLong method and McNemar test.

### RESULTS

The area under the receiver operating characteristic curve (AUC) , accuracy and sensitivity of MMulti in the external test set were 0.93, 83% and 83%, respectively, which were not significantly different from those of experienced radiologists (0.93 [P = 0.88], 85% [P = 0.35] and 86% [P = 0.22] ) and exceeded those of junior radiologists (0.80 [P < 0.001], 65% [P < 0.001] and 54% [P < 0.001]), MRadiomic (0.85 [P=0.005], 77% [P = 0.002] and 73% [P < 0.001]) and MDiag (0.88 [P = 0.048], 75% [P = 0.012] and 70% [P = 0.001]). In the test set, the consistency rates between MMulti and the experienced radiologist group were higher than those between MMulti and the junior radiologist group for enhancement pattern (70% vs 51%, P < 0.001), early dark cortical band (84% vs 70%, P < 0.001), and intra-tumoural vessel (78% vs 71%, P = 0.035).

### CONCLUSION

The multi-task deep learning model incorporating CT radiological features can noninvasively identify ccRCC in solid renal masses with good performance comparable with experienced radiologists and superior to that of junior radiologists, radiomic model and deep learning model without radiological features.

### CLINICAL RELEVANCE/APPLICATION

We developed an artificial intelligence model that is generalizable and can reliably identify ccRCC in solid renal masses. The model may be used as a tool for risk stratification to reduce unnecessary surgery and biopsy of patients and assist clinical decision-making.

## S1-SSGU01-2 CONTRAST-ENHANCED CT RADIOMIC ANALYSIS FOR THE PREOPERATIVE PREDICTION OF PATHOLOGICAL T3A UPSTAGING IN RENAL CELL CARCINOMA: MODEL DEVELOPMENT AND MULTI-SOURCE VALIDATIONS

Bin Song (*Abstract Co-Author*) Nothing to Disclose
Chunlei He, MMEd (*Abstract Co-Author*) Nothing to Disclose
Jin Yao (*Abstract Co-Author*) Nothing to Disclose
Yuntian Chen (*Abstract Co-Author*) Nothing to Disclose
Enyu Yuan, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop and validate the contrast-enhanced CT-based radiomic models for predicting pathological T3a upstaging in patients with renal cell carcinoma.

**METHODS AND MATERIALS**

This study included a total of 1542 patients from 3 medical centers and 4 TCIA cohorts. Radiomic features of the lesion and the 5mm peritumoral area were extracted from the manually labeled portal venous phase CT images. The features were split into tumor-shape, tumor-texture, and peritumor-texture features. Six logistic regression models based on different classes of features were developed and internally nested-cross-validated using data from center 1 (n = 999). Then these models were externally validated using data from center 2 (n = 236), center 3 (n = 120), and TCIA cohorts (n = 187). The best model was selected based on the performance on center 1 dataset. Subgroup analyses were performed by stratifying the T3a invasion into four subtypes. The prognostic value of the best model was also evaluated.

**RESULTS**

In the development set, the tumor-shape based model showed significantly the highest discrimination performance (AUC = 0.868 [0.866-0.870]). The discrimination of the other models ranged from 0.823 to 0.865. The performance of the best model had the lowest coefficient of variation (CoV = 2.9%) among different validations (AUC = 0.868, 0.872, 0.822, and 0.837). The other models also showed low variation of performance in internal and external validations. The subgroup analyses showed the tumor-shape model had the highest sensitivity in tumors with renal vein invasion (sensitivity = 0.943) and the lowest sensitivity in tumors with perinephric fat invasion (sensitivity = 0.740). A total of 550 patients in center 1 were followed up. The survival analysis showed significant worse progression-free survival in model-predicted T3a high risk group than in model-predicted T3a low risk group ($p < 0.0001$).

**CONCLUSION**

The tumor-shape-based radiomic model area showed favorable performance in predicting pathological T3a upstaging preoperatively in renal cell carcinoma patients, which could benefit risk stratification and clinical decision-making.

**CLINICAL RELEVANCE/APPLICATION**

The contrast-enhanced CT-based radiomic model showed good performance and generalizability for preoperative prediction of pathological T3a upstaging in renal cell carcinoma.

## S1-SSGU01-3 IMAGING-BASED RISK STRATIFICATION IN ONCOCYTIC RENAL NEOPLAMS (UPDATED CLASSIFICATION)

Nicola Schieda, MD (*Abstract Co-Author*) Nothing to Disclose
Rajesh Bhayana, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Ankush Jajodia, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Murray Di Loreto, MBBS (*Abstract Co-Author*) Nothing to Disclose

Satheesh Krishna, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Oncocytomas account for the largest cause of benign nephrectomy in renal masses. Renal mass biopsy in this setting is often reported as 'oncocytic neoplasm' and is unreliable in differentiating benign from malignant oncocytic renal masses. In addition, the pathological classification oncocytic neoplasms have been updated with new and emerging entities. The role of imaging in risk stratifying oncocytic neoplasms, in the updated classification scheme is not known.

**METHODS AND MATERIALS**

In this IRB approved retrospective study, 222 consecutive renal oncocytic neoplasms (ON) which underwent nephrectomy from May 2002 to November 2022 were included. A genitourinary pathologist with 10 years of experience, blinded to the original report, reviewed all slides to re-classify the masses by the 2016 WHO classification with the addition of newer and emerging entities in 2021 by the Genitourinary Pathology Society (GUPS) update. Two blinded radiologists reviewed available imaging (n=185) prior to nephrectomy to extract qualitative and quantitative previously described imaging features for renal masses (including size, attenuation, heterogeneity [5-point Likert], margin, calcification, margin/interface, segmental enhancement inversion SEI, central scar, cystic/necrotic features and growth rate mm/y). Outcomes (recurrence/metastasis) were recorded, if any.

**RESULTS**

185 oncocytic neoplasms (ON) were identified of which 28% (51/185) were benign, and 72% (134/185) were malignant. While there was no difference in sex, benign ONs were more common in older patients compared to malignant ONs (64 vs 55y, P<.001). There was no difference in multiplicity (20% vs. 8%, P=.07) or size (4.5 vs 4.6cm, P=.69). Benign ONs had a higher mass-cortex ratio in corticomedullary phase (0.8 vs 0.5, P=.002) and higher attenuation in nephrographic phase (105 vs 74, P<.001) compared to malignant ONs. Calcification was less frequent in benign ONs (8% vs 19%). Homogeneity was less frequent in benign ONs (6% vs 39%, P<.001). There was no difference in margins, SEI, central scar. There was no difference in growth rate (5 vs 4mm/y, P=.28). Of the 134 malignant ONs, 2% (3/134) had metastasis and 2% (2/134) had recurrence. AUC of multivariable model in classifying benign vs malignant ONs was 0.77.

**CONCLUSION**

Benign ONs are more frequently found in older patients, and more heterogeneous, enhance more (higher NG attenuation, higher CMratio), have less calcification compared to malignant ONs. Imaging helps classification of ONs to benign and malignant categories.

**CLINICAL RELEVANCE/APPLICATION**

Imaging stratification of ONs into benign and malignant ONs may help overcome inability of biopsy in differentiation of benign and malignant ONs, enabling increased adoption of active surveillance.

**PURPOSE**

To assess performance of pre-operative functional MRI to diagnose and predict CKD at baseline and at 12 months in patients undergoing surgical management of SRM.

**METHODS AND MATERIALS**

In a prospective, IRB-approved, single-center study, 43 patients (13F/30M, 59.0±11.7y) with SRMs underwent pre-operative 1.5T MRI (Aera, Siemens Healthcare). Protocol included advanced DWI (9 b-values:10-800s/mm2), pCASL, BOLD/R2*, and T1. Advanced DWI was post-processed with ADC, IVIM, tri-exponential, and spectral diffusion models. Baseline CKD was determined as CKD-EPI<60ml/min/1.73m2 at the pre-operative scan. CKD development was determined as CKD-EPI<60ml/min/1.73m2 within 12 months of a healthy baseline eGFR. Ipsilateral and contralateral cortical and medullar ROIs were delineated. Diagnostic performance of logistic regression models, with significant (Mann-Whitney U-test p<0.05) clinical and MR-parameter histogram features, was evaluated through ROC analysis.

**RESULTS**

At baseline, 12 patients had CKD (mean CKD-EPI =49.3ml/min/1.73m2) and 30 patients had healthy function (mean CKD-EPI =80.0ml/min/1.73m2) Follow-up CKD-EPI was available for 19 patients with baseline healthy eGFR; 7 developed CKD and 12 retained normal function.For diagnosis of baseline CKD: R2* and ADC showed increased variance and IVIM showed increased ipsilateral D*. Tri-exponential DWI showed an increased fast diffusion, and spectral diffusion showed a decreased tubular diffusion; median T1 increased. All logistic regression models for baseline CKD were statistically significant (AUC=0.70-0.76, 95%CI>0.5, p=0.01-0.045), and spectral diffusion returned highest AUC=0.76[0.60, 0.91], p =0.036-0.045, SN = 0.83, SP = 0.59.For prediction of CKD development: Tri-exponential, spectral, and T1 values were significant (AUC=0.81-0.95, 95%CI>0.5, p =0.005-0.049). Spectral diffusion showed increased contralateral vasculature and the highest AUC=0.95[0.86, 1.0], SN=0.93, SP=0.91. ADC, IVIM, pCASL, weight, BMI, tumor volume, malignancy, and grade were not predictors of CKD development.

**CONCLUSION**

Spectral and tri-exponential DWI, T1, and BOLD/R2* were associated with CKD diagnosis at baseline and prediction of development of CKD. Classification and prediction of kidney function using MRI could improve diagnosis and prognosis of CKD and treatment planning in patients with SRM undergoing surgery.

**CLINICAL RELEVANCE/APPLICATION**

Patients with solid renal masses (SRM) who have undergone partial or radical nephrectomy are at specific risk of developing renal dysfunction in the post-operative period. Pre-operative glomerular filtration rate (eGFR) is limited in prediction of chronic kidney disease development.

## S1-SSGU01-5 PROSTATE CANCER STAGING RADIO-PATHOLOGIC CORRELATION

Sandy Schaer (*Abstract Co-Author*) Nothing to Disclose
Adrien Richemond (*Abstract Co-Author*) Nothing to Disclose
Jade Matthey-des-Bornels (*Presenter*) Nothing to Disclose

**PURPOSE**

To perform a radio-pathologic correlation of prostate cancer in terms of lesion detection and cancer volume correlation.

**METHODS AND MATERIALS**

This retrospective study included 64 consecutive patients (mean age: 64 ± 9y.o) with radical prostatectomy for biopsy-proven prostate adenocarcinoma between 2018 and 2020. All patients underwent prostate MRI within 6 months before surgery. One radiologist performed 3D prostate cancer lesion segmentation using Mint LesionTM software, for all detected lesions (up to 3 lesions), allowing volume measurements. Segmentations were performed on T2 weighted imaging (WI), diffusion weighted imaging (DWI), apparent coefficient diffusion (ADC) and perfusion. Two pathologists viewed the prostate specimens and measured the volume of each lesion. Radio-pathologic correlation of each lesion considering = grade group 2 and volume = 0.5 ml was tested for detectability and for volume correlation using Pearson's correlation, Bland-Altman limit-of-agreement and Lin's concordance correlation.

**RESULTS**

In total 63 clinically significant prostate cancer lesions (grade group 2 or higher and volume = 0.5 ml) were identified on pathology. 41 patients had one lesion on pathology, 9 had 2 lesions and 1 had 3 lesions. When considering lesion detection detectability diagnostic performance, the sensitivity and specificity were 91.8% and 97.8% for T2WI, 85.2% and 98.5% for DWI, 90.2% and 98.5% for ADC, and 86.9% and 97.1% for perfusion, respectively. The mean lesion volume was 5.8±7.9 ml on pathology and 5±7.6 ml on perfusion MR (p=0.569). Perfusion showed the best correlation with lesion volume derived from pathology compared to T2WI, DWI, and ADC (?c= 0.934, ?c= 0.571, ?c= 0.418, and ?c= 0.485, respectively).

**CONCLUSION**

Prostate MRI allows the detection of clinically significant prostate cancer with high sensitivity and specificity. Perfusion is the most accurate sequence for cancer volume measurement, highlighting the added value of multi-parametric MRI for prostate cancer staging and treatment planning.

**CLINICAL RELEVANCE/APPLICATION**

Perfusion is the most accurate sequence for cancer volume measurement, highlighting the added value of multi-parametric MRI for prostate cancer staging and treatment planning.

## S1-SSGU01-6 MRI-GUIDED IN-BORE BIOPSY POST MRI/US FUSION-GUIDED BIOPSY IN PATIENTS WITH CONTINUING SUSPICIONS OF CLINICALLY SIGNIFICANT PROSTATE CANCER

Michael Quentin, MD (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD (*Abstract Co-Author*) Nothing to Disclose
Kai Jannusch (*Abstract Co-Author*) Nothing to Disclose
Peter Albers, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lars Schimmoeller, MD (*Abstract Co-Author*) Nothing to Disclose
Birte Valentin, MD (*Abstract Co-Author*) Nothing to Disclose
Matthias Boschheidgen (*Presenter*) Nothing to Disclose

### PURPOSE

Patients presenting with suspected clinically significant prostate cancer (csPC) based on multiparametric prostate MRI (mpMRI) findings, yet negative or inconclusive results from MRI/US fusion-guided biopsy (FB), pose a clinical challenge. This study aimed to evaluate the efficacy of MRI in-bore biopsy (IB) in patients with discordant imaging and histopathological findings post-FB.

### METHODS AND MATERIALS

We retrospectively analyzed consecutive patients with Prostate Imaging Reporting and Data System (PI-RADS) category 4 or 5 lesions on 3T mpMRI following FB, who lacked histologically confirmed csPC and subsequently underwent IB between January 2014 and May 2022. The primary goal was to determine the csPC detection rate, while secondary objectives included analyzing clinical and MRI parameters, as well as lesion localization.

### RESULTS

In our final cohort comprising 51 patients, IB yielded an overall detection rate of 71% for prostate cancer (PC) and 47% for csPC. Notably, 55% of cases initially diagnosed with low-grade PC experienced a Gleason score upgrade post-IB. CsPC was frequently localized apically and/or anteriorly. The PC detection rates were 58% and 94% for PI-RADS category 4 and 5, respectively (csPC rates: 39% and 61%, respectively). Patients diagnosed with csPC exhibited statistically significant smaller prostate volumes, higher PI-RADS categories, elevated prostate-specific antigen density (PSAD), and were older.

### CONCLUSION

In a considerable proportion of patients presenting with PI-RADS category 4 or 5 lesions and negative or inconclusive results following FB, but with persistent suspicion of csPC, subsequent IB confirmed the presence of csPC. Thus, IB serves as a valuable adjunct in cases of diagnostic uncertainty.

### CLINICAL RELEVANCE/APPLICATION

Our results indicate the viability of a sequential approach, employing MRI in-bore biopsy as a secondary measure for individuals exhibiting a strong suspicion of clinically significant prostate cancer on mpMRI, yet lacking confirmation from MRI/US fusion-guided biopsy. Particularly, this biopsy method proved advantageous for patients categorized as PI-RADS category 5 or ISUP GG 1 prostate cancer, as well as for those with discernible apical and/or anterior MRI lesions (which may vary depending on the initial biopsy method), and smaller prostate volumes coupled with higher PSA density (PSAD).

## S1-SSHN01-1 CAN SYNTHETIC MRI DISCRIMINATE THE ORIGIN OF METASTATIC LYMPH NODES IN THE NECK: NASOPHARYNX VS. NON-NASOPHARYNX AND TONSILS VS. NON-TONSILS?

Xiaoduo Yu (*Abstract Co-Author*) Nothing to Disclose
Hongmei Zhang (*Abstract Co-Author*) Nothing to Disclose
Haoran Wei (*Abstract Co-Author*) Nothing to Disclose
Meng Lin (*Abstract Co-Author*) Nothing to Disclose
Fan Yang (*Presenter*) Nothing to Disclose

### PURPOSE

Approximately 2%~9% of patients with head and neck squamous cell carcinoma (HNSCC) have an unknown primary site, and diagnostic and therapeutic dilemmas exist in these patients. Unilateral or bilateral tonsillectomy is the diagnostic or therapeutic option of choice. How to identify that metastatic lymph nodes (LNs) from the tonsils can prevent needless injury. Patients with nasopharyngeal carcinoma (NPC) has completely different treatment method compared with others with HNSCC (chemoradiotherapy only vs. surgery). In order not to delay treatment, the first step of this study is to compare the metastatic LNs from NPC and non-NPC. Moreover, the second step is to identify if the remaining metastatic LNs are from tonsil carcinoma to avoid unnecessary treatments and to choose the right treatment options.

### METHODS AND MATERIALS

This study prospectively included patients with biopsy-defined NPC (n = 35) and HNSCC (n = 29). All patients underwent SyMRI (Discovery MR 750, GE Healthcare, USA) scan before contrast agent injection. The detailed information is as follows: repetition time, 6200; echo time, 18.9/94.7; FOV, 26; acquisition matrix, 256 × 320; slice thickness/gap, 4.0/0.4; number of excitations, 1; acquisition time, 7.02. Each patient selected one metastatic LN in level II as a representative. The criteria of representative LN are as follows: 1) surgery-confirmed metastatic LNs (n = 6); 2) LN with maximum axial short diameter = 15mm or with obvious necrosis and extracapsular spread (n = 58). Two senior radiologists delineated the representative LNs manually on SyT2WI, avoiding any obvious necrosis or cystic area. Histogram parameters from T1 map, T2 map, and PD map were obtained through Pyradiomics. SPSS software and R studio were used in statistical analysis. Independent sample t-test or Mann-Whitney U test was used. The areas under the curve (AUCs) for all significant variables were calculated.

### RESULTS

5/29 (17.4%) patients were diagnosed with tonsil carcinoma. All parameters had excellent or good inter-observer agreement. Metastatic LNs from NPC had higher T1_Kurtosis and T1_Skewness and lower T2_75th and 90th than those from non-NPC (all P=0.033, Figure). The AUCs were 0.652~0.678. Moreover, compared with LNs from non-tonsil (n=24), LNs from tonsil (n = 5) had higher T2_Mean and T2_Median (all P=0.019, Figure), with the AUCs were 0.883 (95% CI: 0.761, 1.000) and 0.838 (95% CI: 0.687, 0.988), respectively (Figure).

### CONCLUSION

The parameters from SyMRI could differentiate the origin of metastatic LNs, which could help in timely selection of radiotherapy and avoidance of non-effective treatments.

### CLINICAL RELEVANCE/APPLICATION

Identification of the origin of the lymph nodes prior to treatment facilitates the selection of appropriate treatment

## S1-SSHN01-2 PREDICTION OF BRAF$^{V600E}$MUTATION IN PAPILLARY THYROID CARCINOMABY A CLINICAL-SPECTRAL CTMODEL

Dan Zhang, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The BRAFV600E is the most common mutant oncogene in thyroid cancer and is associated with the aggressiveness of papillary thyroid carcinoma (PTC). The aim of this study was to investigate the effectiveness of a dual-layer detector spectral computed tomography (DLCT)-based model for predicting BRAFV600E mutation in PTC.

**METHODS AND MATERIALS**

Two hundred and fifty-three patients with PTCs who underwent DLCT and BRAFV600E mutation detection (mutant group: n=203; wild group: n=50) were retrospectively reviewed. Quantitative parameters of DLCT in arterial phase, typical image features and clinical information were compared between the mutant and wild-type BRAFV600E groups. The nomogram of the prediction model with the highest area under the receiver operating characteristic curve (AUC) was constructed based on the significantly different variables using logistic regression analysis. The AUC, calibration curve and decision curve analysis (DCA) were used to evaluate the model performance.

**RESULTS**

The normalized iodine concentration (NIC), calcification and Hashimoto's thyroiditis (HT) were identified as independent risk factors of BRAFV600E mutation in PTC. The prediction model based on the three parameters had the highest AUC (0.750; 95% CI: 0.667-0.832). The calibration curve revealed good agreement between the prediction results and the actual observations. The DCA demonstrated that the model can provide net benefit than the all or none intervention strategy within a large range of threshold probabilities.

**CONCLUSION**

As an easily and visually noninvasive prediction tool, the DLCT-based nomogram with NIC, calcification and HT presented moderate effectiveness, which may be a supplementary tool for preoperatively predicting BRAFV600E mutation in PTC.

**CLINICAL RELEVANCE/APPLICATION**

It is an easily and visually noninvasive prediction tool for the preoperative prediction of BRAFV600E mutation in PTC.

## S1-SSHN01-3 MRI BASED MODEL FOR PREDICTING LOCOREGIONALLY ADVANCED NASOPHARYNGEAL CARCINOMA SURVIVAL AT DIFFERENT CENTERS AND DIFFERENT FIELD STRENGTHS: THE COMBAT CORRECTION STUDY

Wei Pei (*Abstract Co-Author*) Nothing to Disclose
Hai Liao (*Abstract Co-Author*) Nothing to Disclose
Dan Ke Su (*Abstract Co-Author*) Nothing to Disclose
Yunyun Wei, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the anti-batch effect of ComBat correction on MRI data from different centers and at different field strengths, and to provide technical support to improve the generalizability of MRI radiomics prognostic prediction model in locally advanced nasopharyngeal carcinoma (LANPC).

**METHODS AND MATERIALS**

MRI data were collected from 572 LANPC patients in two hospitals, all of whom had underwent 1.5T or 3.0T MRI before Induction Chemotherapy (IC) + Concurrent Chemoradiotherapy (CCRT). And the data were all processed according to field strength in ComBat "batch correction". The 3.0T MRI data were taken as the training set, the 1.5T MRI data before ComBat correction were taken as the validation set 1, and the 1.5T MRI data after ComBat correction were taken as the validation set 2. Tumor radiomics features were extracted from MRI images, and principal component analysis (PCA) was used to reduce dimensionality and visualize the results of ComBat correction. Clinical and radiomics features that associated with prognosis were identified by Univariate Cox and LASSO-Cox analyses. And a prediction model was constructed, its ability was assessed by concordance index (C-index).

**RESULTS**

Clinical features were not suitable as the indicator for the prognosis of LANPC patients ($P > 0.05$). Seven radiomics features were associated with the prognosis of LANPC patients ($P < 0.05$) and used to construct a radiomics prediction model. The C-index of the training set, validation set 1, and validation set 2 were 0.713, 0.625 and 0.673, respectively. The prognosis of patients in the high- and low-risk groups divided based on the radiomics features, differed significantly($P < 0.001$). Compared with the validation set 1, the validation set 2 showed improved predictive performance (C-index: 0.625 vs 0.673), and its ability to identify high- and low-risk groups, trend of prognostic curves, and hazard ratios (HR) were all closer to those of the training set.

**CONCLUSION**

The method based on the ComBat can reduce the potential batch effect caused by different centers or different MRI field strengths. The stability and generalization ability of the prediction model constructed from the corrected data are good. And it is helpful for the optimization and clinical generalization of the radiomics model for prognosis prediction in LANPC.

**CLINICAL RELEVANCE/APPLICATION**

The model can provide decision support for clinical treatment and technical reference for model generalization and multicenter radiomics studies.

## S1-SSHN01-4 AN IMPROVED DIAGNOSTIC CRITERION BASED ON NODE-RADS MRI SCORE FOR LYMPH NODE METASTASIS IN PAPILLARY THYROID CARCINOMA

Qiying Tang (*Presenter*) Nothing to Disclose

**PURPOSE**

Accurate preoperative diagnosis of lymph node (LN) metastasis in papillary thyroid carcinoma (PTC) remains challenging. This study aimed to evaluate the diagnostic performance of standard Node Reporting and Data System (Node-RADS) MRI score for detecting LN metastasis in PTC, and to investigate whether a novel diagnostic criterion incorporating modifications to Node-RADS with supplementary MRI features could improve diagnostic accuracy.

**METHODS AND MATERIALS**

In this prospective study, 82 consecutive PTC patients with 156 histopathologically confirmed LNs were enrolled. Standard Node-RADS and supplementary MRI features were evaluated by three radiologists independently. Modifications to Node-RADS were implemented, including a reduction in the "normal" size criterion from <10 mm to <5 mm short-axis diameter. A new diagnostic criterion was further developed by combining modified Node-RADS and significant supplementary MRI features. Sensitivity, specificity, accuracy, positive predictive value, negative predictive value, and area under the curve in receiver operating characteristic curve analysis were calculated to evaluate diagnostic performances. Univariate and multivariate logistic regression identified potential predictors of metastasis. Interobserver agreement was assessed using Kendall W coefficient. A p value < 0.05 was considered statistically significant.

**RESULTS**

Standard Node-RADS demonstrated modest performance (sensitivity 51.4%; specificity 89.5%; AUC = 0.704) in diagnosing LN metastasis in PTC when applying a Node-RADS score = 4 criterion. Modified Node-RADS and T1 hyperintensity were independent predictors of metastasis on multivariate analysis. Then a new criterion combining modified Node-RADS and T1 hyperintensity was developed and showed a better diagnostic performance (sensitivity 89.0%; specificity 91.5%; AUC = 0.953) than the standard Node-RADS.

**CONCLUSION**

The new MRI-based diagnostic criterion incorporating modified Node-RADS and T1 hyperintensity demonstrates improved accuracy for diagnosing LN metastasis in PTC compared to standard Node-RADS.

**CLINICAL RELEVANCE/APPLICATION**

The new criterion based on Node-RADS MRI score enables accurate diagnosis of LN metastasis in PTC patients, contributing to standardized and convenient interpretation of LN conditions.

## S1-SSNMMI01-3 68GA.DATA.SA.FAPI-PET/MRI AND 18F-FDG-PET/CT FOR LOCOREGIONAL STAGING IN BLADDER CANCER: PRELIMINARY RESULTS OF A PROSPECTIVE COMPARATIVE STUDY

Dina Muin (*Presenter*) Nothing to Disclose

### PURPOSE

Fibroblast activation protein (FAP) targeting cancer-associated fibroblasts is frequently overexpressed in various tumor types. This study aimed to compare the diagnostic accuracy of [68Ga]DATA.SA.FAPi PET/MR and [18F]-FDG PET/CT imaging in predicting locoregional tumor stages in patients with muscle-invasive bladder cancer (MIBC).

### METHODS AND MATERIALS

In this prospective, comparative study, MIBC patients planned for radical cystectomy (RC) with or without prior neoadjuvant chemotherapy (NAC) were enrolled. Prior to RC, patients underwent [68Ga]DATA.SA.FAPi-PET/MRI and [18F]-FDG-PET/CT. Patients receiving NAC underwent [68Ga]DATA.SA.FAPi-PET/MRI and [18F]-FDG-PET/CT before and after treatment with chemotherapy, mainly with Gemcitabin und Cisplatin. The primary outcome of interest was the diagnostic accuracy of [68Ga]DATA.SA.FAPi-PET/MRI (mean time PET-RC (days) - 28.7 (± 25.3)) and [18F]-FDG-PET/CT (mean time PET-RC (days) - 20.61 (± 20.20)) for local and nodal staging in MIBC patients with pathology results serving as the reference test.

### RESULTS

Nineteen MIBC patients (67.26 (± 11.91) years, 74% male) were included, with 42% (8/19) receiving NAC. Sensitivity and specificity for [18F]-FDG PET/CT and [68Ga]DATA.SA.FAPi-PET/MRI in histologically positive primary tumors were identical with 58.3% and 71.4%, respectively. For the prediction of histologically positive lymph nodes, [18F]-FDG PET/CT exhibited superior performance with a sensitivity, specificity, PPV and NPV of 75.0%, 100%, 100% and 90.9% versus 50.0%, 90.0%, 66.7% and 81.8%, respectively, for [68Ga]DATA.SA.FAPi-PET/MRI.

### CONCLUSION

Preliminary findings suggest inferiority of diagnostic accuracy of [68Ga]DATA.SA.FAPi-PET/MRI compared to [18F]-FDG PET/CT. While the detection of cancer lesions in the bladder wall was similar for both modalities, [18F]-FDG-PET/CT showed better results for lymph node staging compared to [68Ga]DATA.SA.FAPi-PET/MRI.

### CLINICAL RELEVANCE/APPLICATION

FAPI-PET/MRI is not as stong as FDG-PET/CT in detecting positive lymph nodes. However FDG-PET can be a useful tool for staging of lymphnodes, as it is more accurate than CT alone.

## S1-SSNMMI01-4 SUPERIOR DETECTION OF PRIMARY AND METASTATIC BREAST CANCER LESIONS: A COMPARATIVE ANALYSIS OF $^{68}$GA-FAPI AND $^{18}$F-FDG PET/CT

Umut Elboga (*Abstract Co-Author*) Nothing to Disclose
Akmaral Ainakulova, MD (*Abstract Co-Author*) Nothing to Disclose

Zhandos M. Amankulov, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Madina Gabdullina, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The objective of this study was to compare the diagnostic efficacy of 68Ga-FAPI PET/CT versus 18F-FDG PET/CT in identifying primary breast cancer lesions, lymph node metastases, and distant metastases, emphasizing enhancing accuracy in clinical staging.

### METHODS AND MATERIALS

This prospective study enrolled 17 women diagnosed with breast cancer from January 2024 to April 2024. The mean age of participants was 52.5 years. Each participant underwent both 68Ga-FAPI PET/CT and 18F-FDG PET/CT. The lesions identified were subsequently confirmed histologically.

## RESULTS

We identified 20 primary lesions and 43 metastatic lymph nodes in 17 breast cancer patients, in addition to 10 bone metastases and 6 liver metastases. 68Ga-FAPI PET/CT showed a sensitivity and specificity of 100% (95% CI: 81.47%-100%) and 85.71% (95% CI: 42.13%-99.64%), respectively, for primary lesions. Comparatively, 18F-FDG PET/CT demonstrated sensitivity and specificity of 83.3% (95% CI: 58.58%-96.42%) and 71.43% (95% CI: 29.04%-96.33%) for primary lesions detection. Notably, 68Ga-FAPI PET/CT identified 3 primary lesions smaller than 7 mm in size. Furthermore, the diagnostic accuracy for lymph node metastasis detection was 100% (95% CI: 91.7%-100%) with 68Ga-FAPI PET/CT, significantly surpassing 76.74% (95% CI: 61.37%-88.24%) with 18F-FDG PET/CT. In the context of distant metastases, 68Ga-FAPI achieved a diagnostic accuracy of 100% (95% CI: 79.41%-100%) compared to 87.5% (95% CI: 61.65%-98.45%) for 18F-FDG. The ROC analysis of PET/CT imaging demonstrated a significantly higher area under the curve (AUC) for 68Ga-FAPI PET/CT at 0.945 compared to 0.783 for 18F-FDG PET/CT, indicating superior diagnostic performance ($p < 0.001$).

## CONCLUSION

68Ga FAPI PET/CT markedly enhances the detection rate and staging of primary and metastatic breast cancer, demonstrating superior sensitivity and specificity compared to 18F-FDG PET/CT. Crucially, it also resulted in upstaging in 23.7% of cases (p=0.001).

## CLINICAL RELEVANCE/APPLICATION

The study demonstrates that 68Ga FAPI PET/CT significantly enhances the accuracy of detecting and staging breast cancer compared to 18F-FDG PET/CT. This superior diagnostic capability facilitates more precise treatment decisions, potentially reducing unnecessary interventions and aligning with personalized cancer care.

# S1-SSNMMI01-5 CORRELATION OF FAPI PET SIGNALS WITH HIGH-RESOLUTION HRCT IN PATIENTS WITH INTERSTITIAL LUNG DISEASES TREATED BY LUNG TRANSPLANT: A PRELIMINARY RESULT OF THE PROSPECTIVE EXPLORATORY STUDY

## PURPOSE

Recent studies suggest potential value of fibroblast activation protein (FAP) expression assessed by FAPI PET, and quantitative interstitial lung disease (ILD) patterns by high-resolution CT (HRCT) for predicting the development of a progressive fibrosing ILD phenotype at the time of diagnosis. The primary aim was to compare the FAPI PET signal with ILD patterns on HRCT in patients with ILD treated by lung transplant.

## METHODS AND MATERIALS

This is a preliminary post-hoc analysis of a single-center, open-label, single-arm, prospective exploratory biodistribution study of 68Ga-FAPI-46 PET imaging in ILD. Patients with ILD, confirmed by HRCT and scheduled for transplantation of the affected lung, were included. Volumetric HRCT taken most recently before the FAPI PET scans were used. Quantitative ILD (QILD) scores were obtained from HRCT using high throughput machine learning based on radiomic features. QILD score includes fibrotic reticular patterns of quantitative lung fibrosis (QLF), and inflammatory patterns of ground glass (QGG). Additionally, single time point prediction (STP), extent of progressive ILD, were obtained. The SUVs from FAPI PET/CT were obtained. The findings were summarized in whole lung, most severe lobe among five lobes, and voxels. Mixed effect models were used to test the association in lobar scores. Furthermore, the pair of chest images were registered from HRCT to FAPI PET/CT and the corresponding registered voxels were characterized by SUV from FAPI PET/CT and ILD patterns from HRCT.

## RESULTS

Between November 2021 and April 2022, four patients with ILD underwent FAPI PET/CT before lung transplant. The types of ILD were idiopathic pulmonary fibrosis (n = 2), rheumatoid arthritis ILD (n = 1), and non-specific interstitial pneumonia (n = 1). Mean (±SD) SUVmax was 4.2 (±0.7) in whole lung, and 4.0 (±1.0) at the most severe lobe. Mean (± SD) fibrotic patterns of QLF was 25.1% (± 8.9) in whole lung, and 51.7% (±8.2) at the most severe lobe. Mean (± SD) inflammatory patterns of QGG was 23.1% (±7.4) in whole lung, and 25.5% (±4.3) at the most severe lobe. Mean (±SD) predictive area of STP was 45.1% (±10.9) in whole lung, and 60.3% (±5.5) at the most severe lobe. In five lobes, FAPI PET SUV mean and quantitative ILD scores from HRCT were positively associated (all p-values <0.001) and SUV mean increased by 0.024 for 1% increment of QLF. In the registered voxels, SUVs were correlated with the ILD patterns.

## CONCLUSION

FAPI PET signals positively correlated with ILD patterns of HRCT. These findings may serve to support further exploration of FAPI PET as an imaging marker and as a stratification tool for progressive ILD.

## CLINICAL RELEVANCE/APPLICATION

A phenotype of progressive fibrosing ILD may improve the stratification, leading to better patient’s management.

## S1-SSPH01-1 PERFORMANCE EVALUATION IN PHOTON COUNTING CT (PCD-CT): MEASURING DQE AND DETECTOR DEAD TIME USING AN IMAGE-BASED FRAMEWORK

Ke Li, PhD (*Abstract Co-Author*) Research Consultant, Pulmera Inc.
Guang-Hong Chen, PhD (*Abstract Co-Author*) Nothing to Disclose
Ran Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Linying Zhan, MS (*Presenter*) Nothing to Disclose

### PURPOSE

In photon counting computed tomography (PCD-CT), the performance of photon counting detectors (PCDs) significantly impacts image quality and diagnostic performance. This study addresses the need to evaluate detector deadtime and detective quantum efficiency (DQE)—key factors affecting PCD-CT performance. Traditionally, evaluating PCD properties requires the collection of detector counts at different exposures or energy bins. However, for clinical end-users of PCCT, monitoring PCD quality over time posed a challenge, as direct access to detector counts was typically restricted by the PCCT manufacturer. In this work, we introduced an innovative image-based approach for direct characterization of detector DQE and deadtime from reconstructed PCD-CT images.

### METHODS AND MATERIALS

At the core of the proposed method is a collection of closed-form relationships between the variance of flood-field PCCT images, PCD deadtime, and PCD counts for individual energy bins. For example, the average output counts of an energy bin can be estimated through parametric fitting of the measured PCCT noise power spectrum (NPS) of the same energy bin. Furthermore, by leveraging a novel quantitative relationship between PCCT image variance, PCD deadtime, and tube current (mA), the deadtime can be deduced through parametric fitting of the measured PCCT variance vs. mA curve. These derived theoretical relationships and the proposed PCD characterization method underwent validation using both simulated data and experimental data collected from a clinical whole-body PCCT scanner.

### RESULTS

At an incident photon rate of 5×105 counts per second (cps), the absorbed photon rate estimated from the NPS was (4.21±0.01)×105 cps, resulting in a detector DQE of 84.1±0.1% . Compared to the raw counts-based DQE (85%), the relative error was 1.1%. From PCD-CT images obtained without undergoing any pulse pileup correct and acquired at different incident photon rates ranging from 5×106 to 3.5×107 cps, the PCD deadtime was estimated to be 20.2±5.3 ns. This estimate exhibited a relative error of 1.1% when compared to the raw counts-based deadtime value of 20 ns. For PCD-CT images subject to pulse pileup correction, the proposed method yielded a deadtime of 20.0±7.1 ns, which corresponds to a mean relative error of 0.3%.

### CONCLUSION

Our image-based method successfully estimates PCD-CT detector DQE and deadtime using air scan PCD-CT images, circumventing the need for raw count data.

### CLINICAL RELEVANCE/APPLICATION

This novel framework allows clinical PCD-CT users to effectively assess and monitor their scanners' performance, enhancing operational insights and diagnostic accuracy.

## S1-SSPH01-2 SPECTRAL DEEP SCATTER ESTIMATION FOR PHOTON-COUNTING CT

Eric Fournie (*Abstract Co-Author*) Employee, Siemens AG
Lukas Hennemann, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To provide a scatter estimation and correction algorithm that is specific to the energy threshold information inherent in clinical photon-counting CT (PCCT) scans.

**METHODS AND MATERIALS**

In contrast to conventional energy-integrating (EI) detectors photon-counting (PC) detectors are energy-selective, i.e. they provide spectral information about the energies of the x-ray photons interacting with the detector. Each energy bin receives a different amount of scatter. Moreover, this spectral signature also contains information about the scatter content of a projection and thus can be used for scatter correction. To estimate scatter, we generalized the Deep Scatter Estimation (DSE), a U-Net-like CNN capable of predicting Monte Carlo (MC) scatter distributions as a function of input projections, to be bin-specific. Spectral DSE (sDSE) processes four energy thresholds simultaneously. We compare this to four separate DSE networks, each tuned to a single energy threshold for input and output values. In the training of our networks, we employed simulated data generated by our in-house MC simulation software, utilizing the geometry of the photon-counting CT scanner NAEOTOM Alpha (Siemens Healthineers, Forchheim, Germany). We simulated simple water phantoms as well as semi-anthropomorphic thorax and head phantoms of varying body sizes. The energy thresholds were 20, 55, 70, and 90 keV, respectively, with simulations conducted at a tube voltage of 140 kV. We tested our approach for phantoms of a semi-anthropomorphic thorax phantoms. The spectral DSE was evaluated, and the improvement in image quality was quantified.

**RESULTS**

Threshold images corrected with sDSE show better image quality for three of the four energy thresholds tested in this work, in contrast to the method with four individually trained conventional DSE networks. For the highest energy threshold (90 keV) both sDSE and DSE perform equally well. For spectral applications such as virtual monoenergetic images and iodine maps, sDSE can reduce the mean absolute error (MAE) by up to 80% compared to the uncorrected MC-simulated images. DSE performs slightly worse with around 75% reduction of the MAE. sDSE is also able to reduce the MAE for virtual non-contrast images by up to 75%, while DSE leads to a reduction of 65%.

**CONCLUSION**

Making use of the spectral information inherent in PCCT improves scatter estimation, compared to conventional DSE-based scatter estimation. The ability to utilize the context of different energy thresholds leads to improved performance in scatter estimation, especially for spectral applications.

**CLINICAL RELEVANCE/APPLICATION**

Spectral DSE can improve diagnostic image quality due to the consideration of the different energy thresholds occurring in PCCT scans.

## S1-SSPH01-3 TEMPORAL CONSISTENCY OF SPECTRAL DATA FROM A FIRST-GENERATION DUAL-SOURCE PHOTON-COUNTING CT: A TWO YEAR STUDY

Peter B. Noel, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Advisory Board, Koninklijke Philips NV;Speakers Bureau, Canon Medical Systems Corporation;Advisory Board, Canon Medical Systems Corporation

Harold I. Litt, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Koninklijke Philips NV
Olivia Sandvold, BS (*Abstract Co-Author*) Nothing to Disclose
Leening Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

Photon-counting CT (PCCT) is a novel and paradigm-shifting technology that promises enhanced quantitative imaging capabilities. However, like any new technology, it presents many unknowns, including long-term stability. We evaluated the temporal stability of quantitative spectral results in a first-generation dual-source PCCT over two years.

**METHODS AND MATERIALS**

To assess the quantitative stability of spectral results over time in a first-generation dual-source PCCT (Naeotom Alpha, Siemens Healthineers), a phantom containing tissue-mimicking and material-specific inserts was scanned nearly every week for two years. Scans were performed in both single and dual-source modes at a tube voltage of 120 kVp and a volumetric CT dose index (CTDIvol) of 10 mGy. Notable software and hardware updates occurred at weeks 8, 18, 35, 69, and 80. Virtual monoenergetic images (VMI) between 40 and 190 were measured to determine error relative to the expected value and noise over time. To identify timepoints where spectral quantification changes, a pruned exact linear time algorithm was implemented.

**RESULTS**

Quantification of spectral results was stable across two years with some distinct improvements in accuracy from software and hardware updates, particularly in dual-source mode. For VMI 70 keV, the relative error in single-source mode was 9 ± 7 HU and did not experience significant change points during the two years. VMI 70 keV in dual-source mode, however, demonstrated a significant decrease from 16 ± 10 to 1 ± 7 HU during week 8, which corresponded to hardware and software changes for cross-scatter correction. Similar trends were observed in VMIs at other energies as well as iodine density, where error reduced to -0.3 ± 0.1 mg/mL. Additional change points were also identified at weeks 35 and 69 for different VMIs and iodine density maps but represented small nominal changes ranging from 5 to 15 HU and 0.2 to 0.3 mg/mL, respectively. VMI noise remained stable throughout the two years at 42 ± 1 and 36 ± 1 HU across inserts in single and dual-source modes, respectively.

**CONCLUSION**

PCCT demonstrated high temporal stability in VMIs and iodine density, with significant improvements in quantification with dual-source mode as a result of software and hardware changes. At this point, PCCT delivers high quantitative performance comparable between both single and dual-source modes, offering quantitative imaging across a wide range of clinical applications for the first time.

**CLINICAL RELEVANCE/APPLICATION**

Stable quantification over time in PCCT not only enables the use of quantitative imaging in diagnostic radiology but also establishes confidence that quantitative changes in longitudinal studies, such as cancer staging, are associated with disease progression and treatment.

## S1-SSPH01-4 MULTI-MATERIAL DECOMPOSITION USING FOUR ENERGY THRESHOLDS ON A COMMERCIAL DUAL-SOURCE PHOTON-COUNTING-DETECTOR (PCD) CT

Bernhard Schmidt, PhD (*Abstract Co-Author*) Employee, Siemens AG
Jeffrey Marsh JR, BS (*Abstract Co-Author*) Nothing to Disclose

Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Kevin J. Treb, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To use a dual-source PCD-CT system with 4 energy thresholds to perform multi-material decomposition of iodine, gadolinium, and water.

**METHODS AND MATERIALS**

Experiments were performed on a PCD-CT scanner (NAEOTOM Alpha, Siemens Healthineers) using a special research mode with 4-energy thresholds. Material calibration was performed by scanning multiple diameters (d) of a cylindrical water-equivalent plastic phantom containing samples of contrast material with varying tube current (mA) and distance from the isocenter (r). From these data, per-voxel contrast models were derived for each material by multiple linear regression, where the predictor variables were combinations of mA, r and d up to second order. Subsequent material decompositions can then then be performed on individual voxels of the acquired threshold images using the derived models. After calibration, a 20 cm diameter multi-energy CT phantom (Sun Nuclear) with a uniform solid water background and several quantitative inserts of iodine (2-20 mg/mL), gadolinium (1.25-10 mg/mL), and a mixture of both (5 mg/mL each) was scanned using 140 kV and the 4-energy bin mode with energy thresholds set at 20, 52, 75, and 82 keV. The CTDIvol of the exam was 5.28 mGy (32 cm phantom). Images were reconstructed with a quantitative kernel (Qr44) for each energy threshold, which together with the derived models from calibration were used to generate water, iodine, and gadolinium basis images. Quantitative accuracy of material concentrations was assessed, and image noise was measured.

**RESULTS**

Both iodine and gadolinium were decomposed into their respective material basis maps with no observable cross-talk between material bases. Pixel values in material basis images were linearly related to their nominal concentrations ($R2 > 0.99$). Iodine and gadolinium concentrations from the material basis maps were within 0.55 mg/mL of the nominal values for all material inserts, with average deviations of 0.21 mg/mL I and 0.38 mg/mL Gd. The measured noise in uniform solid water at the phantom center for the water, I, and Gd basis images was 13, 22 (0.77 mg/mL I), and 26 HU (0.79 mg/mL Gd), respectively. Noise in the PCD threshold images (20, 52, 75, 82 keV) was 8, 9, 13, and 16 HU.

**CONCLUSION**

PCD-CT with four energy thresholds enables simultaneous multiple material decomposition of iodine, gadolinium, and water into respective material basis images from the same scan, with quantitative accuracy within 0.38 mg/mL and reasonable image noise (13-26 HU).

**CLINICAL RELEVANCE/APPLICATION**

The availability of multiple (4) energy thresholds in PCD-CT opens the possibility for unique clinical applications such as k-edge imaging, simultaneous multi-contrast imaging, and potential functional and molecular imaging with nanoparticles.

## S1-SSPH01-5 OPTIMIZING IMAGE QUALITY OF ENERGY-INTEGRATING AND PHOTON-COUNTING CT SYSTEMS AT LOW DOSE FOR LOW CONTRAST LUNG NODULES

Mishal Ursan (*Presenter*) Nothing to Disclose

**PURPOSE**

To optimize lung cancer screening (LCS) protocols in ultra-low dose CT for lung nodule contrast of 150 HU and above (ground glass nodules and others) for three different phantom sizes and for three generations of CT systems.

**METHODS AND MATERIALS**

Recommendations for the German LCS program require the detection of nodules with 150 HU contrast at dose levels of at most Dref = 1.3 mGy (for patients of 26 kg/m2 BMI) with a spatial resolution of better than 1 mm. To determine adequate scan protocols, we acquired phantom data on three different CT systems, namely the Somatom Definition Flash, Somaton Force and the Naeotom Alpha (Siemens Healthineers, Germany). The first two are the traditional energy integrating technologies, while the Alpha uses photon counting detectors and has two resolution modes: standard (STD) and ultra-high resolution (UHR). A semi-anthropomorphic thorax phantom used for the experiments consists of two additional modular extension rings to simulate patient sizes of small (20×30 cm), medium (25×35 cm) and large (30×40 cm), resulting in BMIs of about 22, 26, and 30 kg/m2, respectively. Since the phantom did not have a built-in contrast of 150 HU, we created such a lesion manually and placed it into a 10 cm water-equivalent phantom which was then placed on the top of the thorax phantom. The images were generated with iterative reconstruction using kernels ensuring a spatial resolution with a full width at half maximum = 1 mm in both axial and longitudinal direction. The contrast-to-noise ratio (CNR) was used to assess the visibility of lung nodules in all images.

**RESULTS**

With noised-matched acquisitions, a CNR = 1.0 was achieved for both energy integrating (Flash and Force) and photon counting systems (Alpha) at a viewing thickness of 3.0 mm at tube voltages of 120 kV (Flash), 120 kV Sn (Force) and 100 kV Sn (Alpha). The dose / tube currents were determined for each patient size on each CT system as follows: for small, 0.5 mGy / 8 mAs (Flash), 0.3 mGy / 28 mAs (Force), 0.2 mGy / 24 mAs (Alpha STD), 0.1 mGy / 12 mAs (Alpha UHR), for medium, 1.0 mGy / 16 mAs (Flash), 0.7 mGy / 64 mAs (Force), 0.3 mGy / 35 mAs (Alpha STD), 0.3 mGy / 35 mAs (Alpha UHR), for large, 2.3 mGy / 34 mAs (Flash), 1.3 mGy/ 120 mAs (Force), 0.6 mGy / 70 mAs (Alpha STD), 0.7 mGy / 81 mAs (Alpha UHR).

**CONCLUSION**

The considered CT systems are easily capable of providing an image quality sufficient for lung cancer screening according to the German regulations. The dose limit of 1.3 mGy (for the 26 kg/m2 BMI) did not even have to be exhausted by far. When viewed with a slab thickness of 3.0 mm, the ground glass nodules were clearly visible to the reader.

**CLINICAL RELEVANCE/APPLICATION**

A wide variety of clinically deployed CT systems allows for the dose efficient visualization of challenging lung nodules in a low contrast scenario.

## S1-SSPH01-6 VOLUMETRIC LESION DETECTION ON THE PHOTON COUNTING CT SYSTEM: OPTIMIZATION OF IMAGE TYPE AND SLICE THICKNESS

Jason P. Weinman, MD (*Abstract Co-Author*) Reviewer, Parexel International Corporation;Reviewer, Perceptive Informatics, LLC;Adisory Board, Boehringer Ingelheim GmbH;Support, Boehringer Ingelheim GmbH
Donglai Huo, PhD (*Abstract Co-Author*) Nothing to Disclose

Lorna Browne, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Nolan Dang (*Abstract Co-Author*) Nothing to Disclose
Wei Zhou, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the optimal image type and slice thickness options on the photon counting CT (PCCT) for the volumetric lesion detection task in a controlled phantom study.

## METHODS AND MATERIALS

A 10 cm cylinder containing 3D low contrast (-20 HU) spherical lesion targets was inserted into an anthropomorphic 30 x 20 cm abdomen phantom (QRM, Germany). The spherical lesion diameters are 8, 6, 4, 3 mm for investigations. The phantom setting was scanned on a clinical PCCT unit (NAEOTOM Alpha, Siemens) using 120 kV, pitch 0.8, collimation 0.4 x 144 mm, and CTDI of 15 mGy. The acquisition was repeated 25 times to achieve 100 independent target sets (4 each scan) for each lesion size. T3D (full spectrum) and 70 keV virtual monoenergetic image (VMI) were reconstructed using clinical Br40 kernel, QIR level of 3 and 10 cm FOV. The slice thickness options were selected as 3 mm (clinical thick), 1 mm (clinical thin), and 0.4 mm (thinnest). For each condition, lesion detectability index (D') was calculated using a validated multi-slice channelized Hotelling observer (MS-CHO) method. D' was compared across image types and slice thickness.

## RESULTS

As expected, the D' decreases with reduced lesion size, median of 10.64 for 8 mm lesion, 3.19 for 3 mm lesion at T3D and 1 mm slice thickness. When comparing performance between image types, D' of T3D and 70keV VMI are comparable with differences of median values < ±7% at variable conditions. For 4 mm lesion size and 3 mm slice, median D' of T3D and 70keV VMI are 3.58 and 3.62, respectively. The D' increases with reduced slice thickness. At 8 mm lesion and 70keV VMI, 0.4 mm slice (median 12.32) shows a 9.8% improvement of D', compared to 1 mm slice (median 11.22). Such improvement is more prominent in smaller lesions sizes. For instance, at 3 mm lesion size and 70keV VMI, D' of 0.4 mm slice (median 4.08) is 23.2% higher than that of 1 mm slice (median 3.31). The optimal D' of each lesion size stays at the thinnest slice 0.4 mm, with either T3D or 70keV VMI.

## CONCLUSION

The detectability of volumetric lesion detection was dependent on the lesion size, slice thickness and the image type on PCCT. No obvious preference of image type (T3D or 70keV VMI) was found while it is recommended to use the thinnest slice thickness (0.4 mm) to achieve the optimal 3D lesion detection.

## CLINICAL RELEVANCE/APPLICATION

With increased dose efficiency and spectral capacity, the optimal image type and slice thickness is not yet to be determined on PCCT. We investigated the detection task of the clinical lesion mimicking targets (spheres) and provided valuable guidance for PCCT's general utilizations in body imaging.

## S1-STCE1-1 POWER GRID INDEPENDENT LOW FIELD MRI

Hans-Martin Klein, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To provide power grid independant, sustainable MR imaging using a permanent magnet, solar energy, and a generator supported battery system.

### METHODS AND MATERIALS

We installed a 0,4 T MRI system with an open design permanent magnet (Fujifilm Aperto Lucent Plus). Regenerative energy was produced using a 29,8 kWp solar array, combined with a 22 kWh LiFePO4 battery. For periods of power outage and insufficient solar energy, a specially designed, direct current (DC), high voltage diesel generator is used. This generator simulates the power profile of a solar array, and is connected to the solar power converter, feeding the battery.

### RESULTS

Annual energy uptake of the MRI was 7.022 kWh in 2023. RIS and PACS components consumed 4.959 kWh. Heating and air conditioning consumed 12.500 kWh. Total energy consumption of the practice was 26.801 kWh. Total energy production was 30.930 kWh. Energy balance was positive with 4.129 kWh. Battery and DC generator can provide power grid independent operation. Without grid and solar energy, the practice has an energy consumption rate of max. 1,9 l gasoil/hour.

### CONCLUSION

Grid independent MR imaging is possible using permanent magnet technology, solar energy production, battery storage and a specially designed power generator.

### CLINICAL RELEVANCE/APPLICATION

Power outages can represent a problem in medical imaging, particularly in regions with insufficient infrastructure. Use of regenerative energy, reduction of energy consumption, battery storage, and an emergency power generator enable power grid independent MRI and can improve access to care.

## S1-STCE1-2 0.55 T MRI IN CYSTIC FIBROSIS LUNG MANIFESTATION - A CLINICAL APPLICATION STUDY

Michael Uder, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Schnell (*Abstract Co-Author*) Nothing to Disclose
Oliver Rompel, MD (*Abstract Co-Author*) Nothing to Disclose
Armin Nagel (*Abstract Co-Author*) Research Grant, Siemens AG
Rafael Heiss (*Abstract Co-Author*) Speakers Bureau, Siemens AG

Maximilian Hinsen (*Abstract Co-Author*) Nothing to Disclose
Tobias Baeuerle, MD (*Abstract Co-Author*) Nothing to Disclose
Nadine Bayerl, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to compare 0.55 T MRI with chest X-ray (CXR) for the assessment of pulmonary manifestations in patients with cystic fibrosis (CF) attending routine annual check-ups.

### METHODS AND MATERIALS

The prospective study was approved by the local ethics committee and involved 28 CF patients (median age 12 years; age range 6-27 years; 11 females) without contraindications for MRI. CXR (posterior-anterior view) and low-field MRI at 0.55 T were performed on the same day. The MRI protocol included proton density-weighted transverse sequences and T2-weighted fat-suppressed coronal sequences with a slice thickness of 6 mm. The pulmonary findings (including mucus plugging, ground glass opacity, air trapping, bronchiectasis, consolidations and sacculations) were assessed on CXR and MRI by three raters using a semi-quantitative scoring system (modified Eichinger score). The scores were analyzed using Wilcoxon signed-rank tests. Interobserver reliability was evaluated using the intraclass correlation coefficient (ICC).

## RESULTS

Significantly more pulmonary findings were reported with low-field MRI (median score=8.2, interquartile range [IQR]=4-25) compared to CXR (median score=7.5, IQR=5-22; p=0.03), especially in patients with advanced stages of disease. Significant differences were found in the interpretation of mucus plugging (p=0.02), ground glass opacities (p=0.004) and air trapping (p=0.02). No significant differences were observed between MRI and CXR in assessing bronchiectases, consolidations and sacculations. Interobserver agreement was consistently higher for MRI ratings than for CXR (MRI, mean ICC=0.93, CXR, mean ICC=0.72). Limitations of our study were the small sample size and the single-center study design.

## CONCLUSION

The clinical use of low-field MRI for the annual check-up is a superior method of monitoring CF compared to CXR in terms of diagnostic value and radiation exposure.

## CLINICAL RELEVANCE/APPLICATION

Monitoring of pulmonary manifestations in cystic fibrosis using low-field MRI is superior to CXR.

# S1-STCE1-3 QUANTIFYING BRAIN VOLUMES AND LESION BURDEN IN RELATION TO DISEASE DURATION AND SEVERITY IN MULTIPLE SCLEROSIS WITH LOW-FIELD MRI

Serhat Okar (*Abstract Co-Author*) Nothing to Disclose
Joel M. Stein, MD, PhD (*Abstract Co-Author*) Research Grant, Hyperfine Research, Inc;Consultant, Centaur Diagnostics, Inc
Thomas C. Arnold, PhD (*Abstract Co-Author*) Nothing to Disclose

Alfredo Lucas, PhD, MS (*Abstract Co-Author*) Nothing to Disclose
Chetan Vadali (*Presenter*) Nothing to Disclose

## PURPOSE

Multiple sclerosis (MS) causes characteristic central nervous sytem white matter lesions (WML) as well as atrophy. Brain atrophy begins early in MS, may proceed independently of WML disease activity, predicts disease progression and functional impairment, and may also be a target for therapy. We investigated whether lower-cost and more accessible but lower resolution portable 64mT low-field MRI accurately estimates brain volumes and total WML burden, and their relationship with clinical characteristics, relative to 3T MRI in patients with MS.

## METHODS AND MATERIALS

We scanned 50 MS patients on portable 64mT (Hyperfine) and standard 3T scanners (Siemens) at Penn or NIH with T1-weighted, T2-weighted and FLAIR acquisitions. Two super-resolution deep-learning algorithms, SynthSR and LowGAN, were used to generate 3T-like outputs from 64mT inputs. We measured thalamic, lateral ventricle, and cortical gray matter volumes using SynthSeg and manually segmented WMLs at each field strength. We then analyzed correlations between brain volumes, total WML lesion burden, disease duration, and a clinical assessment of functional impairment (Expanded Disability Status Scale [EDSS]).

## RESULTS

Brain volume measures were all strongly correlated, with LowGAN providing the most accurate estimates overall (thalamic: Cohen's d = 0.32, pFDR=0.008; lateral ventricle: Cohen's d = 0.04, pFDR>0.05; cerebral cortex: Cohen's d = 0.031, pFDR>0.05). Low-field-derived volumes accurately depicted a negative correlation between thalamic/cerebral cortex volume and disease duration, with no difference relative to 3T for 64mT+SynthSR in the thalamus and 64mT+LowGAN in the cortex (Steiger's test, p>0.05). Low-field-derived lateral ventricle volumes showed a positive correlation with disease duration, not significantly different from 3T (Steiger's test, p>0.05). Lesion burden estimates at 3T correlated highly with 64mT (r=0.89, p<0.01) and 64mT+LowGAN (r=0.83, p<0.01). We found the same positive correlation between WML lesion burden, disease duration, and EDSS at both field strengths (Steiger's test, p>0.05).

## CONCLUSION

Our findings show strong concordance between 64mT and 3T MRI measurements, suggesting that lower resolution low-field MRI can estimate regional brain volumes and WML burden, and preserve relationships between these measures and clinical characteristics in MS.

## CLINICAL RELEVANCE/APPLICATION

Portable low-field MRI could enable earlier or more frequent imaging in MS, particularly on presentation at the point-of-care or for patients with access limitations, and identifying brain atrophy may improve disease management.

Longyu Sun (*Abstract Co-Author*) Nothing to Disclose
Qing Li (*Abstract Co-Author*) Nothing to Disclose
Chen Qin (*Abstract Co-Author*) Nothing to Disclose
Jun Lyu (*Abstract Co-Author*) Nothing to Disclose
Chengyan Wang, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To summarize effective strategies in developing and validating cutting-edge fast cardiac MRI (CMR) techniques and contribute to the translation of the latest deep learning techniques into clinical practice.

### METHODS AND MATERIALS

We organized the CMRxRecon Challenge (https://cmrxrecon.github.io) in 2023, in collaboration with the 26th International Conference on MICCAI. CMRxRecon is currently the largest cardiac MRI challenge that provides an open dataset consisting of multi-contrast, multi-view, and multi-coil raw k-space data from 300 healthy subjects, which holds crucial value for the development of deep learning algorithms. A total of 10 institutions jointly involved and organized this challenge. Data were collected from two types of 3T scanners (MAGNETOM Vida, Siemens; Ingenia CX, Philips). The released dataset included both cine and mapping raw k-space data with detailed annotations of anatomical structures, such as four chambers and left ventricular myocardium. Long and short-axis, two-chamber, three-chamber, and four-chamber views were collected for cine. T1 and T2 mapping were acquired using MOLLI and T2prep-FLASH sequences. The challenge included two independent tasks: 1) Fast cine imaging, and 2) Fast T1 T2 mapping.

### RESULTS

The challenge attracted more than 285 teams and over 600 participants. All teams used deep learning-based approaches, indicating that deep learning has become a promising solution to the problem. The winning solution achieved PSNR, SSIM, and NMSE scores of 46.873, 0.990, 0.003 for cine, and 45.481, 0.987, 0.004 for mapping reconstruction, respectively. Figure 1 summarizes the characteristics of the models from all participating teams. The top 3 performance teams in both tasks all include the SSIM in their loss functions, which aligns with the evaluation metrics of the challenge. The first-place winner of both tasks utilizes the E2E-VarNet architecture as backbones. In contrast, U-Net was still the most popular backbone for both multi-coil and single-coil reconstructions. Regarding pre-processing, the majority of participating teams opted for normalization of dividing by the maximum value, while a few utilized the z-score normalization method.

### CONCLUSION

This study provides an overview of the CMRxRecon2023 dataset and a summary of the submitted results, including backbone architecture, loss function, pre-processing techniques, physical modeling, and model complexity. Through the training and validation of this dataset using cutting-edge models, our goal is to advance the current research in the field of CMR imaging.

### CLINICAL RELEVANCE/APPLICATION

The advancements from the CMRxRecon2023 challenge will be expected to contribute to more accurate diagnoses and improved patient outcomes in cardiac imaging.

## S1-STCE2-2 INTEGRATING IMAGING DERIVED PHENOTYPES AND GENOMICS DATA TO PREDICT THE RISK OF EIGHT COMMON DISEASES

Longyu Sun (*Abstract Co-Author*) Nothing to Disclose
Qing Li (*Abstract Co-Author*) Nothing to Disclose
Xumei Hu (*Abstract Co-Author*) Nothing to Disclose
Yan Li (*Abstract Co-Author*) Nothing to Disclose
Chengyan Wang, PhD (*Abstract Co-Author*) Nothing to Disclose
Mengting Sun (*Abstract Co-Author*) Nothing to Disclose

Yajing Zhang (*Abstract Co-Author*) Nothing to Disclose
Mengyao Yu (*Abstract Co-Author*) Nothing to Disclose
Meng Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the efficacy of combining multi-organ imaging-derived phenotypes (IDPs) with genomic data to predict the risk of eight common diseases using the UK Biobank (UKBB) dataset.

**METHODS AND MATERIALS**

The UKBB, a prospective cohort study initiated between 2006 and 2010, has amassed data from nearly 500,000 participants across the UK. The cohort includes extensive phenotyping, imaging, and multiple genomic data types. Our research focused on 312 imaging phenotypes from different organs such as heart, brain, kidney, liver, lung, pancreas, and spleen in 8,000 individuals. For the genetic analysis, we calculated Polygenic Risk Scores (PRS) utilizing established genetic markers linked to the diseases under investigation. The diseases studied include atrial fibrillation (AF), heart failure (HF), myocardial infarction (MI), asthma, type 2 diabetes (T2D), chronic kidney disease (CKD), coronary artery disease (CAD), and chronic obstructive pulmonary disease (COPD). We constructed three predictive models per disease: one based solely on imaging features, one on genomic data, and a hybrid model combining both. The predictive model employed was a logistic regression with L1 norm regularization.

**RESULTS**

The fusion of IDPs and PRS in our predictive models led to a significant improvement in the predictive power for seven out of the eight diseases studied. Notably, the combined model for CAD achieved an AUC of 0.81±0.06, outperforming the models relying on imaging features alone (AUC 0.76±0.05) and genomic data alone (AUC 0.66±0.06). Similarly, the PRS+IDPs model for HF also demonstrated enhanced predictive accuracy with an AUC of 0.79±0.12, surpassing the individual contributions of PRS (AUC 0.63±0.16) and IDPs (AUC 0.68±0.15). For AF, imaging features related to the left atrium were identified as pivotal. In the case of T2D, liver-related features were found to be particularly influential. For CAD and COPD prediction, PRS made a more substantial contribution than other IDPs. A decrease in kidney parenchyma volume emerged as a potential indicator for CKD. The lung function parameter was identified as a key factor in the predictive models for both COPD and asthma, underscoring its established significance. For HF, the ejection fraction of the ventricle was the most critical feature among all the features considered. Interestingly, for MI prediction, the fat fraction of the pancreas andthe liver iron corrected T1 value were more predictive than cardiac IDPs.

**CONCLUSION**

The integration of multi-organ imaging features with genetic dataenhances the prediction predictive capabilities forcommon diseases, underscoring the value of a multi-modal diagnostic approach in medical diagnostics and personalized medicine.

**CLINICAL RELEVANCE/APPLICATION**

This study demonstrates the potential of combining imaging and genomic data to enhance disease prediction, which can be crucial for early diagnosis and personalized treatment strategies in clinical settings.

## S1-STCE2-3 UNCERTAINTY-AWARE COLLABORATIVE LEARNING BETWEEN AI AND RADIOLOGISTS FOR PREDICTING NEOADJUVANT THERAPY RESPONSE IN BREAST CANCER

Ritse M. Mann, MD, PhD (*Abstract Co-Author*) Researcher, Siemens AG;Consultant, Siemens AG;Researcher, Bayer AG;Consultant, Bayer AG;Researcher, Medtronic plc;Consultant, Medtronic plc;Researcher, Becton, Dickinson and Company;Consultant, Becton, Dickinson and Company;Researcher, ScreenPoint Medical BV

**PURPOSE**

Integrating artificial intelligence (AI) in radiology as a concurrent or second diagnostic reader holds promise. However, the optimal way to combine AI and human assessments is less clear, particularly when diagnostic outcomes are not immediately evident, as is the case in response prediction to neoadjuvant therapy (NAT). We aimed to develop a deep learning system to enhance the collaboration between AI and radiologists in the radiology decision-making workflow.

**METHODS AND MATERIALS**

This multi-modal study included 3,384 breast cancer patients who underwent NAT followed by surgery, comprising 3,719 longitudinal DCE-MRI exams, 4,802 pre-NAT mammogram (MG) exams, and clinicopathological (CP) data. We developed multi-modal models (MG-CP, MRI-CP, MG-MRI-CP) to predict pathological complete response (pCR). Ten board certified radiologists assessed pCR for test set (n=120) by analyzing scans taken throughout NAT. We introduced the Uncertainty-aware Clinical Decision System (UCDS) to enhance interactions among various combinations of humans and AI participants. UCDS assesses uncertainty scores by evaluating the performance of AI models and radiologists within specified standalone and collaborative patterns to determine the final decision.

**RESULTS**

UCDS significantly surpassed standalone baseline and traditional collaborative methods in all settings (?AUROC = 3.4-6.1%; ?sensitivity = 5.4-13.5%; ?specificity = 2-8.6%). In radiologist collaboration settings (i.e., human-human interactions using optimized threshold searching and weighted fusion), UCDS reached a statistically significant AUROC of 74.7% for predicting pCR (p = 5.2e-03). Compared to the AI-AI collaboration baseline, UCDS achieved an AUROC of 74.5% (p = 1.7e-03). Particularly, in real word collaborative scenarios between human and AI, UCDS achieved an AUROC of 84.9% (p = 6.9e-04), with a 4.9% increase in true positives and a 6.8% increase in true negatives, without increasing false predictions.

**CONCLUSION**

The UCDS model demonstrates effective in managing the integration of AI and human expertise in predicting BC treatment response, enhancing decision-making accuracy by quantifying uncertainty in collaborative settings.

## CLINICAL RELEVANCE/APPLICATION

Consensus decision-making between radiologists and AI systems is valuable but can be resource-intensive in clinical environments facing workforce shortages, potentially leading to errors when outcomes are not immediately evident. The UCDS model efficiently considers the uncertainty of opinions between predictive AI models and radiologists, offering a potential tool in streamlining decision-making processes and improving accuracy in collaborative clinical practices.

### PURPOSE

Performance in (human) double reading breast screening varies with client ethnicity; the variance relates to characteristics like inherent cancer prevalence and breast density. To guarantee fairness, AI systems should not introduce systematic deviations from this human screening pattern.

### METHODS AND MATERIALS

A commercially available breast screening AI system was evaluated in a large retrospective clinical study covering a genetically diverse population, screened between 2017 and 2021. Ethnicity information was available at one of the participating sites where 189,257 cases were included. . Standard double reading (DR) with and without AI was assessed for relevant screening metrics per ethnic subgroup: White, Black, Asian, Mixed/other, Unknown. The spectrum of cancers detected by DR with and without AI were compared using the chi-square test at a significance level of 0.05. DR with AI involved modelling the use of AI to serve as the second reader when AI and the first reader opinions agree 'recall' or 'no recall', otherwise, the historical second reader opinion was used.

### RESULTS

The ethnicity data consisted of 49.0% White, 10.2% Black, 17.7% Asian, 6.5% mixed/other, 13.9% unknown and 2.8% missing ethnicity. DR showed a recall rate (RR) of 5.0%, 4.3%, 4.4%, 5.5% and 4.5% for White, Black, Asian, mixed/other and unknown ethnicities, respectively. DR with AI closely followed the same pattern with recall rates of 4.6%, 3.9%, 4.1%, 4.9% and 4.1%, yielding absolute differences compared to DR of -0.4%, -0.4%, -0.3%, -0.6%, and -0.4%. The PPV of DR was 19.6%, 17.5%, 18.2%, 15.9%, 13.9% for White, Black, Asian, mixed and unknown ethnicity, respectively. DR with AI showed a similar trend for PPV, but yielded improvements with absolute increases of 1.5%, 1.7%, 1.4%, 1.4%, and 1.1%, respectively. The chi-square tests to compare invasiveness and tumour size, grade and lymph node status for invasive cancers detected by DR with or without AI were statistically not significant, for all ethnicities with p-values >0.05 (ranging from 0.72-1).

### CONCLUSION

The AI system demonstrated generalisability across different ethnic groups, with the potential to to support improvements in RR and PPV. Screening metrics for DR with AI showed statistically similar trends between ethnicities to DR, with no systematic decreases in performance for any ethnic subgroup, indicating the safety of using AI across ethnicities.

### CLINICAL RELEVANCE/APPLICATION

Biases in the development of AI can lead to risks around generalisability and ethnic inequalities. The study results demonstrate that double reading with an AI system closely followed human reading patterns for different ethnicities. supporting ethnic fairness and safety in breast screening.

## S2-SSBR01-2 EFFECT OF FULL-FIELD DIGITAL MAMMOGRAPHY SOFTWARE VERSION AND VENDOR ON THE PERFORMANCE OF COMMERCIAL DEEP-LEARNING ALGORITHMS FOR BREAST CANCER DETECTION

**PURPOSE**

Investigating how the performance of deep-learning (DL) algorithms for detection of breast cancer on Full-Field Digital Mammography (FFDM) is affected by software version of the FFDM machine.

**METHODS AND MATERIALS**

210,515 screening FFDM examinations were retrospectively collected from two sites with cancers confirmed by histopathology. Examinations were scored by two commercial DL algorithms (DL-1, DL-2). DICOM headers were used to find 11 FFDM software versions from 3 vendors. Examinations were excluded if they were not scored by both algorithms (50,115) and, subsequently, if a software version subset had lt20 cancers (880). 159,521 exams were analysed, covering 3 versions of GE (GE-A, GE-B, and GE-C) software and 2 from Philips (Ph-A and Ph-B). Each subset was used to define a threshold for DL-1 and DL-2 at 89.8% specificity. Performance at each threshold was then tested across all 5 subsets.

**RESULTS**

Area under the curve (AUC) for DL-1 were 0.90 (GE-A), 0.89 (GE-B), 0.88 (GE-C), 0.86 (Ph-A), and 0.88 (Ph-B). DL-2 AUC were 0.87 (GE-A), 0.87 (GE-B), 0.87 (GE-C), 0.82 (Ph-A), and 0.81 (Ph-B). The intra-vendor recall rate (RR), with thresholds and test subsets from the same vendor, varied between 10.5-11.4% for DL-1 on GE, 10.7-11.2% for DL-1 on Philips, 10.4-11.5% for DL-2 on GE, and 10.7-11.1% for DL-2 on Philips. Variations were statistically significant (plt0.05) for RRs of DL-1 and DL-2 between GE-A and GE-B software versions. The inter-vendor RR varied between 7.9-15.5% and 4.6-23.7% for DL-1 and DL-2 respectively, with significant differences in every combination of threshold and test set. Intra-vendor sensitivity didn't differ significantly for DL-1 or DL-2 on either vendor. Inter-vendor sensitivity varied between 67.9-78.7% for DL-1, which was significant for thresholds set on GE-A and GE-B when applied to Ph-A, and for the threshold set by Ph-A when applied to GE-B. For DL-2, inter-vendor sensitivity varied between 48.9-80.6%, which was statistically significant for all combinations bar a threshold set on GE-C used on Ph-A.

**CONCLUSION**

Performance variations were seen for intra-vendor software versions, however only significantly for the RR between two GE versions. Inter-vendor performance varied more, affecting all RRs as well as 3/12 sensitivity measures of DL-1 and 11/12 from DL-2. Awareness is needed when algorithms thresholds set on one vendor are applied to FFDM acquired on another. This is less the case for software versions from the same vendor, however variations due to major updates or iterative changes should be anticipated.

**CLINICAL RELEVANCE/APPLICATION**

DL algorithm performance depends upon the vendor and software version of the FFDM used to select a threshold. When FFDM software is updated the DL thresholds may need to be reset.

## S2-SSBR01-3 COMBINING TWO OR THREE AI CAD SYSTEMS TO REPLACE RADIOLOGIST DOUBLE-READ AND CONSENSUS DISCUSSION IN BREAST CANCER SCREENING - A RETROSPECTIVE EVALUATION

Hakan Gustafsson, PhD (*Abstract Co-Author*) Nothing to Disclose
Fernando Cossio Ramirez, BSc (*Abstract Co-Author*) Nothing to Disclose
Haiko Schurz, BSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Davida Astrom (*Abstract Co-Author*) Nothing to Disclose

Fredrik Strand, MD, PhD (*Presenter*) Speaker, Lunit Inc

**PURPOSE**

Prospective trials have shown that Artificial Intelligence Computer-Aided Detection systems (AI CAD) may improve the accuracy of breast cancer screening. Trials were implemented with AI CAD replacing one (or none) of the two initial reads followed by a radiologist consensus discussion to decide on recalls. In this study, we examined the results of having one, two or three AI CADs directly recalling.

**METHODS AND MATERIALS**

From the Swedish VAI-B cohort, we extracted screening mammograms from Philips equipment January 2015 to April 2019. A three-year follow-up time defined the ground truth of cancer diagnosis or healthy. If any individual had more than one screening exam, we randomly included one. Healthy observations were up-sampled to attain a realistic 1.1% proportion of cancer. For each AI CAD, we created a ranking list based on exam scores. The AI CAD strategies made the same number of recalls as the original radiologists. For strategies involving an initial flagging step, the AI CADs were set to flag twice the number of recalled individuals. We evaluated three different commercial AI-CAD systems.

**RESULTS**

There were 1214 exams linked to breast cancer diagnosis and 175020 exams (up-sampled from 5834 individuals) linked to healthy status. The original radiologists had recalled 4130 women resulting in screen-detecting 545 cancers. Single-AI CAD strategies recalling women directly based on the score from a single AI CAD resulted in detection ratios (relative to the historic) from 0.97 to 1.08 across the three AI CAD systems. Double-AI CAD strategies resulted in detection ratio of 1.09 to 1.14. Triple-AI CAD strategies resulted in detection ratios of 1.08 to 1.15. For the best AI CADs, the detection ratio only marginally increased when combined with the worst AI CAD in a double-AI CAD strategy. When combining the two best in a double-AI CAD strategy, it was better to use the sum of their assessments to recall rather than using one AI to flag and the other to recall.

**CONCLUSION**

Combining two or three AI CADs ensured that cancer detection was improved compared to the historic records based on double-read and consensus discussion. The largest improvement was the result of combining two similarly performing AI CAD systems. Even though cancer detection overall is likely to increase, around 20% of currently screen-detected cancers would be missed, for which the cause must be further analyzed.

**CLINICAL RELEVANCE/APPLICATION**

Based on a retrospective evaluation it appears that there is a potential for AI CAD to completely replace the read and recall performed by radiologists. The safest implementation would be at least two AI CADs together.

### PURPOSE

Mammography is recognized as the only screening tool that has enabled early diagnosis and subsequent reduction of breast-cancer related mortality.Main limitations include the large amount of mammography yearly produced, shortage of trained radiologist to interpret them and consequent high proportion of false-negative and false-positive results. A tangible solution to these limits may be represented by artificial intelligence (AI).Nevertheless, it is still not known if and in what terms, the use of AI is going to be accepted by the non- scientific community. The aim of our survey was to assess what is the knowledge and perception about AI of the population eligible for breast cancer screening.

### METHODS AND MATERIALS

We conducted a prospective survey consisting of a 11-multiple-choice questionnaire evaluating statistical associations with Chi-Square-test or Fisher-exact-test. Multinomial-logistic-regression was performed on items with more than two response categories. Odds ratio (OR) with 95% CI were computed to estimate the probability of a specific response according to patient's characteristics.

### RESULTS

Of the 800 questionaries that have been analyzed, half of the respondents (51%) declared to have knowledge about AI and of these, 88% expressed a positive opinion about its involvement in medicine.In the non-Italian population, there was a deep awareness about AI more often than Italian respondents (OR = 1.91;95% CI[1.10-3.33]).A better opinion on the use of AI in medicine has been shown by the population with an higher level of education (OR = 4.69;95% CI[1.36-16.12]).Most of the respondents (94%) assessed that the radiologists should always produce their own report on mammograms, whilst 77% agreed that AI should be used as a second reader.52% of the respondents, believed that both the software developer and the radiologist should be held accountable for AI errors.

### CONCLUSION

Our survey has shown that most of the females undergoing screening in our Institute approve the introduction of AI, however only as a support to radiologist’s work and not in place of them. Remains unsolved the accountability in case of AI errors.

### CLINICAL RELEVANCE/APPLICATION

Understanding patient’s demands and concerns about AI, might be a starting point to edit a strategy aimed at improving their knowledge and acceptance of AI application in the breast cancer screening field.

## S2-SSBR01-5 PUTTING IT IN PERSPECTIVE: AI TRIAGE STREAMLINING SCREENING MAMMOGRAM TURNAROUND TIME (TAT) AMID STAFF SHORTAGES

Hakki Celik, MD (*Abstract Co-Author*) Nothing to Disclose
Mohammed Salman Shazeeb, PhD (*Abstract Co-Author*) Nothing to Disclose
Srinivasan Vedantham, PhD (*Abstract Co-Author*) Research collaboration, Koning Corporation Research collaboration, General Electric Company
Gopal R. Vijayaraghavan, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the potential of AI software for prioritizing interpretation to reduce turnaround time (TAT) in breast cancer detection and diagnosis.

### METHODS AND MATERIALS

During a 1-year period (March 2023-Feb 2024), AI scores (Transpara AI, ScreenPoint Medical, The Netherlands) from 47,490 breast cancer screening exams (80% breast tomosynthesis; 20% digital mammography) were prospectively obtained. Blinded to AI results, the exams were interpreted by eight fellowship-trained, board-certified breast imaging radiologists with 2-30 years of experience. Exact Clopper-Pearson 95% confidence intervals (CI) for binomial proportions were obtained.

### RESULTS

AI exam scores ranged from 1-10, with 10 indicating the highest probability of malignancy (elevated risk), scores of 8-9 (intermediate risk) and scores below 7 (low risk). Of the 195 cancers diagnosed, the majority of cancers had a score of 10 (164/195; 84%; CI: 78.6-89.3%) and there were no cancers diagnosed for AI scores of 5 or below. Of 47,490 screens, 27,116 (57%; CI: 56.5%-57.5%) were assigned 7 or higher, indicating that these screens can be prioritized for interpretation to reduce TAT. 1004/7303 (13.8%; CI: 13%-14.6%) cases assigned an AI score of 10 were assigned a BIRADS-0 and called back by radiologist, which indicates the propensity of the AI software to provide higher scores than needed.

### CONCLUSION

Utilizing an AI score of 7 or higher can be beneficial in prioritizing the reading list in at least 57% of screening exams, with the concomitant decrease in TAT from screening to diagnostic workup. However, caution is expressed in using the AI score during interpretation due to its propensity for higher scores than warranted.

### CLINICAL RELEVANCE/APPLICATION

With ongoing shortage of breast imaging radiologists and continually increasing screening volume, AI score, notwithstanding some limitations, can be used for prioritized interpretation list to reduce TAT. For clinical interpretation, using AI provided annotation in addition to the AI score is preferable, to help in clinical decision support.

## S2-SSBR01-6 REAL WORLD EFFECT OF ARTIFICIAL INTELLIGENCE ON HISTOPATHOLOGY AND STAGE IN BREAST CANCER SCREENING WITH DIGITAL BREAST TOMOSYNTHESIS

Jeffrey W. Hoffmeister, MD, MS (*Abstract Co-Author*) Employee, iCAD, Inc
Julie Shisler (*Abstract Co-Author*) Consultant, iCAD, Inc

Shakira Sarquis-Kolber (*Abstract Co-Author*) Nothing to Disclose
Kathy J. Schilling Colletta, MD (*Presenter*) Consultant, General Electric Company;Investigator, General Electric Company

## PURPOSE

To assess impact of an Artificial Intelligence (AI) on radiologists' detection of cancer on digital breast tomosynthesis exams (DBT) based on size, stage, density and histopathology.

## METHODS AND MATERIALS

A retrospective analysis of mammography audit data and screening cancers detected was conducted at four sites during two time periods with nine dedicated breast radiologists. Data was collected from March 1, 2018 to February 29, 2020 prior to install of AI ("pre-AI") and March 1, 2020 to February 28, 2022 with concurrent use of deep learning AI detection (ProFound Detection, iCAD, Nashua, NH) ("post-AI"). Age, breast density, tumor size, staging and histopathology were collected for all screen detected cancers. Endpoints were cancer detection rate (CDR), tumor size, stage and histopathology. Estimates of performance and differences obtained using Chi square test and two-sample independent t-test.

## RESULTS

The pre-AI period had 54,440 exams (339 true positives) and post-AI had 48,742 exams (369 true positives). CDR per 1000 improved from 6.23 (95% CI: 5.60, 6.92) to 7.57 (95% CI: 6.84, 8.38), increase of 1.34 (95% CI: 0.33, 2.36, P < .01). Of the women diagnosed with breast cancer, there were no statistical differences in mean age 67.6 pre-AI and 68.7 post-AI, P = .22, while radiologists detected more cancers in dense breasts post-AI (45.0%, 95% CI: 40.0%, 50.1%) than pre-AI (37.2%, 95% CI: 32.2%, 42.4%), increase of 7.8% (95% CI: 0.6%,15.0%, P = .04). Mean size of invasive cancers in mm, pre-AI was 12.16 (1.0 to 85.0) and decreased to 10.74 (1.5 to 60.0) post-AI, 1.42 mm smaller (95% CI: 0.11, 2.83, P <.05). More invasive cancers were T1 post-AI (92.2%, 95% CI: 88.5%, 94.9%) than pre-AI (85.3%, 95% CI: 80.3%, 89.1%), increase of 7.0% (95% CI: 1.6%, 12.4%, P = .01), without any change in detection of DCIS post-AI (23.0%, 95% CI: 19.0%, 27.6%) vs pre-AI (25.7%, 95% CI: 21.3%, 30.6%), P = .42. Invasive cancer detection per 1000 screened increased from 4.63 (95% CI: 4.09, 5.24) pre-AI to 5.83 (95% CI: 5.19, 6.54) post-AI, difference of 1.20 (95% CI: 0.31, 2.08, P < .01). In the subset of lobular cancers, the detection per 1000 screened increased post-AI from 0.44 (95% CI: 0.29, 0.66) to 0.98 (95% CI: 0.74, 1.31), a difference of 0.54 (95% CI: 0.21, 0.87, P < .001).

## CONCLUSION

Interpretation of screening DBT exams by dedicated breast radiologists with concurrent use of AI resulted in an increase in CDR, invasive and lobular detection rates, an increase in cancers detected in dense breasts and a decrease in mean invasive size and stage. AI was able to detect more invasive cancers without an increase in non-invasive cancers.

## CLINICAL RELEVANCE/APPLICATION

Detection with an AI tool in screening may be useful in identifying difficult to detect lesions without overdiagnosis by overestimating DCIS.

### PURPOSE

Coronary CTA (CCTA) is a first-line modality for the evaluation of coronary artery disease. Wide-detector scanners allow for a full-cardiac cycle acquisition in a single heartbeat, enabling assessment of wall motion abnormalities during CCTA. Regional wall motion abnormalities can be an indication of hemodynamically significant disease, but reliable visual evaluation can be challenging. We therefore investigated the feasibility of using a novel deep learning algorithm to measure myocardial strain on CCTA, providing quantitative metrics to support clinical interpretation.

### METHODS AND MATERIALS

We retrospectively collected 167 CCTA exams performed between Jan 2017 and Jan 2024 in patients who also had invasive coronary catheterization within 30 days. A single mid-ventricular short axis slice was generated from each exam and processed using a deep learning strain algorithm developed in-house. Four subspecialty-trained, board-certified cardiothoracic radiologists rated wall motion in each of six cardiac segments in two phases: first without algorithm results, and subsequently using quantitative maps produced by the algorithm. A subset of 12 exams were read by all four readers. Analyses included Spearman's rho (?), Cohen's kappa (?), and intraclass correlation using a single-rater, 2-way random effects model (ICC).

### RESULTS

Of the 668 coronary arteries, there were 27 with occlusion, 156 with severe stenosis, and 80 with moderate stenosis by invasive catheterization. Peak radial strain showed moderate correlation with independent expert reader assessment of regional wall motion (?=-0.40; ICC 0.44; p<0.001). Intraclass correlation for segments graded by all readers was 0.57 (p<0.001). When provided algorithm results, readers with greater subspecialty experience were more likely to change their interpretation: ?=0.69 (16 years), ?=0.72 (10 years), ?=0.82 (6 years), and ?=0.93 (4 years). Readers upgraded wall motion scores on 46/1002 (4.59%) segments and downgraded scores on 32/1002 (3.19%) segments, increasing overall alignment with the algorithm in their second review (?=-0.52; ICC=0.51; p<0.001).

### CONCLUSION

The deep learning algorithm demonstrated moderate agreement with independent expert visual assessment of segmental wall motion. Readers also demonstrated moderate agreement with each other. When provided algorithm results, readers with more subspecialty experience were more likely to change their interpretation to align with the algorithm.

### CLINICAL RELEVANCE/APPLICATION

We demonstrated the feasibility of applying a deep learning algorithm to quantify regional myocardial function using full cardiac cycle CCTA. Novel algorithms such as these have the potential to assess the functional significance of coronary lesions.

## S2-SSCA01-2 MULTISITE STUDY DEMONSTRATING PERFORMANCE OF A NOVEL, AUTOMATIC, DEEP LEARNING-BASED MODEL FOR DETECTION OF FOUR HIGH RISK PLAQUE PROGNOSTIC FEATURES ON CORONARY CTA

Dijia Wu, PhD (*Abstract Co-Author*) Nothing to Disclose

Jacob M. Agris, MD, PhD (*Presenter*) Officer, ConvaTec Group

**PURPOSE**

CCTA has revolutionized the ability to visualize biomarkers indicative of high risk plaque but radiologist and cardiologists often fail to identify these biomarkers due to the complexity in interpretation, artifacts and variable imaging techniques. A deep-learning based coronary plaque analysis algorithm to automatically identify the four image features of high risk plaque including positive remodeling (PR), low attenuation plaque (LAP), spotty calcification (SC), and napkin ring sign (NRS) was developed.

**METHODS AND MATERIALS**

Our training dataset comprised 10,208 plaques from 1,919 patients, including 2,048 with positive remodeling, 3,137 with low attenuation plaque, 729 with napkin ring sign, and 325 with spotty calcification. A classification model was developed utilizing a convolutional neural network (CNN) based on plaque regions manually annotated along the coronary centerlines, to automatically recognize the four image features associated with high risk plaques. This model consists of two stages. The first stage extracts image features through a series of operations, namely a convolutional layer, followed by a rectified linear unit (ReLU) activation function, and a down-sampling process that is iteratively repeated four times. The resulting feature maps are passed through the second stage, which consists of fully connected layers culminating in a sigmoid function to predict the probability of each high-risk plaque feature. Performance was evaluated with CCTAs from 15 sites that were not used for training which included 2,442 plaques from 482 patients (mean 62 years old), including 521 plaques with positive remodeling, 743 with low attenuation plaques, 164 with napkin ring sign, and 78 with spotty calcification.

**RESULTS**

Truthing for the multisite trial was performed by 4 radiologists, over-read by 2 radiologists, and disagreements adjudicated by a radiologists with 20+ years experience. The DL model achieved an area under the curve (AUC) of 0.89 for PR, 0.85 for LAP, 0.87 for SC and 0.92 for NRS. The sensitivity of the model to predict PR, LAP, SC, and NRS was 81%, 83%, 70%, and 71%, respectively. The specificity for these four vulnerable plaque characteristics was 81%, 72%, 87%, and 94%, respectively.

**CONCLUSION**

AI can automatically identify the four features of high risk plaques on CCTA images with high accuracy and repeatability. Readers have a kappa of 0.2 to 0.4 for these features. Our model aids readers in consistently identifying these high risk plaque features which are highly correlated with a coronary or MACE event within 1 year.

**CLINICAL RELEVANCE/APPLICATION**

AI coronary plaque analysis can aid readers in the detection of high-risk plaques on CCTA images, thereby facilitating treatment to reduce the risk of coronary and MACE events.

## S2-SSCA01-3 FAST AND ROBUST CARDIAC MRI OF MYOCARDIAL EDEMA USING A DEEP LEARNING SUPER-RESOLUTION RECONSTRUCTION OF SINGLE-SHOT T2 STIR BLACK-BLOOD TECHNIQUE

Julian A. Luetkens, MD (*Abstract Co-Author*) Speakers Bureau, Koninklijke Philips NV;Research Consultant, Bayer AG

Alexander Isaak, MD (*Abstract Co-Author*) Nothing to Disclose
Taraneh Aziz-Safaie, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To clinically evaluate a deep-learning (DL) reconstructed single-shot T2-weighted short tau inversion recovery (STIR) sequence to assess myocardial edema.

**METHODS AND MATERIALS**

Besides standard T2-STIR black-blood turbo spin echo breath-hold (standard T2-STIR) images, a retrospective electrocardiogram-gated single-shot (SSH) black-blood T2-STIR sequence was developed and acquired with breath-hold (BH) and free-breathing (FB) in short-axis view on a 1.5T MRI system. Single-shot images were reconstructed using a DL super-resolution algorithm provided by Philips Healthcare that combines and integrates compressed sensing with two distinct convolutional neural networks: Adaptive-CS-Net and Precise-Image-Net. Diagnostic quality (endocardial edge definition and blood-pool to myocardium contrast) and artifact burden were evaluated using a Likert scale (from 1= non-diagnostic to 5 = excellent). Apparent signal-to-noise ratio (aSNR) and contrast-to-noise ratio (aCNR) were calculated. T2 signal intensity ratio (T2 SI ratio) of myocardial and skeletal muscle was assessed. Student’s t-test and Wilcoxon signed-rank test were used.

**RESULTS**

In total, 42 patients (mean age, 52 years ± 19; 27 men) were included. The acquisition duration of BH SSH-T2-STIR was 60,4% lower while that of FB SSH-T2-STIR was 52,5% lower compared to standard T2-STIR (mean duration 30 sec ± 7 vs. vs. 75 sec ± 17, p<.0001; 35 sec ± 4 vs. 75 sec ± 17, p<.0001). Edge definition was superior in FB-SSH-T2-STIR and BH-SSH-T2-STIR compared to standard T2-STIR (4.9± 0.4 vs. 4.8 ± 0.5 vs. 4.5 ± 0.7, p<.0001). BH-SSH-T2-STIR had significantly lower artifact burden compared to FB-SSH-T2-STIR and standard T2-STIR (4.6 ± 0.7 vs. 4.3 ± 0.8 vs. 4.1 ± 0.9, p<.0001). No significant difference were found for aSNR (10.6 ± 4.1 vs. 10.4 ± 2.5; p=.78, 9.3 ± 4.5 vs. 10.4 ± 2.5; p=.10), aCNR (5.0 ± 2.3 vs. 4.5 ± 1.95; p=0.44, 4.1 ± 2.5 vs. 4.5 ± 1.9; p=.34), and T2 SI ratio (1.9 ± 0.4 vs. 1.9 ± 0.4; p=.15; 1.9 ± 0.5 vs. 1.9 ± 0.4; p=.51) between BH-SSH-T2-STIR, FB-SSH-T2-STIR and standard T2-STIR. Visual assessment of presence of focal myocardial or pericardial edema (n = 6/42, 14%) by two readers showed complete agreement between all three sequences.

**CONCLUSION**

DL reconstructed single-shot T2-STIR sequence enabled accelerated acquisition times and non-inferior diagnostic quality.

### CLINICAL RELEVANCE/APPLICATION

DL reconstruction of single-shot T2 STIR sequences might enable fast and robust assessment of myocardial edema, especially in challenging investigation of patients with arrhythmia and shortage of breath. Faster imaging techniques using DL may improve patient comfort and compliance and could be a possible concept for overcoming increasing cardiac MRI investigations in the future.

## S2-SSCA01-4 DEEP LEARNING IN CORONARY ARTERY ORIGIN ANOMALIES: CLASSIFICATION AND CLINICAL IMPLICATIONS

Yonggao Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Jun Li (*Abstract Co-Author*) Nothing to Disclose
Lichen Ren, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Few studies have been conducted to automatically detect coronary origin anomalies through coronary CT angiography scans, because accurately determining the origin and identifying the alignment of an anomalous coronary artery is time-consuming and labor-intensive. The aim of this study is to develop and validate a deep learning model for the automatic identification of coronary artery anomalous origins in CT angiography, as well as to achieve accurate tracking of the vessels' paths.

### METHODS AND MATERIALS

In this study, we employed deep learning techniques, combining convolutional neural networks (CNNs) and recurrent neural networks (RNNs), to achieve automatic identification and vessel tracking of ectopic origins of coronary arteries. Coronary CT angiography images, collected from our hospital between January 2011 and June 2023, were used. These images were divided into a training set and a test set at a ratio of 7:3, and the data were preprocessed and labeled. Subsequently, the model was trained. The image quality of the deep learning (DL) reconstruction was evaluated by two experienced radiologists to determine if it met the needs of clinical diagnosis.

### RESULTS

A total of 656 patients (mean age ± SD, 57.1 ± 14.0 years; 391 men) were included in this study. On a per-vessel basis, the accuracy of the DL-assisted algorithm for identifying ectopic origins of coronary arteries was 96.0% (630 of 656 cases). This reduced the time required by the radiologist to reconstruct the images from 15.2 minutes ± 3.70 to 3.1 minutes ± 0.21 ($P<0.001$). There was good agreement between the two experienced radiologists in their assessment of the images (k coefficient = 0.96), and the quality of the DL-reconstructed images met the diagnostic requirements.

### CONCLUSION

Using deep learning techniques, we have implemented a CT angiography tracking method that can automatically identify and track ectopic origins of coronary arteries. This method can provide better diagnostic and therapeutic decision support for physicians.

### CLINICAL RELEVANCE/APPLICATION

Deep learning-based neural networks can significantly improve the efficiency of reconstructing images of coronary origin anomalies, saving time and cost and improving the efficiency of clinical work.

## S2-SSCA01-5 HIGH RESOLUTION CORONARY CT ANGIOGRAPHY USING ENERGY-INTEGRATING DETECTOR (EID) AND ARTIFICIAL INTELLIGENCE, INFORMED BY ULTRA-HIGH-RESOLUTION PHOTON COUNTING DETECTOR (PCD) CT

Prabhakar Rajiah, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Andrew Missert, PhD (*Abstract Co-Author*) Nothing to Disclose
Jamison Thorne, BSc (*Abstract Co-Author*) Nothing to Disclose
Shaojie Chang, PhD (*Abstract Co-Author*) Nothing to Disclose

Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Hao Gong, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Safa Hoodeshenas, MD (*Abstract Co-Author*) Nothing to Disclose
Emily Koons (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the performance of a convolutional neural network with Improved LUMEN visualization through Artificial super-resoluTion imagEs (ILUMENATE), informed by PCD-CT to improve EID-CT image resolution and its impact on coronary CT angiography (cCTA).

### METHODS AND MATERIALS

After IRB approval and written informed consent, 30 patients undergoing clinically indicated cCTA were scanned with EID-CT (SOMATOM Force, Siemens) and subsequently with ultra-high-resolution (UHR, 120x0.2 mm) PCD-CT (NAEOTOM Alpha, Siemens) on the same day. EID-CT images were reconstructed with medium sharp (Qr40) kernel and 0.6 mm thickness. PCD-CT images were reconstructed with 0.2 mm thickness, Qr40 kernel and a sharp Qr72 kernel. ILUMENATE uses a modified U-Net architecture, with 2 max pooling and 2 up-convolutional layers, rectified linear unit (ReLU) activation function, and mean-squared-error as the loss function. The low-resolution (Qr40) and high-resolution (Qr72) PCD-CT images of 8 patients were used as training input and label, respectively. To combat the noise texture difference between EID- and PCD-CT, noise patches from a uniform water phantom scanned on EID-CT were inserted into the input PCD-CT images, enabling the network to account for noise texture differences during the training. The trained ILUMENATE was applied to 22 unseen EID-CT cases. Spatial resolution was evaluated using line profiles. Percent diameter stenosis was measured using commercial software (syngo.via). Two cardiovascular radiologists, blinded to image type, scored images for overall quality, sharpness (1=worst, 5=best), and noise (1=worst, 4=best). All assessments were compared between the original EID-CT and ILUMENATE output.

### RESULTS

Visual assessment and line profiles showed substantial resolution improvement with ILUMENATE. Of the 22 test patients, 37 stenotic lesions were identified. Percent diameter stenosis was significantly reduced by an average of 5.32% with ILUMENATE ($p<0.001$). Readers preferred ILUMENATE output image in 22/22 cases. The average score for reader 1 was image quality 3.54/3.95, sharpness 2.91/3.95, and noise 3.05/3.91, and for reader 2 image quality 3.86/4.73, sharpness 3.14/4.91, and noise 3.36/4 for EID input/ILUMENATE output, respectively.

### CONCLUSION

ILUMENATE enhanced image resolution (sharpness) and reduced image noise, resulting in improved overall image quality and reduced calcium blooming artifacts in cCTA exams performed using EID-CT.

### CLINICAL RELEVANCE/APPLICATION

The reduced blooming artifact and improved lumen visibility with ILUMENATE could allow UHR cardiac CT to be performed using conventional EID-CT scanners and allow for more accurate assessment of stenotic lesions in patients with coronary artery disease.

## S2-SSCA01-6 ARTIFICIAL INTELLIGENCE-ENABLED INTRALUMINAL ATTENUATION GRADIENT MEASUREMENTSIN CORONARY CT ANGIOGRAPHY FOR DIAGNOSINGIN-STENT RESTENOSIS: A RETROSPECTIVE STUDY

Yanhui Hao (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the use of intraluminal attenuation gradient (TAG) measurements in coronary CT angiology (CCTA) obtained with an AI post-processing technique in the diagnosis of In-Stent Restenosis (ISR).

### METHODS AND MATERIALS

This retrospective study included a total of 23 coronary vessels with stents in 20 patients who underwent CCTA. There were 9 vessels with ISR, while 14 vessels without based on the digital subtraction angiography results. TAG in CCTA was defined by the linear regression coefficient between intraluminal radiological attenuations and vessel length from the ostium to the proximal end of the coronary stent (TAGproximal) or the distal end of the coronary stent to the end of the vessel (TAGdistal). TAGproximal and TAGdistal values of each vessel were obtained using a commercially available AI-post-processing auxiliary diagnosis system. TAGdifference is the difference between TAGproximal and TAGdistal.

### RESULTS

Coronary arteries with ISR showed lower TAGproximal (-11.17±5.43 vs. -4.59±2.57, P=0.006), lower TAGdistal (-4.56±2.89 vs. -2.88±1.58, P=0.138) and higher TAGdifference (6.61±6.17 vs. 1.71±3.16, P=0.020) compared with arteries without. Receiver operating characteristic curve analysis showed that TAGproximal achieved AUC of 0.897 (95% confidence interval: 0.698 to 0.984) with sensitivity of 88.89% and specificity of 85.71% ($p<0.05$), TAGdifference achieved AUC of 0.770 (95% confidence interval: 0.549 to 0.918) with sensitivity of 77.78% and specificity of 78.57% ($p<0.05$) in distinguishing ISR. However, the use of TAGdistal yielded a low AUC value of 0.698 (95% confidence interval: 0.474 to 0.870) with $p>0.05$, indicating no statistically significant difference from the null hypothesis of 0.5.

### CONCLUSION

TAG measurements in CCTA obtained using an AI post-processing technology could be used to noninvasively distinguish ISR with certain accuracy.

### CLINICAL RELEVANCE/APPLICATION

AI-enabled TAG measurements may be used to assist radiologists to differentiate ISR with moderate diagnostic accuracy, improving diagnostic workflow.

### S2-SSGI01-1 AI-BASED ASSESSMENT OF T STAGE OF RECTAL CANCER USING MRI

Ke Zhao (*Abstract Co-Author*) Nothing to Disclose
Tong Tong, PHD (*Abstract Co-Author*) Nothing to Disclose
Huifen Ye, MMEd (*Presenter*) Nothing to Disclose

**PURPOSE**

The purpose of this study was to automatically evaluate the extent of tumor infiltration by artificial intelligence (AI) based on T2-weighted imaging (T2WI) and compare the agreement among AI-mrT, manual T stage (mrT), and pathological T stage (pT).

**METHODS AND MATERIALS**

A total of 938 patients were enrolled in this retrospective study, divided into a training cohort (792 patients from five centers) and a validation cohort (84 patients from one center). In addition, 62 patients from three other centers were used as a independent validation cohort to evaluate the performance of the model. Initially, an automatic segmentation model based on T2WI was constructed using a ResNet-based nnUNet model to segment the areas of tumor, rectum, and mesorectum in the training cohort. The performance of the model was evaluated using the dice similarity coefficient (DSC) in the independent validation cohort. If the tumor area breaks through the rectum area, AI-mrT score was 1, and otherwise it was scored as 0. Inter-reader weighted agreement among AI-mrT, mrT and pT were assessed by the weighted ? statistic. Survival analysis was performed using the Cox proportional hazard model, and the endpoint of the event was the overall survival.

**RESULTS**

In the independent validation cohort, the DSC for rectal tumor, rectum and mesorectum reached an astonishing 0.865, 0.922 and 0.954, respectively. There was moderate agreement between AI-mrT and pT (weighted ? = 0.548). 11 patients were understaged for the T component of the tumor-node-metastasis classification and 8 patients were overstaged. The ? was 0.571 between AI-mrT and mrT. 66 patients were identified correctly, and 8 patients were understaged and 10 patients were overstaged. Kaplan-Meier curves show that score 1 had the more unfavorable overall survival in the validation cohort (Log-rank test, P = 0.047).

**CONCLUSION**

This study highlighted the powerful utility of AI-based automatic segmentation model for evaluating the extent of tumor infiltration of rectal cancer on T2WI. The tumor invasion calculated by AI was moderately consistent with pathological stage and correlated with unfavorable survival.

**CLINICAL RELEVANCE/APPLICATION**

The prognosis and optimal treatment of rectal cancer are directly related to accurate pretreatment stage. With the assistance of AI, inter-observer differences between radiologists with different experience and between different institutions could be bridged.

### S2-SSGI01-2 THE PANORAMA STUDY: PANCREATIC CANCER DIAGNOSIS - RADIOLOGISTS MEET AI

Henkjan Huisman, PhD (*Abstract Co-Author*) Shareholder, QView Medical, Inc;Grant Support, Siemens AG;Grant Support, Canon Medical Systems Corporation
Geert Litjens, PhD (*Abstract Co-Author*) Nothing to Disclose
Pierpaolo Vendittelli (*Abstract Co-Author*) Nothing to Disclose
Derya Yakar, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
John J. Hermans, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Megan Schuurmans (*Abstract Co-Author*) Nothing to Disclose
Natalia Alves, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

The PANORAMA study transparentlly evaluates artificial intelligence (AI) and radiologists in detecting pancreatic ductal adenocarcinoma (PDAC) using contrast-enhanced computed tomography (CECT). The study hypothesizes that state-of-the-art AI algorithms are non-inferior to radiologists, showing promise for opportunistic screening.

**METHODS AND MATERIALS**

This retrospective study includes 3338 CECT abdominal scans of patients without prior history of treatment or positive histopathology findings of PDAC acquired between 2006 and 2021 from 5 centres (Netherlands, Norway, and Sweden) including subsequent workup and follow-up. Of these, 2238 cases (676 PDAC) are publicly available to develop and train AI algorithms, and100 and 1000 cases were sequestered for AI tuning and testing, respectively. The test set comprises data from two external centres not present in the other cohorts. A subset of 400 testing cases is used for a reader study. Both AI and radiologists indicate PDAC likelihood and localization of lesions. AI is developed in a Grand Challenge set-up. A baseline algorithm is provided and teams from multiple institutions and countries are invited to submit AI solutions to the tuning set live leaderboard hosted at panorama.grand-challenge.org. After this development phase, teams can make one final submission to the hidden testing cohort. Patient-level performance is assessed using the area under the receiver operating characteristic curve (AUROC). Multi-reader multi-case analysis is used to compare the diagnostic performance of readers and AI. The study protocol was developed and published open access in conjunction with an international scientific advisory board of 13 experts in AI, radiology, and histopathology to ensure transparent development and validation of pancreas-AI as a benchmark for clinical translation.

**RESULTS**

The PANORAMA study results will be presented for the first time at RSNA 2024. Currently, 45 radiologists (26 centers,13 countries, 2-30 years of experience, median: 9 years) participate in the study. The baseline AI (nnU-Net with cross-entropy loss) achieves 97.95% AUROC in the tuning set. There are currently 165 registered challenge participants. A significant improvement over the baseline is expected in the testing set, in line with previous challenges' results.

**CONCLUSION**

Transparently benchmarked, expert AI can enable opportunistic screening to start catching PDAC at earlier stages and improve patient survival.

**CLINICAL RELEVANCE/APPLICATION**

Early-detected PDAC patients have improved survival but 40% of lesions are missed in pre-diagnostic imaging. AI and expert radiologists' comparison proving non-inferiority can enable AI-based opportunistic screening.

## S2-SSGI01-3 UTILIZING A DOMAIN-SPECIFIC LARGE LANGUAGE MODEL FOR LI-RADS V2018 CATEGORISATION OF FREE-TEXT MRI REPORTS: A FEASIBILITY STUDY

Mario Matute Gonzalez, MD (*Abstract Co-Author*) Nothing to Disclose
Anna Darnell, MD (*Abstract Co-Author*) Speaker, Bayer AG;Grant, Bayer AG
Alexandre Soler, MD (*Abstract Co-Author*) Nothing to Disclose
Maria B. Saborido (*Abstract Co-Author*) Nothing to Disclose
Jordi Rimola, MD, PhD (*Presenter*) Consultant, Alimentiv Health Trust;Speaker, Takeda Pharmaceutical Company Limited;Consultant, Johnson & Johnson;Consultant, Boehringer Ingelheim GmbH;Research Grant, AbbVie Inc

**PURPOSE**

Large language models (LLM) can be utilized on a large scale to extract structured information from free-text radiology reports but its optimal integration for data curation is not well characterized. The aim of the study us to develop a domain-specific LLM for Liver Imaging Reporting and Data System (LI-RADS) v2018 categorisation of hepatic observations based on free-text descriptions extracted from MRI reports.

**METHODS AND MATERIALS**

This retrospective study included 175 MRI reports from a single institution. A total of 171 observation descriptions were extracted and divided into training (n=51) and test (n=120) datasets. The LLM evaluated in this study was LiverAI, a domain-specific chatbot developed on generative pre-trained transformes (GPT) architecture using the OpenAI’s. The performance of the algorithm was assessed in comparison to two independent radiologists in a human replacement scenario and considering two combined strategies (double reading with arbitration and triage). Agreement on LI-RADS category and dichotomic malignancy (LR-4, LR-5, and LR-M) were estimated using linear-weighted ? statistics and Cohen’s ?, respectively. Sensitivity and specificity for LR-5 were calculated. The consensus agreement of three other readers served as the ground truth.

**RESULTS**

The model showed moderate agreement against the ground truth for both LI-RADS categorisation (k=0.54 [95%CI, 0.42-0.65]) and the dichotomized approach (k=0.58 [95%CI, 0.42-0.73]). Sensitivity and specificity for LR-5 were 0.76 (95%CI, 0.69-0.86) and 0.96 (95%CI, 0.91-1.00), respectively. When the chatbot was used as a triage tool, performance improved for LI-RADS categorisation (k=0.86 and k=0.87 for the two independent readers), dichotomized malignancy (k=0.91 and k=0.94) and LR-5 identification (1.00 and 0.98 sensitivity, 0.96 and 0.92 specificity), with no statistical significance compared to the human readers' individual performance. Through this strategy, radiologists' workload decreased by 45%.

**CONCLUSION**

LI-RADS v2018 categorisation from unlabelled MRI reports is feasible using our LLM, and it enhances the efficiency of the data curation process.

**CLINICAL RELEVANCE/APPLICATION**

Our proof-of-concept study provides novel insights into the potential applications of LLMs, offering a real-world example of how these tools could be integrated into a local workflow for research purposes.

## S2-SSGI01-4 AI-DERIVED BODY COMPOSITION PARAMETERS AS PROGNOSTIC FACTORS IN PATIENTS WITH HCC UNDERGOING TACE:RESULTS FROM A MULTICENTER STUDYRESULTS FROM A MULTICENTER STUDY

Roman Kloeckner, MD (*Abstract Co-Author*) Advisory Board, Guerbet SA;Speaker, Guerbet SA;Advisory Board, Bristol-Myers Squibb Company;Advisory Board, Sirtex Medical Ltd;Speaker, Sirtex Medical Ltd;Advisory Board, F. Hoffmann-La Roche Ltd;Speaker, F. Hoffmann-La Roche Ltd;Advisory Board, Boston Scientific Corporation;Speaker, Boston Scientific Corporation;Speaker, BTG International Ltd;Speaker, Siemens AG;Speaker, Eisai Co, Ltd
Lukas Mueller, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Body composition assessment (BCA) parameters have recently been identified as relevant prognostic factors for patients with hepatocellular carcinoma (HCC). Here we aimed to investigate the role of BCA parameters for prognosis prediction in patients with HCC undergoing transarterial chemoembolization (TACE).

### METHODS AND MATERIALS

This retrospective multicenter study included a total of 754 treatment-naļve patients with HCC who underwent TACE at six tertiary care centers between 2010-2020. Fully automated artificial intelligence-based quantitative 3D volumetry of abdominal cavity tissue composition was performed to assess skeletal muscle volume (SM), total adipose tissue (TAT), intra- and intermuscular adipose tissue (IMAT), visceral adipose tissue (VAT), and subcutaneous adipose tissue (SAT) on pre-intervention computed tomography scans. BCA parameters were normalized to the slice number of the abdominal cavity. We assessed the influence of BCA parameters on median overall survival (OS) and performed multivariate analysis including established estimates of survival.

### RESULTS

Univariate survival analysis revealed that impaired median OS was predicted by low SM volume ($p < 0.001$), high TAT volume ($p = 0.013$), and high SAT volume ($p = 0.006$). In multivariate survival analysis, SM remained an independent prognostic factor ($p = 0.039$), while TAT and SAT volumes no longer showed predictive ability.

### CONCLUSION

Skeletal muscle volume is an independent prognostic factor for survival prediction. Thus, the integration of SM into novel scoring systems could potentially improve survival prediction and clinical decision-making. Fully automated approaches are needed to foster the implementation of this imaging biomarker into daily routine.

### CLINICAL RELEVANCE/APPLICATION

BCA parameters, especially skeletal muscle mass, have been identified as relevant prognostic factors for many diseases and treatments. In this study skeletal muscle volume has been identified as an independent prognostic factor for patients with HCC undergoing TACE. Therefore, skeletal muscle mass as a metaparameter could play a role as an opportunistic biomarker in holistic patient assessment and be integrated into decision support systems. Workflow integration with AI evaluation is essential for automated BCA quantification output enabling broad availability in multidisciplinary case discussions.

## S2-SSGI01-5 DETECTING PANCREATIC CANCER ON NON-CONTRAST CT IMAGES WITH DEEP LEARNING

Kao-Lang Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Holger R. Roth, PhD (*Abstract Co-Author*) Employee, NVIDIA Corporation;Researcher, NVIDIA Corporation
Weichung Wang, PhD (*Abstract Co-Author*) Nothing to Disclose
Pochuan Wang (*Abstract Co-Author*) Nothing to Disclose
Dawei Chang (*Abstract Co-Author*) Nothing to Disclose
Wei-Chih Liao, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Po-Ting Chen, MD (*Presenter*) Nothing to Disclose

### PURPOSE

CT is the major imaging modality for detecting/diagnosing pancreatic cancer (PC), and injection of intravenous contrast to augment tissue contrast is generally required for this purpose. However, contrast medium cannot be administered in patients with hypersensitivity or risk of renal failure from contrast-induced nephropathy, rendering the detection/diagnosis of PC in those patients a challenging task. This study aimed to detect/diagnose PCs on non-contrast CT images with deep learning.

### METHODS AND MATERIALS

Non-contrast CT images from a tertiary referral center were collected to develop and validate an end-to-end CAD tool. A total of 3,080 patients [713 with PC, 1,661 with normal pancreas (Normals), and 706 with other pancreatic diseases (OPDs)] were randomly split into training, validation, and hold-out testing sets (3:1:1) with stratification by the three disease status. A convolutional neural network (CNN)-transformer hybrid deep learning model was trained using training and validation sets to distinguish PC from Normals and OPDs. Image slices harboring crucial diagnostic information were provided as key image slices by the CAD tool.

### RESULTS

In the hold-out test set, the developed CAD tool distinguished non-contrast images of PCs from those of Normals and OPDs with 90.8% (95% CI 84.9-95.0) sensitivity [87.2% (72.6-95.7) for tumors < 2 cm, 92.2% (85.3-96.6) for tumors > 2 cm], 93.0% (90.4-95.2) specificity [97.3% (94.9-98.8) for Normals, 83.0% (75.7-88.8) for OPDs], and 92.5% (90.2-94.5) accuracy [AUC 0.975 (0.957-0.993)]. Among the 129 correctly diagnosed PCs, the CAD-designated key non-contrast slices included the tumor in 95 (73.6%) patients and secondary signs of PC (dilation of pancreatic duct, extrahepatic bile duct or intrahepatic bile duct) in 21 (16.3%) patients according to review of the corresponding contrast-enhanced images by an experienced radiologist.

### CONCLUSION

The CAD tool could detect/diagnose PC on non-contrast CT images and indicate the key images to facilitate radiologist interpretation.

### CLINICAL RELEVANCE/APPLICATION

Deep learning-based analysis of non-contrast CT images may enable detection/diagnosis of PC in patients for whom contrast enhancement was contraindicated or not administered when performing CT.

## S2-SSGI01-6 END-TO-END PROGNOSTICATION IN PANCREATIC CANCER BY MULTIMODAL DEEP LEARNING: A RETROSPECTIVE, MULTI-CENTRE STUDY

Megan Schuurmans, BSc, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest cancers, with a five-year survival rate of 5%. Current PDAC staging methods lack prognostic accuracy to correlate significantly with overall survival and prove unreliable in guiding treatment decisions. This study evaluates the

performance of unimodal and multimodal AI models, combining imaging and clinical markers at the time of diagnosis, to predict short—and long-term survival in PDAC patients.

**METHODS AND MATERIALS**

This retrospective study includes 862 PDAC patients from three centres (Netherlands, Spain). Contrast-enhanced computed tomography (CECT) scans and clinical data from 501 patients were split into a development cohort (n=401) and an independent testing cohort (n=100). Three separate AI algorithms were developed to predict short- vs long-term PDAC survival: 1) using only clinical variables, 2) using only imaging data, and 3) a multimodal algorithm combining clinical and imaging data. The AI algorithms were validated in two separate external cohorts of 252 and 109 PDAC patients, respectively.

**RESULTS**

Short-term survival (<230 days) was observed in 89 (22·2%), 23 (23·0%), 64 (25·4%), and 46 (42·2%) patients in the development, internal-, external test set 1 and 2, respectively. In the internal test set and external test sets 1 and 2, the multimodal AI achieved an area under the receiving operating characteristic curve (AUROC) of 0.67, 0·57, and 0·68, respectively. Kaplan-Meier analysis showed statistically significant differences between short- and long-term survivors defined by the AI algorithms (P<0·05).

**CONCLUSION**

Our study showed that integrating patients' information with imaging at the time of diagnosis in a multimodal AI model is favored over unimodal AI models and outperforms current PDAC TNM staging systems at stratifying short-term and long-term survivors at baseline.

**CLINICAL RELEVANCE/APPLICATION**

Exploring the predictive power of AI models, emulating input conditions that clinicians currently use to address complex clinical questions, can help clinicians make more informed decisions.

## S2-SSGI02-1 COMPARING A FULLY AUTOMATED HYBRID APPROACH ON MRI AND FIBROSCAN FOR TRIAGING CLINICALLY SIGNIFICANT LIVER FIBROSIS:COMPARING A FULLY AUTOMATED HYBRID APPROACH ON MRI AND FIBROSCAN FOR TRIAGING CLINICALLY SIGNIFICANT LIVER FIBROSIS:A MULTI-CENTER COHORT STUDY

Junhao Zha, MD (*Presenter*) Nothing to Disclose

### PURPOSE

We aimed to 1) develop and validate the combined radiomics-clinic (CoRC) model on MRI for triaging clinically significant liver fibrosis (= F2), 2) compare or combine with transient elastography-based liver stiffness measurement (TE-LSM) in large-scale samples.

### METHODS AND MATERIALS

This retrospective multi-center study recruited 595 patients with biopsy proven liver fibrosis from Jan 2015 to Dec 2021. Training (n = 276) and internal test (n = 118) sets were randomly allocated. A temporal test set (n = 96) and an external test set (n = 105) were used for validation. Radiomics features were extracted from the ResUNet-based automated MRI entire liver segmentation on fat-suppressed T2-weighted and delayed enhanced T1-weighted images, respectively. CoRC model integrated Radiomics scores and optimal clinical variables in the training set with multivariate logistic regression. Diagnostic performance was mainly evaluated by the area under the receiver operating characteristic curve (AUC) in the test sets.

### RESULTS

n the internal, temporal, and external test sets, the CoRC model yielded AUCs of 0.79 (0.70, 0.86), 0.82 (0.73, 0.89), and 0.81 (0.72-0.91), and outperformed TE-LSM in the temporal test set (integrated discrimination improvement, 12.9% [2.4-23.4%]; P = .02). Additive value of CoRC model to TE-LSM was explored, with combined AUC of 0.86 (0.79-0.94), and 0.81 (0.72-0.90) in the internal, and temporal sets (P = .01). Considering necroinflammation, CoRC model maintained the discriminatory power in the test sets (AUCs range, 0.74-0.86).

### CONCLUSION

CoRC models exhibited promising diagnostic performances for clinically significant liver fibrosis, complementary to TE-LSM.

### CLINICAL RELEVANCE/APPLICATION

Our study used an interactive deep learning approach to automatedly segment the entire volumetric liver contours more effectively. The combined radiomics-clinic model demonstrated good discrimination capability for clinically significant liver fibrosis in all sets, superior to FIB-4 and APRI as routine clinical approaches. Especially, the combined radiomics-clinic model could be a promising alternative and supplement to FibroScan based liver stiffness measurement as the standard imaging modality.

## S2-SSGI02-2 RELIABLE LIVER FAT QUANTIFICATION USING DUAL-SOURCE PHOTON-COUNTING CT: COMPARED WITH MRI

Rong Deng (*Abstract Co-Author*) Nothing to Disclose
Fuhua Yan, MS (*Abstract Co-Author*) Nothing to Disclose
Zhihan Xu, MD (*Abstract Co-Author*) Nothing to Disclose
Huimin Lin (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to assess the value of dual-source photon counting detector (PCD)-CT in liver fat quantification, compared with MRI proton density fat fraction (PDFF).

### METHODS AND MATERIALS

Between September and December 2023, asymptomatic participants were prospectively recruited to undergo a non-contrast abdominal CT scan on a PCD-CT. Participants were randomly assigned to four groups with different PCD-CT protocols of tube voltage (120-, 140-kVp) and dose level (standard- and low-dose). The CT-derived fat fraction (CTFF) was estimated using a material-decomposition method. The agreement evaluation was conducted between CTFF and PDFF. Participants were categorized into normal liver fat content (< 6%), mild (6%-17%), and moderate-to-severe steatosis (>17%), using PDFF as the reference. The Precision-Recall curve was plotted to measure the performance of the binary classifier in distinguishing between different levels of liver fat content.

**RESULTS**

The final cohort comprised 320 participants with a median age of 45. According to their PDFF results, normal liver fat content, mild steatosis, and moderate-to-severe steatosis were noted in 206, 79, and 35 participants, respectively (example case in Figure 1). The intraclass correlation coefficient and mean bias between CTFF and PDFF were 0.9155 (95% CI: 0.907-0.923) and -1.70% ± 2.76%. For detecting fat content = mild steatosis, the F1 score and the area under the precision-recall curve (AUC-PR) were 0.870 and 0.950 (95% CI: 0.929-0.965), with a sensitivity of 0.88 and a specificity of 0.93. Similarly, for detecting fat content = moderate-to-severe steatosis, the F1 score and AUC-PR were 0.904 and 0.948 (95%CI: 0.903-0.973), with a sensitivity of 0.93 and a specificity of 0.91 (Figure 2). The average effective dose for standard-dose and low-dose protocols was 3.09 mSv, and 2.04 mSv, respectively.

**CONCLUSION**

Using a material-decomposition method, PCD-CT showed a robust agreement with MRI-PDFF across various protocols and may serve as a precise alternative for liver fat quantification.

**CLINICAL RELEVANCE/APPLICATION**

PCD-CT holds significant potential for liver fat quantification in routine clinical use, even under low-dose conditions.

## S2-SSGI02-3 ACOUSTIC OUTPUT EXCEEDING REGULATORY LIMITS IS SAFE AND DECREASES SHEAR WAVE ELASTOGRAPHY MEASUREMENT VARIABILITY

Kim Naja, MD, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Metabolic dysfunction-associated steatotic liver disease (MASLD) affects 1 in 3 people worldwide. Ultrasound shear wave elastography (SWE) is widely available to quantify liver fibrosis, but may fail due to ultrasound beam attenuation and distortion from larger body habitus common in MASLD. Current FDA mechanical index (MI) limitations preclude compensatory increases in acoustic energy. We assess the safety and efficacy of conditionally increased acoustic output (CIO) above FDA limits to improve SWE imaging.

**METHODS AND MATERIALS**

This single-center prospective HIPAA-compliant IRB-approved clinical trial (July 2023 - April 2024) enrolled healthy adults stratified by body mass index (BMI). Participants underwent conventional (MI 1.4) and increased energy (MI 2.5) SWE using a GE HealthCare LOGIQ E10 with a GE C1-6 curved abdominal ultrasound probe. 10 conventional and 10 CIO diagnostic measurements were obtained with up to 20 attempts each if initially non-diagnostic. Interquartile range to median ratio (IQRM) was calculated. Participants underwent blood liver function testing <48 hours prior and 1 day after imaging. The primary endpoint assessed increase in aspartate aminotransferase (AST), alanine transaminase (ALT), or alkaline phosphatase (ALP) indicating liver injury with a noninferiority margin defined as the lab value upper limit of normal (AST 40 U/L, ALT 55 U/L, ALP 115 U/L). The secondary endpoints were a reduction in SWE measurement variability by paired t-test and imaging attempts by Wilcoxon Sign Rank Test.

**RESULTS**

24 participants were enrolled; 2 withdrew prior to imaging and were excluded from analysis. 22 participants (39.64 ± 16.3 years; 15 women) had normal BMI (6), overweight (6), class 1 obesity (7), and class 2 obesity (3). The mean [95% CI] increase in LFTs was 1) AST: -0.86 [-2.34, 0.61], p = 0.24, 2) ALT: 0.32 [-1.04, 1.68], p = 0.63, 3) ALP: 1.73 [-1.02, 4.47], p = 0.21. The upper 95% CI for all biomarkers met the criterion for non-inferiority. Mean IQRM was 0.0659 for standard SWE and 0.0466 for CIO. IQRM decreased by 0.019 across exams (p=0.01). The mean number of attempts decreased by 0.68 [IQR: 0,0.75], p=0.058.

**CONCLUSION**

CIO SWE caused no increase in liver function tests to suggest liver injury. It led to reduced measurement variability, suggesting improved exam quality, and a trend toward fewer required measurements. This suggests that CIO SWE is safe to use and may improve exam quality and acquisition efficiency in challenging to image patients.

**CLINICAL RELEVANCE/APPLICATION**

Increased energy shear wave elastography is safe, reduces measurement variability, and may increase image acquisition efficiency. This may improve diagnostic evaluation in challenging to image high body mass index patients at risk for MASLD.

## S2-SSGI02-4 CT-BASED CLINICALLY SIGNIFICANT PORTAL HYPERTENSION: PREDICTING COMPLICATIONS IN HCC HEPATECTOMY

Seung Soo Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Subin Heo, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The role of CT-based clinically significant portal hypertension (CSPH) in predicting short-term and long-term liver-related complications following hepatic resection has not been evaluated.

**METHODS AND MATERIALS**

This retrospective study included patients with advanced chronic liver disease (ACLD) who underwent partial hepatectomy for hepatocellular carcinoma (HCC) with BCLC stage 0 or A between 2017 and 2018. The presence of CT-based CSPH was evaluated in preoperative contrast-enhanced CT, defined as the presence of both splenomegaly and at least one of esophagogastric varix, spontaneous portosystemic shunt, or ascites. We performed multivariable logistic regression and competing risk analysis to evaluate the association of CT-based CSPH with liver-related outcomes. The primary endpoint was severe post-hepatectomy liver failure (PHLF), as defined by International Study Group of Liver Surgery. Secondary endpoints were the occurrence of hepatic decompensation and liver-related death or liver transplantation. Additionally, CT-based CSPH was applied to two well-known PHLF prediction models (Citterio's algorithm and Wang's model), and their performance was compared with that when applying the conventional surrogate CSPH assessment (presence of esophageogastric varix at endoscopy or coexistence of splenomegaly and a platelet count < 100 ×103/μL).

**RESULTS**

A total of 593 patients (mean age, 57.9 years ± 9.3; 460 male) were included in the study. Severe PHLF occurred in 41 patients (6.9 %). The presence of CT-based CSPH was a significant independent predictor for the occurrence of severe PHLF (odds ratio 7.672, 95% confidence interval [CI] 3.209-18.346). The performance of both Citterio's algorithm and Wang's model significantly improved when using the CT-based CSPH criteria compared to the conventional method (AUC 0.724 vs. 0.694, p=0.036, and AUC 0.854 vs 0.830, p=0.011, respectively). CT-based CSPH was also a significant predictor for long-term hepatic decompensation (hazard ratio [HR] 4.518, 95% CI 1.868-10.929) and liver-related death or transplantation (HR 2.756, 95% CI 1.315-5.773).

**CONCLUSION**

The presence of CT-based CSPH predicts short-term and long-term liver related outcomes following partial hepatectomy for HCC in ACLD.

**CLINICAL RELEVANCE/APPLICATION**

The current gold standard for CSPH evaluation is an invasive method involving hepatic venous pressure gradient measurement, which limits its clinical utilization. CT is a routine exam prior to hepatectomy, so CT-based CSPH evaluation is a highly practical method, also with good performance as shown in this study, for predicting postoperative liver-related outcomes. Patients with a high risk of post-operative complications may consider upfront transplantation.

## S2-SSGI02-5 TRAJECTORIES OF LIVER VOLUME AND STEATOTIC LIVER DISEASE ACROSS AGING AND THEIR ASSOCIATION WITH INCIDENT DIABETES IN THE GENERAL POPULATION

Fabian Bamberg, MD, MPH (*Abstract Co-Author*) Speakers Bureau, Bayer AG;Speakers Bureau, Bracco Imaging;Speakers Bureau, Siemens AG;Research Grant, Siemens AG
Jakob Weiss, MD (*Abstract Co-Author*) Nothing to Disclose

Vineet K. Raghu, PhD (*Abstract Co-Author*) Nothing to Disclose
Susanne Rospleszcz (*Abstract Co-Author*) Nothing to Disclose
Matthias Jung, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Steatotic liver disease (SLD) is a public health concern with a global prevalence of 32.4%. SLD is an independent risk factor for cardiometabolic disease. With advances in AI, automated and accurate assessment of hepatic volume and SLD from MRI has become feasible. We used a fully automated deep learning framework to quantify liver volume and SLD from MRI, described their trajectories across aging in the general population, and investigated their prognostic value to predict incident diabetes.

**METHODS AND MATERIALS**

We used data from the UK Biobank (UKBB; n=36,317) and the German National Cohort (NAKO; n=30,349) to quantify liver volume and SLD. The framework takes a T1w dual-echo Dixon MRI as input, and outputs (i) liver volume (mL) and (ii) Dixon-derived liver fat fraction (FF in %). Sex-stratified changes in liver volume and FF across age decades were calculated. Mild, moderate, and severe SLD were defined using established FF thresholds (5%, 15%, and 25%). Trajectories of liver volume and FF were assessed by computing age, sex, and height adjusted normative reference curves. The prognostic value of normative liver volume (volume z-score) and FF was assessed for incident diabetes in the UKBB only. Cumulative incidence curves and log-rank tests investigated time to diabetes for volume z-score (<1; 1-2; >2) and SLD categories. Cox regression assessed the association between volume z-score/FF and diabetes after adjustment for age, sex, BMI, race, serum glucose, Hb1Ac, lipid panel, hypertension, history of cancer, alcohol consumption, and smoking status.

**RESULTS**

Among 66,666 individuals from the general population (57.7±12.9y; BMI: 26.2±4.5 kg/m2, 48.3% female), 3D liver analysis showed that liver volume and variance increased in both sexes until age 60 and decreased after. Hepatic FF increased throughout the lifespan with a higher variability in males compared to females. 70.3% of the cohort had SLD. Normative reference curves showed a similar pattern for both sexes across the lifespan with higher variance in liver volume and FF in males. Cumulative incidence curves showed a higher incidence of diabetes in higher volume and SLD categories (p<0.001). Cox regression revealed an association between volume z-score (aHR:1.17, 95% CI [1.07-1.29], p<0.001) and FF (aHR:1.02, 95% CI [1.01-1.03], p<0.001) and incident diabetes after full adjustment.

**CONCLUSION**

Our results confirm a high prevalence of SLD in the general population. Hepatic fat fraction and normative liver volume predicted incident diabetes beyond traditional risk factors.

**CLINICAL RELEVANCE/APPLICATION**

Applying fully automated deep learning-based liver assessment to routine MRI may help to identify high-risk individuals to improve personalized prevention and lifestyle interventions.

## PURPOSE

To evaluate the performance of ultrasound-derived fat fraction (UDFF) for diagnosing hepatic steatosis using liver biopsy as the gold standard.

## METHODS AND MATERIALS

Patients who had steatosis liver disease and were referred to undergo liver biopsy were enrolled in this prospective study. All patients underwent UDFF and controlled attenuation parameter (CAP) measurements. The histologic hepatic steatosis was graded (S0, < 5 %; S1, 5 % - 33 %; S2, 33 % - 66 %; S3, > 66 %). The Kruskal-Wallis tests were performed to compare UDFF values between different degrees of hepatic steatosis. The area under the receiver operating characteristic curve (AUC) was performed to evaluate the diagnostic performance of UDFF and CAP. The cut-off values were determined to maximize the Youden index. The correlation between UDFF and CAP was evaluated using the Spearman correlation coefficient.

## RESULTS

From February 2023 to March 2024, a total of 41 patients (44.0 % [18/41] men and 56.0 % [23/41] women) were included. The median age and body mass index were 46 years (interquartile range [IQR]: 34 - 58) and 24 kg/m2 (IQR: 22 - 27), respectively. Among the 41 patients, 46.3 % (19/41), 31.7 % (13/41), 9.7 % (4/41), and 12.1 % (5/41) of them were steatosis graded S0, S1, S2, and S3, respectively. The success rate of the UDFF and CAP measurements were 100 % and 97.6 %, respectively. The median UDFF value of all patients was 6.0 % (IQR: 3.3 - 12.0). The median UDFF values of patients with S0, S1, S2, and S3 were 4.0 % (IQR: 3.0 - 6.5), 10.0 % (IQR: 4.0 - 11.5), 10.3 % (IQR: 5.0 - 20.4), and 18.5 % (IQR: 16.5 - 31.8), respectively.There were significant differences in UDFF values between S0 and S2, S0 and S3, S1 and S3, and S2 and S3 ($P < 0.05$). The cut-off value of UDFF for detecting hepatic steatosis was 9.5 %. Both UDFF and CAP had good diagnostic performance in detecting hepatic steatosis, with AUCs of 0.81 (95 % confidence intervals [CI]: 0.68 - 0.94) and 0.87 (95 % CI: 0.76 - 0.98), sensitivity of 63.6 % (95 % CI: 43.0 - 80.3) and 81.8 % (95 % CI: 61.5 - 92.7), and specificity of 94.7 % (95 % CI: 75.4 - 99.7) and 78.9 % (95 % CI: 56.7 - 91.5), respectively. However, The diagnostic performance showed no significant difference between UDFF and CAP ($P > 0.05$). UDFF values had a significant positive correlation with CAP values ($R = 0.77$, $P < 0.001$).

## CONCLUSION

UDFF showed good diagnostic performance in the evaluation of hepatic steatosis. Especially when patients fail to obtain valid CAP values, UDFF measurement could be a potential alternative tool in clinical practice.

## CLINICAL RELEVANCE/APPLICATION

UDFF showed good diagnostic performance in diagnosing hepatic steatosis in patients with steatosis liver disease. UDFF measurement had an excellent success rate and is a potential alternative tool in clinical practice with promising results.

## S2-SSPD01-1 OPTIMIZING CORONARY ARTERY ANEURYSM WITH THROMBOSIS DETECTION IN KAWASAKI DISEASE: A PROSPECTIVE STUDY OF 3T CORONARY MRA WITH COMBINED DIASTOLIC AND SYSTOLIC PHASES IMAGING

Hu Xihong (*Abstract Co-Author*) Nothing to Disclose
Haitang Jiang (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic performance with a new strategy combining diastolic and systolic imaging on coronary MRA for coronary artery aneurysm (CAA) with thrombosis detection in Kawasaki children.

### METHODS AND MATERIALS

From August 2023 to April 2024,29 participants with Kawasaki disease (KD) who had undergone X-ray coronary angiography (CAG) or coronary CT angiography (CCTA) were prospectively enrolled. Each participant underwent 3T water-fat coronary MRAs twice separately in the diastolic and systolic phases. The combined coronary MRA in diastole and systole was considered as the third approach. Using CAG/CCTA as the reference, scan-relevant parameters, subjective image quality score objective image quality measurement (signal-to-noise ratio [SNR], and contrast-to-noise ratio [CNR]) were evaluated in both diastole and systole phases. CAA was defined as the Z score of the vessel diameter being = 2.5. The diagnostic performance for detection CAA and CAA with thrombosis by the three approaches was compared on per-patient, per-vessel, and per-segment basis.

### RESULTS

A total of 29 participants (age 6.6±3, 10.9%female) were evaluated. The mean MR acquisition time was 208.8±43.8s in systole phase, 247.1±127.5 in diastole phase. Compared with the image in diastole phase, the overall image quality($p=0.018$), per-vessel image quality in LCX ($p<0.001$), and per-segmental image quality on p-LAD($p=0.034$), p-LCX ($p<0.001$) and d-LCX ($p < 0.001$) were higher in systole phase. The per-patient sensitivity, specificity, and accuracy of combined coronary MRA were 92.86%, 100% and 93.1%, respectively. Compared with diastolic phase, systolic phase showed higher sensitivity (93.3% vs 84%, $p=0.039$), but lower specificity in a per-vessel basis. Compared with single systolic mode, combined coronary MRA showed lower sensitivity on a per-segment (80.49 %vs 100%, $p=0.008$) and per-vessel (93.33% vs 82.67%, $p=0.021$), but improved specificity on a per-vessel basis (100% vs. 80.49%, $p=0.008$). Compared with single diastolic mode, combined coronary MRA showed equally high sensitivity and specificity of CAA with thrombosis.

### CONCLUSION

Compared with single-phase coronary MRA, dual-phase combined scanning has the advantage of increasing specificity without decreasing sensitivity for detection of CAA with thrombosis.

### CLINICAL RELEVANCE/APPLICATION

Combined coronary MRA is non-invasive and without radiation, may be a superior option for the risk assessment and treatment and also follow-up of children with Kawasaki disease, providing comparable image quality and diagnostic efficacy.

## S2-SSPD01-2 AUTOMATIC AIRWAY SEGMENTATION OF ULTRA-SHORT ECHO TIME (UTE) MRI EXAMS OF NEONATAL PATIENTS WITH PATHOLOGIES

### PURPOSE

To study the performance of benchmark AI models in segmenting neonatal airway passages from ultrashort echo time (UTE) MRI exams - a complex and time-consuming task to perform manually.

### METHODS AND MATERIALS

331 UTE (200 microsections) 1.5T MRI images with a voxel dimension of .703 cubic mm were used in this study. The exams fell under 4 broad categories based on the patient's pathology; 18 were control, 175 were BPD (Bronchopulmonary Dysplasia), 73 were CDH (Congenital Diaphragmatic Hernia), and 65 were from several other pathological conditions. Training and testing sets were formed with stratified sampling across pathologies with an 85-15 percentage split. An expert pulmonary researcher manually segmented the airway passage in 3DSlicer. Based on initial experiments using models in the Medical Open Network for AI (MONAI) framework, the DynUNet architecture was selected and further optimized with various preprocessing and data augmentation schemes. nnUnet is a self-configuring pipeline that has won several medical image segmentation challenges and was chosen to establish a performance benchmark. nnUnet employs a 20-model ensemble that uses 5-fold cross validation and 4 different U-net configurations, resulting in long training and inference times. The custom tuned single DynUNet model was compared to the nnUnet ensemble using Dice Similarity Score (DSC).

### RESULTS

The best DynUNet model achieved a DSC of 0.79 ± 0.09 on a test set of 50 exams. The DSC for each pathology category was BPD: 0.82, CDH: 0.77, control: 0.78, and miscellaneous pathologies: 0.71. Training the nnUnet pipeline resulted in an overall DSC of 0.79 ± 0.09, which matched the performance achieved using a single custom tuned DynUNet. The nnUnet took on average 150 seconds for segmenting the airway in a single scan, while the DynUNet took only 15 seconds on a Nvidia A100 GPU.

### CONCLUSION

A thorough evaluation of automatic airway passage segmentation models for chest UTE MRI exams was performed for the first time in neonatal patients.

### CLINICAL RELEVANCE/APPLICATION

Automatic airway segmentation for neonatal patients can enable quantitative assessment of anatomy for respiratory disease diagnosis, treatment planning and monitoring disease progression for various pulmonary disorders.

## S2-SSPD01-3 NON-ECG-TRIGGERED DUAL-SOURCE DEPENDENT CTA IN CHILDREN WITH CONGENITAL HEART DISEASE

Shipeng Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of non-electrocardiogram-triggered (non-ECG-triggered) on third-generation dual-source computed tomography application in children with congenital heart disease (CHD) and a fast heart rate.

### METHODS AND MATERIALS

Data on children with CHD received cardiac CT angiography (CTA) were collected between November 2019 and March 2022. CT images were obtained using two different protocols: non-ECG-triggered and retrospectively-ECG-triggered (retro-ECG-triggered). All children received transthoracic echocardiography (TTE) before surgery . Sex, age, weight, heart rate, volume CT dose index (CTDI vol), and dose length product (DLP) were recorded, and the effective dose (ED) was calculated. Image quality was rated using five-point Likert scales and the diagnostic values of CTA and TTE were compared.

### RESULTS

Children's age ranged from 1 day to 34 months, with minimum and maximum heart rates of 90 bpm and 160 bpm, respectively. There were significant differences between the retro-ECG-triggered and non-ECG-triggered groups in the average tube current (54.95±23.52 vs. 45.47±24.65 mAs, p=0.003), CTDI vol (2.41±1.6 vs. 0.58±0.27 mGy, p<0.001), DLP (44.43±34.65 vs. 9.92±5.48 mGy.cm, p<0.001), and ED (1.48±0.90 vs. 0.35±0.17 mSv, p<0.001). There was no difference between the two CT examination protocols in the demonstration of extracardiac and intracardiac malformations(all p=0.05).The diagnostic accuracy of both retro and non ECG triggering in intracardiac and extracardiac malformations were high, and there were no significant differences (p=1.00, 0.80,respectively). The diagnostic advantage of TTE is mainly in intracardiac malformations (p=0.03, 0.01,respectively)

### CONCLUSION

High-pitch non-ECG-triggered CTA can significantly reduce radiation dose, whereas there was no significant difference in image quality and diagnostic accuracy between non-ECG-triggered and retro-ECG-triggered CTA.

### CLINICAL RELEVANCE/APPLICATION

High-pitch non-ECG-triggered cardiac CTA can overcome the influence of high rate and respiratory motion on image quality and significantly reduce the radiation dose compared with retro-ECG-triggered cardiac CTA ,and obtain the same high-quality image as retro-ECG-triggered cardiac CTA.

## S2-SSPD01-4 EXPLORING HEMODYNAMIC ALTERATIONS IN FETUSES WITH GASTROSCHISIS AND PLACENTA-RELATED FGR: A FETAL MRI STUDY

Hui Shi (*Presenter*) Nothing to Disclose

### PURPOSE

Fetuses with gastroschisis (GS) exhibit a high incidence of Fetal growth restriction (FGR) and placental fetal vascular malperfusion (FVM) while the underlying cause remains elusive. We aim to identify umbilical vein (UV) compression at the hernial orifice in GS, and the resulting backflow of blood into the placenta and FGR.

### METHODS AND MATERIALS

This retrospective study included 86 GS cases, 30/86 were classified as complex GS according to postnatal outcome (intestinal obstruction, atresia/stenosis, volvulus, perforation). Co-occurrence analysis was conducted based on prenatal MRI and postnatal follow-up data of fetal gastroschisis. Morphological measurements including abdominal wall defect size, abdominal circumference, colon length and diameter, maximum small intestine diameter, UV diameter, and placenta characteristics, were subjected to PCA (Principal Component Analysis) for multivariate data classification between GS cases with FGR and without FGR. Furthermore, twenty-six 1:1 age-matched omphalocele cases and 26 normal cases were incorporated to compare the UV diameter, T2* signal intensity (SI) differences between the left and right lobe of the liver, and placental characteristics.

### RESULTS

The incidence of FGR in simple and complex GS was 66% and 85%, respectively. Co-occurrence analysis displays robust connections between FGR and placenta hemorrhage/infarction, umbilical vein stenosis at the defect, and post-stenotic dilatation, particularly correlated with preterm birth, small for gestational age, PROM. Placentas in the GS with FGR group were significantly thickened (P=0.048), with more frequent lobules (P=0.046), and

hemorrhages (P=0.002), accompanied by UV stenosis at the defect, and significant T2* SI difference between the left and right lobe of the liver. PCA showed different clustering patterns between GS-FGR, GS +FGR, and omphalocele controls.

**CONCLUSION**

GS with placenta-related FGR is possibly due to UV stenosis at the abdominal defect and reduced blood supply to the fetus and is associated with FVM and resulting backflow alterations into the placenta.

**CLINICAL RELEVANCE/APPLICATION**

Complex GS with severe UV stenosis and post-stenotic dilatation might be at risk of hemodynamic compromise and need to be considered as potential candidates for prenatal repair surgery.

## S2-SSPD01-5 FETAL BRAIN T2* MAPPING AND INFANT NEURODEVELOPMENTAL OUTCOMES IN CONGENITAL HEART DISEASE

Shabnam Peyvandi (*Abstract Co-Author*) Nothing to Disclose
Patrick McQuillen (*Abstract Co-Author*) Nothing to Disclose
Lauren Christopher (*Abstract Co-Author*) Nothing to Disclose
Duan Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Jing Liu, PhD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth George, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Fetal T2* mapping has demonstrated altered brain oxygenation in fetuses with congenital heart disease (CHD) compared to normal controls. We sought to assess the association of fetal T2* relaxation time with neurodevelopmental (ND) outcomes among infants with CHD requiring a neonatal intervention.

**METHODS AND MATERIALS**

48 fetuses with transposition of great arteries (TGA) or single ventricle physiology (SVP) underwent fetal brain MRI in the 3rd trimester including T2*mapping. T2* relaxation time was adjusted for gestational age (GA) at time of MRI and sex and a residual T2* was calculated which reflects the difference between the subject's T2* and the expected value based on normal controls. ND outcome was assessed at 18- and 30-months using Bayley Scales of Infant and Toddler Development (BSID, version III or IV). Due to the differences in BSID versions, the primary outcomes at 18 months were abnormal motor, cognition, or language defined as a score < 85 in the corresponding domain (BSID III or IV). The primary outcomes at 30 months were the motor, cognitive, language scores on BSID version IV. Race/ethnicity, GA at birth, cardiac lesion type, length of neonatal hospital stay, maternal education (college graduate or higher vs. partial college or specialized training or lower), and fetal total brain volume (TBV) were included in univariate analysis. Multivariate (MV) analysis included residual T2* and those variables with $p<0.1$ on univariate analysis (after excluding highly correlated variables).

**RESULTS**

The study population was 73% (24/33) male with a median gestational age at birth of 39.1 (IQR: 38.3-39.3) weeks. The median GA at fetal brain MRI was 34.1 (IQR: 33.5-34.6) weeks and median residual T2* was -13.2 (IQR: -26.3- -7.9) msec. On MV analysis, abnormal language at 18 months was associated with low maternal education (OR: 6.51 (0.97-43.54, p=0.5), and there was a trend for abnormal motor and cognition outcome to be associated with cardiac lesion type (SVP relative to TGA, OR: 8.46 (0.82-86.97), p=0.07) and low maternal education (OR: 8.57 (0.72-102.02), p=0.09), respectively. On MV analysis, 30-month motor, language, and cognition scores were associated with cardiac lesion type (ß =-19.97- -23.16, p=0.03-0.04) and maternal education (ß=-19.59- -30.61, p=0.01-0.04).

**CONCLUSION**

Fetal brain T2* is not associated with 18- or 30-month ND outcomes. Maternal education is associated with 18-month language outcome, while both cardiac lesion type and maternal education are associated with 30-month motor, language, and cognition scores.

**CLINICAL RELEVANCE/APPLICATION**

Fetal brain T2* is not associated with early ND outcomes, while cardiac lesion type and the home environment have a greater impact on outcome.

### PURPOSE

The PET-Plan trial was a multicenter, prospective randomized phase II study on patients with inoperable stage III non-small cell lung cancer who were treated with 18F-FDG-PET/CT -based vs conventionally planned definitive concurrent chemoradiotherapy (cCRT). The primary endpoint was previously published (Nestle et al., Lancet Oncol 2020). Here we analyzed, whether pre-treatment radiological external expert (REE) imaging review and discrepancies between the local study center (LSC) and REE read were associated with local tumor control or toxicity.

### METHODS AND MATERIALS

All 205 patients were treated to 60-74 Gy with concurrent platinum-based chemotherapy and randomized to have their target volumes defined by either 18F-FDG-PET/CT alone (experimental arm) or 18F-FDG-PET/CT plus elective nodal irradiation (control arm). We assessed availability of the REE, frequency and characteristics of discrepancies (DIS) between reports of LSC and REE in terms of FDG-avidity of mediastinal lymph node stations (LNS). The relation of DIS to toxicities, nodal in- and out-field recurrences, progression-free and overall survival was analyzed.

### RESULTS

In 172 patients with 2528 LNS who were treated per protocol the interobserver agreement between LSC and REE was excellent (Cohens kappa 0.83;). However, 182 DIS (1.1/case; range 0-6) were documented, mostly in the subcarinal, hilar and paratracheal LNS (n=23). Frequency of DIS was not associated with the number of positive LNS per patient. In LNS with DIS, the SUVmax and nodal size showed no significant differences to patients without DIS. In 26 cases, REE was available for RT prior to treatment planning. PFS and OS were neither affected by availability of REE nor by DIS. With regards to locoregional tumor recurrence, the REE and LSC largely agreed in terms of LNS involved in nodal progression (60/68 = 88%; vs. 8/68 = 12% with DIS). In one case, not treated per protocol (RTQA failure), an isolated out-of-field recurrence was documented with significant DIS between REE and LSS. Target volumes that included more LNS than necessary per REE did not result in higher individual patient toxicity compared to other patients.

### CONCLUSION

We did not observe an impact of pre-treatment REE and not many DIS between REE and LSC after 18F-FDG-PET-based cCRT. This suggests that diagnostic quality and oncological safety based on LSC are sufficient for radiotherapy planning. However, in selected cases, an REE opinion may help to avoid a geographic miss.

### CLINICAL RELEVANCE/APPLICATION

18F-FDG-PET-based radiation treatment planning is the standard of care for patients with LA-NSCLC. Availability of REE does not appear to have a significant impact on oncologic endpoints or toxicity.

## S2-SSRO01-2 DOES CONSECUTIVE DAILY (QD) VERSUS NONDAILY (QOD) SCHEDULING IMPACT LOCAL CONTROL (LC) FOR STEREOTACTIC BODY RADIOTHERAPY (SBRT) IN EARLY-STAGE NON-SMALL-CELL LUNG CANCER (ES-NSCLC)?

Patricia Watkins (*Abstract Co-Author*) Nothing to Disclose
Jackson S. Wilson, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Determine whether QD versus QoD impacts LC for patients with ES-NSCLC treated with 5-fraction SBRT.

**METHODS AND MATERIALS**

Patients with biopsy-proven ES-NSCLC treated with 5-fraction SBRT to >49 Gy from 2011 through 2022 were identified from a single-institution SBRT quality assurance database for study inclusion. The primary outcome measure was freedom from local failure (FFLF), measured from SBRT completion to demonstration of local failure (LF) or last clinical follow-up. Patients scheduled for treatment on consecutive days (excluding holidays/weekends) were considered QD, while all others QoD (every other day or twice per week), constituting the primary analysis (from which patients with treatment break >5 days were excluded to reduce risk of interaction). A secondary analysis of SBRT duration (first to last SBRT treatment, independent of QD/QoD group) was additionally performed, inclusive of all eligible patients. Logistic regression analyses (Cox for continuous variables, chi-square for nominal) were performed on clinicopathologic and treatment variables to determine correlations with FFLF.

**RESULTS**

From 2011 to 2022, 100 patients with 105 SBRT target lesions were identified for inclusion. At a median follow-up and survival of 23mo (range, 1-150), 7 LFs had occurred (4 biopsy-proven), and 77 patients had died (including 33 of/with disease). Median age at SBRT was 75 years (38-93), with 55 (52%) female, 20 (19%) prior lung cancer diagnoses, and 14 prior thoracic RT (13%). Median maximal tumor dimension was 2.3cm (0.6-5.4); 57 (54%) adenocarcinoma and 97 (92%) PET-staged. Median dose was 50 Gy (range 49-55), over median 9 days (range, 4-45), with 21 QD patients (20%) and 81 (77%) QoD (excluding 3 patients with treatment break >5 days, 6-21). Treatment groups were balanced with respect to clinicopathologic and treatment factors, without difference in follow-up. FFLF at 2/5y was 95%/85% for the entire population, without statistically significant difference between QD versus QoD groups (p=0.6; Table). When analyzed as a continuous variable, SBRT duration was not significantly associated with FFLF (p=0.363).

**CONCLUSION**

No significant FFLF differences were identified for 5-fraction SBRT for QD versus QoD schedule or treatment duration.

**CLINICAL RELEVANCE/APPLICATION**

Clinicians may reasonably consider QD versus QoD treatment schedules for 5 fraction SBRT without appreciable impact on FFLF.

## S2-SSRO01-3 ARTIFICIAL INTELLIGENCE IN THE DETECTION OF UNSUSPECTED PULMONARY EMBOLISM IN ONCOLOGY PATIENTS

Tarek Assi (*Abstract Co-Author*) Nothing to Disclose
Corinne Balleyguier, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Angela Ayobi, MENG,MSc (*Abstract Co-Author*) Employee, Avicenna.ai
El Mehdi Mniai, MD (*Abstract Co-Author*) Nothing to Disclose
Astrid Orfali Camez, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The incidence of venous thromboembolism is estimated at around 3% of cancer patients. However, a majority of incidental pulmonary embolism (iPE) can be overlooked by radiologists in asymptomatic patients, performing CT scans for surveillance, which may significantly impact the patient's health and management. Routine imaging in oncology is usually reviewed with delayed hours after the acquisition of images. The advent of AI in radiology could reduce the risk of diagnostic delay of iPE by an optimal triage immediately after the CT exam. This study aimed to determine the accuracy of an AI algorithm (CINA-iPE) in detecting iPE and the time to management for these cancer patients in our center in addition to describing the characteristics of patients with a confirmed PE.

**METHODS AND MATERIALS**

This is a retrospective analysis of the role of Avicenna's CE-certified and FDA cleared CINA-iPE algorithm in oncology patients treated at Gustave Roussy Cancer Campus. The results obtained from the AI algorithm were compared with the attending radiologist's report and analyzed by both a radiology resident and a senior radiologist. In case of any discordant results, the reason was further investigated. The duration between the exact time of the CT scan and images analysis was assessed as well as the duration from the result’s reporting to the start of active management.

**RESULTS**

Out of 3047 patients, 104 alerts were detected for iPE (prevalence of 1.3%) while 2942 had negative findings. 36 of the 104 patients had confirmed PE while 68 alerts were false positives. Only 1 patient reported as negative by the AI tool was deemed to have a PE by the radiologist. The sensitivity and specificity of the AI model were 97.3% and 97.74% while the PPV and NPV were 34.62% and 99.97% respectively. Most causes of FP were artifacts (22 cases, 32.3%) and lymph nodes (11 cases, 16.2%). Seven patients experienced delayed diagnosis, requiring them to return to the ER for treatment after being sent home following their CT scan. The remaining patients received prompt care immediately after their testing with a mean delay time of 8.13 hours.

**CONCLUSION**

The addition of an AI system for the detection of unsuspected PEs on chest CT scans in routine oncology care demonstrated a promising efficacy in comparison to human performance. This study describes the potential synergy between AI and radiologists for optimal diagnosis of iPE in routine clinical cancer care.

**CLINICAL RELEVANCE/APPLICATION**

In the oncology field, iPEs are common with an increased risk of morbidity when missed with a delayed diagnosis. With the assistance of a reliable AI tool, the radiologist can focus on the challenging analysis of oncology results while dealing with urgent diagnosis such as PE by sending the patient straight to

the ER for prompt treatment.

## S2-SSRO01-4 EVALUATION OF ONCOGENIC RISK AND CUMULATIVE DOSE FROM RADIOLOGICAL INVESTIGATIONS IN INTENSIVE CARE UNIT PATIENTS. VARIABILITY BETWEEN BEIR VII VS RADRAT VS ICRP 103 VS US EPA MODEL RISKS

Marta Paiusco, MPH (*Abstract Co-Author*) Nothing to Disclose
Chiara Zanon, MD,MS (*Abstract Co-Author*) Nothing to Disclose
Francesca De Monte (*Abstract Co-Author*) Nothing to Disclose
Emilio Quaia, MD (*Presenter*) Speakers Bureau, Bracco Group

### PURPOSE

To compare additional oncogenic risk (AOR) related to radiation exposure according to different risk model including biological effects of ionizing radiation seventh report (BEIR VII), Radiation Risk Assessment Tool (RadRAT), International Commission on Radiological Protection (ICRP) 103, and U.S. Environmental Protection Agency (EPA) risk models in intensive care unit (ICU) patients.

### METHODS AND MATERIALS

This was an IRB-approved observational retrospective study. 150 patients (45 F; 105 M, mean age 63.2 ± 27 years) admitted to intensive care multivisceral transplant unit (MTU, 44 patients) or cardiac surgery unit (CSU,106 patients), who underwent x-ray radiological examinations between april and june 2023, were included. For each patient, the cumulative effective dose during one single hospital admission was calculated and AOR for all cancer and leukemia were estimated according to the risk models.

### RESULTS

All cancer risks was lower according to ICRP 103 vs BEIR VII vs U.S. EPA vs RadRAT (20 ± 105 vs 40 ± 226 vs 41.88± 254 vs 47.5 ± 346 $p < 0.001$), while it was higher in male patients according to BEIR VII (male vs female median ± IQR, 58.6 ± 279 vs 18.6 ± 112), RadRAT (77.2 ± 456 vs 24.2± 130), ICRP 103 (20 ± 121 vs15.94 ± 64) and U.S. EPA (69.40 ± 329 vs 20.59 ±125).Leukemia risk was higher in the U.S. EPA vs BEIR VII vs RadRAT vs ICRP 103 vs (7.75 ± 41 vs 7.6 ± 37 vs 7.27 ± 42 vs 1.8 ± 13, $p < 0.001$), while it was higher in male patients both according to all the models: BEIR VII (male vs female median ± IQR, 9.5 ± 52 vs 2.12 ± 11 ), RadRAT (9.94 ± 50 vs 2.03 ± 12), ICRP 103 ( 2.17± 18 vs ± 0.92 ± 4 ) and U.S. EPA (9.83 ± 51 vs 2.34 ± 12).

### CONCLUSION

The ICRP 103 risk model estimated a lower radiation-induced cancer risk for all cancer risks. The U.S. EPA estimated an increased radiation-induced leukemia risk compared to BEIR VII, U.S. EPA and RadRAT.

### CLINICAL RELEVANCE/APPLICATION

Our study shows the wide variability between the most used model risks which should deserve further research to establish a more consistent risk assessment.

## S2-SSRO01-5 PRE-TREATMENT 18F-FDG PET BASED RADIOMICS IN PREDICTING OUTCOMES IN OLIGOMETASTATIC NON-SMALL CELL LUNG CANCER PATIENTS RECEIVING DEFINITIVE STEREOTACTIC BODY RADIATION THERAPY

Victor Lee, BSC (*Abstract Co-Author*) Nothing to Disclose
Sajid Hossain (*Abstract Co-Author*) Nothing to Disclose
Joshua Zhu, MS (*Abstract Co-Author*) Nothing to Disclose
Durga Sritharan (*Abstract Co-Author*) Nothing to Disclose
James Laird (*Abstract Co-Author*) Nothing to Disclose
Thomas Hager (*Abstract Co-Author*) Nothing to Disclose
Nicholas S. Moore, MD (*Abstract Co-Author*) Nothing to Disclose
Sanjay Aneja, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Stereotactic body radiation therapy (SBRT) is increasingly used to treat oligometastatic non-small cell lung cancer (NSCLC) and has been associated with improved outcomes compared to chemotherapy alone. Current clinical challenges are focused upon identifying the patients who would benefit the most from SBRT while balancing toxicity associated with additional local therapy. PET Radiomics have been shown to be an effective method to personalize treatment in locally advanced NSCLC but have been unexplored in patients with oligometastatic disease. In this study we hypothesize that the PET radiomic features would improve prognostic ability for patients with oligometastatic NSCLC.

### METHODS AND MATERIALS

A total of 152 oligometastatic NSCLC lesions treated with definitive radiation therapy at our institution were used for this study. The main outcome of interest was 1 year progression free survival (PFS). PET radiomic features were collected from pre-treatment PET/CT images features including SUV and intensity histogram (n = 37), shape (n = 4), gray level co-occurrence matrix (GLCM, n = 7), gray-level run-length matrix (GLRLM, n = 11), neighborhood gray-tone difference matrix (NGTDM, n = 5), gray-level size zone matrix (GLSZM, n = 11), normalized GLCM (n = 6), neighboring gray level dependence (NGLD, n = 5), texture feature coding (TFC, n = 4), TFC GLCM (n = 8) and texture spectrum (TS, n = 2). Random forest models were used to construct classification models for 1-year PFS. Discriminatory performance was measured by C-statistics. PET Radiomic models were compared to models using SUV statistics and total tumor volume.

### RESULTS

Of 152 oligometastatic NSCLC lesions, 105 were used for training and 47 as a blinded validation cohort. The random forest models using PET radiomic features showed strong prognostic ability for 1-year PFS (c-statistic 0.81, 95% CI 0.70-.92). PET radiomics showed stronger discriminatory ability compared to simple SUV statistics (c statistic 0.81 vs 0.62, $p = 0.043$) and total tumor volume (c statistic 0.81 vs 0.52, $p<.001$). PET Radiomic features of greatest importance included SUV Skewness, SUV bias-correct Skewness, and SUV mean sphericity.

### CONCLUSION

PET radiomic features appear to have prognostic ability in patients with oligometastatic NSCLC treated with SBRT. As PET directed therapy becomes increasingly used in treatment further studies are needed to leverage PET radiomic signatures to personalize treatments and optimize outcomes for patients with NSCLC.

## CLINICAL RELEVANCE/APPLICATION

This study provides evidence that PET imaging features have prognostic value. Moreover, our findings suggest PET imaging features can be used to tailor therapy for patients with oligometastatic non-small cell lung cancer.

## PURPOSE

Myxoid liposarcoma (mLPS) treatment response is typically assessed by tumor shrinkage using RECIST 1.1 imaging criteria. This study investigates the potential of MRI scans to monitor mLPS size changes before and after neoadjuvant radiotherapy (nRT) as a measure of treatment effectiveness.

## METHODS AND MATERIALS

Thirty patients with pathologically confirmed mLPS that received nRT with or without chemotherapy were selected in this IRB-approved study. Tumor size measurements, including two perpendicular axial diameters and the longest vertical diameter, were obtained from pre- and post-nRT MRI scans by four independent readers (three trained radiologists and one researcher). In addition to measurements, cross-sectional areas and tumor volume were calculated. Inter-reader agreement for all size measurements was evaluated using Kendall's concordance coefficient. Patients with =10% viable cells on post-treatment pathology were classified as responders (R), while those not meeting this criterion were classified as non-responders (NR). Changes in tumor size between responders and non-responders were compared using one-way ANOVA and Tukey's honestly significant difference (HSD) test for multiple comparisons of means.

## RESULTS

The study included 14 responders and 16 non-responders. Inter-reader agreement for all size measurements was high (Kendall's $W>0.8$, $p>0.00001$). Both responder and non-responder groups showed a decrease in tumor size after nRT. However, the difference in size reduction between the groups was weak or not statistically significant across all size measures except the tumor volume. For example, the percentage change in the longest diameter (RECIST criteria) was -15.1% for responders and -13.3% for non-responders, with a non-significant difference of -1.8% (95% CI: -8.9 to 5.4, $p = 0.62$). Only the change in tumor volume demonstrated a statistically significant difference. Responders experienced a larger decrease (-42.9%) compared to non-responders (-27.3%), with a difference of -15.6% (95% CI: -30.2 to -0.99, $p = 0.036$).

## CONCLUSION

mLPS tumors demonstrated a decrease in size after nRT, suggesting RECIST 1.1 remains a viable response criterion. However, RECIST diameter changes did not significantly differentiate responders from non-responders based on pathology. Only changes in tumor volume showed significant results, suggesting that volumetry might be a more sensitive measure of treatment effectiveness in mLPS after nRT.

## CLINICAL RELEVANCE/APPLICATION

This study suggests that traditional RECIST criteria may not be sufficient for assessing treatment response in mLPS. However, larger decreases in tumor volume might offer an earlier indication of treatment effectiveness.

# Abstract Archives of the RSNA, 2024

S2-STCE1

**Science Session (Theranostics)**

Sunday, Dec. 1 10:30AM - 11:00AM Room: LEARNING CENTER THEATER 1

**Sub-Events**

## S2-STCE1-1 APPLYING FAS-4-1BB IMMUNOMODULATORY FUSION PROTEIN (IFP)-ENGINEERED T-CELLS FOR TARGETED THERANOSTIC NANOMEDICINE USING COMPUTED TOMOGRAPHY-IMAGEABLE PARTICLES THAT RELEASE THE BISPECIFIC ANTIBODY IMC-KRAS$^{G12D}$WITH THE KRAS$^{G12D}$NEOANTIGEN, DIRECTED BY TWO RADIATION SESSIONS

Satoshi G. Harada, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Fas-4-1BB IFP-engineered CD3+ T cells were applied to theranostic nanomedicine for CD3+ bispecific antibodies associated with the KRASG12D neoantigen by two radiation sessions in Rag2-/- C57BL/6 mice with KP9093FasL+ sarcoma in the left foot pad with lung metastases. Computed tomography (CT)-imageable hyaluronate-alginate nanocapsules (HA-NCs, ? 564 nm) and liposome-protamine-hyaluronate nanoparticles (LPH-NPs, ? 43 nm) that released their contents upon radiation exposure were evaluated.

### METHODS AND MATERIALS

T cells were engineered to express Fas-4-1-BB IFP via retroviral transduction and transferred into mice. Sessions 1 and 2 were conducted 28 days after the transfer. In session 1, KRASG12D and IFN-? LPH-NPs were prepared using the self-assembly method and encapsulated into ?4ß1-antibody-labeled HA-NCs with P-selectin, using electrospray and Fe. Nine hours after the intravenous injection of 1 × 1010 HA-NCs, 10 or 20 Gy 60Co ?-rays were administered to the primary tumor and metastatic lesion. In session 2, the JD1a96b35 × anti-CD3 ScFv-bispecific antibody (IMC-KRASG12D), which has a high affinity for KRASG12D and CD3+T-cell) was encapsulated into P-selectin-antibody-labeled HA-NCs. HA-NCs were intravenously injected 24 h after the first irradiation. Subsequently, session 2 was performed 24 h after the injection in the same manner as session 1.

### RESULTS

Proliferation of transferred Fas-4-1BB IFP engineered CD3+ T cells in mice. In session 1, anti-?4ß1-Ab-HA-NCs were accumulated in the primary tumor and metastasis, which were imaged by CT. Upon the 1st radiation, the HA-NCs discharged IFN? and KRASG12D LPN-NPs continuously released IFN? and KRASG12D, respectively. The released IFN? induced HLA-A*11 and the released KRASG12D were captured by HLA-A*11, which formed an HLA-A* 11-KRASG12D complex. HA-NCs released P-selectins into the tumor vessels. In session 2, P-selectin Ab-labeled HA-NCs accumulated to P-selectin, and a second dose of radiation was administered. HA-NCs continuously released IMC-KRASG12D and formed an immunological synapse consisting of HLA-A* 11-KRASG12D, IMC-KRASG12D, and Fas-4-1BB IFP-engineered CD3+ T-cells, which converted FasL-mediated inhibitory/death signals into activating/survival signals in T cells and enhanced the release of perforin/granzymes to attack the primary tumor and metastasis. These phenomena in sessions 1 and 2 resulted in an EF of 1.7 and an 83 % reduction in metastasis, respectively.

### CONCLUSION

The combination of Fas-4-1BB IFP-engineered CD3+T-cells with thoranostic nanomedicine will lead to better diagnosis and new radiotherapies.

### CLINICAL RELEVANCE/APPLICATION

Our theranostic nanomedicine combined with Fas-4-1BB IFP-engineered CD3+ T cells led to improved diagnostic and therapeutic effects.

## S2-STCE1-3 REAL-TIME MONITORING OF INTRATHERAPEUTIC BODY FAT LOSS DURING RADIOLIGAND THERAPY WITH [177LU]LU-PSMA PREDICTS SURVIVAL IN PROSTATE CANCER PATIENTS

Markus Galler (*Abstract Co-Author*) Nothing to Disclose
Tristan Ruhwedel, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Patients with metastatic castration-resistant prostate cancer (mCRPC) respond differently to radioligand therapy (RLT). Therefore, prognostic factors to estimate overall survival (OS) are required. Body composition (BC) analysis is done to quantify the relative amounts of different body tissues as a

measure of physical fitness and tumor cachexia. We used BC to investigate whether relative changes in BC parameters between baseline imaging before the start of RLT and interim staging after two cycles of RLT can predict OS.

## METHODS AND MATERIALS

This is a single-center, retrospective analysis of 92 patients treated with a median of 3 cycles (range 2 - 8 cycles) of RLT with [177Lu]Lu-PSMA. Patients underwent baseline staging within 6 weeks before RLT and interim staging 6-8 weeks after the second RLT cycle. BC parameters were obtained from computed tomography (CT) at the L3 vertebral level using an AI-based, PACS-integrated software tool. Relative BC changes were determined as the percentage difference at interim staging from baseline. Cox regression was used to determine the prognostic impact on OS. All variables with a p-value below 0.1 in univariable Cox regression were included in multivariable regression in a stepwise fashion (likelihood ratio).

## RESULTS

During follow-up, 78 patients (85%) died. Median OS was 16.3 months; median follow-up in survivors was 25.6 months. In univariable Cox regression, 3 parameters representing relative changes in BC, previous treatment with Xofigo, previous chemotherapy of any type, lymph node metastases, liver metastases, baseline prostate-specific antigen (PSA) level, hemoglobin level, and De Ritis ratio were significant predictors of OS (each $p<0.05$). The relative change in body mass index (BMI) achieved a $p<0.1$. In multivariable regression, a higher relative decrease in the visceral adipose tissue (VAT) (HR: 0.26; $p = 0.006$), previous chemotherapy of any type (HR: 2.4; $p = 0.003$), the presence of hepatic metastasis (HR: 2.4; $p = 0.018$) and a higher baseline De Ritis ratio (HR: 1.4; $p < 0.001$) remained independent predictors of shorter OS. Patients with a higher decrease in VAT (?VAT < -20%) had a median OS of 10.2 months versus 18.5 months in patients with a lower VAT decrease or increase (?VAT = -20%) (logrank test: $p = 0.008$). In a separate Cox model, the change in VAT predicted OS ($p = 0.005$) independent of the best PSA response after 1-2 RLT cycles ($p = 0.09$), and there was no interaction between the two ($p=0.09$).

## CONCLUSION

Real-time, PACS-integrated, AI-based BC monitoring during therapy detects relative changes in the VAT, which emerged as an independent predictor of shorter OS in our population of patients undergoing RLT. Beyond traditional clinical markers like PSA response, understanding how body composition changes influence outcomes provides a more holistic approach to patient care. Interventions aimed at preserving muscle mass and managing nutritional status could potentially improve treatment tolerance and overall outcomes in these patients undergoing RLT.

## CLINICAL RELEVANCE/APPLICATION

In summary, the study's findings on body fat loss, particularly VAT reduction, during RLT highlight its clinical relevance by offering a novel prognostic indicator and potential target for optimizing patient management strategies in metastatic castration-resistant prostate cancer. The study opens avenues for further research into the mechanisms underlying VAT loss and its impact on treatment outcomes in prostate cancer and potentially other cancers treated with RLT.

Jacques Du Plessis, MBChB, FFRad(D)SA (*Presenter*) Nothing to Disclose

### PURPOSE

Strengthening environmental sustainability of radiology requires adaptation strategies to build resiliency and address adverse health effects of climate change. Climate change contributes to poor air quality and is associated with cardiovascular morbidity, but the underlying pathophysiological mechanisms are unclear. The purpose of this study was to evaluate the relationship between long-term exposure to ambient fine particulate matter (PM2.5) air pollution and myocardial fibrosis.

### METHODS AND MATERIALS

All adult patients with dilated cardiomyopathy undergoing cardiac MRI at 1.5T or 3T between 2018-2022 were included in this single-center retrospective cohort study. Left ventricular end-diastolic volume (LVEDV), ejection fraction (LVEF), native T1 z-score (marker of interstitial fibrosis), and T2 z-score (marker of edema) were evaluated. Long-term air pollution exposure was assessed as the mean of daily ambient PM2.5 levels over the one-year period prior to cardiac MRI based on direct measurements from the closest monitoring station to each patient's home postal code. Multivariable linear regression models were used to investigate the relationship between one-year mean PM2.5 exposure and individual cardiac MRI parameters, adjusting for age, sex, body surface area, field strength, ambient temperature, and cardiac risk factors (hypertension, hyperlipidemia, smoking status, and diabetes mellitus).

### RESULTS

493 patients were included (71% male, mean age 48±16 years) with mean LVEF 39±17%, indexed LVEDV 129±41 mL/m2, median native T1 z-score 1.4 [IQR 0.4, 2.5], median T2 z-score 0.2 [IQR -0.6, 0.9], and LGE in 65%. Median one-year mean daily PM2.5 concentration was 7.8 (IQR 7.4, 8.1) μg/m3. In a fully adjusted multivariable model, one-year mean ambient PM2.5 exposure was associated with 0.22 higher native T1 z-score per 1 μg/m3 increase PM2.5 (ß-coefficient 0.22, 95%CI, 0.07, 0.38, P=.004), corresponding to a native T1 increase of 7 ms at 1.5T and 8 ms at 3T. Long-term PM2.5 exposure explained 2.2% of the variance in native T1, but was not associated with LVEF (ß-coefficient -1.3, 95%CI, -2.8, 0.12, P=.07), indexed LVEDV (ß-coefficient 1.3, 95%CI, -2.4, 4.9, P=.49) or T2 z-score (ß-coefficient 0.04, 95%CI, -0.06, 0.14, P=.44) in multivariable models.

### CONCLUSION

Higher past exposure to fine particulate air pollution was associated with increased myocardial native T1, a marker of interstitial fibrosis, even at relatively low exposure levels meeting current air quality standards.

### CLINICAL RELEVANCE/APPLICATION

Chronic exposure to air pollution is a modifiable risk factor and public health measures are needed to reduce ambient levels. Medical imaging has an important role in identifying the deleterious effects and mechanisms of disease.

## S2-STCE2-2 DISPARITIES OF ACCESS TO MEDICAL IMAGING TECHNOLOGY ACROSS THE U.S. AS A FUNCTION OF SOCIAL VULNERABILITY

Ehsan Samei, PHD (*Abstract Co-Author*) Research Grant, General Electric Company;Advisory Board, General Electric Company;Research Grant, Siemens AG;Advisory Board, Siemens AG;Advisory Board, medInt Holdings, LLC;Advisory Board, Metis Health Analytics;Research Consultant, Nanox Imaging Ltd;Royalties, General Electric Company;Royalties, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Mirion Technologies, Inc;Royalties, Cambridge University Press;Royalties, John Wiley & Sons, Inc
David Crowley (*Abstract Co-Author*) Nothing to Disclose
Ehsan Abadi, PhD (*Abstract Co-Author*) Nothing to Disclose
Isabel Montero, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Equity of technological access and its impact on patient-centered care is an often-overlooked aspect of the clinical imaging landscape. This study investigates the relationship between the age of CT scanners across the United States and the Social Vulnerability Index (SVI). The aim is to identify metrics that may indicate disparities in access to medical imaging technologies.

**METHODS AND MATERIALS**

Data were extracted regarding the location and year of assembly of CT scanners across the U.S. from the Food and Drug Administration (FDA). SVI scores were sourced for each applicable U.S. County from the CDC-ATSDR (Center for Disease Control - Agency for Toxic Substances and Disease Registry) database. Statistical analysis methods such as linear regression explored associations between the SVI scores and CT scanner ages. Additionally, CT phantom image data were analyzed for image quality metrics such as noise magnitude and compared as a function of scanner technology age.

**RESULTS**

Approximately 40,000 CT scanners, aged 3-28 years, and corresponding SVI scores were analyzed. Significant associations found between the CT scanner age and SVI scores ($p < 0.05$), suggesting that a county's social conditions may impact CT technology access. Data shows positive correlation between the counties with higher percentiles of persons with disabilities (slope = 0.45 yr/SVI unit, 95% CI [0.3,0.6]), those 65 or older (slope = 0.35 yr/SVI unit, 95% CI [0.2,0.5]), or in extreme poverty (slope = 0.16 yr/SVI unit, 95% CI [0.1,0.3]), and the age of CT scanners. Conversely, negative correlation was found between the counties with higher percentiles of minority populations (slope = -0.41 yr/SVI unit, 95% CI [-0.5,-0.3]), crowding (slope = -0.26 yr/SVI unit, 95% CI [-0.4,-0.1]), or cost-burdened housing (slope = -0.30 yr/SVI unit, 95% CI [-0.4,-0.2]), and the age of CT scanners. Further, analysis of comparable phantom images from scanners developed 11 and 23 years ago demonstrated an 8.7 HU increase in noise magnitude in older models.

**CONCLUSION**

The study highlights disparities in medical imaging technology across the U.S. as it relates to social vulnerability, potentially exacerbating healthcare inequities for socially vulnerable populations. The findings provide a quantitative benchmark to target future improvements and depict, for the first time, the "cost" of such disparities in terms of patient safety and image quality.

**CLINICAL RELEVANCE/APPLICATION**

Identification of disparities in access to medical imaging technologies based on social vulnerability underscores the need for mitigating healthcare inequities to ensure equitable, patient-centered care across diverse populations. Addressing these disparities can enhance diagnostic accuracy and safety, particularly for vulnerable groups.

## S2-STCE2-3 IMPACT OF PATIENT VOLUME ON IODINATED CONTRAST MATERIAL WASTE WITH MULTIDOSE CONTRAST INJECTORS

Seyedeh Niloufar Rafiei Alavi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Multidose iodinated contrast media (ICM) injectors have shown promise in reducing waste. However, the effect of varying patient volumes on ICM waste in multidose injectors compared to common single-dose injectors has not yet been explored. This study aims to evaluate the impact of patient volume on ICM waste in multidose injectors.

**METHODS AND MATERIALS**

We included 12,290 contrast-enhanced CT studies with a multidose injector at our emergency CT unit. We recorded the ICM volume for each injection and calculated total annual ICM waste, accounting for the 500 mL containers' 8-hour usage limit in multidose injectors. We then calculated the ICM waste in the same patient cohort assuming single-dose vials were used instead. To assess the impact of patient volume, we categorized days into four subgroups based on daily patient counts: Group 1 (20-29 patients/day), Group 2 (30-39 patients/day), Group 3 (40-49 patients/day), and Group 4 (>50 patients/day), and compared the annual ICM waste for both injector types. Additionally, we simulated low patient volumes by randomly removing half of the dataset, creating two new subgroups: Group 5 (<10 patients/day) and Group 6 (10-19 patients/day). ICM waste per patient was calculated for both injector types in these two new groups and compared with the previous four subgroups.

**RESULTS**

In total, using multidose injectors reduced annual ICM waste by 86.1% compared to single-use injectors. Waste was zero for days with over 50 patients and minimal (253 mL) for days with 40-49 patients, indicating negligible waste for patient volumes above 40 per day. In contrast, waste was substantially higher in groups with 20-39 patients per day, with Group 1 generating 9,087 mL of waste. A significant negative correlation between patient volume and ICM waste was observed ($r = -0.365$, $p < 0.0001$). Mean ICM waste per patient was 2.5 times higher in Group 5 (<10 patients/day) and 71.4% higher in Group 6 (10-19 patients/day) with multidose injectors compared to single-dose injectors. Conversely, in groups with at least 20 patients per day, mean ICM waste per patient was lower with multidose injectors, with waste reduced by 100% in Groups 3 and 4, 88.9% in Group 2, and 53.9% in Group 1.

**CONCLUSION**

High patient throughput centers with over 40 patients per day can nearly eliminate ICM waste with multidose injectors. However, using multidose injectors in centers with lower patient volumes (<20 patients per day) may lead to increased ICM waste compared to single-dose injectors.

**CLINICAL RELEVANCE/APPLICATION**

Multidose iodinated contrast media (ICM) injectors significantly reduce contrast waste in high-volume centers. However, in facilities with lower patient volumes, ICM waste is less in single-dose injectors, underscoring the importance of aligning injector choice with patient volume to optimize resource utilization and minimize waste.

### PURPOSE

Spectral photon-counting CT (SPCCT) is an emerging technology that not only capitalizes on all the advantages of lung morphological CT imaging, but also offers a cutting-edge imaging method known as color K-edge imaging. This method allows a specific and quantitative identification of one or more atoms concomitantly within a tissue, enabling the simultaneous functional imaging of independent or interactive processes. However, it is still limited by its low sensitivity. Hence, we aim to compare sensitivity for various atoms-based contrast agents of Color K-edge imaging.

### METHODS AND MATERIALS

Eight agents based on gadolinium (Gd), holmium (Ho), ytterbium (Yb), hafnium (Hf), tantalum (Ta), tungsten (W), gold (Au) and bismuth (Bi) were prepared in 1.5 mL tubes of 12 increased concentrations (from 0 to 2 mg/mL). Tubes were inserted in an anthropomorphic thorax phantom (QRM GmbH), and scanned with a clinical prototype SPCCT (Philips, Israel). Parameters matched with a standard chest CT protocol using a radiation dose of 4 mGy (voltage fixed at 120 kVp), a voxel size of 0.7 mm3 and 5 axial scans. Energy thresholds were set at 51-72-30-62-81 for Gd,Yb and Au, at 51-68-30-62-81 for Hf and Ta, at 30-50-60-69-80 for W, at 30-56-60-69-80 for Ho and at 30-51-63-78-92 for Bi. Regions of interest were drawn to measure contrast-to-noise ratios (CNR) and quantification accuracy.

### RESULTS

Mean CNR in K-edge images were high for all elements and increased respectively with increased concentrations. CNR were significantly higher in K-edge images than in conventional CT images, with a slope of 26.3, 14.9, 14.0, 12.1, 9.4, 8.4, 7.6 and 7.2, respectively for Gd, Yb, Au, Ho, W, Bi, Ta and Hf. Mean relative error between prepared and measured concentrations across all elements was on average of 25%, with the best accuracy for Yb (± 10%) and lowest accuracy for Tantalum (± 75%) and Bismuth (± 50%). Altogether, these performances are highlighting a dependence of the contrast and the accuracy on the atomic number of the elements and the photon statistics of X-ray tube. This is explained by the ratio between photons and the K-edge energies of each atom.

### CONCLUSION

Color K-edge imaging is feasible with dedicated contrast agents while outperforming sensitivity in comparison to conventional CT images, opening to the development of lung functional imaging. However, there is room to adapt the X-ray tube voltage in order to provide greater performances for high-Z atoms.

### CLINICAL RELEVANCE/APPLICATION

Proving the feasibility of Color K-edge imaging with dedicated contrast agents paves the way for lung functional imaging.

## S4-SSCH02-2 COMBINATION OF SPECTRAL CT AND IMMUNE CELL PARAMETERS FOR PREDICTING EARLY RECURRENCE/PROGRESSION OF POSTOPERATIVE ADJUVANT CHEMOTHERAPY IN NON-SMALL CELL LUNG CANCER

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Liangna Deng, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the predictive value of spectral CT quantitative parameters for early recurrence/progression (ERP, =24 months) of postoperative adjuvant chemotherapy in non-small cell lung cancer (NSCLC), a diagnostic model was constructed and visualized as a nomogram to assist clinical preoperative treatment decisions.

**METHODS AND MATERIALS**

70 patients with NSCLC underwent spectral CT before surgery and were divided into two groups: ERP and non-ERP (NERP). Paraffin-embedded resected specimens were stained by immunofluorescence, and the density percentiles of CD8+ T cells, PD-L1 and PD-L1 CD8+ TIL co-expression were quantified. Clinical baseline characteristics, imaging features and spectral CT parameters were collected. ?2 test, t-test, U test and Kruskal-Wallis test were used for calculated differences between groups. Then, multivariate logistic regression was used to select the most discriminating features, build a predictive model and visualize the model as a nomogram. ROC curves, calibration curves and decision curves analysis (DCA) were used to evaluate prediction performance and clinical utility.

**RESULTS**

The CD8+ TIL and PD-L1 CD8+ TIL co-expression was statistically different between ERP and non-ERP groups ($P < 0.05$). CD8 and PD-L1 CD8+ TIL co-expression were negatively correlated with iodine concentration (IC) and normalized iodine concentration (NIC) in dual phase, PD-L1 was negatively correlated with IC in dual phase and NIC in venous phase, and PD-L1 and PD-L1 CD8+ TIL co-expression were positively correlated with NIC (A/V) (all $P < 0.05$). 31 patients with ERP and 39 patients with NERP in NSCLC receiving postoperative adjuvant chemotherapy. IC and NIC in venous phase, and IC (A/V) differed between the ERP and NERP groups ($P < 0.05$). Multivariable analysis revealed that PD-L1 CD8+ TIL co-expression and IC (A/V) were independently associated with ERP, and were used to construct a nomogram. The AUC of combined model were 0.82 (95%CI: 0.72~0.91). The sensitivity and specificity were 0.97 and 0.64, respectively.

**CONCLUSION**

Spectral CT parameters provided a promising way to predict the immune cell of NSCLC and to infer clinical outcomes for patients who had been treated with postoperative adjuvant chemotherapy. The nomogram is helpful to predict ERP for patients who are candidates for postoperative adjuvant chemotherapy.

**CLINICAL RELEVANCE/APPLICATION**

The nomogram is helpful to predict ERP for patients who are candidates for postoperative adjuvant chemotherapy, which can assist in clinical preoperative decision-making and patient risk stratification.

## S4-SSCH02-4 EXPLORING THE DIAGNOSTIC VALUE OF VIRTUAL CALCIUM IMAGING FROM LOW-DOSE CHEST CT USING PHOTON-COUNTING DETECTOR CT FOR UPPER LUMBAR VERTEBRAL OSTEOPOROSIS

QING ZHANG (*Abstract Co-Author*) Nothing to Disclose
Dong Sheng Jin (*Abstract Co-Author*) Nothing to Disclose
Ji Liang Chen (*Abstract Co-Author*) Nothing to Disclose
Bei Chen (*Abstract Co-Author*) Nothing to Disclose
Song Luo (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the feasibility and accuracy of virtual calcium imaging (VCI) from low-dose chest CT(LDCT)with photon-counting detector CT (PCD-CT) for diagnosing upper lumbar vertebral osteoporosis (OP).

**METHODS AND MATERIALS**

A prospective collection of patients who underwent both low-dose chest CT with photon-counting CT and dual-energy X-ray absorptiometry (DXA) examinations from January to April 2024 was conducted. LDCT scan range covered the thoracic inlet to L2. VCI was generated by adjusting the dual-energy liverVNC parameters to the ratio of calcium (1.55@120kV). Two readers independently measured virtual calcium CT values (CM), calcium density values (CaD), virtual monoenergetic 70keV CT values (ME70), virtual non-contrast (VNC) and fat percentage (Fat), and at three levels in the mid-coronal plane of the lumbar vertebrae. Intra-class correlation coefficient (ICC) assessed inter-reader agreement. Spearman correlation coefficients evaluated the correlation between PCD-CT measurements and DXA-derived BMD and T-scores. Receiver operating characteristic (ROC) curves analyzed the diagnostic performance of VCI parameters for OP.

**RESULTS**

Exclusions were based on specific criteria, 63 patients participated, with 26 males (average age: 73±9 years). The mean CTDIvol was 1.01 mGy, and the mean DLP was 38.15 mGy·cm, the mean of effective dose (ED) was 0.53mSv. High inter-reader agreement was observed (ICC:0.91-0.95). The medians and percentiles of CM, CaD, and ME70 were 143.20 (121.78, 176.79), 5.00 (4.35, 6.29), and 124.83 (92.46, 150.46), respectively. CM, CaD, and ME70 values significantly correlated with BMD ($r=0.704$, 0.719, 0.667, respectively; all $p<0.01$) and T-scores ($r=0.751$, 0.836, 0.719, respectively; all $p<0.01$). For CM=133.13HU, CaD=4.93mg/cm³, and ME70=109.4HU, the areas under the curve were 0.872, 0.844, and 0.841, with sensitivities of 83.87%, 100%, 83.87%, and specificities of 79.49%, 67.86%, 76.92%, respectively.

**CONCLUSION**

VCI from low-dose chest PCD-CT accurately assesses upper lumbar vertebral bone density, offering a potential additional screening tool for osteoporosis during routine lung disease screening.

**CLINICAL RELEVANCE/APPLICATION**

This study demonstrates the feasibility and promising diagnostic accuracy of VCI using low-dose chest PCD-CT for osteoporosis assessment, potentially offering a valuable tool for early osteoporosis detection and intervention.

## S4-SSCH02-5 SPECTRAL CT FOR PRECISE NEEDLE BIOPSY PLANNING IN LUNG CANCER WITH OBSTRUCTIVE LESION

Yaqiong Ma (*Abstract Co-Author*) Nothing to Disclose
Xiaoyue Zhang (*Abstract Co-Author*) Nothing to Disclose
Yongkun Zheng (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to utilize spectral parameters derived from dual-layer spectral detector computed tomography (SDCT) to precisely identify regions for lung cancer biopsy in cases with obstructive lesions. It ensured that the most effective tissue samples can be obtained for biomarker testing.

**METHODS AND MATERIALS**

This prospective study enrolled 40 patients with suspected lung cancer with obstructive lesions who decided to undergo lung biopsy and then another 15 patients were recruited to verify the accuracy of main body tumor. Initially, each patient underwent contrast-enhanced spectral chest CT. Subsequently, the suspected lung cancer tissue and suspected obstructive lesion area were delineated before biopsy according to spectral CT multi-parameter images. Then two biopsies were performed respectively. The samples of different areas were fixed in different bottles for hematoxylin-eosin staining and immune histochemical detection. Pathologists, blinded to the study, evaluated and recorded the percentages of tumor cells in the biopsy samples. Samples were categorized into main body tumor (= 20% tumor cells) and obstructive lesion (< 20% tumor cells) groups. The performance of spectral parameters in distinguishing between tumors and surrounding obstructive lesion areas were analyzed. The cutoff value of optimal spectral parameter was used to prospectively guide the biopsy of the tumors in 15 cases for further validation, and then the accuracy was calculated.

**RESULTS**

Spectral parameters demonstrated superior performance over conventional CT in identifying tumors (all $p < 0.05$). Specifically, iodine density in the arterial phase, with a cutoff value of 1.44 mg/mL, exhibited good performance (specificity: 93.70%) in identifying tumors. It was applied to 15 cases for validation, and the accuracy rate was 100 %.

**CONCLUSION**

Spectral parameters are effective in distinguishing between lung cancer tumors and surrounding obstructive lesions, so as to ensure the acquisition of optimal tissue specimens for biomarker detection.

**CLINICAL RELEVANCE/APPLICATION**

The findings suggest that spectral parameters are helpful to identify between lung cancer and its surrounding obstructive lesions, and have potential clinical application value in the preoperative planning of lung cancer needle biopsy complicated with obstructive lesions.

## S4-SSCH02-6 EXPLORATION OF THE DIAGNOSTIC VALUE OF ENERGY SPECTRAL CT TECHNOLOGY BASED ON IRON EXTRACTION IN THE IMAGING DIAGNOSIS OF ARC-WELDERS' PNEUMOCONIOSIS

Li Xin Lu (*Abstract Co-Author*) Nothing to Disclose
Yuan Ou (*Abstract Co-Author*) Nothing to Disclose
Min Xue Wang (*Abstract Co-Author*) Nothing to Disclose
Weiling Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of iron extraction by spectral CT in the imaging diagnosis of arc-welders' pneumoconiosis (AWP).

**METHODS AND MATERIALS**

This study prospectively recruited 57 subjects and divided into three groups: Group A (n=24, healthy people with no history of dust-related occupational history), Group B (n=21, welder's occupational history of more than 5 years), Group C (n=12, no welder's occupational history, chest CT showed similar imaging findings of AWP: diffuse centrilobular ground-glass nodules in both lungs).Chest energy spectrum CT scans in all three groups and the whole lung extraction was performed by thresholdeffect, and lung_volume and 70kev_CT values were measured at the same time.The mean values of Fe2O3 (Water), Water (Fe2O3) and Z Effective were obtained by substrate material separation technology. The receiver operating characteristic (ROC) curve of the subjects determined the optimal cut-off value of the corresponding AWP index, and judged its sensitivity and specificity.

**RESULTS**

The mean value of Fe2O3 in Group B was significantly higher than that in the other two groups, and there was a statistical difference ($P<0.05$). There were no statistically significant differences($P>0.05$) in the mean of Water, Z Effective, 70kev_CT values and lung_volume among the groups. The results of pairwise comparison between groups showed that there were statistically significant differences in the mean values of Fe2O3 between Group A and Group B, Group B and Group C ($P<0.05$), and there was no significant difference in the mean values of Fe2O3 between Group A and Group C ($P=1.000$). The area under the curve (AUC) of the mean Fe2O3 between Group B and Group C was 0.815, the associated criterion was 0.777, the sensitivity was 57.14%, and the specificity was 91.67%. The AUC value of Fe2O3 between Group A and Group B was 0.893, the associated criterion was 0.664, the sensitivity was 76.19%, and the specificity was 100.00%.

**CONCLUSION**

The mean value of Fe2O3 in the whole lung of the welder's occupational population was significantly higher than the non-occupational population, and it was highly specific, which had certain diagnostic value for AWP.

**CLINICAL RELEVANCE/APPLICATION**

The diagnosis of AWP must rely on the comprehensive diagnosis of clinical-imaging-pathology, among which the imaging diagnosis mainly depends on the CT features, and it is difficult to distinguish under similar imaging findings . The high specificity of the mean Fe2O3 in the whole lung of energy spectrum CT can play a certain role in the differential diagnosis of diseases.

### PURPOSE

This study explores the potential of GPT-4 a large language model (LLM), with its Advanced Data Analytics (ADA) capability, to autonomously develop machine learning (ML) models for classifying glioma types based on radiomic features extracted from preoperative MRI scans.

### METHODS AND MATERIALS

MRI data from n=615 newly diagnosed glioma patients were classified by IDH and 1p/19q status for multiclass classification and split into an 80/20 training/testing ratio. Radiomic features were extracted from these scans. External validation used glioma datasets from UCSF (n=410) and TCGA (n=160). We utilized ADA within GPT-4 to develop modeling strategies autonomously, construct an ML model, and benchmark performance against an established hand-crafted model. The effectiveness of these models was evaluated using various normalization methods (N4, Z-score, WhiteStripe) to compare the accuracy and consistency of GPT-4's outcomes with established benchmarks.

### RESULTS

The highest accuracy of 0.820 (95% CI=0.819-0.821) was achieved by a GPT-4 model in the UCSF dataset with N4/WS normalization, significantly outperforming the benchmark model's accuracy of 0.678 (95% CI=0.677-0.680) ($p<0.001$). A class-wise analysis revealed performance variations between different glioma types. In the IDH-wt group, the GPT-4 model achieved a high recall of 0.997 (95% CI=0.997-0.997), substantially surpassing the benchmark model's recall of 0.742 (95% CI=0.740-0.743). For the IDH-mut 1p/19q-non-codel group, the GPT-4 model had a recall of 0.275 (95% CI=0.272-0.279), which was lower than the benchmark's recall of 0.426 (95% CI=0.423-0.430). In the IDH-mut 1p/19q-codel group, the GPT-4's recall was 0.199 (95% CI=0.191-0.206), below the benchmark's recall of 0.730 (95% CI=0.721-0.738). In contrast to the UCSF dataset, the accuracy of GPT-4 on the TCGA dataset was significantly lower ($p<0.001$) than the benchmark model's accuracy, e.g. with N4/WS normalization GPT-4 achieved an accuracy of 0. 0.668 (95% CI=0.666-0.671) as compared to 0.719 (95% CI=0.717-0.722) for the benchmark model ($p<0.001$) with class-wise analysis revealing the same pattern as observed in UCSF.

### CONCLUSION

GPT-4 can develop radiomics-based ML models comparable to handcrafted ones without an expert data scientist, but its poorer class-wise performance due to unbalanced datasets shows limitations in handling complete end-to-end ML pipelines.

### CLINICAL RELEVANCE/APPLICATION

This study shows that LLM like GPT-4 can develop radiomics-based ML models with performance comparable to handcrafted benchmarks, thus bridging the gap between ML developers and clinicians. However, GPT-4 models still require human fine-tuning to optimize their effectiveness in real-world settings.

## S4-SSIN01-2 PROSTATE CANCER AND RADIOMICS FOR AGGRESSIVENESS CLASSIFICATION - INFLUENCE OF SEGMENTATION MASK, MRI SEQUENCE, AND MRI VENDOR

Ana Carolina Rodrigues, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

In recent years, interest has grown in employing artificial intelligence and radiomics for stratifying the aggressiveness of prostate cancer using magnetic resonance imaging. However, methodological guidelines are unclear: whether AI models should be trained on multi- or single-vendor data, individual or all bpMRI sequences, or if radiomic features should be calculated on the index lesion or entire gland. The latter approach is less common in the literature, despite the multifocal nature of prostate cancer.

**METHODS AND MATERIALS**

The ProstateNet dataset (5649 patients from 13 institutions, 9 countries and 3 MRI vendors), was employed to develop bpMRI radiomics models to assess Prostate Cancer aggressiveness (N=4983 for training, N=200 for testing, N=466 for prospective validation). Three definitions of aggressiveness were considered: (A) ISUP=1 vs ISUPgt;1, (B) ISUP=2 vs ISUPgt;2, and (C) ISUP=3 vs ISUPgt;3. Radiomic features were extracted from automatically segmented lesions and whole glands. Machine learning models were trained on various combinations: all or specific vendors (Siemens, Philips, GE), all or individual bpMRI sequences (T2, DWI, ADC), and with/without clinical variables (PSA, age, PI-RADS, index lesion location). The chosen models were validated prospectively and assessed for explainability and fairness in different subgroups (age, MRI vendor, endorectal coil).

**RESULTS**

In all target definitions, whole gland radiomics outperformed lesion radiomics, which were less prone to generalize prospectively. Models utilizing all bpMRI sequences yielded better results than those trained on individual sequences for definitions (A) and (C). However, DWI-based models exhibited the best performance for definition (B), albeit with reduced prospective generalization. In general, models developed using heterogeneous data (encompassing all vendors) surpassed vendor-specific models. Models relying solely on radiomic features produced the best results for definitions (A) and (C), whereas the incorporation of clinical variables led to the best outcomes for definition (B). Fairness assessments revealed comparable sensitivities among vendors, but consistently higher specificities for Philips. Specificity declined with age, and performance deteriorated for studies employing endorectal coils.

**CONCLUSION**

Large heterogeneous datasets are essential for prospective generalization. Whole-gland radiomics has higher predictive power and results in less overfitting than lesion-radiomics.

**CLINICAL RELEVANCE/APPLICATION**

It is uncommon to find studies with large datasets, prospective validation, and assessing the model performance on data subgroups. These are essential to a positive clinical translation of AI models.

## S4-SSIN01-3 A NOMOGRAM COMBINING CLINICAL INFORMATION, IMAGING FEATURES AND DECT IODINE MAP-BASED RADIOMICS FROM MULTI-REGIONS FOR PREOPERATIVE PREDICTION OF AXILLARY LYMPH NODE METASTASIS

Lin Lin, MBBS (*Abstract Co-Author*) Nothing to Disclose
Suping Chen (*Abstract Co-Author*) Nothing to Disclose
Fang Zeng, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the value of an integrated nomogram using clinical parameters, CT and ultrasonography (US) features of axillary lymph node (ALN), dual-energy CT based iodine map radiomics extracted from multi-regions to preoperatively predict ALN metastasis (ALNM) in clinical T1/2 stage breast cancers.

**METHODS AND MATERIALS**

This study enrolled 197 patients with breast cancer who underwent preoperative contrast-enhanced DECT from March 2021 to May 2022. The patients were randomly divided into training (n=139) and testing cohorts (n=58). Radiomics features were extracted from iodine map in the venous phase from three regions of interest (ROIs): ALN, tumoral region and peritumoral region (2.5 mm around the tumor). Clinical information, CT and US parameters were recorded and evaluated. Eight models were built: 1) A clinical model; 2) CT ALN features-based model; 3) US ALN features-based model; 4) tumor-based iodine-mapping radiomic model; 5) peritumor-based iodine-mapping radiomic model; 6) ALN-based iodine-mapping radiomic model; 7) combined radiomics model integrating 4) and 6); 8) integrative nomogram combing 1), 2), 3) and 7). Their ALNM prediction performances and clinical usefulness were assessed and compared.

**RESULTS**

The radiomic signatures using the features of ALN, tumor, peritumoral and muti-ROIs showed good or moderate abilities in predicting ALNM with AUC of 0.860, 0.709, 0.747 and 0.890 in the training cohort, and 0.860, 0.676, 0.663, and 0.890 in the test cohort, respectively. An integrated nomogram with clinical parameters, ALN features from CT and US, and radiomic features increased the discriminatory ability with AUC of 0.923 in the training cohort and 0.914 in the test cohort. The nomogram also showed good calibration and clinical usefulness.

**CONCLUSION**

A nomogram combining clinical information, DECT- and US- reported ALN features, and iodine map-derived radiomic features from both primary breast tumor and ALNs can be used to improve the preoperative prediction of ALN status non-invasively.

**CLINICAL RELEVANCE/APPLICATION**

The nomogram model can be used to preoperatively predict ALN status non-invasively, and could be a powerful and individualized tool to assist clinicians in personalized therapeutic regimen selections for patients with early-stage breast cancers.

## UTILIZING AI TO PREDICT OSTEOPOROSIS AND OSTEOPENIA: A FUSION OF DEEP TRANSFER LEARNING AND CLASSICAL RADIOMICS FROM SINGLE-SOURCE DUAL-ENERGY CT IMAGING

### PURPOSE

To develop and validate a predictive model for osteoporosis and osteopenia prediction by fusing deep transfer learning (DTL) features and classical radiomics features based on single-source dual-energy computed tomography (CT) virtual monochromatic imaging.

### METHODS AND MATERIALS

A total of 606 lumbar vertebrae with dual-energy CT imaging and quantitative computed tomography (QCT) evaluation were included in the retrospective study and randomly divided into the training (n=424) and validation (n=182) cohorts. Radiomics features and DTL features were extracted from 70-keV monochromatic CT images, followed by feature selection and model construction, radiomics and DTL features models were established. Then, we integrated the selected two types of features into a features fusion model. We developed a two-level classifier for the hierarchical pairwise classification of each vertebra. All the vertebrae were first classified into osteoporosis and non-osteoporosis groups, then non-osteoporosis group was classified into osteopenia and normal groups. QCT was used as reference. The predictive performance and clinical usefulness of three models were evaluated and compared.

### RESULTS

The area under the curve (AUC) of the features fusion, radiomics and DTL models for the classification between osteoporosis and non-osteoporosis were 0.981, 0.999, 0.997 in the training cohort and 0.979, 0.943, 0.848 in the validation cohort. Furthermore, the AUCs of the abovementioned models for the differentiation between osteopenia and normal were 0.994, 0.971, 0.996 in the training cohort and 0.990, 0.968, 0.908 in the validation cohort. The overall accuracy of the abovementioned models for two-level classifications was 0.979, 0.955, 0.908 in the training cohort and 0.918, 0.885, 0.841 in the validation cohort. Decision curve analysis (DCA) showed that all models had high clinical value.

### CONCLUSION

The feature fusion model can be used for osteoporosis and osteopenia prediction with improved predictive ability over a radiomics model or a DTL model alone.

### CLINICAL RELEVANCE/APPLICATION

With the aging population of society, osteoporosis and osteoporosis-related fractures are leading causes of morbidity and mortality in the elderly. Our approach combines radiomics features with deep transfer learning features based on virtual monochromatic spectral images generated from single-source dual-energy CT, and uses QCT as a reference standard to perform two-level osteoporosis and osteopenia prediction, shedding lights onto a class of bone mineral density (BMD)-related diagnosis methods without the need for QCT or a dedicated phantom.

## S4-SSIN01-5 PREOPERATIVE PREDICTION OF ADHERENT PERINEPHRIC FAT USING CT RADIOMICS COMBINED WITH DEEP LEARNING:A PROSPECTIVE, MULTICENTER STUDY

Xu Li (*Abstract Co-Author*) Nothing to Disclose
Hongcheng Liu (*Abstract Co-Author*) Nothing to Disclose

Mingyang Li (*Abstract Co-Author*) Nothing to Disclose
Xiaobo Ding, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Developing and validating CT radiomics features to preoperatively identify APF, indirectly estimating the surgical complexity of renal tumor patients, and validating the performance of the model in an independent cohort.

### METHODS AND MATERIALS

Renal tumor patients who underwent surgical treatment in a domestic medical institution from December 2020 to May 2023 were retrospectively collected, and randomly divided into cross-validation set and internal test set in a ratio of 7:3. Kidney tumor patients who underwent surgical treatment in three other domestic medical institutions from June to September 2023 were prospectively collected as an external test set. Perirenal 5mm fat was covered by deep learning-based automated kidney segmentation and manual delineation of the 3D-Unet on each part of noncontrast-enhanced CT images. Features are reduced and selected using ANOVA and minimum absolute value convergence and selection operator algorithm. Subsequently, radiomics, clinical and fusion models were established using Logistic regression. Finally, the intra-and inter-observer reproducibility of renal segmentation was measured by the Dice similarity coefficient. The diagnostic efficiency of the model was assessed by the receiver operating characteristic curve and the area under the curve.

### RESULTS

A total of 460 patients with renal tumors (mean [SD] age, 60.1 [8.7] years) were included and analyzed. Both the intra-and interobserver dice similarity coefficient were greater than 0.80. Twenty-eight imaging omic features and three clinical features were selected for modeling. In the training, validation, cross-validation, internal test, and external test sets, radiomics models showed high efficacy in distinguishing adherent and non-adherent renal fat, with area under the curve (AUC) of 0.95 (95% CI,0.94-0.97), 0.91 (95% CI,0.87-0.94), 0.951 (95% CI,0.925-0.977), 0.867 (95% CI,0.798-0.935), and 0.802 (95% CI,0.672-0.933), respectively.

### CONCLUSION

The radiomics model constructed based on perinephric fat radiomics features derived from CT showed high diagnostic efficacy for discrimination of adherent perinephric fat from non-adherent perinephric fat.

### CLINICAL RELEVANCE/APPLICATION

The status of perinephric fat significantly impacts the complexity of renal tumor surgery. Currently, clinical practice heavily relies on subjective high-image scoring for estimation, which has limited accuracy and repeatability in assessment. There is a lack of objective methods to assess the presence of adherent perinephric fat (APF) preoperatively.

## S4-SSMK01-2 MRI EVALUATION OF PACINIAN CORPUSCLE NUMBER AND DISTRIBUTION IN THE FOREFOOT IN DIABETIC SENSORIMOTOR POLYNEUROPATHY

Michele Hubli (*Abstract Co-Author*) Nothing to Disclose
Reto Sutter, MD (*Abstract Co-Author*) Nothing to Disclose
Adrian Marth, MD (*Abstract Co-Author*) Nothing to Disclose
Georg Feuerriegel, MD (*Abstract Co-Author*) Nothing to Disclose
Felix Waibel (*Abstract Co-Author*) Nothing to Disclose
Sophia Goller, MD, MBA (*Presenter*) Nothing to Disclose

### PURPOSE

Pacinian corpuscles (PC) can be visualized with MRI. However, pathologic changes of these cutaneous mechanoreceptors in diabetic sensorimotor polyneuropathy (DSP) remain to be explored. The purpose of this study was to evaluate PC number, size, and distribution in the feet of type 2 diabetes mellitus (DM)-derived DSP compared to healthy volunteers with MRI.

### METHODS AND MATERIALS

This was a combined retro- and prospective single-center study on 16 DSP patients (mean age 67.4 ± 9.9 years, 11 males) who underwent clinical routine forefoot MRI and on 16 gender- and age-matched healthy subjects who underwent a 3T MRI forefoot examination. Two radiologists rated MR examinations concerning PC number and distribution. Correlations between PC number and duration of DM, as well as HbA1c values, were assessed.

### RESULTS

Quantitative analysis revealed the highest number of PC at the plantar side of the metatarsophalangeal (MTP) joints and proximal phalanges in both DSP patients and healthy subjects. In DSP patients, the total number of PC on the forefoot was significantly reduced compared to healthy subjects (85.8 ± 42.5 vs. 267.4 ± 48.7, P<.001), which was also true for each individual digit ray. In DSP patients, the maximum diameter of PC was 3 mm (1-3 mm), while that of healthy subjects was 5 mm (1-5 mm). In contrast to the typically “chain-like” configured PC in healthy subjects, their arrangement in DSP patients was heterogeneous and showed a more isolated PC pattern. In the DSP cohort, the mean duration of DM was 234.8 ± 130.4 months, while the mean HbA1c was 7.6 ± 1.1 %. There was no significant correlation between the number of PC and DM duration and HbA1c values, respectively.

### CONCLUSION

Compared to healthy subjects, DSP patients had significantly reduced numbers of PC in the forefoot, which were smaller in maximum size and showed a disturbed arrangement with a lack of the "chain-like" configuration typically seen in healthy subjects.

### CLINICAL RELEVANCE/APPLICATION

These results might open up the possibility of using MRI as a non-invasive diagnostic tool for assessing patients with DSP.

## S4-SSMK01-3 OPPORTUNISTIC CT-DERIVED ASSESSMENT OF FATTY MUSCLE FRACTION PREDICTS OUTCOME IN PATIENTS UNDERGOING MITRACLIP

Ulrike I. Attenberger, MD (*Abstract Co-Author*) Consultant, Bayer AG
Daniel Kuetting, MD (*Abstract Co-Author*) Nothing to Disclose

Leon Bischoff, MD (*Abstract Co-Author*) Nothing to Disclose
Babak Salam, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Sarcopenia is strongly interrelated with frailty, which is considered a major risk factor for poor outcomes in patients undergoing MitraClip. This study aimed to investigate the prognostic value of fatty muscle fraction (FMF), measured from routine preinterventional CT, as an objective surrogate for frailty

in patients undergoing MitraClip for treatment of recurrent mitral regurgitation.

**METHODS AND MATERIALS**

Consecutive patients undergoing MitraClip between February 2011 and November 2022 at the Heart Center Bonn were retrospectively evaluated. Based on pre-interventional CT scans, skeletal muscle area at the L3/L4 level was determined using densitometric threshold values. Subsequently, skeletal muscle area was subdivided into regions of fatty and lean muscle, and FMF was calculated.

**RESULTS**

A total of 196 patients (mean age: 78.3±8.0 years, mean EuroSCORE II: 5.1±3.8%) were investigated. 1-year survivors had a significantly lower FMF compared to non-survivors (49.5±13.5% vs. 58.9±14.2%, P<0.001). According to their FMF values, patients were divided into tertiles and were defined to have low (<44.42 %), medium (44.42-56.69 %), and high FMF (>56.69%), respectively. Following MitraClip, high FMF was related to increased 30-day (1.5% vs. 6.1% vs. 15.4%, P=0.010), 1-year (6.7% vs. 19.7% vs. 29.2%, P=0.007), 2-year (12.3% vs. 22.7% vs. 35.4%; P=0.008), and 3-year mortality (13.8% vs. 22.7% vs. 36.9%; P=0.008). On multivariate Cox regression analysis, FMF (Hazard Ratio 1.05 [95% Confidence Interval: 1.02-1.08]; P<0.001), as well as age (HR 0.93 [95% CI: 0.89-0.98]; P=0.004) and male sex (HR 3.10 [95% CI: 1.28-7.51]; P=0.012) were identified as independent predictors of 1-year mortality.

**CONCLUSION**

Our results indicate CT-derived FMF as a potentially new frailty marker, which provides additional information for risk stratification in MitraClip patients. Future studies should explore the clinical value of FMF compared with other frailty markers and the prognostic role of FMF for other cardiovascular and oncologic diseases.

**CLINICAL RELEVANCE/APPLICATION**

FMF from preinterventional CT emerges as a novel frailty marker, aiding risk assessment in MitraClip patients, thus enhancing prognostic insights for better clinical management of recurrent mitral regurgitation.

## S4-SSMK01-4 TRAJECTORIES OF ABDOMINAL CT MEASUREMENTS OF BODY COMPOSITION AND ASSOCIATION WITH POST-KIDNEY TRANSPLANTATION OUTCOMES

Clifford R. Weiss, MD (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Siemens AG;Research Grant, Boston Scientific Corporation;Consultant, Boston Scientific Corporation;Research Grant, Medtronic plc;Consultant, Medtronic plc;Research Grant, Guerbet SA;Consultant, Guerbet SA
Dorry Segev, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Omid Shafaat, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Early post-kidney transplantation (KT) changes likely impact body composition and susceptibility to aging. With CT as a more comprehensive measurement for body composition compared with BMI, the goal of this study was to estimate the post-KT trajectories of CT-based body composition and quantify associated risks of mortality and death-censored graft loss (DCGL).

**METHODS AND MATERIALS**

We leveraged a prospective cohort of adult KT recipients (n=301) from 12/2008 to 2/2020 who underwent abdominal CT scans during 1-year pre-KT to KT admission. Body composition measurements were obtained including skeletal muscle index (SMI) for muscle quantity and skeletal muscle radiation attenuation (SM-RA) for muscle quality using OsiriX software by manual segmentation; lower values of SMI and SM-RA indicate worse muscle quantity and quality. We used mixed linear regression models to estimate the post-KT trajectories of SMI and SM-RA, as well as Cox proportional hazards models to quantify the association between time-varying CT-based body composition measures and post-KT mortality and DCGL, respectively.

**RESULTS**

The mean SMI at KT was 47.9 cm2/m2 (SD=10.4) and mean SM-RA at KT was 31.8 Hounsfield units (HU) (SD=8.1). After KT, muscle quantity (SMI:-1.5 cm2/m2/year) and quality (SM-RA:-1.1 HU/year) decreased over time. Overall, lower muscle quantity (SMI) was not associated with the risks of post-KT outcomes. However, the association was modified by frailty (p-interaction=0.044) and age (p-interaction=0.016). Among frail KT recipients, lower muscle quantity (SMI) was associated with increased risk of mortality (aHR: 1.07, 95%CI=1.01-1.14, per 1 unit), while there was no association among non-frail recipients. In KT recipients =65 years, lower muscle quantity (SMI) was associated with elevated risk of DCGL (aHR: 1.10, 95%CI=1.00-1.22, per 1 unit), while there was no association among those <65 years. After adjustment, lower muscle quality (SM-RA) was associated with elevated risks of mortality (aHR: 1.08, 95%CI=1.05-1.1,2 per 1 unit) and DCGL (aHR: 1.07, 95%CI=1.02-1.12, per 1 unit). The association of muscle quality (SM-RA) did not differ by other factors.

**CONCLUSION**

Muscle quality is stronger as a risk factor for KT outcomes than muscle quantity. With the development of artificial intelligence, pre-existing CT measurements may be a convenient and valuable tool for risk stratification among KT recipients, particularly in older and frail recipients.

**CLINICAL RELEVANCE/APPLICATION**

Tracking muscle quality and quantity post-kidney transplant is crucial for predicting patient outcomes. CT-based metrics can identify high-risk individuals, allowing for targeted interventions that improve long-term survival and graft success in transplant recipients.

## S4-SSMK01-5 CORRELATION BETWEEN SKELETAL MUSCLE AND FATTY DEGREE OF L3 VERTEBRAL BODY AND BONE MINERAL DENSITYIN PATIENTS WITH CHRONIC KIDNEY DISEASE BASED ON ENERGY SPECTRUM CT

Hua He, MMedSc (*Presenter*) Nothing to Disclose

**PURPOSE**

The risk of osteoporosis in patients with chronic kidney disease (CKD) with sarcopenia is significantly higher than that in normal people. Therefore, this study is based on energy spectrum CT to explore the correlation between skeletal muscle and fatty degree of L3 vertebral body and bone mineral density (BMD) in patients with chronic kidney disease.

**METHODS AND MATERIALS**

GSI scanning mode combined with 40% ASiR-V, automatic modulated tube current (Smart mAs) were used in 42 patients with CKD. ?Using GSI Viewer software, the images of HAP (FAT)-based material pairs were reconstructed from 0.625mm thick images, and the Region of interest (ROI) was placed in the middle layer of L3 vertebral body. The HAP concentration in L3 vertebral body was recorded, and divided into osteoporosis group and non-

osteoporosis group with the boundary value of 116.16 mg/cm3. ?Using "X Section" software, the edges of skeletal muscle and adipose tissue were manually delineated on the cross-sectional images of the transverse process of L3 vertebral body. The CT values of skeletal muscle and adipose tissue were set in the ranges of-29 ~ 150HU and-190 ~-30HU. The software automatically calculated the area and average CT values of the corresponding tissues in the delineated ranges. Record the skeletal muscle area of L3 Vertebral Plane (L3 SMA), fat area of skeletal muscle space, and calculated the skeletal muscle index (L3SMI=L3 SMA/[height (m)] 2. Independent sample T test was used to compare L3SMI and intermuscular fat between the two groups. Pearson correlation analysis was used to compare the correlation between L3SMI, intermuscular fat and HAP concentration in L3 vertebral body.

**RESULTS**

The intermuscular fat(18.52±1.88)cm2 in osteoporosis group was significantly different from that in non-osteoporosis group(13.82±1.15)cm2($P<0.05$). The intermuscular fat was negatively correlated with HAP concentration in L3 vertebral body ($r=-0.263$, $P<0.05$), while L3SMI was positively correlated with HAP concentration in L3 vertebral body ($r=0.34$, $P<0.05$).

**CONCLUSION**

L3SMI and skeletal muscle space fat in patients with CKD are related to HAP concentration in L3 vertebral body, and skeletal muscle space fat in osteoporosis group is higher than that in non-osteoporosis group.

**CLINICAL RELEVANCE/APPLICATION**

Interventions aimed at reducing fracture risk in CKD patients should focus on reducing fat content and improving muscle quality to improve patients' quality of life.

## S4-SSMK01-6 METAL ARTIFACT REDUCTION MRI OF OSTEOSARCOMA LIMB SALVAGE SURGERY METALLIC ENDOPROSTHESES

Mingfei Xie, MMed (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess high-bandwidth (BW), slice encoding for metal artifact correction (SEMAC) and compressed sensing (CS)-SEMAC turbo spin echo techniques for metal artifact reduction MRI of osteosarcoma limb salvage surgery (LSS) metallic endoprostheses.

**METHODS AND MATERIALS**

Following institutional approval and consent, 39 subjects (29 men, 10 women; mean age, 22 years; age range, 8-68 years) with osteosarcoma LSS metallic endoprostheses underwent 1.5-T MRI prospectively. We compared high-BW, SEMAC and CS-SEMAC sequences with acquisition times of 3-4, 7-8 and 3-4 min, respectively. Outcome variables included bone-implant interfaces, image quality, periprosthetic structures, artifact size, and signal- and contrast-to-noise ratios (SNR and CNR) and abnormal findings. Statistical analysis included Friedman, repeated measures analysis of variances, and Cohen weighted k tests. Bonferroni-corrected p-values of 0.005 and less were considered statistically significant.

**RESULTS**

Metal artifact reduction and visibility of bone-implant interfaces, periprosthetic structures were very good and significantly better on both types of SEMAC than on high-BW images ($P < 0.005$). The implant artifact size was 5% to 11% larger on high-BW images when compared with SEMAC and CS-SEMAC images ($P < 0.005$). The SNRs of fat tissue, muscle tissue, tendon tissue, fluid and the CNRs of fluid and muscle, fluid and tendon as well as fat and muscle were significantly higher on SEMAC and CS-SEMAC images ($P < 0.005$, respectively). There was no statistical difference of outcome variables of SEMAC and CS-SEMAC images. CS-SEMAC was superior to high-BW in showing the periosteal reaction (50 % difference, $p=0.480$), fluid collection (56 % difference, $p=0.001$), soft tissues edema (19 % difference, $p=0.248$).

**CONCLUSION**

Compressed sensing acceleration of SEMAC is feasible for high-quality metal artifact reduction MRI of osteosarcoma LSS metallic endoprostheses and yields better quality and improves the diagnosis of abnormal findings than high-BW.

**CLINICAL RELEVANCE/APPLICATION**

Osteosarcoma is the most common primary malignancy of the bone. Limb salvage surgery (LSS) has become one of the standard treatment methods for patients with limb osteosarcoma, with 90% of patients undergoing LSS and a success rate of 60%-80%. However, complications and failures of metallic endoprostheses remain high compared to other arthroplasty procedures. CS-SEMAC provides superior metal artifact reduction capabilities and enables better visualization of peri-prosthetic bone and soft tissues, and thus improves the detection of complications. Early and accurate detection of complications is crucial to guide patient management and improve outcome.

## S4-SSMK02-2 THE INFLUENCE OF EXTRAOSSEOUS VASCULAR LUMINAL DIAMETER ON THE DEVELOPMENT OF OSTEOCHONDRAL LESIONS OF THE TALAR DOME

Lercan Aslan (*Abstract Co-Author*) Nothing to Disclose
Gregory Waryasz (*Abstract Co-Author*) Nothing to Disclose
Cemil Gedik (*Abstract Co-Author*) Nothing to Disclose
Soheil Ashkani Esfahani, MD (*Abstract Co-Author*) Nothing to Disclose
Samir Ghandour, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the relationship between the luminal diameters of the posterior tibial artery (dPTA) and sinus tarsi artery (dSTA), and the incidence and characteristics of osteochondral lesions of the talar dome (OLT).

### METHODS AND MATERIALS

This retrospective study included 77 patients with OLT and 77 subjects with peroneal tendinitis as a matched control group (age range: 30-40 years). Using MRI, the dPTA was measured at 1 cm above the tibial plafond, the plafond, and at the level of the medial malleolar tip. Likewise, dSTA was measured at the level of the talar neck. The area, volume, depth, localization, and surgical intervention for OLT were recorded as well. Two observers performed the measurements separately, and interobserver reliability was evaluated using ICC.

### RESULTS

The OLT group had significantly smaller dPTA at all three levels (1.05±0.22mm, 0.99±0.18 mm, 0.98±0.31 mm, proximal to distal, respectively) compared to the control group (1.25±0.23mm, 1.20±0.22mm, 1.14±0.18 mm, respectively) (P<.001). The dSTA was also significantly lower in the OLT group as compared to the control group (0.5±0.11mm vs. 0.57±0.08 mm, respectively; P=.001). The mean dPTA (of all three levels) cutoff value for predicting the occurrence of OLT was 1.1 mm with 74% sensitivity and 75% specificity. A significant negative correlation was observed between OLT area and arterial diameters (P<.02). ICC between the two observers was excellent (0.95; P<.001).

### CONCLUSION

Smaller luminal dPTA and dSTA appear to be associated with a higher incidence of OLT, with defect size inversely correlated to arterial diameter. The determined cutoff values for dPTA may help clinicians identify high-risk patients who may develop OLT after an acute ankle injury. Further elucidation of these vascular abnormalities, particularly dPTA, might represent a prognostic factor and be used to predict disease progression and the likelihood of surgical success in OLT treatment.

### CLINICAL RELEVANCE/APPLICATION

Understanding the vascular contributions to OLT can enhance diagnostic accuracy and improve patient outcomes by identifying individuals at higher risk following ankle injuries, potentially guiding earlier and more tailored interventions that may prevent lesion incidence and progression.

## S4-SSMK02-4 THE DIFFERENCE BETWEEN POWER DOPPLER AND SUPERB MICROVASCULAR IMAGING IN THE ASSESSMENT OF RHEUMATOID ARTHRITIS AND OTHER ARTHROPATHIES

Alberto Paternain, MD (*Abstract Co-Author*) Nothing to Disclose
Pablo Del Nido Recio (*Abstract Co-Author*) Nothing to Disclose
Jesus D. Aquerreta, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Carmen Mbongo, MD (*Abstract Co-Author*) Nothing to Disclose
Manuel Rafael Lopez De La Torre Carretero (*Abstract Co-Author*) Nothing to Disclose
Marcos Jimenez Vazquez, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Superb Microvascular imaging (SMI) has been proven to be a reliable Doppler technique and to have more sensitivity when detecting active synovitis, compared to Power (conventional) Doppler (PD). SMI upgrades Doppler activity in comparison to PD. This study aims to analyze whether the upgrade Doppler activity, when comparing SMI and PD, is significantly different in Rheumatoid Arthritis (RA), compared to other arthropathies.

## METHODS AND MATERIALS

Between May 2023 and April 2024, we prospectively analyzed a cohort of 57 joints of 21 different patients who underwent ultrasound exams at our center. Most of them were previously diagnosed with RA and other arthropathies, such as Osteoarthritis, Psoriatic Arthritis, Gout, etc. PD and SMI imaging were obtained in all joints and the individual grades for Doppler Activity were registered for each joint with active synovitis, raging from 0 to 3, according to the EULAR - OMERACT US Score (European League Against Rheumatism - Outcome Measure in Rheumatology):; Grade 0: no Doppler activity.; Grade 1: up to three single Doppler spots.; Grade 2: greater than Grade 1 but <50% of Doppler Signals in the total affected hypoechoic region.; Grade 3: >50% of Doppler signals in the affected region.Means of each grading for PD, SMI and the difference between PD and SMI were registered. Mann-Whitney U test was applied to calculate means in independent samples. Two-tailed p-values of $<0.05$ were considered statistically significant.

## RESULTS

21 joints of 8 patients with RA and 36 joints of 13 patients with other arthropathies were studied. Metacarpophalangical joints were the most frequently analyzed in the RA group (11), and interphalangeal joints were the most frequently analyzed in the other group (18). No statistically significant differences were found between the group with RA and the group with other arthropathies in terms of age (60.38 vs. 54.17 years, $p = 0.41$) or gender (5 women vs. 7 women, $p = 1$). When comparing Doppler activity, the mean PD was significantly higher in the RA group compared to the other group (1.14 vs. 0.75, $p = 0.043$). When upgrading the Doppler activity with SMI, we did not find statistically significant differences (2.52 vs 2.69, $p = 1.04$). Nevertheless, when comparing the mean of the difference between SMI and PD, it was significantly lower in the RA group (1.38 vs. 1.94, $p = 0.016$).

## CONCLUSION

Our results indicate that a higher upgrade between PD and SMI exams is more likely seen in arthropathies such as oligoarthritis, Psoriatic Arthritis or Gout, rather than in RA.

## CLINICAL RELEVANCE/APPLICATION

A higher difference between the PD and SMI grading could be used as a feasible technique to assess the diagnosis of an unknown arthropathy, considering the location of the affected joint and other clinical and systemic features.

## S4-SSNR01-1 NEUROIMAGING CORRELATES OF THE MAIN COGNITIVE METRICS DERIVED FROM THE NIH TOOLBOX IN CHILDREN

Tal Zeevi (*Abstract Co-Author*) Nothing to Disclose
Pratheek Bobba, BS (*Abstract Co-Author*) Nothing to Disclose
Alicia Stephan (*Abstract Co-Author*) Nothing to Disclose
Ajay Malhotra, MD, MMM (*Abstract Co-Author*) Nothing to Disclose
Seyedmehdi Payabvash, MD (*Abstract Co-Author*) Nothing to Disclose
Hector Acosta Rodriguez, BS (*Presenter*) Nothing to Disclose

### PURPOSE

The NIH Toolbox is a comprehensive set of measures designed to assess cognitive, emotional, motor, and sensory functions across a wide age range. In this study, we investigated the microstructural, morphological, and functional connectivity correlates of NIH Toolbox cognitive scores using brain MRI in adolescents.

### METHODS AND MATERIALS

We obtained imaging, clinical, and cognitive information from the ABCD (Adolescent Brain Cognitive Development) database, which originally contained 11,868 subjects. Subjects with incomplete clinical information, a history of traumatic brain injury, a mental disorder, or those who failed MRI quality control were excluded. Mixed linear models, controlling for age and education and applying the False Discovery Rate to correct for multiple comparisons, were used to establish the association of the NIH Toolbox Fluid Cognition Composite Score with various neuroimaging metrics. These metrics included fractional anisotropy (FA), neurite density (ND), mean (MD), radial (RD), and axial (AD) diffusivity of white matter (WM) tracts, as well as cortical region thickness, surface areas, and functional network connectivity correlations from resting-state fMRI.

### RESULTS

We analyzed the information of 4,934 children with mean (± standard deviation) age of 9.9 (±0.6) years. Subjects with higher toolbox scores demonstrated significantly higher average FA and ND, most prominently in the left and right corticostriatal and corticostriatal parietal cortex WM tracts. Conversely, higher scores were associated with significantly lower average MD, RD, and AD, particularly in the inferior frontal superior frontal cortex WM tracts. Higher scores also correlated with reduced cortical thickness, especially in the left superior parietal region, and increased cortical surface area, predominantly in the right lateral orbitofrontal region. Lastly, higher cognitive scores were associated with greater positive connectivity between the Cingulo-parietal Network and Retrosplenial Temporal Network, and between the Sensorimotor Hand Network and Sensorimotor Mouth Network.

### CONCLUSION

The NIH Toolbox was developed as part of the NIH Blueprint for Neuroscience Research, to create a standardized set of brief, comprehensive assessments of neurological and behavioral functions. We showed the microstructural, morphological, and functional connectivity correlates of Fluid Cognition Composite Score derived from NIH-toolbox among children.

### CLINICAL RELEVANCE/APPLICATION

This study underscores the clinical relevance of using neuroimaging to identify cognitive performance in children based on widely used NIH-toolbox metrics. These insights can guide early therapeutic interventions and personalized educational strategies.

## S4-SSNR01-2 TRAJECTORIES OF BRAIN STRUCTURE AND FUNCTIONS IN NORMAL AGING

Yaqin Zhang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Di Wu (*Presenter*) Nothing to Disclose

### PURPOSE

The collaboration among components of the neurovascular unit plays a vital role in sustaining normal brain function. The evolution of the vascular function and oxygen metabolism indicating neural activity during normal aging remain underestimated. We examined the trajectories of brain structure, vascular and oxygen metabolic functions and evaluated the sex differences in order to understand normal aging and explore potential targets for study of pathological conditions.

### METHODS AND MATERIALS

Population 137 healthy subjects between 20~70 years old were enrolled with conventional MRI, structural 3D-T1WI, 3D-mGRE, and 3D-pCASL acquired by 3.0T MR scanner (Discovery MR750, GE Healthcare). Reconstruction The oxygen extraction fraction (OEF) maps were reconstructed based on QSM plus qBOLD model from 3D-mGRE data. The cerebral blood flow (CBF) maps were reconstructed through AW4.6 workstation from 3D-pCASL images. The cerebral metabolic rate of oxygen (CMRO2) maps were calculated as follows: CMRO2 = CBF· OEF · [H]a, [H]a = 7.377 μmol/mL. Segmentation 3D-T1WI images were segmented into global gray matter (GM), global white matter (WM), and cerebrospinal fluid. Statistical analysis The GM/WM volume was divided by total intracranial volume to generate relative GM/WM volume (rel_GM/rel_WM) for each subject. Sex differences in OEF, CBF, CMRO2, relative volume of GM/WM and age group were analyzed. Generalized additive models (GAMs) were used to evaluate the aging trajectories of brain structure and functions. We also evaluated the feasibility of age prediction by brain structure and functions. $P < 0.05$ was considered statistically significant.

### RESULTS

Females had larger rel_GM and higher CMRO2 and CBF of GM/WM than males ($P < 0.05$, Table 1). GAMs showed that CBF, CMRO2, and relative volume of GM all declined with aging ($R2 = 0.278$, $P < 0.001$; $R2 = 0.16$, $P < 0.001$; $R2 = 0.522$, $P < 0.001$) while controlling for sex. Specifically, CBF significantly declined between 20 and 31 years (Figure 1A). CMRO2 declined subsequently from 33 to 41 years (Figure 1B). Rel_GM decreased significantly at all ages (20~69 years) (Figure 1C). The combination of CBF, CMRO2, relative volume of GM, and sex were feasible to explain the age deviance at the level of 62.6% with an R2 of 0.565.

### CONCLUSION

There are sex disparities of functions of neurovascular unit. Furthermore, the evolution of cerebrovascular and oxygen metabolic functions follows sequential manner during aging, coinciding with a continuous decline in brain volume.

### CLINICAL RELEVANCE/APPLICATION

The age trajectories of brain structure and functions in healthy individuals provide insights into normal aging, which can be utilized for age prediction as well as delineating deviations in pathological conditions.

## S4-SSNR01-6 ASSOCIATION OF CHILDHOOD NEIGHBORHOOD DEPRAVATION INDEX WITH METRICS OF BRAIN WHITE MATTER MICROSTRUCTURE INTEGRITY DURING ADOLESCENCE

Alicia Stephan (*Abstract Co-Author*) Nothing to Disclose
Ajay Malhotra, MD, MMM (*Abstract Co-Author*) Nothing to Disclose
Seyedmehdi Payabvash, MD (*Abstract Co-Author*) Nothing to Disclose
Pratheek Bobba, BS (*Abstract Co-Author*) Nothing to Disclose
Tal Zeevi (*Abstract Co-Author*) Nothing to Disclose
Hector Acosta Rodriguez, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the association of children's home address "Area Deprivation Index" (ADI) with brain white matter microstructural integrity at baseline and during adolescence.

### METHODS AND MATERIALS

We obtained baseline imaging, clinical, and demographic information for baseline, 2- and 4-year follow-up from the Adolescent Brain Cognitive Development (ABCD) Study database, which originally included 11,868 American Children. Subjects with incomplete clinical information, any traumatic brain injury, a mental disorder, or those who failed MRI quality control were excluded. Mixed linear models (MLM), controlling for age and education and applying the False Discovery Rate to correct for multiple comparisons, were used to establish the association of ADI with various neuroimaging metrics, including fractional anisotropy (FA), neurite density (ND), mean (MD), radial (RD), and axial (AD) diffusivity of white matter (WM) tracts. MLM was also applied to perform an interaction analysis on the effect of baseline neuroimaging metrics on the follow-up metrics.

### RESULTS

We analyzed the information of 5,341 children with mean (± standard deviation) age of 9.9 (±0.6) years at baseline; 2,629 with mean age of 12.0 (±0.6 years) at 2-year follow-up; and 910 with mean age of 14.1 (±0.7 years) at 4-year follow-up. Children living in neighborhoods with higher ADI showed significantly higher average FA, AD, and ND but lower RD and MD at baseline, most notably in the corpus callosum, cingulum, forceps minor and major, and anterior thalamic radiation. Similar pattern was observed in year-2 follow-up but with diminished number of tracts showing significant ADI association. No significant association was found for year-4 follow-up. Among children with follow-up scans, FA and ND tend to increase, whereas MD, AD, and RD decreased on 2- and 4-year follow-ups. However, ADI had opposite-direction interaction with the relationship of baseline diffusion metrics to follow-up values.

### CONCLUSION

Children from neighborhood with higher socioeconomic disadvantage depicted evidence of higher brain white matter microstructural integrity at age 9-to-10 year, even after correcting for parental education and family income. However, the association of neighborhood ADI and microstructural integrity abated over time on follow-up scans and became undetectable by age 13-to-14 years.

### CLINICAL RELEVANCE/APPLICATION

Understanding the neural impacts of socioeconomic status can guide subject selection in future study design interventions. It also informs policies to reduce disparities in underprivileged adolescents.

## S4-SSNR02-1 IN VIVO DETECTION OF PATHOLOGY AT THE DEPTHS OF CORTICAL SULCI IN SPORTS REPETITIVE HEAD IMPACTS

Richard Lipton (*Abstract Co-Author*) Nothing to Disclose
Walter F. Stewart, MPH, PhD (*Abstract Co-Author*) Nothing to Disclose
Mimi Kim (*Abstract Co-Author*) Nothing to Disclose
Thomas Kaminski (*Abstract Co-Author*) Nothing to Disclose
Roman Fleysher (*Abstract Co-Author*) Nothing to Disclose
Michael L. Lipton, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kenny Ye, MD (*Abstract Co-Author*) Nothing to Disclose
Molly E Zimmerman (*Abstract Co-Author*) Nothing to Disclose
Bluye Demessie (*Presenter*) Nothing to Disclose

### PURPOSE

Post-mortem evidence suggests the depths of sulci (DoS) are vulnerable to repetitive head impacts (RHI). Diffusion MRI (dMRI) has identified microstructural features of brain injury but has largely overlooked the juxtacortical white matter (jWM). We assessed the relationship of RHI due to heading in soccer players with dMRI in DoS jWM. RHI has been associated with worse verbal learning; we assessed the mediating role of dMRI in this relationship.

### METHODS AND MATERIALS

Healthy amateur adult soccer players (n=380; 18-53 years old; 30% female) and healthy non-collision athlete controls (82; 18-50; 61%) were included. We assessed the cross-sectional relations among estimated 12-month RHI (HeadCount) represented in quartiles (medians: 43, 300, 782, 2,607) and verbal learning (International Shopping List).3T dMRI (2mm3, 109 directions, b=300, 800, 2000) was processed to extract DTI (fractional anisotropy, FA; axial diffusivity, AD; radial diffusivity, RD; mean diffusivity, MD) and NODDI (orientation dispersion index, ODI; neurite density index, NDI; isotropic water fraction, ISO) metrics from jWM subjacent to the DoS, jWM subjacent to the crests of gyri (CoG), and deep WM (dWM: corticospinal tract, corpus collosum, fornix, and uncinate fasciculus). dMRI metrics at each region for each RHI quartile were compared to non-collision athletes, using linear models adjusted for age, sex, and concussion history. Significant associations underwent causal mediation analysis using bootstrapping to test the significance the mediating effect of a dMRI metric on the relationship of RHI with verbal learning. Bonferroni correction was applied.

### RESULTS

dMRI metrics in DoS jWM differed from controls in an RHI dependent fashion. The highest RHI quartile exhibited (corrected $P<0.001$) lower FA in the frontal lobe (FL), orbitofrontal cortex (OFC), parietal lobe (PL), temporal lobe (TL), and occipital lobe (OL); lower AD in OFC, PL, TL, and OL; higher RD in FL, OFC, PL, TL, and OL; higher ODI in FL, OFC, PL, TL, and OL; and lower NDI in OFC. DoS effect sizes were larger than CoG or dWM. jWM ODI in OFC partially mediated the association of greater RHI with worse verbal learning ($P=0.008$); other white matter regions had no mediation effect.

### CONCLUSION

Microstructural injury related to RHI in young healthy individuals is most prominent in DoS jWM. The adverse association of RHI with verbal learning is partially mediated by OFC DoS jWM, consistent with measurable functional effects of subclinical axonal injury, demyelination, and/or inflammation.

### CLINICAL RELEVANCE/APPLICATION

Our findings suggest DoS jWM holds potential for identifying clinically significant injury pathology in RHI, which can be applied to expand and improve the use of imaging in assessment of traumatic brain injury.

## S4-SSNR02-2 CHANGES IN BRAIN STIFFNESS AFTER TRAUMATIC BRAIN INJURY: INSIGHTS FROM VIRTUAL MR ELASTOGRAPHY BASED ON DWI

Jin Wook Choi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Su Jeong Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Miran Han, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to assess changes in brain stiffness after traumatic brain injury (TBI) using virtual MR elastography (vMRE), a non-invasive and novel technique based on DWI. TBI often leads to significant morbidity and mortality. While early standard neuroimaging like CT is critical for evaluating serious intracranial injuries, it has ineffectiveness in detecting minor brain tissue alterations after injury, and cannot assess mechanical characteristics. MR elastography offers a solution but is limited by its invasiveness and long scan duration.

**METHODS AND MATERIALS**

We retrospectively analyzed MR imaging performed within 2 months of TBI from March 2021 to March 2024. Patients was groups into a no hemorrhage group, consisting of individuals with a history of traumatic brain injury but no parenchymal hemorrhage evident on MR, and a traumatic axonal injury (TAI) group. The TAI group was further categorized into three grades: Grade 1, where the bleeding is confined to the lobar white matter; Grade 2, which includes cases of bleeding in the corpus callosum; and Grade 3 where the bleeding extends to the brain stem. Shifted apparent diffusion coefficient was calculated from DWI (b=200 and 1500sec/mm2) and converted to DWI-based virtual shear modulus (μ). Brain stiffness was measured across the whole brain and specific anatomical regions. Independent t-tests and multiple comparison tests were performed to evaluate changes in brain stiffness following traumatic injury, according to the degree of brain hemorrhage.

**RESULTS**

Finally, 71 patients without hemorrhage and 81 patients with TAI were included in this study. The mean interval from trauma to MR acquisition was 15.2 ± 13.5 days. The TAI group showed significantly lower value of virtual shear modulus (μ) in brain, particularly in cerebral white matter ($p = 0.012$), frontal ($p = 0.011$) and temporal lobe ($p = 0.006$). The brain stiffness also decreased according to the grade of TAI in the whole brain ($p = 0.010$), cerebral WM ($p = 0.004$), temporal lobe ($p = 0.008$), parietal lobe ($p = 0.007$), hippocampus ($p = 0.047$) and corpus callosum ($p = 0.047$).

**CONCLUSION**

Higher TAI grades were associated with lower brain stiffness. It is suggested that edema and tissue necrosis following traumatic injury may contribute to the decrease in viscoelastic property of brain tissue. However, future research is required to investigate the correlation between these quantitative brain stiffness data and the clinical outcomes of patients.

**CLINICAL RELEVANCE/APPLICATION**

This research highlights how vMRE, a novel DWI-based technique, can provide insights into the biomechanical impacts of TBI, aiding in the evaluation and management of this condition.

## S4-SSNR02-3 REVISITING OCCIPITAL CONDYLE FRACTURES: NEW INSIGHTS FROM TRAUMA DATA

David M. Yousem, MD, MBA (*Abstract Co-Author*) Royalties, RELX;Speaker, MRI Online;Board Member, MRI Online;
Mahla Radmard, MD (*Abstract Co-Author*) Nothing to Disclose
Armin Tafazolimoghadam (*Abstract Co-Author*) Nothing to Disclose
Dhairya Lakhani, MD (*Abstract Co-Author*) Nothing to Disclose
Akua Amoah, MD, MPH (*Presenter*) Nothing to Disclose

**PURPOSE**

Occipital condyle fractures may be a marker for severe head and craniocervical trauma. If not specifically searched for they may be easily overlooked. We sought to assess the incidence of occipital condyle fractures in a large cohort of patients with head trauma and to characterize their presentations.

**METHODS AND MATERIALS**

The study was IRB-approved and HIPAA-compliant. We retrospectively reviewed the brain and cervical spine reports of CT scans performed in our two Emergency Departments performed from 2018 to 2023. Variables studied included age, gender reported, coincident brain and cervical spine injuries, and Anderson and Montesano classification

**RESULTS**

Of 21986 patients studies reviewed there were 55 patients with occipital condyle fractures (0.25%). The mean age was 51.0 years (median 51, SD 20.1). There were 17 females and 38 males. The incidence of occipital condyle fractures in patients less than 65 years old was 42/12531 (0.34%) was significantly higher than those 65 and older (13/9455 = 0.14%) which may be associated with the higher rate of motor vehicle collisions as the cause of trauma in the younger group. 26/55 (47.3%) had concomitant brain injuries and 16/55 (29.1%) had a cervical spine injury as well. The Type III Anderson was the most common being Type III (29/55) with the remainder split between Types I and II.

**CONCLUSION**

Occipital condyle fractures in patients suffering trauma are uncommon (0.25%) and often are the potentially unstable Anderson and Montesano Type III variety. However, they may be associated with brain (47.3%) or cervical spine (29.1%) injuries. Recognizing their presence may be helpful in planning treatment for head and neck trauma patients.

**CLINICAL RELEVANCE/APPLICATION**

Being aware of occipital condyle fractures and types is important in the emergency radiology evaluation of trauma patients, particularly in the young and those involved in MVCs.

## S4-SSNR02-4 CHANGES OF THE GLYMPHATIC SYSTEM IN INDIVIDUALS EXPOSED TO HIGH VERSUS LOW BLAST IMPACT

Rafael Glikstein, MD (*Abstract Co-Author*) Nothing to Disclose
Gerd Melkus, PhD (*Abstract Co-Author*) Nothing to Disclose
Nerses Nersesyan, MD (*Abstract Co-Author*) Nothing to Disclose
Chris Skinner (*Abstract Co-Author*) Nothing to Disclose
Betty Anne Schwarz, PhD (*Abstract Co-Author*) Nothing to Disclose
Azza Reda, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore changes in DTI and glymphatic system activity among individuals Exposed to High versus Low Blast Impact with mild traumatic brain injury (mTBI) suggesting axonal damage.

### METHODS AND MATERIALS

Total of 68 military personnel with low and high exposure to explosive operations have undergone longitudinal MRIs (including volumetric T1 and DTI sequences). FSL software was used for registration of the diffusion datasets into MNI standard space and spherical ROIs were placed into projection and association area to calculate the DTI-ALPS index. DTI-ALPS was compared between the initial and follow-up scan of the high- and low exposure group using a paired t-test. The automated longitudinal Freesurfer pipeline was used to calculate brain volumes and volume changes. Volumetric changes were compared to changes in the ALPS-Index using Spearman correlation (?).

### RESULTS

significant increased ALPS-Index from the initial scan to the follow-up scan for the whole group ($p<0.05$). The dichotomization into low and high exposure group retained this significance increase of the ALPS-index for both groups, and the p-value was lower in the high exposure group Significant decrease of the corpus callosum volume with an increase of the ALPS-index (? = -0.34). Further the cortical volume (? = -0.28) and the gray matter (? = -0.27) decreased significantly with an increasing ALPS index.

### CONCLUSION

The difference in the glymphatic system in mTBI individuals exposed to low and high impact blast, plays a crucial role. The increase in the ALPS-index suggests an enhanced compensating mechanism to reduce secondary damage by facilitating the clearance of endotoxic products.

### CLINICAL RELEVANCE/APPLICATION

These findings of altered glymphatic system may help in understanding the effect on the brain after mTBI and determine prognostic evaluation for individuals exposed to traumatic injuries.

## S4-SSNR02-5 DEVELOPMENT OF A QUANTITATIVE IMAGING TOOL TO IDENTIFY CANDIDATES FOR TRANEXAMIC ACID TREATMENT IN ACUTE TRAUMATIC BRAIN INJURY

Holly Hinson, MD (*Abstract Co-Author*) Research Consultant, Biogen Idec Inc;Former Research Consultant, iSchemaView, Inc
Samir Dagher, MD (*Abstract Co-Author*) Nothing to Disclose
Max Wintermark, MD (*Abstract Co-Author*) Consultant, Magnetic Insight, Inc;Consultant, icoMetrix NV;Consultant, Subtle Medical, Inc;Consultant, EMTensor Imaging
Prashant Raghavan, MD (*Abstract Co-Author*) Speaker, Siemens AG
Susan Rowell (*Abstract Co-Author*) Nothing to Disclose
Peter Kamel, MD (*Abstract Co-Author*) Nothing to Disclose
Maguy Farhat, MD, BS (*Presenter*) Nothing to Disclose

### PURPOSE

Tranexamic acid (TXA) has been shown to mediate the blood-brain barrier and limit vasogenic edema after Traumatic Brain Injury (TBI) in preclinical models. Our purpose was to develop a novel CT-based quantitative imaging tool to identify patients with TBI that will show survival benefit from TXA initiated in the prehospital setting.

### METHODS AND MATERIALS

This study is a post hoc analysis of the Phase II prehospital TXA in TBI trial. We included patients in both placebo and TXA arms with moderate or severe TBI and available head CT scan at baseline. Patients with >25 ml intracranial hematoma, gunshot wounds, and those who died unrelated to TBI were excluded. Using a MATLAB code, we performed densitometric analysis quantifying the percentage (%) of voxels within the density scale. We determined that % voxel in 10-20 HU correlated the best with mean ADC values for 101 patients that had available MRIs. To determine whether % voxel in 10-20 HU predicts response to TXA, multivariate logistic regression with interaction term voxel %: TXA was performed. Wald test was then used to identify the minimum % voxel cutoff value in 10-20 HU beyond which significant survival benefit of TXA is observed. The reduction in relative risk (RR) in mortality was calculated in % of voxel group above the selected cutoff value at hospital discharge, 28 days, and at 6 months.

### RESULTS

Logistic regression showed significant effect of % voxel in 10-20 HU ($p = 0.0387$) on survival benefit, implying that the impact of TXA varies across different voxel %s. Threshold analysis revealed a significant difference in survival benefit to TXA when at least 3% of voxels were in the 10-20 HU density range (~40 ml vasogenic edema) ($p = 0.04$). Within the subgroup with a minimum of 3% of voxels of 10-20 HU, the administration of TXA exhibited a significant reduction in RR of mortality of 62.5% at hospital discharge (n=550), 62.7% at 28 days (n=549), and 61.5% at 6 months (n=499).

### CONCLUSION

A CT imaging biomarker quantifying more than 40 ml of vasogenic edema may serve as a promising imaging biomarker for identifying TXA treatment candidates in patients presenting with moderate/severe acute TBI. This biomarker needs further validation in prospective studies.

### CLINICAL RELEVANCE/APPLICATION

Secondary edema is a major cause of death in patients with acute TBI. TXA may be effective in decelerating cerebral edema progression, and baseline CT can help identify TBI patients who may benefit from TXA.

## S4-SSNR02-6 ASSOCIATIONS OF COMORBID RISK FACTORS WITH WHITE MATTER HYPERINTENSITIES IN PATIENTS WITH MILD TRAUMATIC BRAIN INJURY

Travis H. Snyder, DO (*Abstract Co-Author*) Nothing to Disclose
Leo Germin, MD (*Abstract Co-Author*) Nothing to Disclose
Thomas Knoblauch, MS (*Abstract Co-Author*) Nothing to Disclose
Cheryl E. Vanier, PhD (*Abstract Co-Author*) Nothing to Disclose
Enrico Fazzini, DO,PhD (*Abstract Co-Author*) Nothing to Disclose
Alan Rodriguez, MD (*Presenter*) Nothing to Disclose

### PURPOSE

White matter hyperintensities (WMH) may appear in neuroimaging after a mild traumatic brain injury (mTBI). Not all; however, will be a result of trauma. This study explores the incidence of WMH with reported comorbidities in mTBI patients.

## METHODS AND MATERIALS

A medical chart review of 531 mTBI patients (57.8% female, 48.6% under 40) ages 18-82 (mean=42) was performed to extract demographic and comorbid data, including sex, age, diabetes (D), lipidemia (L), obesity (O), smoking (S), and hypertension (H). From a 3T MRI scanner, axial and sagittal T2 weighted and T2 FLAIR sequences with 4.0mm slice thickness were selected to measure the presence of WMH and their distance to cortex (DTC) taken from the center of the hyperintensity to the nearest gray-white matter junction. A modified Fazekas scale was implemented to report any identified confluence as either present, moderate or severe. Comorbidities and age were analyzed relative to presence of WMH lesions or confluence using logistic regression, and the (log-transformed) DTC was analyzed using linear regression.

## RESULTS

At least one comorbidity (D (3.4%), L (2.3%), O (7.2%), S (5.1%), and H (9.4%)) was reported in 15.6% of patients. All comorbidities except obesity and smoking were more common in patients 40 and over. WMH were 4.7 times more likely in patients 40 and over compared to those under 40 ($p<0.001$) and 2.4 times more likely in patients with hypertension ($p=0.025$). No confluence was observed in patients <40. Confluence was less common in males than females (OR=0.5, $p=0.045$) while the odds of any degree of confluence was 7.1-fold higher in those with lipidemia ($p=0.005$) and 6.7-fold higher in those with hypertension ($p<0.001$). Participants classified as obese had WMH more distant from the cortex (mean distance=3.33mm) compared to those who were not obese (mean distance=2.20mm; $p=0.013$). WMH in patients <40 were more distant from the gray-white matter junction (mean distance=3.8mm) relative to those 40 and over (mean distance 1.8mm; $p<0.001$).

## CONCLUSION

Risk factors, specifically those affecting the health of blood vessels, predict the presentation of WMH after mTBI. The distance a WMH was from the cortex was generally not influenced by comorbid risk factors. It is known that head injury is associated with WMH, yet further research is needed to help determine how mTBI and pre-existing risk factors may interact to influence the morphology and development of hyperintensities.

## CLINICAL RELEVANCE/APPLICATION

Although Wallerian degeneration and diffuse axonal injury may play a pivotal role in the formation of WMH after injury, it is important to consider comorbid factors.

## S4-SSPH02-1 IMPACT OF FLYING FOCAL SPOT TECHNIQUE ON THE IMAGING PERFORMANCE AND MICROCALCIFICATION DETECTION OF DIGITAL BREAST TOMOSYNTHESIS

Wei Zhao, PhD (*Abstract Co-Author*) Research support, Siemens AG
Xiaoyu Duan (*Abstract Co-Author*) Nothing to Disclose
Hailiang Huang, PHD (*Abstract Co-Author*) Nothing to Disclose
Jann Stavro, PhD (*Abstract Co-Author*) Nothing to Disclose
Xiangyi Wu, MS (*Presenter*) Nothing to Disclose

### PURPOSE

Continuous-motion (CM) and step-and-shoot (SS) are two gantry motion techniques used in clinically available digital breast tomosynthesis (DBT) systems. CM introduces image blur due to focal spot (FS) motion during x-ray exposures, which could degrade the conspicuity of microcalcifications. SS reduces FS motion with a stationary source during exposures, however, the tube may wobble when stopped and introduce additional blur. The flying focal spot (FFS) technique has recently been adopted for DBT, where the FS is virtually stationary during image acquisition, thus minimizing FS blur. This work aims to investigate the impact of FFS on imaging performance and compare DBT systems with FFS (Siemens B. Brilliant*), CM (Siemens Revelation), and SS modes (GE Pristina).

### METHODS AND MATERIALS

Effective FS size in the tube travel direction was measured for DBT using a slit camera. System pre-sampling modulation transfer functions (MTF) were measured in DBT projection images as a function of projection angle and height above the detector with a slanted edge. The impact of FS blur on spatial resolution was evaluated by comparing the MTF among tube motion modes after eliminating the effect of pixel pitch. The conspicuity of microcalcifications in the reconstructed DBT volume for FFS and CM acquisition modes were evaluated using the ACR Model 156 phantom and CIRS Model 011 phantom. The assessed microcalcifications range in size from 165 μm to 320 μm and are located at different positions in the images.

### RESULTS

Effective FS sizes in the tube travel direction are 2.370 ± 0.302 mm, 0.636 ± 0.017 mm, and 0.297 ± 0.146 mm for CM, SS, and FFS techniques, respectively. At 4 cm above the detector cover, the spatial frequencies for 50% MTF values (MTF50%) in central projections are 2.5 lp/mm, 4.0 lp/mm, and 7.5 lp/mm for CM, SS, and FFS, respectively. In 12-degree projection images, MTF50% decrease to 2.4 lp/mm, 3.7 lp/mm, and 6.9 lp/mm, respectively. In reconstructed DBT slices of phantoms, FFS shows improved conspicuity of microcalcifications compared to CM.

### CONCLUSION

FFS provides the smallest effective FS size and the highest MTF at high frequencies among the three tube motion modes investigated. The reconstructed in-plane slices of phantoms show that FFS improves the conspicuity of microcalcifications compared to CM.

### CLINICAL RELEVANCE/APPLICATION

DBT systems featuring FFS may offer superior microcalcification detection by minimizing FS blur. *The product/feature and/or service offerings mentioned herein for B. Brilliant are not commercially available in all countries and/or for all modalities. Their future availability cannot be guaranteed.

## S4-SSPH02-2 A TWO-DIMENSIONAL MULTIPLE X-RAY-SOURCE ARRAY FOR DIGITAL BREAST TOMOSYNTHESIS

Jeffrey H. Siewerdsen, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Advisory Board, Siemens AG;Research Grant, Medtronic plc;Advisory Board, Carestream Health, Inc;License agreement, Carestream Health, Inc;License agreement, Precision X-Ray, Inc;License agreement, Elekta AB;;;
Paul R. Schwoebel, PhD (*Abstract Co-Author*) Nothing to Disclose
John M. Boone, PhD (*Abstract Co-Author*) Board of Directors, Izotropic Corporation;Shareholder, Izotropic Corporation;Co-author with royalties, Wolters Kluwer nv;Patent agreement, The Phantom Laboratory;In-kind support, Canon Medical Systems Corporation
Alejandro Sisniega, PhD (*Presenter*) Research Grant, Siemens AG;Research Grant, Micro-X Ltd;Research Grant, Izotropic Corporation

### PURPOSE

To develop a two-dimensional (2D) Multiple X-ray-source Array (MXA), that will improve image quality in digital breast tomosynthesis (DBT) by: 1) Reducing the under-sampling inherent with one-dimensional (1D) scan geometries used in commercial DBT systems; and 2) Eliminating mechanical motion of the X-ray source to reduce scan time to < 1s and minimize blur and artifacts from source and patient motion.

### METHODS AND MATERIALS

The stationary source used in this feasibility study was a linear (1D) MXA of 11 X-ray sources with a common rotating anode shaft and 11 individual thermionic cathodes. A 2D MXA can be achieved using a second array of thermionic cathodes on the other side of the anodes. In the current work, the 2D MXA geometry with cathode separation of 23 mm was simulated using 1D 11-source MXA and translating the detector and object. Image quality comparisons between the 1D and 2D MXA geometries were quantified in quantitative and anatomical phantom studies measuring out-of-plane background clutter, noise-power spectrum, and slice sensitivity profile (SSP).

### RESULTS

The 2D MXA source configuration reduced background clutter by 10.2% (median) and 16.9% (90th percentile). The background clutter power spectrum of the 1D MXA showed a distinct null cone in the Fourier domain in the anterior field of view (far from the chest wall). The null cone was eliminated with the 2D MXA, consistent with improved sampling. In addition, the 2D MXA improved the median FWHM of the SSP by 15% (6.1 mm for 1D MXA vs 5.3 mm for 2D MXA) and increased conspicuity of both microcalcifications and tumor features compared to 1D MXA and mammography.

### CONCLUSION

The 2D MXA geometry significantly improved image quality compared to 1D MXA and mammography by improved tomosynthesis sampling and narrowing the SSP. These studies have guided the design and fabrication of a prototype 2D MXA DBT system.

### CLINICAL RELEVANCE/APPLICATION

The 2D MXA has the potential to provide next-generation tomosynthesis with a scan time < 1 s and improved image quality compared to current DBT systems.

## S4-SSPH02-3 EVALUATING THE EFFICACY OF NEW AUTO-EXPOSURE CONTROL (S-AEC) IN PORTABLE ANTEROPOSTERIOR CHEST RADIOGRAPHY: A RETROSPECTIVE EXAMINATION OF RADIATION DOSE OPTIMIZATION AND IMAGE QUALITY

Myung Jin Chung, MD (*Abstract Co-Author*) Research Consultant, Samsung Electronics Co, Ltd;Research Consultant, Pharmex Advanced Laboratories, SL;Research Grant, Lunit Inc;Research Grant, VUNO Inc
Jung Han Woo (*Presenter*) Nothing to Disclose

### PURPOSE

The latest advancement in the field of chest radiography had led to incorporation of an Auto-Exposure Control (AEC) system within the detector, which holds the promise of significantly enhancing image quality and managing radiation dose effectively. This innovation has yet to gain widespread acceptance in portable radiographic systems. Our study retrospectively examines the efficacy of new AEC system (S-AEC) embedded in portable X-ray devices, employing artificial intelligence to fine-tune image quality alongside radiation dosage.

### METHODS AND MATERIALS

In this retrospective analysis, we evaluated the performance of an approved portable X-ray apparatus outfitted with a Detector Auto-Exposure Control system (DAEC). Anteroposterior chest radiographs were obtained between November 17, 2023, and December 10, 2023, at a single tertiary referral center. A comparative quantitative evaluation comparing manual controls with DAEC was conducted, focusing on exposure indices (EI) and dose-area products (DAP). Furthermore, observer-based analysis of image quality was performed by two board-certified thoracic radiologists for lowest exposure (EI < 200 μGy; 3% threshold outliers) and average exposure images within both the manual and DAEC groups, by utilizing a 5-point visual grading scale. Paired comparisons (manual and DAEC conducted within a one-week interval) were also executed.

### RESULTS

A total of 2093 examinations (1235 manual, 858 DAEC) were conducted on 467 patients. The DAEC group demonstrated a significant reduction in DAP (1.99 dGycm2, manual; 1.64 dGycm2, DAEC) and EI (393 uGy, manual; 266 uGy, DAEC) compared to the manual group ($p<0.001$). When evaluating the average and lowest exposure images, the DAP and EI were consistently lower in the DAEC group ($p<0.01$). In the observer-based analysis of lowest exposure images, the DAEC group yielded a significantly higher score compared to the manual group (12.5, manual; 13.4, DAEC; $p<0.001$). The DAEC group outperformed the manual group in the paired comparison in terms of higher observer analysis score (manual, 14.1; DAEC, 14.3; $p=0.029$) and 18% lower DAP (manual, 1.98; DAEC, 1.63; $p<0.001$).

### CONCLUSION

The implementation of the Detector Auto-Exposure Control system (DAEC) within portable X-ray devices significantly improves image quality while reducing radiation exposure, as substantiated by both quantitative and qualitative metrics.

### CLINICAL RELEVANCE/APPLICATION

The clinical application of the DAEC system represents a substantive advancement in patient safety and image precision in portable chest radiography, suggesting a pivotal change in radiological practices and a move towards more AI-integrated diagnostic tools.

## S4-SSPH02-4 LUNG FUNCTION MEASUREMENT FROM DYNAMIC CHEST RADIOGRAPHY USING RESPIRATORY MOTION ESTIMATION BY IMPLICIT NEURAL REPRESENTATION

### PURPOSE

To estimate respiratory motion and develop quantitative measurements of lung function from dynamic chest radiography (D-CXR) and to correlate these new radiographic metrics to the first-second Forced Expiratory Volume (FEV1) by conventional spirometry.

### METHODS AND MATERIALS

The D-CXR protocol involves a serial radiographic sequence collected at 8 frames/second. Eight subjects performed forced expiration during a D-CXR acquisition, followed by a separate spirometry test to obtain FEV1. Lung parenchyma projections were segmented from the D-CXR series by a Deep Learning (DL) model trained on digitally reconstructed radiographs computed from CT volumes. Each segmented frame during a one-second-long inspiration-expiration (INSP-EXP) interval was deformably registered to the reference INSP projection using an Implicit Neural Representation (INR) with a multi-layer perceptron model of respiratory motion and temporal regularization to promote consistent deformations across the sequence. The INR was computed by one-shot learning minimizing a joint Normalized Cross-Correlation of all segmented frames. The registration aligned the shape of lung parenchyma in each D-CXR view to the reference INSP shape but preserved local radiographic density change during expiration. Ventilation maps at each time point were then obtained by pixel-by-pixel subtraction of the aligned segmentations from INSP density. An estimate of the exhaled volume of air was calculated as a spatial average of the ventilation map at EXP multiplied by the total lung parenchyma area at INSP.

### RESULTS

The INR deformable registration of D-CXR frames provided an estimate of the projected respiratory deformation field (DF). After applying the DF to align the segmented lung parenchyma projections, the shape mismatch across the 1 sec expiration sequence was reduced from ~18% (area difference averaged across the study sample) to ~0.5%. Averaged estimated INSP-EXP displacements of lung parenchyma ranged ~4.4 mm - 32 mm, depending on the subject; relative change in average radiographic density ranged 5% - 46%. Preliminary results indicate a Pearson correlation between the exhaled air volume estimated from D-CXR and FEV1 of 0.81 after removing outliers (2 cases)

### CONCLUSION

A D-CXR sequence combined with DL segmentation of lung parenchyma and INR deformable registration enables quantitative evaluation of respiratory DFs and radiographic density changes during breathing. The volume of exhaled air estimated from D-CXR appears to agree with conventional spirometry in a pilot human subject study.

### CLINICAL RELEVANCE/APPLICATION

Dynamic chest radiography combined with advanced image analysis techniques might provide new quantitative markers of lung function.

## S4-SSPH02-5 DEVELOPMENT OF A QUALITY CONTROL PROGRAM FOR CONTRAST-ENHANCED MAMMOGRAPHY: PHANTOM EVALUATION

William R. Geiser, MS (*Abstract Co-Author*) Nothing to Disclose
Cayla Wood, PhD (*Abstract Co-Author*) Nothing to Disclose
Megan C. Jacobsen, PhD (*Abstract Co-Author*) Honorarium and Travel, Kyoto Kagaku
Emily Thompson, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Dual-energy contrast-enhanced mammography (CEM) has emerged as a promising modality for improving the detection and characterization of breast lesions. However, quality control (QC) procedures have not been well-defined. A CEM QC program plays a crucial role in standardizing imaging protocols, assessing image quality, verifying contrast agent uptake, monitoring system performance, and ensuring quality assurance in clinical practice. This study seeks to evaluate the suitability of commercially available CEM phantoms and their role in a clinical QC program.

### METHODS AND MATERIALS

Two commercially available CEM phantoms were assessed for quality control: Contrast Enhanced Spectral Mammography Phantom Model 022 (CIRS, VA, USA) [Phantom A] and the Mammo CESM?? Phantom PN 805929 (Sun Nuclear, WI, USA) [Phantom B]. Phantoms were evaluated for feasibility in terms of ease of use and comparing SNR, CNR, and reproducibility across Hologic, GE, and Siemens mammography systems. Additionally, breast texture cancellation and the ability to evaluate image signal as a function of iodine concentration measured in the breast tissue of differing thickness and composition (glandular vs. adipose) were also evaluated.

### RESULTS

Both phantoms demonstrated potential for use in a routine quality control program and can be used to evaluate SNR, CNR, reproducibility, breast texture cancellation, and iodine concentration at different breast thicknesses and tissue combinations. Phantom A offers several iodine concentrations, tissue thickness, and composition combinations and provides a reproducible phantom setup. Given the simple design, Phantom A is well-suited for routine clinical QC performed by multiple people (physicists, technologists). Phantom B enables a deeper analysis of smaller changes in tissue composition and iodine concentration by providing more combinations in smaller increments. However, this functionality increases the complexity of phantom setup, rendering Phantom B a well-designed phantom for troubleshooting or research applications.

### CONCLUSION

This study emphasizes the importance of selecting CEM phantoms suited for specific quality control or research objectives. By considering SNR, CNR, reproducibility, breast texture cancellation, and image signal evaluation as part of quality control programs, this research guides informed decision-making in phantom selection for a robust CEM quality control program that advances breast cancer diagnosis and management.

### CLINICAL RELEVANCE/APPLICATION

Appropriate phantom selection is essential for a successful CEM quality control program and facilitates the optimization and maintenance of CEM systems to deliver consistent and high-quality diagnostic results.

## S4-SSPH02-6 ADVANCES IN BREAST TOMOSYNTHESIS ACQUISITION TECHNOLOGIES

Nikolaos A. Gkanatsios, PHD (*Abstract Co-Author*) Nothing to Disclose
Andrew P. Smith, PhD (*Abstract Co-Author*) Employee, Hologic, Inc

Andrew D. Maidment, PhD (*Presenter*) Research support, Hologic, Inc;Research support, Barco nv;Research support, Analogic Corporation;Founder, Daimroc Imaging LLC;Scientific Advisory Board, Real Time Tomography, LLC;Spouse, Employee, Real Time Tomography, LLC;Spouse, Stockholder, Real Time Tomography, LLC;;

### PURPOSE

Minimizing Digital Breast Tomosynthesis (DBT) scan time can reduce the likelihood of image-degrading patient motion and lessen patient discomfort by shortening compression time. DBT systems can be classified into two main scan motions - step-and-shoot or continuous. Of commercially available systems, those with the shortest scan times utilize continuous tube motion. Systems with conventional x-ray tube technology may have reached the limits

of scan speeds, as faster scans can lead to image-degrading focal spot motion blur. One solution is to use steered-beam x-ray tube technology, recently introduced by some mammography vendors. With these x-ray tubes, the focal spot is steered at the same speed but in the opposite direction of tube motion. The emitted x-rays appear stationary with respect to the detector and breast and virtually eliminate focal spot motion blur. This allows faster scans without image degradation and can improve image quality compared to systems without this innovation. The purpose of this study is to characterize the timing and imaging resolution of a DBT system that employs steered-beam technology.

**METHODS AND MATERIALS**

The imaging performance of a DBT system using steered-beam technology was evaluated for spatial resolution as a function of height in the breast. The spatial resolution was characterized by quantifying the imaging spread of an object in the in-focus slice of the reconstructed image for objects placed 2 to 8 cm above the breast platform. Line pair resolution phantoms were imaged to quantify system resolution in the scanning and perpendicular direction. Finally, the time for the DBT scan was measured from the start of the first exposure to the end of the last exposure. The same methods were repeated on a system not employing this technology for a baseline comparison.

**RESULTS**

For a fixed object, the average object width (full-width half-max) using conventional x-ray tube technology was 1.52, 1.69, 2.17, and 3.23 mm at heights of 2, 4, 6, and 8 cm above the breast platform, while when using steered-beam x-ray tube technology the values were 1.45, 1.47, 1.76, and 1.88 mm. The system with steered-beam x-rays had a spatial resolution improvement of 5% for objects 2 cm above the breast platform, 13% at 4 cm, 19% at 6 cm, and 42% at 8 cm. The scan time was shortened by about 1/3 from 3.7 sec to 2.5 sec.

**CONCLUSION**

This new technology demonstrated a reduction in scan time of about 33% while simultaneously improving spatial resolution.

**CLINICAL RELEVANCE/APPLICATION**

DBT systems employing steered beam x-ray tubes can provide benefits such as shorter scan times and improved spatial resolution compared to systems not employing this technology. The spatial resolution improvement is greatest at the largest compressed breast thicknesses.

### S4-SSVA01-1 PRE-SURGICAL LYMPHATIC AND VENOUS MAPPING WITH NON-CONTRAST ULTRA HIGH FREQUENCY ULTRASOUND

Leo L. Tsai, MD, PhD (*Abstract Co-Author*) Stockholder, Agile Devices Inc;Consultant, Agile Devices Inc
Dhruv Singhal, MD (*Abstract Co-Author*) Nothing to Disclose
Clarissa Lee (*Abstract Co-Author*) Nothing to Disclose
James Fanning (*Abstract Co-Author*) Nothing to Disclose
Ivan Diogo Queiros, MD,MMed (*Abstract Co-Author*) Nothing to Disclose
Charissa Kim, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Lymphaticovenous mapping is a necessary component of lymphaticovenous anastomosis (LVA) surgery but is limited by the costly nature of existing preoperative planning techniques, including indocyanine green fluorescent lymphography and contrast-enhanced ultrasound, which both require contrast administration. There is a clinical need for noninvasive imaging modalities to assess lymphatic channels for LVA. The purpose of the study was to determine whether ultra-high frequency ultrasound (UHFUS) performed on patients with upper or lower extremity lymphedema can accurately estimate the target lymphatic channel and vein diameters before LVA surgery.

#### METHODS AND MATERIALS

In this single-institution retrospective study, UHFUS (48-70 MHz) was performed between 09/2021-08/2023 on patients with upper or lower extremity lymphedema to identify lymphatic channels and veins for LVA. The results of UHFUS mapping were compared to the number and size of lymphatic channels and veins identified during LVA, with surgical data serving as the reference standard. Bland-Altman analyses were performed to quantify bias and agreement intervals between UHFUS and LVA diameter estimates. Linear mixed-effects models were constructed to estimate all analysis parameters since participants may contribute multiple measurements.

#### RESULTS

Twenty-four patients were included in the study (20 women, mean age, 54 years ± 13 [SD]). A total of 32 LVAs were performed: One LVA was performed in 16 patients (67%), and two were performed in 8 (33%). UHFUS was performed, on average, 184 days (range, 1-432) prior to LVA. The estimated bias associated with the lymphatic channel diameter was 0.02 (95%CI: -0.07, 0.12), and the corresponding agreement interval was -0.50 (-0.66, -0.34) to 0.54 (0.38,0.70). Similarly, the bias and agreement interval for the vein diameter was -0.02 (-0.10, 0.08) and -0.50 (-0.65,-0.35) to 0.46 (0.32, 0.62).

#### CONCLUSION

UHFUS is a noninvasive imaging modality that can accurately and without systematic bias map lymphatic channels and veins in patients with lymphedema for LVA without intravenous contrast.

#### CLINICAL RELEVANCE/APPLICATION

UHFUS is a noninvasive imaging modality that can accurately map suitable lymphatic and venous targets for LVA.

### S4-SSVA01-2 FULLY AUTOMATEDASSESSMENTOFTHE FLR IN A BLOOD-FREE SETTINGVIACT BEFORE MAJOR HEPATECTOMY VIA DEEP LEARNING

Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Guanxun Cheng, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Tingting Xie JR, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Automated segmentation of hepatic veins and portal veins for preoperative planning has been reported recently. However, these studies have focused mainly on developing new models to improve segmentation performance or volumetry of the right lobe for living donor liver transplantation. Adequate validation in diverse liver conditions and application in preoperative future liver remnant (FLR) assessment are lacking. We aimed to develop a deep learning (DL) model for automated segmentation of hepatic veins and portal veins, validate the segmentation performance of the model, and apply the model in blood-free FLR assessments via CT before major hepatectomy.

### METHODS AND MATERIALS

3D U-Net models were developed for the automatic segmentation of hepatic veins and portal veins on contrast-enhanced CT images. A total of 170 patients treated from January 2018 to March 2019 were included. The hepatic veins and portal veins were annotated by radiologists. 3D U-Net models were trained and tested under various liver conditions (146 patients with different pathological livers and 32 patients who were candidates for major hepatectomy). The Dice similarity coefficient (DSC) and volumetric similarity (VS) were used to evaluate the segmentation accuracy. The use of quantitative volumetry for evaluating resection was compared between blood-filled and blood-free settings and between manual and automated segmentation.

### RESULTS

The DSC and VS in the test dataset for hepatic veins and portal veins were 0.66 ± 0.08 and 0.80 ± 0.10 and 0.67 ± 0.07 and 0.74 ± 0.08, respectively. No significant differences in FLR, FLR% assessments, or the percentage of major hepatectomy patients were noted between the blood-filled and blood-free settings (P=0.67, 0.59 and 0.99 for manual methods, P=0.66, 0.99 and 0.99 for automated methods, respectively) according to the use of manual and automated segmentation methods.

### CONCLUSION

Fully automated segmentation of hepatic veins and portal veins and FLR assessment via blood-free CT before major hepatectomy are accurate and applicable in clinical cases involving the use of DL.

### CLINICAL RELEVANCE/APPLICATION

Preoperative CT volumetry of FLR has been criticized for under- and overestimating real FLR mainly because volumetry on CT images is blood-filed while intraoperative volumetry is blood-free. Blood vessels account for 9% of total liver volume, which has potential to change the prediction of resection because the minimum FLR% which required to preserved ranged from 20% to 40%. So, a precise FLR Blood-free calculation, and a comparison between FLR Blood-filled and FLR Blood-free are essential. Our fully automatic models could provide FLR Blood-free assessment before major heptatectomy with reliable outcomes.

## S4-SSVA01-3 CONJUGATE GRADIENT ITERATION WITH DEEP LEARNING RECONSTRUCTION IMPROVES WORKFLOW EFFICIENCY IN THREE-DIMENSIONAL ULTRASHORT ECHO TIME ABDOMINAL MR ANGIORAPHY

Hideki Ota, PhD (*Presenter*) Grant, Canon Medical Systems Corporation

### PURPOSE

While 3-dimensional (3D) ultrashort TE (UTE)-based non-contrast MR angiography enables the visualization of visceral arteries treated by endovascular interventions, prolonged scan time remains a challenge to achieve satisfactory image quality. This study aimed to assess whether the application of conjugate-gradient iteration combined with denoising deep learning reconstruction can reduce scan time without compromising image quality in 3D UTE abdominal MR angiography.

### METHODS AND MATERIALS

In this IRB-approved prospective study, 10 healthy subjects (7 men, mean age 30 ± 7.5 years) underwent 3D UTE time-spatial Labeling Inversion Pulse (time-SLIP) MR angiography on a 3T MR scanner. Scan parameters included a 3.7ms TR, 0.096ms TE, 5 degrees flip angle, 9960 trajectories (k-space filling ratio 4.84%), 120 segments, 1500ms blood-traveling TI, and spatial resolution of 1.29mm × 1.29mm × 2mm. Two sets of raw data were generated: 1) full data with 9960 trajectories and 2) 67% data with 6640 trajectories. Image reconstruction comprised two steps: conjugate-gradient reconstruction (CG-recon) and denoising deep learning reconstruction (dDLR). Each raw data set yielded four image data sets per subject: two with CG-Recon and two without; dDLR was applied to all data sets. Image quality was assessed using a five-point scale (1, poor; 5, excellent), and the number of visualized renal arterial branches was noted. Statistical analyses included Friedman test with post-hoc Bonferroni correction, Wilcoxon signed-rank tests, and paired t-tests ($p < 0.05$ considered significant).

### RESULTS

Mean scan time was 10.0 ± 1.8 minutes. Images reconstructed with CG-Recon demonstrated significantly higher quality than those without CG-Recon in all raw data sets. 6640-trajectory images with CG-Recon showed comparable quality to 9960-trajectory images without CG-Recon (4.0 vs. 4.1, $p = 0.66$). CG-recon significantly improved branch visualization in 6640-trajectory images compared to those without (2.9 vs. 2.2, $p < 0.01$), whereas no significant difference was observed in 9960-trajectory images.

### CONCLUSION

The combination of CG-recon with dDLR enabled trajectory reduction without sacrificing image quality in 3D UTE time-SLIP MR angiography. This approach has the potential to facilitate broader adoption of UTE-based non-contrast MRA in patients with visceral arterial diseases.

### CLINICAL RELEVANCE/APPLICATION

Conjugate gradient iteration combined with denoising deep learning reconstruction compensates for image quality in 3D UTE abdominal MR angiography with 33%-reduced trajectories, potentially enhancing workflow and patient experience in MR practice by reducing scan time.

## S4-SSVA01-4 4D FLOW MRI FOR THE ASSESSMENT OF RENAL TRANSPLANT DYSFUNCTION: A COMPARISON WITH ULTRASONOGRAPHY

Yaqi Shen, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Gen Chen (*Abstract Co-Author*) Nothing to Disclose
Zhen Li, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hao Tang (*Presenter*) Nothing to Disclose

### PURPOSE

4D flow MRI is an emerging technique enabling visualization and quantification of 3D blood flow in renal vascular transplants. However, studies assessing its accuracy are scarce. Thus, we compared blood flow quantification using 4D flow MRI with ultrasonography (US).

### METHODS AND MATERIALS

Sixty-seven prospectively enrolled renal transplant patients underwent both ultrasonography and 4D flow MRI. 4D flow coronal oblique acquisitions were conducted in the transplant renal artery (RA) at 3.0T. Test-retest repeatability and inter-observer reproducibility were evaluated using Cohen’s kappa and Bland-Altman statistics.

### RESULTS

A total of 65 transplant renal arteries were compared. 4D flow MRI underestimated peak systolic velocity (PSV) by 18% (62.6±21 cm/s vs 76.4±25 cm/s) compared to US (P<0.05). Resistance index (RI) values were comparable between MRI and US (0.72±0.11 vs 0.73±0.09; not significant). Reproducibility and inter-observer agreement of 4D flow MRI were excellent (K=0.89).

### CONCLUSION

4D flow parameters exhibited superior repeatability in the transplant renal artery. Despite a moderate underestimation of PSV compared to US, 4D flow MRI provided accurate measurements of PSV and RI in renal transplant patients.

### CLINICAL RELEVANCE/APPLICATION

4D flow MRI shows promise for future integration with MRA to comprehensively evaluate transplant renal artery stenosis and associated changes in renal transplant function.

## S4-SSVA01-5 DIAGNOSTIC PERFORMANCE, INTER-OBSERVER RELIABILITY, AND SAFETY OF INTRANODAL CT LYMPHANGIOGRAPHY WITH WATER-SOLUBLE IODINATED CONTRAST MEDIUM FOR DETECTING LYMPHATIC LEAKAGE

Hiroshi Kondo, MD (*Abstract Co-Author*) Nothing to Disclose

Takeshi Wada, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnostic performance, inter-observer reliability, and safety of intranodal CT lymphangiography with water-soluble iodinated contrast medium (ICTL-WSI) for detecting leakage of lymphorrhea patients.

### METHODS AND MATERIALS

This retrospective study examined patients who underwent ICTL-WSI as an index test to detect lymphatic leakage. During January 2020 - March 2023, consecutive patients with suspected lymphorrhea were enrolled. Patients underwent ICTL-WSI followed by intranodal lymphangiography (IL) with an oil-based iodinated contrast medium. The presence of leakage and location of disrupted lymphatic vessels were found by consensus between two board-certificated radiologists as the reference standard. Two other board-certificated radiologists independently examined the presence and location of leakage in ICTL-WSI without patient clinical information. The sensitivity, specificity, and area under the receiver operator characteristic curve (AUC) were calculated to assess diagnostic performance. Kappa coefficients for inter-observer reliability, complications associated with ICTL-WSI, and radiation exposure were analyzed.

### RESULTS

In all, 28 patients (ages 15-83 years; 11 female and 17 male; 17 nontraumatic and 11 traumatic lymphorrhea) and 30 examinations were included. The sensitivity, specificity, and AUC for the presence of leakage were, respectively, 1.00, 0.895, 0.971 by Reader 1 and Reader 2. The ICTL-WSI scores for depicting disrupted lymphatic vessel by Reader 1 and Reader 2 were, respectively, 13/13 (100%) and 11/13 (84.6%). The inter-observer reliability for detecting leakage was excellent (kappa coefficients, 1.00). No complication associated with ICTL-WSI was observed. The median volume-weighted CT dose index and the median dose-length product of ICTL-WSI were, respectively, 11.2 mGy (range, 4.7-24.8) and 725.6 mGy cm (range, 321.0-1551.9).

### CONCLUSION

For detecting leakage in lymphorrhea patients, ICTL-WSI can be a reliable, safe, and diagnostically important examination.

### CLINICAL RELEVANCE/APPLICATION

ICTL-WSI can be an effective alternative to IL with oil-based iodine contrast medium, especially for patients with difficulty using oil-based iodine contrast medium.
